Cause. This disease also may arise either from an organic affection, or an atonic state of the parts. The taste may be diminished by crusts, filth, mucus, aphthæ, pellicles, warts, &c. covering the tongue; it may be depraved by a fault of the saliva, which, being discharged into the mouth, gives the same sensation as if the food which the person takes bad really a bad taste; or it may be entirely destroyed by injuries done to the nerves of the tongue and palate. Few things prove more hurtful either to the sense of tasting or smelling than obstinate colds, especially those which affect the head.

Ageustia.

Cure. When the taste is diminished by filth, mucus, &c. the tongue ought to be scraped, and frequently washed with a mixture of water, vinegar, and honey, or some other detergent. When the saliva is vitiated, which seldom happens unless in fevers or other diseases, the curing of the disorder is the cure of this symptom. To relieve it, however, in the mean time, the following practices may be of use: if there be a bitter taste, it may be taken away by vomits, purges, and other things which evacuate bile: what is called a *nidorous taste*, arising from putrid humours, is corrected by the juice of citrons, oranges, and other acids: a salt taste is cured by plentiful dilution with watery liquors: an acid taste is destroyed by absorbents and alkaline salts, as powder of oyster-shells, salt of wormwood, &c.

When the sensibility of the nerves which supply the organs of taste is diminished, the chewing of horse-radish, or other stimulating substances, will help to recover it.

GENUS C. ANÆSTHESIA. 367
Defect of the Sense of FEELING.

Sauv. gen. 161. *Lin.* 218. *Vog.* 267.

Causes, &c. This sense may be hurt by any thing that obstructs the nervous influence, or prevents its being regularly conveyed to the organs of touching, as pressure, extreme cold, &c. It may likewise be hurt by too great a degree of sensibility, when the nerve is not sufficiently covered by the cuticle or scarf-skin, or where there is too great a tension of it, or it is too delicate. Whatever disorders the functions of the brain and nerves, hurts the sense of touching. Hence it appears to proceed from the same general causes as palsy and apoplexy, and requires nearly the same method of treatment.

In a *stupor*, or defect of touching, which arises from an obstruction of the cutaneous nerves, the patient must first be purged; afterwards such medicines as excite the action of the nerves, or stimulate the system, may be used. For this purpose, the spirit of hartshorn, either by itself or combined with essential oils, horse-radish, &c. may be taken inwardly; the disordered parts, at the same time, may be frequently rubbed with fresh nettles or spirit of sal ammoniac. Blisters and sinapisms applied to the parts will likewise be of use; and also warm bathing, especially in the natural hot-baths.

ORDER II. DYSOREXIÆ. 368

SECT. I. *APPETITUS ERRONEI.*

Morositates, *Sauv.* Class VIII. Order II. *Sag.* Class XIII. Order II.

Anorexiæ

Pathetici, *Lin.* Clafs V. Order II.

369 Genus CI. BULIMIA.
Insatiable Hunger, or *Canine Appetite.*

Bulimia, *Sauv.* gen. 223. *Lin.* 79. *Sag.* gen. 335.
Bulimus, *Vog.* 296.
Addephagia, *Vog.* 297.
Cynorexia, *Vog.* 298.

This difeafe is commonly owing to fome fault in the ftomach, by which the aliments are thrown out too foon; and unlefs the perfon be indulged in his defire for eating, he frequently falls into fainting fits. Sometimes it is attended with fuch a ftate of the ftomach, that the aliment is rejected by vomit almoft immediately after being fwallowed; after which the appetite for food returns as violent as ever. But there are many circumftances which feem to render it probable that it more frequently arifes from a morbid condition of the fecreted fluid poured into the ftomach, by means of which the aliment is diffolved. When the activity of this fluid is morbidly increafed, it will both produce too fudden a folution of the folid aliment, and likewife operate as a powerful and peculiar ftimulus to the ftomach, giving an uneafy fenfation, fimilar to that which takes place in natural hunger. Such things are proper for the cure as may enable the ftomach to perform its office: chalybeates and other tonics will generally be proper. In fome, brandy drunk in a morning has been ufeful; and frequent fmoking tobacco has relieved others. Oil, fat meat, pork, opiates, and in fhort every thing which in a found perfon would be moft apt to pall the appetite, may alfo be ufed as temporary expedients, but cannot be expected to perform a cure In fome, the pylorus has been found too large; in which cafe the difeafe muft have been incurable.

370 Genus CII. POLYDIPSIA.
Excessive Thirst.

Polydipfia, *Sauv.* gen. 224. *Lin.* 80. *Vog.* 275. *Sag.* 336.

This is almoft always fymptomatic; and occurs in fever, dropfy, fluxes, &c. The cure is very generally obtained only by the removal of the primary difeafe; and it is beft palliated by the gradual introduction of diluents: But when thefe are contraindicated, it may often be fuccefsfully obviated by fuch articles taken into the mouth as have effect in augmenting the flow of faliva.

371 Genus CIII. PICA.
Longing, or *Falfe Appetite.*

Pica, *Sauv.* gen. 222. *Sag.* 334.
Citta, *Lin.* 78.
Allotriophagia, *Vog.* 299.
Malacia, *Vog.* 300.

The pica is alfo very generally fymptomatic of other difeafes, as of worms, chlorofis, pregnancy, &c.; and is therefore chiefly to be combated by the removal of the primary affection. It may, however, be obferved, that peculiar longings occurring in certain dif-

cafes, as for example in fevers, often point out a natural cure. The indulgence of fuch appetites to a moderate degree is feldom productive of any inconvenience, and often followed by the beft confequences.—Hence there are fome practitioners who think that fuch craving fhould very generally be indulged; particularly when the patient can affign no reafon whatever for fuch particular longings, but is merely prompted by an uncommon and inexplicable defire. Pica.

Genus CIV. SATYRIASIS. 372

Satyriafis, *Sauv.* gen. 228. *Lin.* 81. *Sag.* 340.

Satyriafis is a violent defire of venery in men, even fo that reafon is depraved by it. The pulfe is quick, and the breathing fhort; the patient is fleeplefs, thirfty, and loathes his food; the urine is evacuated with difficulty, and a fever foon comes on. Thefe fymptoms, however, are probably not fo much the confequence of fatyriafis, as merely concomitant effects refulting from the fame caufe. And indeed this affection is moft frequently the concomitant of a certain modification of infanity. The nature and caufe of this affection are in moft inftances very little afcertained; but as far as we are acquainted with the treatment, it agrees very much with the affection next to be mentioned, which, of the two, is the moft common occurrence.

Genus CV. NYMPHOMANIA. 373
Furor Uterinus.

Nymphomania, *Sauv.* 229. *Sag.* 341.
Satyriafis, *Lin.* 81.

The *furor uterinus* is in moft inftances either a fpecies of madnefs or an high degree of hyfterics. Its immediate caufe is a preternatural irritability of the uterus and pudenda of women (to whom the diforder is proper), or an unufual acrimony of the fluids in thefe parts.—Its prefence is known by the wanton behaviour of the patient: fhe fpeaks and acts with unreftrained obfcenity; and as the diforder increafes, fhe fcolds, cries, and laughs, by turns. While reafon is retained, fhe is filent, and feems melancholy, but her eyes difcover an unufual wantonnefs. The fymptoms are better and worfe untill the greateft degree of the diforder approaches, and then by every word and action her condition is too manifeft.—In the beginning a cure may be hoped for; but if it continue, it degenerates into a mania.—In order to the cure, blood-letting is commonly had recourfe to in proportion to the patient's ftrength. Camphor in dofes of 15 or 20 grains, with nitre, and fmall dofes of the tincture of opium, fhould be repeated at proper intervals. Some venture to give cerufa acetata in dofes from three to five grains. Befides bleeding, cooling purges fhould alfo be repeated in proportion to the violence of fymptoms, &c. What is ufeful in maniacal and hypochondriac diforders, is alfo ufeful here, regard being had to fanguine or phlegmatic habits, &c. When the delirium is at the height, give opiates to compofe; and ufe the fame method as in a phrenitis or a mania. Injections of barley-water, with a fmall quantity of hemlock-juice, according to Riverius, may be frequently thrown up into the uterus: this

Dysorexiæ this is called *specific*; but matrimony, if possible, should be preferred. For although this cannot be represented as a cure for the disease when in an advanced state, yet there is reason to believe that it has not unfrequently prevented it where it would otherwise have taken place.

374 GENUS CVI. NOSTALGIA.
Vehement Desire of revisiting one's Country.

Nostalgia, *Sauv.* gen. 226. *Lin.* 83. *Sag.* 338.

This is to be reckoned a species of melancholy; and unless it be indulged, it very commonly proves not only incurable but even fatal. Although it cannot be considered as altogether peculiar to any nation, yet it is observed to be much more frequent with some than with others; and it has particularly been remarked among Swiss soldiers in the service of foreign states.

SECT. II. *APPETITUS DEFICIENTES.*

Anepithymiæ, *Sauv.* Clafs VI. Ord. II. *Sag.* IX. Ord. II.
Privativi, *Lin.* Clafs VI. Order III.
Adynamiæ, *Vog.* Clafs VI.

GENUS CVII. ANOREXIA.
Want of Appetite.

Anorexia, *Sauv.* gen. 162. *Lin.* 116. *Vog.* 279. *Sag.* 268.

The anorexia is symptomatic of many diseases, but seldom appears as a primary affection; and it is very generally overcome only by the removal of the affection on which it depends.

376 GENUS CVIII. ADIPSIA.
Want of Thirst.

Adipsia, *Sauv.* gen. 163. *Lin.* 117. *Vog.* 281. *Sag.* 269.

This by Dr Cullen is reckoned to be always symptomatic of some distemper affecting the *sensorium commune*.

377 GENUS CIX. ANAPHRODISIA.
Impotence to Venery.

Anaphrodisia, *Sauv.* gen. 164. *Sag.* 270.
Atecnia, *Lin.* 119.
Agenesia, *Vog.* 283.

For this, see the article IMPOTENCE in the alphabetical order.

378 ORDER III. DYSCINESIÆ.

379 GENUS CX. APHONIA.
Loss of Voice.

Aphonia, *Sauv.* gen. 166. *Lin.* 115. *Vog.* 253. *Sag.* 272.

The loss of voice may proceed from various causes. If one of the recurrent nerves, which are formed by the *par vagum* and the *nervus accessorius*, and reach the larynx, be cut, the person is capable of only as it were a half-pronunciation; but if both be cut, the speech and voice are both lost. The loss of speech happening in hysteric patients is also called *aphonia*; but more properly that loss of speech is thus named which depends on some fault of the tongue. Aphonia.

Seeing that the motion of any part is destroyed, or lessened at least, by the interception of the nervous fluid in its passage thither, and that the nerves destined for the motion of the tongue arise principally from the fifth pair, it appears that the seat of this disorder is in the said fifth pair of nerves, and that the immediate cause is a diminution or total destruction of the nervous power in them. Hence a palsy of the tongue, which is either antecedent or subsequent to hemiplectic or apoplectic disorders, demand our utmost attention.

If an aphonia appears alone, it generally bespeaks an approaching hemiplegia or apoplexy; but if it succeed these disorders, and is complicated with a weak memory and a sluggishness of the mental powers, it threatens their return. That aphony usually terminates the best which proceeds from a stagnation of serous humours compressing the branches of the fifth pair of nerves, which run to the tongue; but it is no less afflictive to the patient, and is very obstinate of cure.

Other causes of this disorder are, the striking in of eruptions on the skin, a congestion of blood in the fauces and tongue, obstructed periodical evacuations in plethoric habits, spasmodic affections, worms, a crumb of bread falling into the larynx, fear, too free an use of spirituous liquors; also whatever destroys the ligaments which go from the arytænoid to the thyroid cartilages, will destroy the voice.

The *prognostics* vary according to the cause or causes. That species which is owing immediately to spasms, soon gives way on the removal of them. If a palsy of the tongue be the cause, it is very apt to return, tho' relieved, but often continues incurable.

In order to the *cure*, we must endeavour first to remove whatever obstructs the influx of the nervous fluid into the tongue, and secondly to strengthen the weak parts. These general intentions, in all cases, being regarded, the particular causes must be removed as follows:

If worms be the cause, antispasmodics may give present relief; but the cure depends on the destruction or expulsion of the animals themselves. In case of a congestion of blood about the head, bleeding and nitrous medicines are to be used.—That species of aphony which remains after the shock of an hemiplegia or apoplexy, requires blisters to be applied to the nape of the neck; other means are rarely effectual.—If spasmodic constrictions about the fauces and tongue be the cause, external paregorics are of the greatest service, anodyne antispasmodics may be laid under the tongue, and the feet bathed in warm water; carminative clysters also are useful.—When a palsy of the tongue produces this complaint, evacuations, according to the patient's habit, must be made, and warm nervous medicines must be externally applied, and internally administered; blisters also should be placed between the shoulders.—In case of repelled cuticular eruptions, sudorifics should be given, and the patient's drink should be warm. The spiritus ammoniæ succinatus, or vinum antimonii, may be employed either in combination

Iſcineſiæ tion with other articles or by themſelves, and given, at proper diſtances of time, in the patient's drink, or on a lump of ſugar.—Sometimes the ſerum flows ſo rapidly to the fauces and adjacent parts, in a ſalivation, as to deprive the patient of all power to ſpeak; in this caſe diaphoretics and laxatives, with a forbearance of all mercurials, are the ſpeedieſt remedies.

380 GENUS CXI. MUTITAS.
DUMBNESS.

Mutitas, *Sauv.* gen. 165. *Vog.* 257. *Sag.* 271.

Dumb people are generally born deaf; in which caſe the diſtemper is incurable by medicine: though even ſuch people may be taught not only to read and write, but alſo to ſpeak and to underſtand what others ſay to them. For ſome obſervations on the method in which this has been accompliſhed, we may refer the reader to the article DUMBNESS in the alphabetical order. But in theſe caſes, admitting of cure in the manner above alluded to, the dumbneſs proceeds principally, if not ſolely, from the deafneſs. For when it proceeds from a defect of any of the organs neceſſary for ſpeech, the tongue for inſtance, it is always incurable; but if it ariſe from a palſy, the medicines applicable in that caſe will ſometimes reſtore the ſpeech.

381 GENUS CXII. PARAPHONIA.
Change in the Sound of the VOICE.

Paraphonia, *Sauv.* gen. 168.
Cacophonia, *Sag.* 274.
Raucedo, *Lin.* 146.
Raucitas, *Vog.* 252.
Aſaphia, &c. *Vog.* 250, 251, 254, 255, 256.

The voice may be changed from various cauſes. In males it becomes much more hard about the time of puberty; but this can by no means be reckoned a diſeaſe. In others it proceeds from a catarrh, or what we call a *cold*; it ariſes alſo from affection of the noſe and palate, as polypi, ulcers, &c. in which caſe the cure belongs properly to SURGERY. In ſome it ariſes from a laxity of the *velum pendulum palati* and glottis, which makes a kind of ſnoring noiſe during inſpiration. The cure of this laſt caſe is to be attempted by tonics and ſuch other medicines as are of ſervice in diſeaſes attended with laxity.

382 GENUS CXIII. PSELLISMUS.
Defect in PRONUNCIATION.

Pſelliſmus, *Sauv.* gen. 167. *Lin.* 138. *Sag.* 273.
Traulotis, &c. *Vog.* 258, 259, 260, 261.

Of this diſeaſe (if ſuch it may be called), there are many different kinds. Some cannot pronounce the letter S; others labour under the ſame difficulty with R, L, M, K. &c.; while ſome who can with ſufficient eaſe pronounce all the letters, yet repeat their words, or the firſt ſyllables of them, in ſuch a ſtrange manner, that they can ſcarce be underſtood. Very frequently theſe defects ariſe entirely from habit, and may then be got the better of by thoſe who have the reſolution to attempt it; as we are told that Demoſthenes the celebrated orator got the better of a habit of ſtammering by declaiming with pebbles in his mouth. Sometimes, however, pronunciation may be impeded by a wrong conformation of the tongue or organs of ſpeech; and then it cannot by any pains whatever be totally removed. Pſelliſmus.

GENUS CXIV. STRABISMUS. 383
SQUINTING.

Strabiſmus, *Sauv.* gen. 116. *Lin.* 304. *Vog.* 514. *Sag.* 222.

Deſcription. This diſeaſe ſhows itſelf by an uncommon contraction of the muſcles of the eye; whereby the axis of the pupil is drawn towards the noſe, temples, forehead, or cheeks, ſo that the perſon cannot behold an object directly.

Cauſes, Prognoſis, &c. I. This diſeaſe may proceed from cuſtom and habit; while in the eye itſelf, or in its muſcles, nothing is preternatural or defective.

Thus children by imitating thoſe that ſquint, and infants by having many agreeable objects preſented to them at once, which invite them to turn one eye to one and the other eye to another, do frequently contract a habit of moving their eyes differently, which afterwards they cannot ſo eaſily correct. Infants likewiſe get a cuſtom of ſquinting by being placed obliquely towards a candle, window, or any other agreeable object capable of attracting their ſight: for though, to ſee the object, they may at firſt turn both eyes towards it; yet, becauſe ſuch an oblique ſituation is painful and laborious, eſpecially to the moſt diſtant eye, they ſoon relax one of the eyes, and content themſelves with examining it with the eye that is next it; whence ariſes a diverſity of ſituation and a habit of moving the eyes differently.

In this caſe, which may admit of a cure if not too much confirmed, it is evident, that objects will be ſeen in the ſame place by both eyes, and therefore muſt appear ſingle as to other men; but becauſe, in the eye that ſquints, the image of the object to which the other eye is directed falls not on the moſt ſenſible and delicate part of the retina, which is naturally in the axis of the eye, it is eaſy to ſee that it muſt be but faintly perceived by this eye. Hence it is, that while they are attentive in viewing any object, if the hand be brought before the other eye, this object will be but obſcurely ſeen, till the eye change its ſituation, and have its axis directed to it; which change of ſituation is indeed very eaſy for them, becauſe it depends on the muſcles of the eyes, whoſe functions are entire; but, by reaſon of the habit they have contracted of moving their eyes differently, the other eye is at the ſame time frequently turned aſide, ſo that only one at a time is directed to the object.

That all this may be the better perceived; for an object, cauſe them to look at the image of the upper part of your noſe in a plain mirror, while you ſtand directly behind them, to obſerve the direction of their eyes.

II. The *ſtrabiſmus* may proceed from a fault in the firſt conformation, by which the moſt delicate and ſenſible part of the retina is removed from its natural ſituation, which is directly oppoſite to the pupil, and is placed a little to a ſide of the axis of the eye; which obliges them to turn away the eye from the object they

Dyscinesiæ they would view, that its picture may fall on this most sensible part of the organ.

When this is the case, the disease is altogether incurable, and the phænomena that arise therefrom differ in nothing from the phænomena of the former case, excepting only that here, 1. The object to which the eye is not directed will be best seen; which is the reverse of what happens when this disease arises barely from habit and custom. 2. No object will appear altogether clear and distinct: for all objects to which the eye is directed, by having their image painted in the retina at the axis of the eye, where it is not very sensible, will be but obscurely seen; and objects that are placed so far to a side of the optic axis as is necessary for making their image fall on the most sensible and delicate part of the retina, must appear a little confused, because the several pencils of rays that come therefrom fall too obliquely on the crystalline to be accurately collected in so many distinct points of the retina; though it must be acknowledged, that this confusion will, for the most part, be so small as to escape unobserved.

III. This disease may proceed from an oblique position of the crystalline, where the rays that come directly to the eye from an object, and that ought to converge to the point of the retina, which is in the axis of the eye, are, by reason of the obliquity of the crystalline, made to converge to another point on that side of the visual axis where the crystalline is most elevated; and therefore the object is but obscurely seen, because its image falls not on the retina at the axis of the eye, where it is most sensible: But the rays that fall obliquely on the eye, will, after refraction, converge to this most sensible part of the retina; and, by converging there, must impress the mind with a clearer idea of the object from whence they came. It is for this reason that the eye never moves uniformly with the other, but turns away from the object it would view, being attentive to the object to which it is not directed. When this is the case, it is in vain to expect any good from medicine.

The symptoms that naturally arise from it are, 1. The object to which the eye is directed will be but faintly seen, because its image falls on the retina where it is not very sensible. 2. The object to which the eye is not directed, by having its image painted on the retina at the axis of the eye, will be clearly perceived. But, 3. This same object must appear somewhat indistinct, because the pencils of rays that flow from it are not accurately collected in so many distinct points in the retina, by reason of their oblique incidence on the crystalline. 4. It must be seen, not in its proper place, but thence translated to some other place situated in the axis of vision. And, 5. Being thus translated from its true place, where it is seen by the other eye that does not squint, it must necessarily appear double; and the distance between the places of its appearance will be still greater, if the crystalline of the other eye incline to the contrary side.

IV. This disease may arise from an oblique position of the cornea; which, in this case, is generally more arched and prominent than what it is naturally.

Strabismus. When the eye has this conformation, no object to which it is directed can be clearly seen, because its image falls not on the retina at the axis of the eye; and therefore the eye turns aside from the object it would view, that its image may fall on the most sensible part of the retina.

When the strabismus proceeds from this cause, the prognostic and the phænomena that attend it will be much the same as in the case immediately preceding; from which nevertheless it may be distinguished by the obliquity of the cornea, which is manifest to the senses and if the cornea be also more arched and prominent than what it is naturally, which is commonly the case, the eye will also be short-sighted.

V. This want of uniformity in the motions of our eyes, may arise from a defect, or any great weakness or imperfection, in the sight of both or either of the eyes; and this, according to Dr Porterfield, is the most common cause of this disease. The prognostic in this case is the same with that of the disease from which it proceeds.

VI. Another cause from which the strabismus may proceed, lies in the muscles that move the eye. When any of those muscles are too short or too long, too tense or too lax, or are seized with a spasm or paralysis, their equilibrium will be destroyed, and the eye will be turned towards or from that side where the muscles are faulty.

In this case, the disease frequently yields to medicine, and therefore admits of favourable prognostic; excepting only when, by a fault in the first conformation, any of the muscles are longer or shorter than their antagonist; in which case, if ever it should happen, no medicine can be of any use.

As to what concerns the optical phænomena, they are the same here as in case first: only when the disease commences not till, by custom and habit, the uniform motion of the eyes has been rendered necessary, all objects do for some time appear double; but in time they appear single.

Lastly, This want of uniformity in the motions of our eyes may proceed from a preternatural adhesion or attachment to the eye-lids: of this we have an instance in Langius. And that the same thing may also be occasioned by a tumor of any kind within the orbit, pressing the eye aside, and restraining it from following the motions of the other, is so evident, that instances need not be brought to prove it. Here also the case may admit of a favourable prognostic; and as for what concerns the optical phænomena, they must be the same as in the case immediately preceding.

The *cure*, in confirmed cases, is to be effected by mechanical contrivances, by which the person may be obliged to look straight upon objects, or not see them at all; or at least that he may see with uneasiness and confusedly when he squints. In the 68th volume of the Philosophical Transactions we have an account of a confirmed case of squinting of a very uncommon kind. The patient was a boy of five years old, and viewed every object which was presented to him with but one eye at a time. If the object was presented on his right side, he viewed it with his left eye; and if it was presented on his left side, he viewed it with his right eye. He turned the pupil of that eye

Dyſcineſiæ eye which was on the ſame ſide with the object in ſuch a direction that the image of the object might fall on that part of the bottom of the eye where the optic nerve enters it. When an object was held directly before him, he turned his head a little to one ſide, and obſerved it with but one eye, viz. that moſt diſtant from the object, turning away the other in the manner above deſcribed; and when he became tired of obſerving it with that eye, he turned his head the contrary way, and obſerved it with the other eye alone, with equal facility; but never turned the axis of both eyes on it at the ſame time. He ſaw letters which were written on bits of paper, ſo as to name them with equal eaſe, and at equal diſtances, with one eye as with the other. There was no perceptible difference in the diameters of the iriſes, nor in the contractility of them after having covered his eyes from the light. Theſe obſervations were carefully made by writing ſingle letters on ſhreds of paper, and laying wagers with the child that he could not read them when they were preſented at certain diſtances and in certain directions.

As from theſe circumſtances it appeared that there was no defect in either eye, which is frequently the caſe with perſons who ſquint, and hence that the diſeaſe was ſimply a depraved habit of moving his eyes, the diſeaſe ſeemed capable of a cure. A paper gnomon was made for this purpoſe, and fixed to a cap; and when this artificial noſe was placed over his real noſe, ſo as to project an inch between his eyes, the child, rather than turn his head ſo far to look at oblique objects, immediately began to view them with that eye which was next to them. But having the misfortune to loſe his father ſoon after this method was begun to be followed, the child was neglected for ſix years, during which time the habit was confirmed in ſuch a manner as ſeemed to leave little room to hope for a cure. The ſame phyſician, however, being again called, attempted a ſecond time to remove the deformity by a ſimilar contrivance. A gnomon of thin braſs was made to ſtand over his noſe, with a half circle of the ſame metal to go round his temples: theſe were covered with black ſilk, and by means of a buckle behind his head, and a croſs-piece over the crown of his head, this gnomon was worn without any inconvenience, and projected before his noſe about two inches and an half. By the uſe of this machine he ſoon found it leſs inconvenient to view all oblique objects with the eye next to them inſtead of the eye oppoſite to them.

After this habit was weakened by a week's uſe of the gnomon, two bits of wood, about the ſize of a gooſe-quill, were blackened all but a quarter of an inch at their ſummits; theſe were frequently preſented to him to look at, one being held on one ſide the extremity of his black gnomon, and the other on the other ſide of it. As he viewed theſe, they were gradually brought forwards beyond the gnomon, and then one was concealed behind the other: by theſe means, in another week, he could bend both his eyes on the ſame object for half a minute together; and by continuing the uſe of the ſame machine, he was in a fair way of being cured when the paper was written.

Dr Darwin, who writes the hiſtory of the above caſe, adds, that all the other ſquinting people he had occaſion to attend, had one eye much leſs perfect than the other: theſe patients, ſays he, are certainly curable by covering the beſt eye many hours in a day; as by a more frequent uſe of the weak eye, it not only acquires a habit of turning to the objects which the patient wiſhes to ſee, but gains at the ſame time a more diſtinct viſion; and the better eye at the ſame time ſeems to loſe ſomewhat in both theſe reſpects, which alſo facilitates the cure. Strabiſmus.

GENUS CXV. CONTRACTURA. 384
Contractions of the LIMBS.

Contractura, *Sauv.* gen. 119. *Lin.* 299. *Sag.* 225.
Obſtipitas, *Sauv.* gen. 11.
Caput obſtipum, *Vog.* 513.
Digitium, *Vog.* 221.

The contraction of various muſcles of the body is generally the conſequence of ſome other diſeaſe, as the rheumatiſm, gout, ſcurvy, or palſy, eſpecially that ſpecies of the latter which follows the *colica Pictonum*. It is exceedingly difficult of cure; though the warm medicinal waters are much recommended, and have ſometimes done great ſervice. Of late electricity has been found to perform ſurpriſing cures in this way.

ORDER IV. APOCENOSES. 385

Apocenoſes, *Vog* Claſs II. Ord. II.
Fluxus, *Sauv.* Claſs IX. *Sag.* Claſs V.
Morbi evacuatorii, *Lin.* Claſs IX.

GENUS CXVI. PROFUSIO. 386
FLUX of BLOOD.

Profuſio *Lin.* 239.
Hæmorrhagia, *Vog.* 81. *Boerh.* 218.

The diſeaſe commonly known by the name of *bloody flux*, is the putrid or contagious dyſentery, a diſeaſe which has already been treated of. But independent of the diſcharge of blood which then takes place, hæmorrhagy may take place from the alimentary canal as well as from other parts of the ſyſtem. In ſuch inſtances, however, if we except the place from which the diſcharge occurs, the phenomena are very much the ſame as in menorrhagia, hæmoptyſis, and other hæmorrhagies already treated of; while the diſeaſe is to be combated on the ſame principles and by the ſame remedies.

GENUS CXVII. EPHIDROSIS. 387
Exceſſive SWEATING.

Ephidroſis, *Sauv.* gen. 258. *Sag.* gen. 194.
Sudor, *Lin.* 208.
Hydropedeſis, *Vog.* 121.

This is generally ſymptomatic; and occurs in almoſt all fevers, but eſpecially in the latter ſtages of the hectic. Sometimes it is a primary diſeaſe, ariſing merely from weakneſs; and then eaſily admits of a cure by the uſe of the Peruvian bark, the cold bath, and other tonics.

GENUS CXVIII. EPIPHORA. 388
FLUX of the LACHRYMAL HUMOUR.

Epiphora, *Sauv.* gen. 259. *Lin.* 172. *Vog.* 99. *Sag.* 195.

THIS by Sauvages is deſcribed as an involuntary effuſion effufion of tears without any remarkable itching, heat, or pain. It follows long-continued ophthalmias; or it may be occafioned by immoderate ftudy, or any thing that weakens the eyes: hence it comes on about the age of 50 years, when the eyefight naturally becomes weak. It in general grows worfe in the winter-time, and is very hard to cure Some authors recommend purgatives, and blifters on the nape of the neck, in order to draw off the abundant humours; but as the difeafe evidently proceeds from weaknefs, it would rather feem proper to purfue a contrary method. Sauvages recommends to the patients to abftain from ftudy, wine, and falted meats; and alfo to avoid fmoke or wind, and at night to foment the eyes with an infufion of four cloves in two ounces of proof-fpirit.—Hungary water, rofe water with white vitriol diffolved in it, &c. have alfo been recommended.

389 GENUS CXIX. PTYALISMUS.
SALIVATION.

Ptyalifmus, *Sauv.* gen. 261. *Lin.* 176. *Vog.* 103. *Sag.* 197.

A falivation is often fymptomatic, but rarely a primary difeafe. Dr Cullen is of opinion, that when the latter happens to be the cafe, it arifes from laxity; and then is to be cured by aftringents and tonics. In the Medical Tranfactions we have the following account of a falivation brought on by a foreign fubftance irritating one of the parotid glands.

In the month of April 1751, a young lady about the age of 16 years, of a delicate habit, but fubject to no particular complaints, perceived the beginning of a difeafe which afterwards proved moft obftinate and loathfome, *viz.* an inceffant fpitting. The quantity of this difcharge was different at different times, varying from one pint to two pints and an half in 24 hours. As to its quality, it feemed to be no other than the ordinary fecretion of the falival glands. By fo large and conftant an evacuation, her ftrength became extremely impaired, and the moft efficacious medicines had proved ufelefs. She had taken large quantities of the Peruvian bark, both alone and combined with preparations of iron: and afterwards the fetid gums, opium, amber, alum, and the Neville-Holt-water, had in fucceffion been given her. In the mean time an exact regimen had been prefcribed: fhe had been ordered to ride conftantly; and to confine herfelf to a mucilaginous diet, fuch as veal, calve's feet, &c. Likewife a gently opening medicine had now and then been interpofed. The difeafe ftill continued unaltered, fhe had afterwards tried the *tinctura faturnina*; and had, at the fame time, been encouraged to chew the Peruvian bark, and to fwallow the faliva But all thefe attempts had been vain; and after fhe had taken fome or other of the medicines above mentioned until the end of September 1753, namely, above two years, it appeared to her phyfician, Sir George Baker, unreafonable to expect relief in fuch a cafe from any internal medicines whatever.

He now conceived a fufpicion, that fome extraneous body having accidentally found its way into the *meatus auditorius*, might poffibly be the caufe of this extraordinary fecretion, by keeping up a continued irritation in the parotid glands. With this view he examined her ears, and extracted from them a quantity of fetid wool. How, or when, it came thither, no account could be given.

To this fubftance he attributed the beginning of the falivation, notwithftanding that the difeafe did not immediately abate on the removal of the wool; as it appeared to be no improbable fuppofition that the difcharge might be continued by the force of habit, though the original caufe no longer remained.

It feemed therefore expedient to introduce fome other habit, in the place of the increafed fecretion of faliva; which habit might afterwards be gradually left off With this intention, he prevailed on the patient to chew perpetually a little dry bread, and to fwallow it with her fpittle. In a few weeks, it became neceffary for her to chew the bread only at certain hours in the day; and thus, after two months, fhe became entirely free from a moft difguftful and tedious diforder.

It is worthy of obfervation, that, at firft, the fwallowing of fo much faliva frequently occafioned a naufea; and that then, for a few hours, fhe was obliged to fpit it out as ufual; and that, during the greateft part of the time, when fhe chewed the bread, fhe had a ftool or two every day more than common.

GENUS CXX. ENURESIS. 390
An involuntary FLUX *of* URINE.

Enurefis, *Sauv.* gen. 264. *Lin.* 195. *Vog.* 113. *Sag.* 200.

THIS is a diftemper which frequently affects children, otherwife healthy, when afleep; and is extremely difagreeable. Often it is merely the effect of lazinefs, and may be driven off by proper correction; but fometimes it proceeds from an atony or weaknefs of the fphincter of the bladder. Many ridiculous cures have been prefcribed for it, and among the reft fieldmice dried and powdered. Tonics are frequently of ufe; but fometimes the diftemper proves obftinate, in fpite of every thing we can ufe. In the London Medical Obfervations we find blifters much recommended in this difeafe, when applied to the region of the os facrum. A girl of 13 years of age had been fubject to an enurefis for four years. She could retain her water but a very little while in the day-time, but it flowed continually in the night. She had taken Peruvian bark and elixir of vitriol in confiderable quantities; alfo Valerian and the volatile julep, without effect. She was feverely threatened, as the phyfcian fufpected it might arife from a bad habit; but this producing no effect, a blifter was applied to the os facrum, which in 24 hours totally removed the difeafe. A man aged 32, having been feized with an incontinence of urine and palfy of the lower extremities in confequence of taking a quack medicine, was cured of the incontinence of urine in 24 hours by one blifter, and of the palfy itfelf by another. A woman of 50 having been feized with an enurefis and paralytic affection of the right thigh and leg in confequence of a ftrain, was cured of both by a fingle blifter. Several other cafes are there mentioned, by which the power of blifters in removing this diftemper feems to exceed that of every other medicine whatever.

Apyrenoses Gonorrhœa

91

Genus CXXI. GONORRHOEA.

Gonorrhœa, *Sauv.* gen. 268. *Lin.* 200. *Vog.* 118. *Sag.* 204.

The gonorrhœa is a flux of viscid matter of various colours, from the urethra in men and the vagina in women. It commonly proceeds from coition with a person infected with the venereal disease, and is one of the most common forms under which that disease shows itself.

Description. The first symptoms of the disease in men are commonly a sensation at the end of the penis not unlike a flea-bite, together with a fulness of the lips of the urethra, and some degree of tension in the penis, the urinary canal feeling as if tightened, and the urine flowing in a small and unequal stream: a little whitish mucus is to be seen about the orifice of the urethra, and oozing from it when slightly pressed, especially if the pressure be made on the spot where the soreness is most felt. The discharge soon increases in quantity, and varies in its colour according to the degree of inflammation. The patient feels a sensation of heat and pain in evacuating his urine, particularly at certain spots of the urethra, and above all towards its orifice; and the involuntary erections to which he is subjected from the stimulus, particularly when warm in bed, occasion a distortion or curvature of the penis, attended with exquisite pain. When the inflammation is violent, the glans appears tumid and transparent, the tension extends through the whole of the penis, the perinæum is affected with swelling and redness, and even the loins, buttocks, and anus, sympathize and afford a very uneasy sensation. Sometimes the prepuce inflames about the end of the penis, and cannot be drawn back, occasioning what is called a *phymosis*; at other times, as in the *paraphymosis*, it remains in an inflamed state below the glans, so that it cannot be drawn forwards; and, if the stricture and inflammation be violent, may terminate in gangrene. Now and then, especially when there is a phymosis, we may perceive a hard chord extending along the back of the penis. This is an inflamed lymphatic, and may be considered as a prelude to a bubo. When, however, a bubo does appear, almost universally some ulceration is previously to be discovered about the præputium, or glans penis; which gives ground to presume that some other contagious matter besides that of gonorrhœa may have been applied to the urethra. For it is certain that matter capable of communicating the contagion of gonorrhœa to a female, is often copiously applied to the whole glans penis of a male for several days together, without giving either ulceration or bubo.

In mild cases, the seat of the disease is in the urethra, not far from its orifice; but it frequently happens that the virus insinuates itself much higher up, so as to affect Cowper's glands, the prostate, and parts very near to the neck of the bladder.

In the generality of cases, the inflammation goes on increasing for several days, commonly for a week or a fortnight; after which the symptoms begin to abate; and the running, when left to itself, gradually lessens in quantity, and becomes whiter and thicker, till at length it totally stops. The colour of the mucus, however, is by no means a certain guide in these cases: for in many patients it is of a yellowish, and sometimes of a greenish hue to the very last; but in general it becomes more consistent towards the close of the disease.

In women, the external parts of generation being fewer and more simple, the disease is less complicated than in men. Sometimes the vagina only is affected; and when this happens, the symptoms are very trifling: but in general it comes on with an itching and sensation of heat as in the other sex; and is attended with inflammation of the nymphæ, inside of the *labia, clitoris, caruncula myrtiformes*, the orifice and sometimes the whole of the *meatus urinarius*. Very often the deep-seated glands of the vagina are affected, and it is sometimes difficult to distinguish the discharge of a gonorrhœa from that of the fluor albus.

Causes, &c. Many ingenious arguments have of late been advanced to prove, that the gonorrhœa and the lues venerea are different affections, originating from two distinct species of virus; and this controversy still, perhaps, remains to be decided by future facts. Certain it is, that in 19 of 20 cases of gonorrhœa, no symptom whatever of syphilis appears; and that the disease readily admits of cure without having recourse to those remedies which are universally requisite for combating the contagion of syphilis. It is by no means wonderful, that in some cases both contagions, supposing them different, should be communicated at the same time. Nay, cases are by no means rare, where the contagion of itch, though essentially different from both, has been communicated with either. But as undeniable proof that the contagion in both cases is precisely the same, it has been alleged by some, that the matter of a chancre introduced into the urethra will generate a gonorrhœa, and that the discharge from a gonorrhœa will produce chancre, bubo, and every other symptom of syphilis. On the other hand, however, it is contended, that when experiments of this nature are conducted with the greatest accuracy, the matter of syphilis uniformly produces syphilis, and that of gonorrhœa, gonorrhœa only. Without pretending to decide on which of these experiments the greatest dependence is to be put, we may only observe, that while an almost inconceivably small portion of syphilitic matter applied to the glans penis, from connection with an infected female, infallibly produces syphilis if it be not speedily removed, the matter of gonorrhœa, in every instance of that disease, is applied to the whole surface of the glans penis for many days together without producing almost any bad effect whatever. From this, therefore, there is ground for inferring, either that it is not capable of being absorbed, or that if absorbed it is innocent.

But while there have been disputes with regard to the peculiar nature of the matter in gonorrhœa, there have also been controversies with respect to the source from whence it is derived. While some suppose it to be principally purulent matter arising from ulcerations, others assert that no such ulceration is ever produced in the urethra by gonorrhœa. They contend that the increased secretion in these cases is exactly similar to what happens in the catarrh. But the comparison will by no means hold good in every particular: in the latter the whole membrane of the nose is equally irritated; whereas in the gonorrhœa, only particular parts

Apocenoses of the urethra seem to be affected. The disease, in the generality of cases, seldom extends more than an inch and a half along that canal, and in many is confined (at least in the beginning) to a small spot about an inch from the extremity of the glans. The discharge is produced from that part of the urethra where the pain is felt; and the patient, when he voids his urine, feels no smarting till it reaches the inflamed spot: but as the disorder increases, the inflammation affects a greater number of points, just in the same manner as chancres affect different parts of the glans. It might be supposed that dissection would at once clear up this matter, and put an end to the dispute; but this is far from being the case. Dr Simmons has seen several urethras opened in persons who had a gonorrhœa at the time of their death: in three of them the surface of the urethra, as in the cases related by Morgagni, appeared for some way down of a slight red colour, and in all of them was covered with mucus; but without any appearance of ulceration, except in two dissections at Paris, in which most of the gentlemen present were convinced that they saw evident marks of it: but Dr Simmons says that the appearances were to him not sufficiently satisfactory to enable him to decide with certainty on the subject. On the other hand, when we consider that the discharge in a gonorrhœa is sometimes tinged with blood, and that when this happens a little blood-vessel is no doubt ruptured, we can have no reason to doubt that an ulceration may, and sometimes does, happen in these cases; especially as we often observe an excoriation near the orifice of the urethra. It is certain, that wherever there is considerable inflammation, there will be danger of ulceration. Besides, from a neglected or badly-treated gonorrhœa, we often see fistulas *in perineo*, and other ulcers of the urethra, penetrating through its substance, and affording a passage to the urine. And there can be no doubt that slight ulcerations of this canal often occur, and are afterwards perfectly obliterated, in a similar manner to what happens in the papillæ of the tongue, the tonsils, &c. Such an obliteration will the more readily take place in a part like the urethra, defended with mucus, and not exposed to the air, which is known to have no little effect in hardening a cicatrix.

But whether ulcers take place or not, whether the virus of gonorrhœa be precisely of the same kind with that which gives syphilis, or of a different kind, there is reason from the phenomena of the disease to conclude, that the matter first acts by mixing with the mucus at the extremity of the urethra; and that from thence it is propagated upwards, particularly where the excretories of mucus are most numerous; and that on the parts to which it is applied, it operates as a peculiar irritating cause. The consequences of this irritation will be inflammation and an increased secretion of mucus; and so far the complaint will be local. In ninety-nine cases of an hundred a local affection of this kind constitutes the whole of the disease; and of this inflammation, ulcerations within the urethra, strictures, and other local affections, may be the consequence. But whether a disease of the habit ever takes place, unless when the contagion of syphilis is communicated with that of gonorrhœa, still remains to be determined by future observations and experiments. Gonorrhœa

Nothing can be more variable than the period at which the disease makes its appearance after infection. Perhaps, at a medium, we may place it between the 4th and 14th day: but in some cases it happens within 24 hours; and in others, not before the end of five or even six weeks: neither of these extremes, however, are common.

From what has been said of the manner in which the contagious matter in gonorrhœa acts, and of the influence it exerts on those parts with which it comes in contact, it follows, that the prevention of gonorrhœa must depend on the removal of the contagious matter as soon as that can be done; and where this is either altogether neglected or not properly accomplished, that the cure must depend on counteracting the inflammation which this contagious matter excites, and the consequences which result from it.

The first of these intentions may be most certainly and most easily accomplished by careful lotion of all the parts to which the contagious matter has any chance of being applied. These parts, at least on the first application of the matter, are readily accessible: for even in men there is no reason to believe that it at first penetrates to any extent in the urethra. This washing of the parts should be performed as soon as possible; because then the matter is both most accessible and least involved with mucus: but although washing cannot be accomplished at an early period, it should not be neglected afterwards; for from the disease uniformly commencing, even when it does not appear till a considerable time after the application of the contagious matter, with a peculiar sense of titillation at the external parts, particularly in men at the extremity of the urethra, there is reason to believe that the contagious matter attached to the mucus may remain latent there for a very considerable time. For the purpose of washing, with a view to the prevention of this disease, recourse may be had to almost any watery fluid, provided it be not so stimulant as to produce bad effects from injuring the parts. Pure water, properly applied, is perhaps one of the best lotions; but there can be no doubt that its power in removing the contagious matter may be somewhat increased by such additions as render it a more powerful solvent of mucus. With this intention, one of the most powerful additions is the vegetable alkali, either in its mild or caustic state. In the latter state it is the most active, but in the former it is most safe; and the *lixiva purificata* of the Edinburgh pharmacopœia, to the extent of half a drachm, dissolved in six or eight ounces of water, is one of the best lotions that can be employed. The purpose of removing the contagion may often also be effectually answered from washing with water impregnated with soap; for there the alkali, though in a caustic state, is prevented from exerting any disagreeable effects, in consequence of its being combined with oily matters.

With the view of preventing gonorrhœa, some have advised, that the alkali either in its mild or caustic state, properly diluted with water, should be injected into the urethra: and there can be no doubt, that by this

Gonorrhœa.

this means the contagious matter, when it has entered the urethra, may be removed. A removal may also be effected by the injection of a weak solution of corrosive sublimate, which seems to act not by dissolving the mucus but by producing an augmented secretion. But at a very early period of the disease, injections are probably unnecessary; and if it has made any considerable progress, they are dangerous: for from the augmented sensibility of the part, even very gentle ones are apt to excite a high degree of inflammation.

There are practitioners who, supposing that the body possesses powers to expel the virus, and that the disease has a certain period to run through its several stages of progress, acme, and decline, are for leaving the cure to nature; or at least content themselves with assisting her by an antiphlogistic regimen, gentle evacuations, and the like.

That in many cases the disorder admits of a natural cure, there can be no doubt; the increased secretion of mucus carrying off the virus faster than it is formed, till at length the infection is wholly removed: But it is equally certain, that in every case, by the application of suitable remedies to the inflamed part, we may shorten the duration of the complaint, and abridge the sufferings of the patient, with the same certainty and safety as we are enabled to remove the effects of an ophthalmia or any other local inflammation, by proper topical applications. General remedies, such as occasional blood-letting, a cooling diet, the liberal use of diluting liquors, and mild purges, are by all allowed to be useful, and even necessary. Astruc was of opinion that in these cases blood-letting ought to be repeated five or six times; and there are still many practitioners who depend much on repeated evacuations of this sort for a removal of the inflammation. But there is, perhaps, not one case in ten in which it is at all requisite; and this small number of cases will consist only of the strong and plethoric: in such, when the chordee is frequent and painful, and the pulse hard and full, the loss of from eight to twelve ounces of blood will be beneficial, but it will be seldom necessary to repeat the operation. The inflammation in these cases is kept up by the local stimulus of the virus and the urine; and all that we can expect from venesection is to moderate the pain and the frequency of erection. In persons of a delicate habit, and of an irritable fibre, the evacuation will do no good; but if repeated will certainly be liable to do harm, by increasing irritability, and of course rendering the patient more susceptible of stimulus.

The utility, and even the necessity, of a cooling regimen, are sufficiently obvious; wine and spirituous liquors, spiceries, a fish-diet, much animal-food, and salted and high seasoned dishes of every sort, will constantly add to the complaint. The patient should eat meat only once a-day, and that sparingly. He should abstain from hot suppers. Milk, mild vegetables, and fruit, should constitute the principal part of his diet while the inflammatory symptoms continue. Every thing that tends to excite the venereal imagination should be studiously avoided; for whatever promotes erections of the penis will increase the inflammation, and of course add fuel to the disease. For the same reasons much walking or riding on horseback will be hurtful, from the irritation kept up in the perinæum by such means. Violent exercise of any kind, or any thing that is liable to increase the heat and the momentum of the blood, will of course be improper.

The drinking freely of mild, cooling, mucilaginous liquors, such as linseed-tea, orgeat, whey, milk and water, almond emulsion, and the like, will be extremely useful, by diluting the urine, and preventing its salts from stimulating the urethra. When the heat and pain in making water are very considerable, mucilaginous substances are found to have the best effect, particularly the gum tragacanth. It is a common practice to give equal doses of this gum or gum-arabic and nitre, and to dissolve nitre in the patient's drink, with a view to lessen the inflammation. But in these cases nitre is always improper: it is known to be a powerful diuretic, its chief action being upon the urinary passages; so that the stimulus it occasions will only serve to increase the evil it is intended to alleviate. Cream of tartar, on account of its diuretic quality, will be equally improper. Our view here is not to promote a preternatural flow of urine; for the virus, being insoluble in water, cannot easily be washed away by such means; but our object ought to be, to render the urine that is secreted as mild and as little stimulating as possible.

Mild purges, which constitute another material part of the general remedies, are no doubt extremely useful when exhibited with prudence; but it is well known that the abuse of purgative medicines in this disease has been productive of numerous evils. Formerly it was a pretty general practice to give a large dose of calomel at bed-time, three or four times a-week; and to work it off the next morning with a strong dose of the *pilulæ cocciæ*, or some other drastic purge. This method was persevered in for several weeks: in consequence of which the patient often found himself troubled with an obstinate gleet, and perhaps his constitution materially injured; the effect of such a method being (especially in irritable habits) to weaken the stomach and bowels, and lay the foundation of hypochondrial complaints. Violent purging likewise often occasions strangury, hernia humoralis, and other troublesome symptoms.

The purges employed in these cases should be gentle; such as Rochelle salt, manna, tartarised alkali, and the like. They should be given only in a dose sufficient to procure two or three stools, and be repeated only every two or three days. The daily use of the purgative electuaries that are still given by some practitioners, serves only to keep up a continual irritation on the bladder, and of course to prolong the inflammation.

The topical remedies that are used consist chiefly of different sorts of injections, the ingredients of which are extremely various; but their modes of operation may in general be referred to their mucilaginous and sedative, or to their detergent, stimulating, and astringent qualities. In the hands of skilful practitioners, great advantages may doubtless be derived from the use of these remedies; but, on the other hand, the improper and unseasonable administration of them may prove a source of irreparable mischief to the patient.

We know that mucilaginous and oily injections will tend to allay the local inflammation; and that a sedative

Apocenoses tive injection, such as a solution of opium, will lessen the irritability of the parts, and of course produce a similar effect; the utility of such applications is therefore sufficiently obvious.

A detergent injection, or one that will act upon the mucus of the urethra, increase the discharge of it, wash it away, and with it the venereal virus that is blended with it, can only be used as a prophylactic before the symptoms of infection have made their appearance. But great circumspection is necessary in the use of this kind of injection. If it be too weak, it can be of no efficacy; and if it be too strong, it may prove dangerous to the patient. A suppression of urine has been brought on by the improper use of an injection of this kind. When the symptoms of inflammation have once made their appearance, the stimulus of such an injection must be extremely hazardous. Excoriation of the urethra has but too often been produced by remedies of this sort in the hands of adventurous and unskilful practitioners.

While the inflammation of the urethra continues, every thing that stimulates it must be hurtful. If the injection excites a painful sensation in the urethra, as is but too often the case, it will be liable to produce swelled testicles, difficulty in making water, excoriation, and other effects of increased inflammation: if, by its astringency, the running be checked before the virus that excited the discharge be properly subdued, the patient will be exposed to fresh dangers; and perhaps to a variety of local complaints, such as obstructions in the urethra, and abscesses *in perinæo*, which are well known to be sometimes owing to applications of this sort improperly managed.

When the inflammation has subsided, gently stimulating and astringent injections may be used with safety, and with considerable advantage: for as the inflammation is at first excited by the stimulus of the venereal virus, so when the former begins to lessen, we may be assured that the activity of the latter has abated in proportion; and, in general, when the inflammatory symptoms are entirely removed, it will be found, that the mucus is no longer of an infectious nature, but is merely the effect of an increased secretion and of relaxation. Mild astringents will therefore serve to brace and strengthen the vessels secreting mucus, and in this way will lessen the discharge, and greatly promote the cure. It is certain, that in the greater number of cases, a gonorrhœa, which if treated by internal remedies alone, would continue for five or six weeks, or longer, may, when judiciously treated with injections, be cured in a fortnight, and very often in less time. The great aim, therefore, of the practitioner ought to be at first to make use of such injections only as will tend to lubricate the surface of the urethra, and to counteract and destroy the stimulus of the virus: as the inflammation abates, he may add some gently astringent preparation to a mucilaginous and sedative injection; taking care that its astringency be suited to the state of the disease, and to the irritability of the patient. Amongst a great variety of substances, mercury in different forms is one of those that is the most frequently employed in injections. All these mercurial injections have more or less of astringency; and, according to Dr Simmons, it is solely to this property that we are to ascribe their effects; for the idea of Gonorrhœa their correcting the venereal virus was originally introduced, and has, he thinks, been continued upon mistaken principles

Calomel, mixed with the mucus discharged in a gonorrhœa, has no more power in destroying the infectious properties of that mucus than ceruse or any other preparation would have. A diluted solution of sublimate injected into the urethra, will, like a solution of verdigrise, or blue vitriol, or any other styptic, constringe the mouths of the lacunæ; but this is all that it will do, for it will never lessen the infectious nature of the virus. The same thing may be observed of crude mercury extinguished by means of mucilage, or of mercurial unction, blended with the yolk of an egg, and which, when thrown up into the urethra, will act nearly in the same manner as balsam of copaiva, or any other stimulating injection. The stimulus of calomel, however, has often been found of considerable efficacy; and in women, when the vagina only was affected, after washing the parts well, the cure has been accomplished by rubbing them repeatedly with mercurial ointment.

As the gonorrhœa is only a local affection, it may be inferred, that the internal use of mercury is unnecessary towards the cure. Very often indeed this complaint may be removed without having recourse to mercurials. Sometimes patients have been met with whose general health has been greatly impaired by a long continued use of mercury in such cases, while the original disease, the gonorrhœa, was rendered much worse by it. In some it degenerated into a gleet, that was cured with extreme difficulty; in others it brought on a variety of distressing symptoms. In cases of gonorrhœas, therefore, whenever mercury is administered, it ought to be, not with a view to expedite the cure, but merely to obviate the dangers of syphilis. When the infection is apparently slight, and the inflammation and the symptoms trifling, we may proceed without the assistance of mercury, especially if the patient be of a weak, relaxed, and irritable habit, likely to be injured by mercurial medicines. On the other hand, when the discharge is violent, the inflammation considerable, or the seat of the disease high up in the urethra, it is perhaps the most prudent plan to give mercurials in small doses, and in such forms as seem the best adapted to the constitution of the patient.

The *pilulæ hydrargyri*, as prepared according to the receipts inserted in the last edition either of the London or Edinburgh pharmacopœias, in both of which the mercury is rendered active merely by triture, may perhaps be considered as one of the mildest and most efficacious forms under which mercury can be exhibited by the mouth. Its efficacy will depend on its not irritating the bowels, and so passing off by stool; care must likewise be taken to prevent its affecting the mouth. Of the chemical preparations of mercury, the mildest and least irritating is calomel. It may be given from gr. iss. to gr. iii. at bed time, occasionally interposing a mild purgative to prevent it from salivating; but in general the mercurial pill just mentioned is to be preferred.

When there is no chancre nor bubo, no appearance in short of syphilitic infection, it would be improper

Apocenoses. to adminifter corrofive fublimate, the mercurius calcinatus, or any other of the more acid preparations of mercury.

After a gonorrhœa proceeding from venereal caufes has been removed, another kind of running without pain, called the *gonorrhœa mucofa*, or *gleet*, fometimes remains. Sometimes it arifes from a conftriction and excoriation of the urethra, and frequently it is the effect of an enlargement and difeafed ftate of the proftate. In each of thefe cafes, as the gleet is the effect of irritation, the cure will depend on the removal of the local difeafe that occafions it. But there is another fpecies of gleet that feems to depend chiefly on relaxation. It is in general free from infection, and is moft common in thofe who have had long and frequent gonorrhœas. It is likewife often the effect of a debilitated habit, from fevere purging, or a long continued ufe of mercurials. A difcharge of this kind is more frequent in women than in men; or, at leaft, the fluor albus, after a gonorrhœa, will often be miftaken for a gleet.

When there is no reafon to fufpect remaining contagion, aftringent injections will be of the greateft fervice. It will be neceffary, at the fame time, to attend to the health of the patient, by employing the Peruvian bark, chalybeate waters, cold bathing, and fuch other remedies as will tend to ftrengthen the fyftem: and indeed by the ufe of thefe, particularly by the Peruvian bark, fuch runnings are often fuccefsfully combated in thofe who from apprehenfion of dangerous confequences cannot be prevailed upon to employ injections. When there is no tendency to inflammation, the balfam of copaiva may be prefcribed with advantage in large dofes. Dr Simmons fays he once faw a complaint of this fort removed by applying a blifter to the perinæum, after it had refifted a variety of other remedies. In the Medical Obfervations alfo we have an account of a gleet and incontinence of urine removed at once by a blifter to the os facrum. In general however, the other methods above mentioned will be fufficient to remove it, though fometimes it will continue for a long time in fpite of all our endeavours to check it.—Other kinds of gonorrhœa, in which the femen itfelf is ejected, efpecially during fleep, may be cured by tonics and a mild cooling regimen

392 ORDER V. EPISCHESES.

393 GENUS CXXII. OBSTIPATIO.
COSTIVENESS.

Obftipatio, *Lin.* 166. *Vog.* 128. *Sag.* 221.

Coftivenefs is fometimes occafioned by debility in dyfpeptic perfons, fometimes it is the effect of rigidity, and fometimes it is fymptomatic of the colic. It may proceed from an exceffive heat of the liver; drinking rough red wines, or other aftringent liquors; too much exercife, efpecially on horfeback: it may likewife proceed from a long ufe of cold infipid food, which does not fufficiently ftimulate the inteftines. Sometimes it is owing to the bile not defcending to the inteftines, as in the jaundice; and at other times it proceeds from difeafes of the inteftines themfelves, as a palfy, fpafms, tumors, a cold dry ftate of the inteftines, &c. Obftipatio.

Exceffive coftivenefs is apt to occafion pains of the head, vomiting, colics, and other complaints of the bowels. It is peculiarly hurtful to hypochondriac and hyfteric perfons, as it generates wind and other diftreffing fymptoms.

Perfons who are generally coftive fhould live upon a moiftening and laxative diet; as roafted or boiled apples, pears, ftewed prunes, raifins, gruels with currants, butter, honey, fugar, and fuch like. Broths with fpinage, leeks, and other foft pot-herbs, are likewife proper. Rye-bread, or that which is made of a mixture of wheat and rye together, ought to be eat. No perfon troubled with coftivenefs fhould eat white bread alone, efpecially that which is made of fine flour. The beft bread for keeping the belly foluble is what in fome parts of England they call *meflin*. It is made of a mixture of wheat and rye, and is very agreeable to thofe who are accuftomed to it.

Coftivenefs is increafed by keeping the body too warm, and by every thing that promotes the perfpiration; as wearing flannel, lying too long a-bed, &c. Intenfe thought, and a fedentary life, are likewife hurtful. All the fecretions and excretions are promoted by moderate exercife without doors, and by a gay, cheerful, fprightly temper of mind.

The drink fhould be of an opening quality. All ardent fpirits, auftere and aftringent wines, as port, claret, &c. ought to be avoided. Malt liquor that is fine and of a moderate ftrength is very proper Buttermilk, whey, and other watery liquors, are likewife proper, and may be drank in turns, as the patient's inclination directs.

Thofe who are troubled with coftivenefs ought, if poffible, to remedy it by diet, as the conftant ufe of medicines for that purpofe is attended with many inconveniences, and often with bad confequences. In time the cuftom becomes neceffary, and generally ends in a total relaxation of the bowels, indigeftion, lofs of appetite, wafting of the ftrength, and death.

The learned Dr Arbuthnot advifes thofe who are troubled with coftivenefs to ufe animal-oils, as frefh-butter, cream, marrow, fat broths, &c. He likewife recommends the expreffed oils of mild vegetables as olives, almonds, piftaches, and the fruits themfelves; all oily and mild fruits, as figs; decoctions of mealy vegetables; thefe lubricate the inteftines; fome faponaceous fubftances which ftimulate gently, as honey, hydromel, or boiled honey and water, unrefined fugar, &c.

The doctor obferves, that fuch lenitive fubftances are proper for perfons of dry atrabilarian conftitutions, who are fubject to aftriction of the belly and the piles, and will operate when ftronger medicinal fubftances are fometimes ineffectual; but that fuch lenitive diet hurts thofe whofe bowels are weak and lax. He likewife obferves, that all watery fubftances are lenitive; and that even common water, whey, four milk, and buttermilk, have that effect:—That new milk, efpecially affes milk, ftimulates ftill more when it fours on the ftomach; and that whey, turned four, will purge ftrongly:—That moft part of fruits are likewife laxative; and that fome of them, as grapes, will throw

Epischeses such as take them immoderately, into a cholera morbus, or incurable diarrhœa.

When the body cannot be kept open without medicine, gentle doses of rhubarb may be taken twice or thrice a-week. This is not near so injurious to the stomach as aloes, jalap, or the other drastic purgatives so much in use. Infusions of sena and manna may likewise be taken, or half an ounce of tartarised alkali dissolved in water-gruel. About the size of a nutmeg of lenitive electuary taken twice or thrice a-day, generally answers the purpose very well.

394 Genus CXXIII. ISCHURIA.
Suppression of *Urine*.

Ischuria, *Sauv.* gen. 293. *Lin.* 167. *Vog.* 129. *Sag.* 212. *Home's* Clinical Experiments, sect. xv.

This distemper is distinguished into various species, according as the seat of it is in the kidneys, the ureters, the bladder, or the urethra; and hence these species are named *renalis*, *ureterica*, *vesicalis*, and *urethralis*.

395 1. *Ischuria renalis*, or a suppression of urine from an affection of the kidneys, happens but rarely; however, Dr Home in his Clinical experiments describes such a case. In the end of December 1774, a man of a full habit, aged 35, was seized with shivering, coldness, and severe cough. Three days after, his urine appeared high-coloured, was passed with pain, and in small quantity. About the 8th of January 1775, he was attacked with violent pains in the small of his back, over the whole abdomen, and in the ankles, with pain in the region of the liver when pressed. A general swelling was afterwards observed all over the body, but mostly in the ankles and abdomen, which last was tense and hard. These were attended with vomiting, bad appetite, and considerable thirst. When he entered the clinical ward (January 21st), the cough, sickness, and vomiting, had gone off, but the suppression of urine remained. The little which he made was passed with his stools, so that Dr Home saw it but once; and then it was pale, and had a white powder at bottom. The pains and swellings, which retained the impression of the finger, continued; he had a head-ach, and a very slow pulse, beating only 48 strokes in a minute. He had taken a great many diuretic medicines before he came in. The day after his reception, he was seized with a spontaneous diarrhœa, which continued during the remainder of his life. Crystals of tartar were exhibited in doses of half an ounce each morning; at bed-time he took 20 drops of tincture of opium with a scruple of nitre, and continued this course for eight days without any increase of urine. The stronger and heating diuretics were then tried, as an infusion of juniper berries and pills of garlic; but they were attended with no sensible advantage. Whenever the pulse became so strong that he could bear bleeding, eight ounces of blood were taken away, which was sizy. This was thrice repeated; he appeared easier after each bleeding, his pulse bore it well, and the swellings and other symptoms abated. The heating diuretics, in this state, were given up; and a mixture of vinegar and nitre was substituted in their place, in each dose of which, taken every two hours, there was a scruple of nitre. Fomentations were applied to the region of the kidneys, Ischuria. and camphorated oil was afterwards rubbed on the part He was ordered the semicupium, which from a deficiency of water in the hospital at that time he got only once; and which then seemed to have a good effect, as he passed a gill of urine when he was in it. Notwithstanding this, however, the disease continually gained ground; he became comatose, delirious, and died ten days after his admission.—On dissection, the kidneys were found of an irregular form; some watery vesicles appeared on their surface, containing black gritty particles like fine sand; and the lower part of the right kidney was considerably inflamed. The pylorus, part of the duodenum, and a considerable part of the small intestines, were much inflamed. In the abdomen were found about five pounds of fluid, and in the cavities of the thorax about half a pound. The lungs were a little inflamed, and full of small tubercles on their surface and in their substance: the heart was large, and a polypus in each ventricle About six ounces of fluid were found in the pericardium: in the brain nothing preternatural appeared, except about an ounce of water in each ventricle.

Dr Home seems to have been at a loss for the remote cause of this suppression of urine, which manifestly had its immediate origin from the kidneys having lost the power of performing their functions. He thinks the inflammation which appeared in the right kidney was scarce sufficient to have occasioned the distemper, as the other would have supplied its place: for which reason also he thinks that the ischuria was owing to a general affection of the system; and that it was of an arthritic nature, the patient having been troubled with complaints of that kind for a long time before.

2. The *ischuria ureterica* is also a rare disease, unless 396
the obstruction proceeds from a stone or clot of blood stopping up the passage. Gravel or stones, indeed, are very frequently formed in the kidneys; and, by falling into the ureters, occasion an ischuria, with violent pain, and symptoms more or less urgent in proportion to the size and shape of the stones. Sometimes it is attended with coldness of the extremities, nausea, vomiting, and spastic constriction of the præcordia, a difficulty of making water, constipation of the belly, difficulty of breathing, stupor of the thigh, retraction of the testicle to the *os pubis*, inquietude, loss of strength, syncope, and convulsion fits. When the violent pain has continued for several days and nights without intermission, and has brought the patient exceeding low, and the suppression of urine is complete, with coldness of the extremities and convulsions of the tendons, death is at hand. Nor is it a good sign when the stone continues long in the ureter; for then the appetite decays, a nausea and retching to vomit supervene, and the patient is consumed with a hectic heat. Sometimes the pain is attended with an inflammation of the stomach and intestines; and sometimes the disease ends in a dropsy of the breast, or lethargy, which soon carry off the patient.

The indications of cure are, to exclude the stone as easily as possible, and prevent the breeding of others. If the patient be of a sanguineous temperament, Sydenham recommends to take away ten ounces of blood

from

Ifchurefes — from the affected fide; and then to give the patient a gallon of poffet-drink in which two ounces of marfhmallow roots have been boiled, injecting at the fame time an emollient glyfter. After the poffet-drink has been vomited up, and the clyfter returned, give a pretty large dofe of an opiate. But if the patient be old or weak, or fubject to nervous affections, bleeding may be omitted, efpecially if his urine at the beginning of the fit be coffee-coloured, and mixed with gravel; but as to other things, the cure is the fame.—Huxham greatly recommends an emollient bath prepared of a decoction of marfh-mallow root, linfeed, fœnugreek feed, and flowers of chamomile, to which may be added a few white-poppy feeds. By the ufe of this bath he fays he has feen the moft cruel fit of the gravel fuddenly ended, when neither copious bleeding nor opiates had the leaft effect. Mild diuretics are alfo of fervice Hoffman recommends dulcified fpirit of nitre as proper to relax the fpaftic ftricture. It is to be taken with fuitable diftilled waters and fyrup of poppies; or in broth, with a few fpoonfuls of oil of fweet almonds. Turpentine glyfters are alfo accounted very ferviceable; and may be prepared of ten ounces decoction of chamomile, with half an ounce of turpentine diffolved in the yolk of an egg, and about as much honey. The *fal diureticus*, or acetated alkali, is much efteemed by fome, when taken along with an opiate. But when the ftone is too big to pafs, Arbuthnot recommends a cool and diluent diet to hinder the further growth of it. Whey, infufion of linfeed, decoction of marfhmallows, and gently refolving diuretics, are alfo proper To put a ftop to the vomiting, *balfamum traumaticum* may be ufed with fuccefs when almoft every other means have failed.

397 3. The *ifchuria veficalis* may arife from a ftone in the bladder; and this indeed is the moft common caufe of it: but there are certain cafes in which, though the ufual quantity of urine, or perhaps more, be paffed, the patient dies from the retention of a ftill greater quantity in the bladder. Of this Dr Home gives the following inftances. A man of 58 years of age, of a ftrong fpare habit, and never fubject to the gravel, had, during the winter of 1777, a cough with expectoration, which went off in the beginning 1778. About the 17th of February 1778 he felt fome difficulty in paffing his urine, and much pain about the region of the bladder. He continued in this way for ten days, after which he became eafier on application of fome medicines. The abdomen then fwelled, and he had pains in his loins and thighs. On the 3d of March he was admitted into the clinical ward: his abdomen was then fwelled and tenfe; and an evident fluctuation was felt, which fome that touched him thought was fonorous and produced by wind. A tumor was difcovered betwixt the navel and fpine of the os ilium on the left fide, which gave him much pain, efpepially when preffed. This tumor became more eafily felt after the fwelling of the abdomen decreafed, feemed round, and very near as large as the head of a child. It appeared very much on the left fide, even when the patient lay on the right, and the tumor then became dependent. He paffed urine frequently, and rather more than in health, as it was computed at four pints a-day. It was always clear, and of a light colour. His body had a ftrong difagreeable fmell; his fkin was dry, belly bound, and his appetite entirely gone, fo that he had hardly taken any food for 12 days. His legs fwelled flightly for fome days in the evening. His pulfe was generally regular, fometimes flower than natural, and fometimes a little quicker; being once felt at 64, and another time at 92. He was often feized, efpecially after eating or drinking, with hiccough; which increafed and lafled till his death. On the 20th day of his difeafe, after fome dofes of fquills, the general fwelling of his abdomen fell, became much fofter, and more diftinctly difcovered the fwelling of the left fide. The next day a vomiting came on; he became delirious, and died the day following. The body being opened, it appeared that the tumor which was fo diftinctly felt on the left fide of the abdomen, was owing to a diftenfion of the bladder with urine. Its fundus reached to about the divifion of the aorta into the iliacs; it entirely filled the pelvis, and contained between five and fix pounds of urine of a pale colour. On examining the external furface, its neck, and the beginning of the urethra, were found to be furrounded with a fcirrhofity, which impeded the evacuation of the urine. The bladder itfelf was much thickened, but not more in one part than another. The ureters entered naturally; but were much thickened in their upper half near the kidney. The kidneys were fomewhat enlarged; particularly the left, which had feveral watery veficles on its external furface. Thefe organs were not in their ufual fituation; but lay clofe on each fide of the fpine, and very near the aorta; fo that the renal veffels were very fhort. What was very fingular, the lower end of each rofe over the fpine, and they were united together by their membranes and fubftances, the aorta paffing beneath the union. The bladder had preffed confiderably on this part; and the peritoneum covering them was confiderably thicker than natural. The lungs adhered every-where to the pleura, and in in fome places very firmly; they were of a loofe texture and black colour; and the veins of the lower extremities were turgid with blood. It does not appear that this patient got any medicines farther than a few dried fquills, which diminifhed the fwellings and brought off much wind. He alfo got a mixture of mufk, and afterwards of opium, for his hiccough; but without fuccefs. His difeafe was miftaken for an afcites; and the catheter was not tried: but in another cafe the ufe of this inftrument was apparently of more fervice than any internal medicines. This laft patient was about 90 years of age, and laboured under fymptoms very fimilar to thofe already mentioned. When admitted into the clinical ward, he had the hypogaftric region fwelled, and difficulty of paffing his water; but without pain, vomiting, or hiccough. He had loft all appetite; was thirfty, and coftive. His pulfe was 110, and weak. In the evening about three Englifh pints of pale clear urine were drawn off by means of the catheter: the next day all the fymptoms were gone off or abated. After this he continued to pafs fome urine, fometimes voluntarily, fometimes involuntarily and infenfibly; but fo much always remained behind, that his bladder was conftantly full, unlefs when the urine was drawn

Ifchuria.

Epiſcheſes off, which was done twice every day. The urine was ſometimes pale, ſometimes of a deep red colour; and once there was ſome blood mixed with it, which perhaps might have been occaſioned by the catheter. About the ſixth day the urine was very putrid, with much purulent-like matter at the bottom, and was paſſed with more pain. About the 11th, the putrid ſmell went off. The next day all the urine paſſed inſenſibly except what was drawn off; and an hiccough, though not very ſevere, had come on. In this way he continued without fever, though frequently troubled with the hiccough, eſpecially during thoſe nights in which the urine had not been drawn off. A month after admittance, the bladder, with the aſſiſtance of the catheter, was almoſt entirely, though inſenſibly evacuated, and the hiccough had left him; he had no other complaint but that of voiding his urine inſenſibly, the natural effect of a ſcirrhous bladder, and which was probably incurable. With this patient the hot bath and mercurials were tried, in order to ſoften the ſcirrhoſity of the bladder, but without effect.

298 4. The *iſchuria urethra's* ariſes from ſome tumour ſtopping up the paſſage of the urethra, and thus hindering the flow of urine. It is an uncommon diſtemper, and generally follows a gonorrhœa. Dr Home gives us an example of this alſo.—The patient was a man of 60 years of age, who had laboured under a gonorrhœa ſix months before, and which was ſtopped by ſome medicines in two or three days. He felt, ſoon afterwards, a difficulty in paſſing his urine, which gradually increaſed. About 10 days before his admiſſion into the clinical ward, it was attended with pains in the glans, and *ardor urinæ;* he had paſſed only about eight ounces the day before his admiſſion, and that with very great difficulty; and the hypogaſtric region was ſwelled and pained. On introducing the catheter, three pounds of urine were drawn off, by which the pain and ſwelling were removed. The inſtrument required force to make it paſs the neck of the bladder, and blood followed the operation; and the finger, introduced into the anus, felt a hard tumour about its neck. He was treated with mercurial pills and ointment, by which the ſwelling about the neck of the bladder ſoon began to decreaſe; but at the ſame time a ſwelling of the right teſticle appeared. He was vomited with four grains of turbith-mineral, which operated gently; and here Dr Home obſerves, that though theſe vomits are little uſed, from a miſtaken notion of their ſeverity, he never ſaw them operate with more violence than other vomits, or than he could have wiſhed. The ſwelling diminiſhed in conſequence of the vomit and ſome external applications; and the cure was completed by bleeding and a decoction of mezereon-root.

399 Genus CXXIV. DYSURIA.

Difficulty of discharging urine.

Dyſuria, *Sauv.* gen. 265. *Lin.* 57. *Vog.* 164 *Sag.* 213.

Stranguria *auctorum.*

A difficulty of making water may ariſe from many different cauſes; as from ſome acrid matter in the blood, cantharides, for inſtance: and hence a ſtrangury very often ſucceeds the application of bliſters. Dyſuria. In many caſes it ariſes from a compreſſion of ſome of the neighbouring parts; of the uterus, for inſtance, in a ſtate of pregnancy. Or it may ariſe from a ſpaſmodic affection of the bladder, or rather its ſphincter; or from an inflammation of theſe parts, or others near them. Hence the diſeaſe is diſtinguiſhed into ſo many ſpecies, the cure of which depends upon the remedies indicated by their different cauſes.

But the moſt common, as well as the moſt dangerous ſpecies is that ariſing from a calculous concretion, or

Stone in the Bladder. 400

Dyſuria calculoſa, *Sauv.* ſp. 12.

The ſigns of a ſtone in the bladder are, pain, eſpecially about the ſphincter; and bloody urine, in conſequence of riding or being jolted in a carriage; a ſenſe of weight in the *perinæum;* an itchineſs of the *glans penis;* ſlimy ſediment in the urine; and frequent ſtoppages in making water; a *teneſmus* alſo comes on while the urine is diſcharged: but the moſt certain ſign is, when the ſtone is felt by the finger introduced into the anus, or by the catheter.

Cauſes, &c. It is not eaſy to ſay what the particular cauſes are that occaſion the apparently earthy particles of the fluids to run together, and form thoſe calculous concretions which are found in different parts of the body, and eſpecially in the organs for ſtraining off and diſcharging the urine.

The gout and ſtone are generally ſuppoſed to have ſome affinity, becauſe gouty people are for the moſt part afflicted with the gravel. But perhaps this is in part owing to their long confinement, and to the lying on the back, which people who labour under the gout are often obliged to ſubmit to; ſince the want of exerciſe, and this poſture, will naturally favour the ſtagnation of groſs matters in the kidneys: beſides, there are many inſtances of peopl ſeverely afflicted with the ſtone for the greateſt part of a long life, who have never had the leaſt attack of the gout.

There is, however, good reaſon for believing, that ſome farther connection takes place between the two diſeaſes; and when treating of the gout we have already given ſome account of the opinion of an ingenious anonymous author, who has endeavoured to prove, that both the one and the other depend on a peculiar acid, the concreting or lithic acid, which is always preſent in blood; and which may be precipitated from thence by various cauſes, ſuch as the introduction of other acids, or the like. When thus precipitated, he ſuppoſes it to produce the whole phenomena of both diſeaſes. The objections we formerly ſtated to his theory of gout, do not equally militate againſt that of calculus; and it is at leaſt certain, from the beſt chemical analyſis, that what are commonly called *urinary calculi*, and have been conſidered as entirely an earthy matter, conſiſt principally of acid in a ſolid ſtate united only with a ſmall proportion of earth or mucus. We may, therefore, whether this hypotheſis be altogether well founded or not, juſtly view lithiaſis as depending on the ſeparation of an acid from the blood.

Whatever may be the particular cauſe of the diſpoſition

Diseases position to *lithiasis*, the kidneys appear to be the most likely places for particles to concrete or run together, because of the great quantity of blood which passes through the renal arteries, and which comes immediately from the heart, fraught with various newly-received matters, that have not undergone much of the action of the vessels, and therefore cannot as yet be supposed to be thoroughly assimilated.

Anatomists who have carefully examined the kidneys in the human subject, particularly M. Bertin, inform us, that there are two sets of *tubuli uriniferi*; the one continued directly from the extremities of the renal artery, and the other springing from that vesicular texture which is conspicuous in the kidneys.

It is in this vesicular part of the kidney that we presume the particles of the concreting matter first stagnate and coalesce: for it is hardly to be supposed, that such solid matters could be allowed to stop in the extremities of the renal arteries, since the blood, and the urine separated from it, must flow through these vessels with great degrees of force and velocity; but in the intermediate vesiculæ the particles may lie, and there attracting each other, soon come to acquire sensible degrees of magnitude, and thus become sand or gravel. As long as this sand or gravel formed in the vesicular part of the kidney lies quiet, there will be no pain or uneasiness, until the concretions become large enough to press either on the adjoining *tubuli*, or on the blood-vessels; then a sense of weight, and a kind of obtuse pain in the loins, will be felt. But when the small pieces of concreting matter shall be dislodged and washed off by the force of the circulating fluids, or loosened by some spasmodic action of the moving fibres in these parts, they will in their passage create pain, raise different degrees of inflammation, or perhaps lacerate some blood-vessels, and cause bloody urine. When these little concretions happen to be detained in the pelvis of the kidney, or any other place where a flow of urine continually passes, they soon increase in size, and become calculi, from the constant accession of particles, which are attracted by the original bit of sand, which thus becomes the nucleus of a stone.

It is an opinion which Hippocrates first advanced, and which has been almost universally adopted by his followers, and has remained till lately uncontroverted, that the stone and gravel are generated by the use of hard water. And from this quality, which the waters of certain springs possess, of depositing a large earthy sediment, either in the aquæducts thro' which they are conveyed, or in the vessels in which they are boiled or preserved, it was conjectured, that in passing through the kidneys, and especially whilst retained in the bladder, they would let fall their grosser particles, which by the continued apposition of fresh matter, connected by the animal gluten, and compacted by the muscular action of that organ, would in time form a calculus sufficiently large to produce a train of the most excruciating symptoms. And this reasoning *à priori* has been supposed to be confirmed by facts and experience; for not to mention the authority of Hippocrates, Dr Lister has observed, that the inhabitants of Paris are peculiarly subject to the stone in the bladder. Nicholas de Blegny has related the history of one who was dissected at Paris, in whom the pylorus, a great part of the duodenum, and the stomach itself, were found incrustated with a stony matter, to the thickness of a finger's breadth. And it is well known, that the water of the river Seine, with which that city is supplied, is so impregnated with calcareous matter, as to incrustate, and in a short time to choak up, the pipes through which it runs. But on the other hand it is objected, that the human calculus is of animal origin, and by chemical analysis appears to bear very little analogy to the stony concretions of water: and though it be allowed, that more persons are cut for the stone in the hospitals at Paris than in most other places; yet upon inquiry it is found, that many of those patients come from different provinces, and from towns and villages far distant from the Seine.

Dysuria.

Dr Percival conjectures, that though this disease may chiefly depend upon a peculiar disposition to concrete in the animal fluids, which in many instances is hereditary, and in no instance can with certainty be imputed to any particular cause; yet hard water is at least negatively favourable to this diathesis, by having no tendency to diminish it. The urine of the most healthy person is generally loaded with an apparently terreous matter, capable in favourable circumstances of forming a calculus; as is evident from the thick crust which it deposits on the sides of the vessels in which it is contained. And it seems as if nature intended by this excretion to discharge all the superfluous salts of the blood, together with those earthy particles, which are either derived from our aliment, and fine enough to pass thro' the lacteals, though insuperable by the powers of circulation, or which arise from the abrasion of the solids, or from the dissolution of the red globular part of our fluids. Now water, whether used as nature presents us with it, or mixed with wine, or taken under the form of beer or ale, is the great diluter, vehicle, and menstruum, both of our food, and of the saline, earthy, and excrementitious parts of the animal juices. And it is more or less adapted to the performance of these offices, in proportion to its degree of purity. For it must appear evident to the most ordinary understanding, that a menstruum already loaded, and perhaps saturated with different contents, cannot act so powerfully as one which is free from all sensible impregnation. Nor is this reasoning founded upon theory alone; for it is observed, that Malvern water, which issues from a spring in Worcestershire remarkable for its uncommon purity, has the property of dissolving the little sabulous stones which are often voided in nephritic complaints. And the solution too, which is a proof of its being complete, is perfectly colourless. Hence this water is drunk with great advantage in disorders of the urinary passages. And during the use of it, the patient's urine is generally limpid, and seldom deposits any sandy sediment. Yet notwithstanding this appearance of transparency, it is certainly at such times loaded with impurities, which are so diluted and dissolved as not to be visible. For it is attended with a strong and fetid smell, exactly resembling that of asparagus. Hoffman mentions a pure, light, simple water in the principality of Henneberg, in Germany, which is remarkable for its efficacy in the stone and gravel; and a water of similar virtues was discovered not many years ago

Epifchefes ago in the black foreft, near Oftcrod, which upon examination did not afford a fingle grain of mineral matter. Indeed it is worthy of obfervation, that moft of the fprings which were formerly held in great efteem, and were called *holy wells*, are very pure, and yield little or no fediment.

Dr Percival informs us that a gentleman of Manchefter, who had been long fubject to nephritic complaints, and often voided fmall ftones, was advifed to refrain from his own pump-water, which is uncommonly hard, and to drink conftantly the foft water of a neighbouring fpring; and that this change alone, without the ufe of any medicine, has rendered the returns of his diforder much lefs frequent and painful. A lady alfo, much affected with the gravel, was induced by the perufal of the firft edition of Dr Percival's Effay, to try the effect of foft water; and by the conftant ufe of it remained two years entirely free from her diforder.

In nephritic cafes, diftilled water would be an excellent fubftitute for Malvern water, as the following experiment evinces.

Two fragments of the fame calculus, nearly of equal weight, were immerfed, the one in three ounces of diftilled water, the other in three ounces of hard pump-water. The phials were hung up clofe together in a kitchen-chimney, at a convenient diftance from the fire. After 14 days maceration, the calculi were taken out, and carefully dried by a very gentle heat. The former, *viz.* that which had been immerfed in diftilled water, was diminifhed in its weight a grain and a half; the latter had loft only half a grain.

It is the paffage of thefe calculi from the kindeys down into the bladder, which occafions the pain, vomiting, and other fymptoms, that conftitute what is ufually termed a *fit of the gravel* or *ftone*.

When an inflammation is actually raifed, the difeafe is known by the name of *nephritis*, and has been already treated of.

As foon as the ftone paffes through the ureter, and falls into the bladder, the pain and other nephritic fymptoms ceafe; and every thing will remain quiet, either till the ftone be carried into the urethra, or until it has remained long enough in the bladder to acquire weight fufficient to create new diftrefs.

If a ftone happens to be fmooth and of a roundifh form, it may lie in the bladder and acquire confiderable bulk before it can be perceived by the patient; but when it is angular, or has a rugged furface, even though it may be fmall in fize, yet it feldom fails to raife pain, and occafion bloody urine, or the difcharge of a flimy fluid, with tenefmus, and difficulty in making water.

There have been various attempts made to diffolve the ftone; and there are certainly fome articles which have this effect when applied to them out of the body; but the almoft total impoffibility of getting thefe conveyed to the kidneys, renders it extremely doubtful whether a folvent ever will be difcovered. Of all the articles employed for this purpofe, no one perhaps has had greater reputation than fixed alkaline falt in its cauftic ftate, particularly under the form of the *aqua lixivi cauftica*: but this being of a very acrid nature, it requires to be well fheathed by means of fome gelatinous or mucilaginous vehicle. Veal-broth is as convenient as any for this purpofe; and accordingly Dyfuria. it is ufed by thofe who make a fecret of the cauftic alkali as a folvent of calculus.

Mr Blackrie, who has taken much pains in this inquiry, has proved very fatisfactorily, that Chittrick's noftrum is no other than foap-lees given in veal-broth, which the patients fend every day to the doctor, who returns it mixed up with the medicine, in a clofe veffel fecured by a lock.

It is not every cafe, however, that either requires or will bear a courfe of the cauftic alkali. Some calculi are of that foft and friable nature, that they will diffolve even in common water; and there are cafes wherein it appears that the conftant ufe of fome very fimple decoction or infufion of an infignificant vegetable, has brought away large quantities of earthy matter, in flakes which apparently have been united together in layers to form a ftone. Dr Macbride affures us, that a decoction of raw coffee, only 30 berries in a quart of water, boiled till it acquired a deep greenifh colour, taken morning and evening to the quantity of eight or ten ounces, with ten drops of fweet fpirit of nitre, had the powerful effect of bringing away, in the courfe of about two months, as much earthy matter in flakes as filled a large tea-cups. The patient was far advanced in years; and, before he began this decoction, had been reduced to great extremities by the continuance of pain and other diftreffing fymptoms: he was purged occafionally with *oleum ricini*.

Very lately the alkali in a mild ftate, and in a different form, has been much ufed by many calculous patients and with great advantage, under the form of what is called *alkaline aërated water*. For the introduction of this medicine, or at leaft for its extenfive ufe, we are chiefly indebted to that ingenious phyfician Dr William Falconer of Bath. He has lately publifhed an account of the *Aqua Mephitica Alkalina*, or Solution of fixed alkaline falt, faturated with fixable air, in calculous diforders; which contains a number of cafes ftrongly fupporting the benefit to be derived from it. But whether the good effects obtained in thefe inftances are to be explained from its operating as a folvent of calculus, feems to be extremely doubtful. There are indeed cafes in Dr Falconer's treatife, of patients in whom, after ufing it for a confiderable time, no ftone could be detected by founding, although it had been difcovered in that way before they began the employment of it. But in many inftances, the relief has been fo fudden, that it may be concluded, that, notwithftanding the eafe obtained, the calculus ftill remained. In fuch cafes, it probably removed from the urine that quality by which it gives to the calculus frefh accretions, producing that roughnefs of its furface by which it is chiefly capable of acting as a ftimulus. For the diftreffing fymptoms refulting from ftone, are more immediately to be attributed to the inflammatory and fpafmodic affections which it induces; and when its furface is leaft capable of operating as a ftimulus, thefe of courfe will be leaft confiderable It is therefore not improbable, that this remedy produces relief, by preventing frefh additions being made to the calculus.

An infufion of the feeds of *daucus fylveftris* fweetened with honey, is another fimple and much celebrated remedy;

Ischuria. remedy; it has been found to give considerable ease in cases where the stomach could not bear any thing of an acrid nature: the leaves of the *uva ursi* were strongly recommended by the late very celebrated De Haen; and, whatever its way of operating may be, seems to have been productive of good effects in some instances. There is no reason to believe that it has any influence in dissolving calculus; and indeed it seems to be chiefly useful in these instances where ulcerations take place in the urinary passages.

In the Edinburgh Medical Commentaries, vol. 3. we have an account of a method used by the inhabitants of Arabia Petræa for curing the stone, to which they are very much subject, and which the author (an English gentleman of experience and candour) affirms he has seen frequently performed with never-failing success. By means of a catheter they inject into the bladder a weak ley of alkali with the purified fat of a sheep's tail, and a proper quantity of opium all put together. Their catheters are made of gold; and in performing the operation they introduce them quite into the bladder; so that the composition is safely conveyed to the stone without hurting any other part. But when a stone is situated in the kidney, they have no method of cure.

If this method of curing by injection could be safely practised, it would no doubt greatly have the advantage over that of taking alkalies by the mouth, where the medicine is not only much weakened, but the constitution of the patient runs the risk of being greatly injured. But from some experiments mentioned in the second volume of the Medical Transactions, it appears that the human calculi are very different from one another in their natures. Some, for instance, will easily yield to an alkaline menstruum, and very little to an acid; while others are found to resist the alkali, and yield to the acid; and some are of such a compact nature, that they yield neither to acids nor alkalies. An attention, however, to the fragments, scales, or films, which the stone may cast off, and also to the contents and sediment of the urine, may lead to the discovery of what solvent is proper, or whether the stone can be dissolved by any. To use either alkalies or acids improperly may be hurtful; though there may be such kinds of calculi as demand the alternate use of acids and alkalies; nay, there may be found calculi of opposite kinds in the same subject.

In such cases as will not allow us to think of dissolving the stony concretions, and where the only scheme is to palliate and procure ease from time to time, little more can be done than to keep the bowels open occasionally by some gentle cathartic, and wash off as much of the loose gravelly matter and slime as can be removed by such mild diuretic infusions and decoctions as shall be found to pass freely and sit well on the stomach. Persons afflicted with the stone should be careful in respect of their diet, and studiously avoid all heavy and flatulent food, as well as high sauces that are apt to turn rancid. For the same reason, butter and acids are to be shunned; for these often create heartburning, and every thing that offends the stomach raises the nephritic pain; such is the sympathy that obtains between the digestive and the uropoietic organs.

There have been surgeons bold enough to entertain an idea of cutting even into the kidney, in order to extract a stone: this, however, except in cases where an abscess has been formed, and nature points out the way, is merely chimerical. But cutting into the bladder for the same purpose, is an ancient and well-known operation, and often crowned with success. A description, however, of this operation belongs to the article Surgery, to which we refer; and here shall only make this remark, that a surgeon should never begin his operation, until he and his assistants are perfectly satisfied, from actually feeling the stone, that there is one in the bladder; because it has sometimes happened, that when the incision has been made, no stone could be found: and the patient having died in consequence of the operation, and the body being opened, it has appeared that the symptoms which occasioned the belief of a stone in the bladder arose from some other cause.

Dysuria. When a dysuria proceeds from any acrimonious matter thrown into the blood, it may be readily cured by bleeding, emollient clysters, cooling and diluting drinks with gum arabic or gum tragacanth, linseed tea, or the warm bath. When it arises from inflammations of the bladder or parts adjoining to it, we are to regard it only as a symptomatic affection; and the remedies used to remove the primary disease will also remove the dysuria. Sometimes it may arise from an ulcer of the bladder; in which case it is generally incurable; a mild nutritious diet will, however, protract the patient's life.

Genus CXXV. DYSPERMATISMUS. 401
Difficult Emission *of* Semen.

Dyspermatismus, *Sauv.* gen. 260.
Sterilitas, *Lin.* 171. *Sag.* 211.
Agenesia, *Vog.* 283.

This impediment proceeds generally from obstructions in the urethra, either by tumors in itself, or in the cavernous bodies of the penis; in which case the treatment is the same as in the ischuria urethralis; sometimes it is owing to a kind of epileptic fit which seizes the man in the venereal act; and sometimes the semen, when ejected from the proper receptacles, is again absorbed by them, or flows into the bladder, and is expelled along with the urine. The last case is very difficult, or indeed impossible to cure; as proceeding from scirrhi, or other indissoluble tumors of the verumontanum, or the neighbouring parts. In some it proceeds merely from too violent an erection; in which case emollient and relaxing medicines will be of service; and we have an example of a cure performed by means of these in the first volume of the Edinburgh Medical Essays.

Genus CXXVI. AMENHORRHOEA. 402
Suppression *of the* Menses.

Amenorrhœa, *Vog.* 130.
Dysmenorrhœa, *Lin.* 168. *Sag.* 218.

This, with some other symptoms, as dyspepsia, yellowish or greenish colour of the skin, unusual appetites, &c. constitutes the *chlorosis* already treated of, and which seldom or never appears without a suppression of the menses. In Dr Hume's Clinical Experiments

Epiſcheſes

ments we find the virtues of ſeveral emmenagogues ſet forth in the following manner. Chalybeates ſeldom or never ſucceeded: they were always found more uſeful in diminiſhing the evacuation when too violent, than in reſtoring it when deficient. The tincture of black hellebore proved ſucceſsful only in one of nine or ten caſes, though given to the length of four tea-ſpoonfuls a-day, which is double the quantity recommended by Dr Mead. Compreſſion of the crural artery, recommended by Dr Hamilton in the Phyſical and Literary Eſſays, Vol II. proved ſucceſsful only in one of ſix caſes. From the effects produced by this compreſſion, it has the ſtrongeſt appearance of loading the uterus with blood; from the ſenſations of the patient it produces the ſame effects as the approach of the menſes, and has every appearance in its favour; yet does not ſucceed. Dr Hume ſuppoſes that the uterus is more frequently in too plethoric and inflammatory a ſtate; in which caſe, this remedy will do more hurt than in a ſtate of inanition; however, he owns, that in the caſe in which it did ſucceed, the patient was plethoric and inflammatory. Veneſection is recommended as an excellent remedy; the Doctor gives three inſtances of its ſucceſs, and ſays he could give many more. It acts by removing the plethoric ſtate of the uterus, relaxing the fibres, and giving the veſſels full play; ſo that their action overcomes all reſiſtance, and the evacuation takes place. It is of no great moment from whence the blood is taken: the ſaphænic vein will perhaps empty the uterus moſt; but it is difficult to get the proper quantity from it, and the quantity of the diſcharge cannot be ſo well meaſured. The powder of ſavine is a moſt powerful remedy; and proved ſucceſsful in three caſes out of four in which it was tried. It was given to the quantity of half a drachm twice a-day. It is a ſtrong topical ſtimulus, and ſeems improper in plethoric habits. Madder-root, according to Dr Hume, is a very powerful medicine in this diſeaſe; and proved ſucceſsful in 14 out of 19 caſes in which it was tried, being ſometimes exhibited in the quantity of two ſcruples, or a drachm, four times a-day. It has ſcarce any ſenſible effects; never quickens the pulſe, or excites inflammatory ſymptoms: on the contrary, the heat, thirſt, and other complaints abate; and ſometimes theſe ſymptoms are removed, though the diſeaſe be not cured; but when it ſucceeds, the menſes appear from the third to the 12th day.—For other methods of curing the amenorrhœa, ſee CHLOROSIS.

Amenor-rhœa.

WE have now conſidered all thoſe diſeaſes enumerated in Dr Cullen's Noſology, whoſe cure is to be attempted chiefly by internal medicines. The other genera either require particular manual operations, or a very conſiderable uſe of external applications; and therefore properly fall under the article SURGERY. To this, therefore, we ſhall refer the genera which fall under the three laſt orders of this claſs of locales, viz. the *tumores*, *ectopiæ*, and *dialyſes*; and we ſhall add, by way of Appendix, a few obſervations on ſome important affections to which Dr Cullen has not given a place in his ſyſtem.

APPENDIX.

403

ANGINA PECTORIS.

DR HEBERDEN was the firſt who deſcribed this diſeaſe, though it is extremely dangerous, and, by his account, not very rare. It ſeizes thoſe who are ſubject to it when they are walking, and particularly when they walk ſoon after eating, with a moſt diſagreeable and painful ſenſation in the breaſt, which ſeems to threaten immediate deſtruction: but the moment they ſtand ſtill, all the uneaſineſs vaniſhes. In all other reſpects the patients at the beginning of this diſorder are well, and have no ſhortneſs of breath; from which the *angina pectoris* is totally different. After it has continued ſome months, the fits will not ceaſe inſtantaneouſly on ſtanding ſtill; and it will come on not only when the patients are walking, but when they are lying down, and oblige them to riſe up out of their beds every night for many months together. In one or two very inveterate caſes, it has been brought on by the motion of a horſe or carriage, and even by ſwallowing, coughing, going to ſtool, ſpeaking, or by any diſturbance of mind. The perſons affected were all men, almoſt all of whom were above 50 years of age, and moſt of them with a ſhort neck and inclining to be fat. Something like it, however, was obſerved in one woman, who was paralytic; and one or two young men complained of it in a ſlight degree. Other practitioners have obſerved it in very young perſons.

When a fit of this ſort comes on by walking, its duration is very ſhort, as it goes off almoſt immediately upon ſtopping. If it comes on in the night, it will laſt an hour or two. Dr Heberden met with one in whom it once continued for ſeveral days; during all which time the patient ſeemed to be in imminent danger of death. Moſt of thoſe attacked with the diſtemper died ſuddenly: though this rule was not without exceptions; and Dr Heberden obſerved one who ſunk under a lingering illneſs of a different nature.

The *os ſterni* is uſually pointed to as the ſeat of this malady; but it ſeems as if it was under the lower part of that bone, and at other times under the middle or upper part, but always inclining more to the left ſide; and in many caſes there is joined with it a pain about the middle of the left arm, which appears to be ſeated in the biceps muſcle.

The appearance of Dr Heberden's paper in the Medical Tranſactions very ſoon raiſed the attention of the faculty, and produced other obſervations from phyſicians of eminence; namely, Dr Fothergill, Dr Wall of Worceſter, Dr Haygarth of Cheſter, and Dr Percival of Mancheſter. It alſo induced an unknown ſufferer under the diſeaſe to write Dr Heberden a very ſenſible letter, deſcribing his feelings in the moſt natural manner; which, unfortunately, in three weeks after the date of this anonymous epiſtle, terminated in a ſudden death, as the writer himſelf had apprehended.

The youngeſt ſubject that Dr Fothergill ever ſaw afflicted

afflicted with this diforder was about 30 years of age; and this perfon was cured. The method that fucceeded with him was a courfe of pills, compofed of the mafs of gum pill, foap, and native cinnabar; with a light chalybeate bitter: this was continued for fome months, after which he went to Bath feveral fucceffive feafons, and acquired his ufual health: he was ordered to be very fparing in his diet; to keep the bowels open; and to ufe moderate exercife on horfeback, but not to take long or fatiguing walks.

The only fymptom in this patient that is mentioned, was a ftricture about the cheft, which came on if he was walking up hill or a little fafter than ordinary, or if he was riding a very brifk trot; for moderate exercife of any kind did not affect him: and this uneafy fenfation always obliged him to ftop, as he felt himfelf threatened with immediate death if he had been obliged to go forward.

It is the fharp conftrictive pain acrofs the cheft, that (according to Dr Fothergill's obfervation) particularly marks this fingular difeafe; and which is apt to fupervene upon a certain degree of mufcular motion, or whatever agitates the nervous fyftem.

In fuch cafes as fell under the infpection of Dr Fothergill, he very feldom met with one that was not attended with an irregular and intermitting pulfe; not only during the exacerbations, but often when the patient was free from pain and at reft: but Dr Heberden obferves, that the pulfe is, at leaft fometimes, not difturbed; and mentions his having once had an opportunity of being convinced of this circumftance, by feeling the pulfe during the paroxyfm.

But no doubt thefe varieties, as well as many other little circumftances, will occur in this difeafe as they do in every other, on account of the diverfity of the human frame; and if thofe which in general are found to predominate and give the diftinguifhing character be prefent, they will always authorife us in giving the name to the difeafe: thus, when we find the conftrictory pain acrofs the cheft, accompanied with a fenfe of ftrangling or fuffocation; and ftill more, if this pain fhould ftrike acrofs the breaft into one or both arms; we fhould not hefitate to pronounce the cafe an *angina pectoris*.

As to the nature of this difeafe, it appears to be purely fpafmodic: and this opinion will readily prefent itfelf to any one who confiders the fudden manner of its coming on and going off; the long intervals of perfect eafe; the relief afforded by wine, and fpirituous cordials; the influence which paffionate affections of the mind have over it; the eafe which comes from varying the pofture of the head and fhoulders, or from remaining quite motionlefs; the number of years for which it will continue, without otherwife difordering health; its bearing fo well the motion of a horfe or carriage, which circumftance often diftinguifhes fpafmodic pains from thofe which arife from ulcers; and laftly, its coming on for the moft part after a full meal, and in certain patients at night, juft after the firft fleep, at which time the incubus, convulfive afthma, and other ills, juftly attributed to the difordered functions of the nerves, are peculiarly apt to return or to be aggravated.

From all thefe circumftances taken together, there can be little doubt that this affection is of a fpafmodic nature: but though it fhould be admitted, that the whole diftrefs in thefe cafes arife from fpafm, it may not be fo eafy to afcertain the particular mufcles which are thus affected.

The violent fenfe of ftrangling or choaking, which fhows the circulation through the lungs to be interrupted during the height of the paroxyfm; and the peculiar conftrictive pain under the fternum, always inclining (according to Dr Heberden's obfervation) to the left-fide; together with that moft diftreffing and alarming fenfation, which, if it were to increafe or continue, threatens an immediate extinction of life; might authorife us to conclude that the heart itfelf is the mufcle affected: the only objection to this idea, and, if it had been conftantly obferved, it would be infurmountable, is, that the pulfe is not always interrupted during the paroxyfm. The appearances in two of the diffections, favour the opinion that the fpafm affects the heart; as in one fubject the left ventricle (and, though it be not mentioned, we may prefume the right one alfo) was found as empty of blood as if it had been wafhed; and in another, the fubftance of the heart appeared whitifh, not unlike a ligament; as it fhould feem, in both cafes, from the force of the fpafm fqueezing the blood out from the veffels and cavities.

If this hypothefis be allowed, we muft conclude that the fpafm can only take place in an inferior degree, as long as the patient continues to furvive the paroxyfm; fince an affection of this fort, and in this part, of any confiderable duration or violence, muft inevitably prove fatal: and accordingly, as far as could be traced, the perfons who have been known to labour under this difeafe have in general died fuddenly.

The diffections alfo fhow, that whatever may be the true feat of the fpafm, it is not neceffary for the bringing of it on, that the heart, or its immediate appendages, fhould be in a morbid ftate; for in three out of the fix that have as yet been made public, thefe parts were found in a found ftate.

On opening the body of the poor gentleman who wrote the letter to Dr Heberden, "upon the moft careful examination, no manifeft caufe of his death could be difcovered; the heart, in particular, with its veffels and valves, were all found in a natural condition."

In the cafe communicated by Dr Percival to the publifhers of the Edinburgh Medical Commentaries, "the heart and aorta defcendens were found in a found ftate." And in Dr Haygarth's patient, "on opening the thorax, the lungs, pericardium, and heart, appeared perfectly found." Not to mention Dr Fothergill's patient (R. M.), in whofe body the only morbid appearance about the heart was a fmall white fpot near the apex. So that the caufe, whatever its nature might have been, was at too great a diftance, or of too fubtile a nature, to come under the infpection of the anatomift. But there was a circumftance in two of the fubjects that is worthy of remembrance; and which fhows that the crafis of the blood, while they were living, muft have been greatly injured, namely, its not coagulating, but remaining of a cream-like confiftence, without any feparation into ferum and craffamentum.

From all that we have feen hitherto publifhed, it does

Angina Pectoris.

does not appear that any considerable advances have been made towards the actual cure of this anomalous spasm.

The very judicious and attentive Dr Heberden (to whom the public are highly indebted for first making the disorder known) confesses, that bleeding, vomits, and other evacuations, have not appeared to do any good: wine and cordials, taken at bed-time, will sometimes prevent or weaken the fits; but nothing does this so effectually as opiates: in short, the medicines usually called *nervous* or *cordial*, such as relieve and quiet convulsive motions, and invigorate the languishing principle of life, are what he recommends.

Dr Wall mentions one patient, out of the 12 or 13 that he had seen, who applied to him early in the disease, and was relieved considerably by the use of antimonial medicines joined with the fetid gums: he was still living at the time the Doctor wrote his paper, (November 1772), and going about with tolerable ease. Two were carried off by other disorders; all the rest died suddenly.

Dr Fothergill's directions are chiefly calculated with the view to prevent the disorder from gaining ground, and to alleviate present distress. Accordingly he enjoins such a kind of diet as may be most likely to prevent irritability: in particular, not to eat voraciously: to be particularly abstemious in respect to every thing heating; spices, spirits, wines, and all fermented liquors: to guard most scrupulously against passion, or any vehement emotions; and to make use of all the usual means of establishing and preserving general health: to mitigate excesses of irritability by anodynes; or pains, if they quicken the circulation: to disperse flatulencies when they distend the stomach, by moderate doses of carminatives; amongst which, perhaps, simple peppermint water may be reckoned one of the safest. But since obesity is justly considered as a principle predisposing cause, he insists strongly on the necessity of preventing an increase of fat, by a vegetable diet, and using every other practicable method of augmenting the thinner secretions.

These were the only means which occurred to the English physicians of opposing this formidable disease: but Dr Smyth of Ireland has, we are told, discovered that it may be certainly cured by issues, of which Dr Macbride gives the following instance.

" *A. B.* a tall, well made man; rather large than otherwise; of healthy parents, except that there had been a little gout in the family; temperate; being very attentive to the business of his trade (that of a watch-maker), led a life uncommonly sedentary; had, from his boyhood upwards, been remarkably subject to alarming inflammations of his throat, which seized him, at least, once in course of the year; in all other respects well.

" In 1767, (then 48 years of age), he was taken, without any evident cause, with a sudden and very dispiriting throbbing under the sternum. It soon afterwards increased, and returned upon him every third or fourth week, accompanied with great anxiety, very laborious breathing, choaking, a sensation of fulness and distension in the head, a bloated and flushed countenance, turgid and watery eyes, and a very irregular and unequal pulse. The paroxysm invaded, almost constantly, while he was sitting after dinner; now and then he was seized with it in the morning, when walking a little faster than usual; and was then obliged to stop, and rest on any object at hand. Once or twice it came on in bed; but did not oblige him to sit up, as it was then attended with no great difficulty in breathing. In the afternoon fits, his greatest ease was from a supine posture; in which he used to continue motionless for some hours, until, quite spent and worn out with anguish, he dropt into a slumber. In the intervals between these attacks, which at length grew so frequent as to return every fourth or fifth day, he was, to appearance, in perfect health.

" Thus matters continued for more than two years; and various antispasmodics were ineffectually tried for his relief. In 1769, there supervened a very sharp constrictory pain at the upper part of the sternum, stretching equally on each side, attended with the former symptoms of anxiety, dyspnœa, choaking, &c. and with an excruciating cramp, as he called it, that could be covered with a crown-piece, in each of his arms, between the elbow and the wrist, exactly at the insertion of the pronator teres; the rest of the limb was quite free. The fits were sometimes brought on, and always exasperated, by any agitation of mind or body. He once attempted to ride on horseback during the paroxysm; but the experiment was near proving fatal to him. The difference of season or weather made no impression upon him. Still, in the intervals, his health was perfectly good; except that his eyes, which before his illness were remarkably strong and clear, were now grown extremely tender; and that his sight was much impaired. He had no flatulency of stomach, and his bowels were regular.

" In this situation, February 22. 1770, he applied to me for assistance. I had seen, I believe, eight or ten of these frightful cases before. Two of the patients dropt dead suddenly. They were men between 40 and 50 years of age, and of a make somewhat fleshy. The fate of the others I was not informed of; or, at least, cannot now recollect.

" Having found the total inefficacy of blisters and the whole class of nervous medicines in the treatment of this anomalous spasm, I thought it right to attempt the correcting or draining off of the irritating fluid in the case now before us. To this purpose, I ordered a mixture of lime-water with a little of the compound juniper-water, and an alterative proportion of Huxham's antimonial wine: I put the patient on a plain, light, perspirable diet; and restrained him from all viscid, flatulent, and acrimonious articles. By pursuing this course, he was soon apparently mended; but after he had persisted regularly in it for at least two months, he kept for some time at a stand. I then ordered a large issue to be opened on each of his thighs. Only one was made. However, as soon as it began to discharge, his amendment manifestly increased. The frequency and severity of the fits abated considerably; and he continued improving gradually, until, at the end of 18 months, he was restored to perfect health; which he has enjoyed, without the least interruption, till now, except when he has been tempted (perhaps once in a twelvemonth) to transgress rules, by making a large meal on salted meat, or indulging himself in ale or rum-punch, each of which never failed to disorder

Angina Pectoris.

order him from the beginning of his illness: and even on these occasions he has felt no more than the slightest motion of his former sufferings; insomuch that he would despise the attack, if it did not appear to be of the same stock with his old complaint. No other cause has had the least ill effect on him.

"Though rum was constantly hurtful, yet punch made with a maceration of black currants in our vulgar corn-spirit, is a liquor that agrees remarkably well with him.

"He never took any medicine after the issue began to discharge; and I have directed that it shall be kept open as long as he lives. The inflammations of his throat have disappeared, for five years past; he has recovered the strength and clearness of his sight; and his health seems now to be entirely re-established."

Dr Macbride, in a letter to Dr Duncan, published in the Edinburgh Medical Commentaries, gives the following additional observations on this disease.

"Within these few weeks I have, at the desire of Dr Smyth, visited, three or four times, a very ingenious man who keeps an academy in this city, of about 34 years of age, who applied to the Doctor for his advice in January last.

"I shall give you his symptoms as I had them from his own mouth, which appear to me to mark his case to be an angina pectoris, and as deplorable as any that I have read of. It was strongly distinguished by the exquisite constrictory pain of the sternum, extending to each of his arms as far as the insertion of the deltoid muscle, extreme anxiety, laborious breathing, strangling, and violent palpitation of the heart, with a most irregular pulse. The paroxysms were so frequent, that he scarcely ever escaped a day, for six or seven years, without one. They were usually excited by any agitation of mind or body, though slight. He had clear intervals of health between the fits. The distemper seems hereditary in him, as he says his father was affected in the same manner some years previous to his death. He has a strong gouty taint, which never showed itself in his limbs; and he has led a life of uncommon sedentariness, from intense application to mathematical studies, attention of mind, and passion, even from his boyish years. These circumstances may, perhaps, account for his having been taken with this disease at so early an age as 17.

"A large issue was immediately opened in each of his thighs. In a month afterwards he began to mend, and has gone on improving gradually. He can now run up stairs briskly, as I saw him do no later than yesterday, without hurt; can bear agitation of mind; and has no complaint, excepting a slight oppression of the breast, under the sternum, which he feels sometimes in a morning, immediately after dressing himself, and which he thinks is brought on by the motion used in putting on his clothes; though for a complete week preceding the day on which I saw him last, he told me that he had been entirely free from all uneasiness, and was exulting that he had not had such an interval of ease for these last seven years.

"Doctor Smyth also showed me, in his *adversaria*, the case of a gentleman who had been under his care in 1760, which he had forgotten when my book went to the press, and which he was reminded of the other day by a visit from his patient. It was a genuine angina pectoris, brought on by a very sedentary life, and great vexation of mind, clearly marked by the exquisite pain under the sternum, that extended acutely to the upper extremities, particularly along the left arm, together with the other symptoms of dyspnoea, anxiety, palpitation of the heart, &c. recited in the case above. The disorder went off in 1762, by large spontaneous discharges from the piles, but returned upon him severely in 1765. Issues in his thighs were then recommended to him, but not made. But, whether it was by the persuasion of some friend, or of his own accord, he went into a course of James's powder, in small alterative doses, combined with a little castor and asafœtida. This he persisted in for about six weeks; in the meanwhile, he had large acrimonious gleetings from the scrotum, and a plentiful discharge of ichor from the anus.—From this time he began to find his complaints grow less and less distressing, and he has now been totally free from them for six years past."

The PUERPERAL, or Child-bed Fever.

404

This species of fever, as its name imports, is peculiar to women in child-bed; and is usually the most fatal of all the disorders to which the sex is liable. But, notwithstanding the prevalence of it in all ages, its real nature has remained, to the present time, a subject of much dispute and uncertainty. The critical period of its invasion, when febrile commotions are apt to be excited by various accidents, and the equivocal symptoms which accompany it, have even afforded room for questioning whether it be a primary or a secondary disease. Some writers have considered it as proceeding entirely from an inflammation of the uterus; others have imagined it to be the consequence of an obstruction to the secretion of the milk; while the greater number has been inclined, for reasons equally if not more plausible, to impute it to a suppression of the lochia. If we examine this fever attentively, however, according to its natural course, and independently of all the accidental concomitant symptoms with which it is not essentially connected, we may safely pronounce it to be a primary disease of a particular characteristic, and perhaps not the necessary consequence of any of the causes above-mentioned.

This fever is most generally incident to women within 48 hours after delivery, though it may supervene on the fourth or fifth day, and sometimes considerably later. It is preceded, like other fevers, by a rigor, which is commonly violent; and, when happening during the time of labour, may be confounded with the pains of parturiency. In its earlier stage it is attended with the signs of inflammation. A great pain is felt in the back, hips, and the region of the uterus; which, in the part last mentioned, is accompanied with the sense of heat and throbbing. A sudden change in the quality or quantity of the lochia now also takes place; the patient is frequently troubled with a tenesmus; and the urine, which is very high coloured, is discharged in small quantity and with pain. At the first attack of the fever, the woman is generally seized with a vomiting of porraceous matter, as in the *cholera morbus*, to which disease it then bears a strong resemblance.—But instead of this symptom, there is sometimes only a

Puerperal Fever.

a nauſea, or loathing at the ſtomach, with a diſagreeable taſte in the mouth. The belly ſwells to a conſiderable bulk, and becomes ſuſceptible of painful ſenſations from the ſlighteſt impreſſion. The tongue is generally dry, though ſometimes moiſt, and covered with a thick browniſh fur. When the fever has continued a few days, the ſymptoms of inflammation uſually ſubſide, and the diſeaſe acquires a more putrid form. At this period, if not at the very beginning of the diſorder, a bilious or putrid diarrhœa, of a dangerous and obſtinate nature, ſupervenes, and accompanies it through all its future progreſs; each motion to ſtool being preceded by a temporary increaſe, and followed by an alleviation of pain. The patient uſually nauſeates all kind of food and drink, except what is cold and acidulated. A brown or blackiſh ſordes, the conſequence of putrid exhalations, adheres to the edges of the teeth; a troubleſome hiccough is at length produced, which greatly exaſperates the pains of the abdomen; petechiæ or vibices alſo appear, with ſometimes a miliary eruption, but which produces no mitigation of the diſeaſe. Through the whole courſe of the fever, the patient is affected with great anxiety and dejection of ſpirits.

Such in general is the courſe of the puerperal fever; the ſymptoms of which, however, may be often varied, according to the conſtitution of the patient, the degree of the diſeaſe, and its earlier or later invaſion. When the woman is naturally weak, or her ſtrength has been greatly reduced by immoderate evacuations after delivery; when the diſeaſe is violent, and immediately follows that period; its progreſs and termination are proportionably rapid and fatal. In ſuch unfortunate circumſtances, many have been known to expire within 24 hours from the firſt attack of the diſeaſe; nay, there are ſome inſtances where the rigor has concluded the ſcene. The cataſtrophe, however, is moſt generally ſuſpended for ſome days; and the number of theſe is variable, though the 11th from the commencement of the fever may juſtly be fixed as the period which is uſually deciſive. In whatever ſtage of the diſeaſe an unfavourable termination may happen, it would ſeem as if the commencement of the patient's recovery were not marked by any critical revolution of the fever, as depending on an alteration of the humours; but that the cure is gradually effected, either by a ſpontaneous vomiting, or a long-continued diſcharge by ſtool of that porraceous matter, the exiſtence of which in the ſtomach is uſually evinced at the firſt attack of the diſeaſe. The moſt unfavourable prognoſtic, therefore, ariſes from ſuch a weakneſs of the patient as renders her unable to ſupport ſo tedious an evacuation as that by which the fever is overcome. When the lochia return to their former ſtate, when the ſwelling and tenderneſs of the abdomen abate, and there is a moiſture on the ſkin, we have reaſon to hope for a happy termination of the diſeaſe.

Though the puerperal fever may generally be aſcertained from the deſcription which has been given, and chiefly by that remarkable tenderneſs of the abdomen which particularly diſtinguiſhes it; yet, as ſome of its ſymptoms may be confounded with thoſe ariſing from other diſeaſes, and which require a different method of cure, it will be proper to mention here the circumſtances whereby it may be known with greater certainty.

The pains of the abdomen, attending the child-bed fever, may be diſtinguiſhed from thoſe called *after-pains*, by their uninterrupted continuance through the courſe of the diſeaſe, though ſometimes they ſuffer exacerbations; whereas, in the latter, they often totally intermit. They are alſo diſtinguiſhable by the abſence of fever with concomitant ſymptoms in the one, and their evident exiſtence in the other.

Many circumſtances evince a diſſimilarity between the puerperal and miliary fevers, notwithſtanding the ſymptoms of anxiety and oppreſſion are common to both; inſomuch that the nature of the approaching diſeaſe may be aſcertained at the very commencement of its attack. In the puerperal fever the rigor is more violent, of longer duration, and not interrupted, as in the other. The pulſe is fuller and ſtronger; the ſkin is more hot; and the tongue, whether moiſt or dry, though generally the latter, is not of a white, but browniſh appearance; and the urine is alſo higher coloured. Eruptions, which are critical in miliary fevers, procure no mitigation of the puerperal fever, and cordials generally increaſe it.

When the original attack of the puerperal fever happens to coincide with the febrile commotion which is excited in child-bed women by the milk, the nature of it may at firſt be miſapprehended; but the concomitant ſymptoms, and greater violence of the diſeaſe, muſt in a ſhort time diſſipate ſuch an error.

From all the moſt accurate accounts of this diſeaſe, and from the period at which it generally commences, there ſeems reaſon to conclude, that it owes its riſe more immediately to accidents after delivery. For it is allowed that it may follow a labour under the beſt and moſt favourable circumſtances, though endeavours to dilate the os internum are ſuppoſed frequently to produce it. The more immediate cauſes generally aſſigned by authors are a ſtoppage of perſpiration, the too free uſe of ſpices, and the neglect of procuring ſtools after delivery; ſudden frights, too haſty a ſeparation of the placenta, and binding the abdomen too tight. The putrid appearance, however, which this diſeaſe ſo ſoon aſſumes, affords ground to ſuſpect that the prediſpoſing cauſe of it is a vitiated ſtate of the humours; for it is generally obſerved to be moſt prevalent in an unhealthy ſeaſon, and among women of a weakly and ſcorbutic conſtitution.

Within theſe few years this fever has been treated of by ſeveral writers, moſt of whom have differed from each other in their ſentiments of the nature of the diſeaſe. The firſt in the order of publication is Dr Denman, who ſeems to be of opinion, that it may derive its origin either from a redundancy or too great acrimony of the bile, the ſecretion of which appears to be much interrupted in the time of geſtation. In Dr Manning's treatiſe on this fever, he mentions its being highly probable that ſuch a cauſe contributes greatly to produce the diſeaſe, eſpecially where the putrid tendency of the humours is increaſed by unwholeſome air and diet.

It has likewiſe been the fate of the puerperal fever, that no diſeaſe has more divided the ſentiments of phyſicians in regard to the method of cure. The apparent

Puerperal Fever.

rent indications and contra-indications of bleeding, and other remedies, arifing from the complication of inflammatory and putrid fymptoms; the equivocal appearance of the vomiting and purging, as whether they be critical or fymptomatical; and the different caufes whence fymptoms fimilar to each other may arife in pregnant women; all thefe circumftances concur to involve the fubject in great obfcurity and indecifion. If we carefully attend to the feveral characteriftics of the difeafe, however, fo as to be able to diftinguifh it from every other puerperal complaint, and obferve at the fame time the ufual manner of its declenfion, our judgment may be guided in the method of cure by the falutary efforts of nature. But, in order to obtain a clearer view of the genuine indications, it will be proper to confider them under the feveral lights in which they have been generally agitated by authors.

One of the moft effential points to be afcertained in the cure of the child-bed fever, refpects the propriety of bleeding. A free ufe of the lancet has been generally regarded as the moft fuccefsful expedient in practice; and there are fome inftances of critical hæmorrhagies which would feem to confirm its utility. But Dr Denman thinks we may fafely affirm from experience, that for one who will be benefited by large bleeding, a much greater number will be injured, and that even almoft irretrievably. Nor can this feem furprifing, when we confider the fituation of child-bed women. In moft, the evacuations confequent upon delivery are fufficient to diminifh any undue fuperabundance of the fluids; and if, as frequently happens, the difeafe be produced by too hafty a feparation of the placenta, the confequence of which is generally a very copious difcharge of blood, we can never fuppofe that nature will be affifted in overcoming the febrile commotion, by the farther evacuation of the vital fluid, through the defect of which fhe is now rendered unequal even to the ordinary fupport of the animal œconomy. We may appeal to every practical phyfician, how much he has known the pulfe to fink, and what a train of nervous fymptoms he has obferved to fucceed an excefs of the difcharge abovementioned. Befides, it is an axiom in phyfic, that a remedy which cures any diforder, will always prove fufficient to prevent it; and therefore, if bleeding were the proper cure in the child-bed fever, the difeafe ought to have been prevented by a large evacuation of blood, when that happened previous to its feizure. Experience, however, in this, as in all other difeafes, is the only unerring guide we can follow; and whoever regulates his practice by fact and obfervation, will be convinced that bleeding, efpecially in a larger quantity, is, in general, very far from being attended with fuccefs. Bleeding is feldom proper, except in women of plethoric conftitutions, and in whom the figns of inflammation rife high. Nor even in fuch patients ought it to be repeated without great caution, and the exiftence of ftrong indications. Bleeding, when ufed in proper circumftances, may unqueftionably palliate the fever; but that it often fhortens the duration of it, appears to be a matter of much doubt. On this account the practice becomes ftill more fufpicious and exceptionable, when we confider that by venefection improperly ufed the perfon's ftrength may be fo far reduced as not to fupport the tedious loofenefs by which the difeafe is generally carried off. Though bleeding, however, ought in general to be ufed with great caution, there are certainly many cafes in which it is both neceffary and advantageous.

The genuine nature and effects of the loofenefs in this difeafe, is another controverted point of the higheft importance, and which merits the moft attentive inquiry. Phyficians, obferving that women who die of the puerperal fever are generally molefted with that evacuation, have been induced to confider this fymptom as of the moft dangerous and fatal tendency; and what, therefore, we fhould endeavour by every means to reftrain. In this opinion, however, they would feem to have been governed by too partial an obfervation of facts. For experience certainly authorifes the affertion, that more women appear to have recovered of the child-bed fever, through the intervention of a diarrhœa, than have been deftroyed by that caufe. If it alfo be confidered, that purging is ufually almoft the only fenfible evacuation in the more advanced ftate of the difeafe, and is that which accompanies it to its lateft period, we fhall have the ftrongeft reafon to think that it is critical rather than fymptomatical, and ought therefore to be moderately fupported, inftead of being unwarily reftrained. Nay, the advantage which is found to attend vomiting as well as purging, in the earlier ftage of the difeafe, would feem to evince that the matter difcharged by thefe evacuations is what chiefly foments the difeafe. Emetics and purgatives, therefore, in the opinion of Dr Manning, are the only medicines on which any rational dependence is to be placed in this fever; at leaft, they are certainly fuch as are found the moft fuccefsful. It is an eftablifhed rule in practice, to prefcribe a vomit at the beginning of every fever attended with any naufea or loathing of the ftomach, and where there is not any reafon to apprehend an inflammation of that organ. Nor does the ftate of child-bed women afford the fmalleft ground for prohibiting our recourfe to the fame expedient in anfwering a fimilar indication.

It is fo feldom a phyfician is called during the rigor preceding the puerperal fever, that he has few opportunities of trying the effects of remedies in that early ftate of the difeafe. When fuch occur, however, we fhould endeavour as much as poffible to abate and fhorten that period, as the fucceeding fever is generally found to bear a proportion to the violence and duration of it. For this purpofe, warm diluting drinks fhould be plentifully ufed, with a fmall quantity of volatile fpirits or brandy. When Dr Manning apprehended fuch an accident, he fometimes ordered the nurfe to give immediately a difh or two of warm fackwhey; taking care that it was not too ftrong, which is a caution that ought always to be remembered: for though a freer ufe of the more cordial and fpirituous kinds of liquors might perhaps foon abate the rigor, there is danger to be feared from their influence on the approaching fever, efpecially in women of a ftrong and healthy conftitution. In all cafes, warm applications to the extremities, fuch as heated bricks, towels, or toafted grains in a linen bag, may be ufed with perfect fafety, and fome advantage.

When the hot fit is advanced, the firft thing Dr Manning orders is fome emollient injection, as chickenwater,

Puerperal Fever.

water, or water and milk, which ought to be frequently repeated through the courſe of the diſeaſe. Theſe prove beneficial, not only by promoting the diſcharge from the inteſtines, which ſeems in fact to be the ſolution of the diſeaſe; but alſo by acting as a kindly fomentation to the uterus and adjacent parts. With this intention they are particularly ſerviceable when the lochia are ſuppreſſed. Great care, however, is requiſite in adminiſtering them, on account of the tenderneſs and inflammatory diſpoſition, which at that time render the parts in the pelvis extremely ſuſceptible of pain.

The next ſtep in the method of cure ought to be to promote the diſcharge of the morbid matter both by the ſtomach and inteſtines. This intention is beſt anſwered by the remedy preſcribed by Dr Denman, of which the following is the receipt.

R. Tartar. emetic. gr. ii.
Ocul. cancror. præp. ℈i. Intimè miſceantur.

Of a powder thus prepared, Dr Denman gives from two to ſix grains, and repeats it as circumſtances require. If the firſt doſe do not procure any ſenſible operation, he repeats it in an increaſed quantity at the end of two hours, and proceeds in that manner; not expecting any benefit but from its ſenſible evacuation.

Should the diſeaſe be abated, but not removed, (which ſometimes happens), by the effect of the firſt doſe, the ſame medicine muſt be repeated, but in a leſs quantity, till all danger be over. But if any alarming ſymptoms remain, he does not heſitate one moment to repeat the powder, in the ſame quantity as firſt given; though this be ſeldom neceſſary, if the firſt doſe operates properly.

It is to be obſerved, ſays Dr Denman, that as the certainty of cure depends upon the proper repetition of the medicine, the method of giving it at ſtated hours does not appear eligible. If the firſt doſe produce any conſiderable effect by vomiting, procuring ſtools, or plentifully ſweating, a repetition of the medicine in a leſs quantity will ſeldom fail to anſwer our expectations; but great judgment is required in adapting the quantity firſt given to the ſtrength of the patient and other circumſtances. We are not to expect that a diſeaſe which from the firſt formation carries ſo evident marks of danger, ſhould inſtantly ceaſe, even though a great part of the cauſe be removed.

Frequent doſes of the ſaline draughts ought alſo to be given, which not only promote the evacuation by the inteſtines, but likewiſe increaſe the ſalutary diſcharges of urine and perſpiration. Theſe medicines are particularly ſerviceable in ſubduing the remains of the fever, after its violence has been broken by the more efficacious remedies above mentioned; but when they are uſed even in the decline of the diſeaſe, gentle laxatives of rhubarb and magneſia, as adviſed by Dr Denman, ought to be frequently interpoſed, ſince, as he juſtly obſerves, without ſtools we can do little ſervice.

Notwithſtanding the diſcharge by the inteſtines appears to have the moſt ſalutary effect in this diſeaſe, yet when the ſtomach has not been properly unloaded of offenſive matter, though a great nauſea and ſickneſs had indicated the expediency of ſuch an evacuation at the beginning of the fever, the continuance of the looſeneſs is ſometimes ſo long protracted as in the end to prove fatal. In this alarming ſtate of the diſeaſe, when the ſtools are very frequent and involuntary, and all appearances threaten danger, Dr Denman ſays, that a clyſter of chicken-water injected every one, two, or three hours, or as often as poſſible without fatiguing the patient too much, with the following draught taken every ſix hours, has produced better effects than could be expected.

R. Pulv. rad. ipecacuan. gr. i.
Conſect. Damocrat. ℈i.
Aq. alexiter. ſimp. vel.
Cinnamom. ſimp. ℥iſs. M. f. Hauſtus.

While theſe medicines are uſing, we ſhould endeavour to mitigate the pains of the belly by relaxing applications. During the courſe of the diſeaſe, the patient ought to drink freely of diluting liquors, and abſtain from every thing of a heating quality, unleſs great faintneſs ſhould indicate the uſe of a ſmall quantity of ſome cordial medicine.

Such is the practice recommended in this diſeaſe by Dr Denman. We ſhall now take a curſory view of the ſentiments of ſucceeding writers on this ſubject.

According to Dr Hulme, the proximate cauſe of the puerperal fever is an inflammation of the inteſtines and omentum; for the confirmation of which opinion he appeals to diſſections. He ſuppoſes the chief prediſponent cauſe of the diſeaſe to be the preſſure of the gravid uterus againſt the parts above mentioned. The omentum, ſays he, in the latter ſtage of pregnancy, muſt either be flat, which is its natural ſituation, or be rumpled or carried up by the gravid uterus in folds or doublings. When the latter is the caſe, which he obſerves is probably not ſeldom, the danger of a ſtrangulated circulation will be greater.

Mr White, who has alſo written on this diſeaſe, judiciouſly remarks, that were Dr Hulme's hypotheſis well founded, the diſorder ought rather to take place before delivery, and be immediately removed at that period: That it would likewiſe moſt generally happen to women at their firſt labour, when the abdominal muſcles are leſs yielding, and the pains more violent; the contrary of which is moſt frequently experienced to be the caſe.

It alſo deſerves to be remarked, that, upon Dr Hulme's ſuppoſition, we cannot account for the diſeaſe being more common and fatal in large towns and in hoſpitals, than in the country and private practice, while other inflammatory diſorders are more endemic among thoſe who live in the latter than the former ſituation. Even admitting the friction of the inteſtines and omentum againſt the uterus to be as violent as Dr Hulme ſuppoſes, is it not highly improbable, that any inflammation could be occaſioned by the preſſure of ſuch ſoft ſubſtances upon each other? Or, were this effect really produced, ought not the puerperal fever to be more common and fatal after the moſt laborious deliveries? But this obſervation is not ſupported by experience.

Dr Hulme, in favour of his own hypotheſis, alleges that it gives a ſatisfactory anſwer to the queſtion, "Why all lying-in women have been, and ever will be, ſubject to this diſeaſe?" In this propoſition, however, the Doctor ſuppoſes ſuch an univerſality of the diſeaſe as is not confirmed by obſervation. It is affirmed

firmed upon undoubted authority, that in many parts of Britain the puerperal fever is hardly known; whereas, were it really produced by the caufes he affigns, it would be equally general and unavoidable.

But how peculiar foever this author's fentiments are in refpect of the proximate caufe of this difeafe, they have not led him to any method of cure different from the eftablifhed practice. On this fubject Dr Hulme divides his obfervations into two parts, comprehending under the former the more fimple method of treatment, and under the latter the more complex. He fet out with remarking, that the patient being generally coftive at the beginning of the difeafe, an emollient opening clyfter will often give immediate relief; but if this fhould not prove effectual, recourfe muft be had to cathartics. Thofe which he found anfwer his purpofe beft, were the *fal catharticus amarus*, the *oleum ricini*, emetic tartar, and antimonial wine. When the bowels have been fufficiently cleared and the pain abates, he advifes encouraging a gentle diaphorefis by medicines which neither bind the body nor are heating; fuch as fmall dofes of ipecacuan, emetic tartar, and antimonial wine, combined with an opiate in a moderate dofe, and given once or twice in the courfe of 24 hours; adminiftering the faline draughts in the intermediate fpaces. If, preceding or during this courfe, a ficknefs at ftomach or vomiting attend, he advifes affifting the efforts of nature, by drinking plentifully of camomile tea, warm water, or any other diluting liquor. He concludes with recommending a cooling regimen, reft of body, and tranquillity of mind; prohibiting all kinds of bandage upon the abdomen, and enjoining particular attention to the ftate of the bowels, which ought to be kept gently open for fome time, even after the diforder feems to be gone off, till the patient be quite out of danger.

So much for the fimple treatment: we now proceed to the fecond part, where he defcribes the method of practice when the difeafe is in its more irregular and complicated ftate.

When a diarrhœa accompanies the difeafe, he obferves that it ought by no means to be checked, but fupported, by ordering the patient to drink plentifully of mild aperient liquors. If the pain of the hypogaftric region be attended with ftitches in the fides or over the pit of the ftomach, and a pulfe that refifts the finger pretty ftrongly, he remarks that bleeding would then be highly neceffary: declaring, however, his opinion, that, in the puerperal fever, bleeding is to be confidered only as a fecondary means of relief, though the firft in point of time; that it ought to be advifed with great caution; and that the greateft dependence is always to be placed upon evacuations by ftool.

Mr White, above mentioned, imputes the puerperal fever to a putrefcent difpofition of the humours, contracted during pregnancy, and fomented by the hot regimen commonly ufed by women in child-bed. In conformity to this opinion, the chief means which he recommends for preventing the difeafe is a cool regimen and free circulation of air, which he evinces to be of the greateft importance. In refpect of bleeding, he informs us, that, upon the ftricteft inquiry, he cannot find that thofe who have bled the moft copioufly have had the greateft fuccefs, either in private or hofpital practice. He even feems to queftion the propriety of this evacuation in any cafe; but approves of emetics, cathartics, and clyfters, for cleanfing the *primæ viæ*, and likewife of fuch medicines and diet as will correct the putrid humours: adding, that an upright pofture and free ventilation are at all times ufeful, and abfolutely neceffary, both for the prevention and cure of the difeafe.

Another writer who treats of the child-bed fever is Dr Leake, who has publifhed the refult of his obfervations on this difeafe from April 1768 to the autumn of the year 1770; but chiefly from December 1769 to May 1770, during which period the child-bed fever prevailed much about London.

Dr Leake tells us that this fever generally commenced the evening of the fecond or morning of the third day after delivery, with a rigor or fhivering fit. Sometimes it invaded foon after delivery; and at other times, though rarely, it has feized fo late as the fifth or fixth day. Now and then it feemed to be occafioned by catching cold, or by errors in diet; but oftener by anxiety of mind. Sometimes the thirft was great; tho' the tongue had, in general, a better appearance at the beginning than is common in other fevers. It was feldom ever black or very foul; but, as the difeafe advanced, became white and dry, with an increafe of thirft; and at laft was of a brownifh colour towards the root, where it was flightly covered with an infpiffated mucus. The lofs of ftrength was fo great and fudden, that few of the patients could turn in bed without affiftance, even fo early as the firft or fecond day after the attack. The lochia, from firft to laft, were not obftructed, nor deficient in quantity; neither did the quality of this difcharge feem to be in the leaft altered from its natural ftate; a prefumption, fays the author, that the uterus was not at all affected. Of this he was convinced by making a confiderable preffure above the pubes with the hand, which did not occafion pain; but when the fame degree of preffure was applied higher, between the ftomach and umbilical region, it became almoft intolerable. A perfect crifis feldom if ever happened in this fever, which he imputes to the great oppreffion of the vital powers, whereby they were rendered unable to produce fuch an event. When the difeafe proved mortal, the patient generally died on the 10th or 11th day from the firft attack. In thofe who died of the fever, the omentum was found fuppurated; an inflammation of which part, or of the inteftines, Dr Leake concludes to be the proximate caufe of the difeafe.

In confequence of this idea of the caufe of the difeafe, Dr Leake affirms that venefection is the only remedy which can give the patient a chance for life. But, though it be the principal refource to be depended upon at the beginning of the fever, he obferves that it will feldom prove of fervice after the fecond or third day; and, if directed yet later, will only weaken and exhauft the patient; when, matter having begun to form in the omentum, the progrefs of the difeafe can no longer be prevented by that evacuation. At this period the blood begins to be tainted by the abforption of the purulent fluid; and the fever, from being inflammatory, is changed into a putrid nature.

After bleeding in fuch a quantity as the fymptoms require, he advifes that the corrupted bile be evacuated and corrected as foon as poffible; that the diar-

Puerperal Fever.

rhœa, when exceſſive, be reſtrained by emollient anodyne clyſters and gentle ſudorifics, or even by opiates and mild aſtringents, when the patient's ſtrength begins to ſink under the diſcharge; and, laſtly, that where the ſigns of the putrefaction or intermiſſion take place, antiſeptics and the Peruvian bark may be adminiſtered.

The great uniformity of the ſymptoms in all Dr Leake's patients might authoriſe an opinion, that the fever which he deſcribes was in a great meaſure a diſeaſe *ſui generis*, and depended much upon the conſtitution of the air preceding and during the period in which the fever prevailed.

Dr Kirkland has alſo made judicious obſervations on this ſubject. He rejects the opinion that the puerperal fever is a diſeaſe *ſui generis*, and ariſes always from the ſame cauſe. The particular ſituation of child-bed women, he acknowledges, occaſions a ſimilarity in the appearance of all the febrile ſymptoms: but he affirms that the ſame kind of fever may be produced by various cauſes; for inſtance, by an inflammation of the uterus or abdomen, by putrid blood or other matter, and putrid miaſms. The ſymptoms, he obſerves, will vary according to the time of ſeizure. If the fever happens in three or four days after delivery, all the ſymptoms uſual to the ſituation of the patient will make their appearance; but if it do not invade till the milk has been ſecreted, and the lochial diſcharge be nearly finiſhed, the ſymptoms, if the breaſts are properly drawn, will, for the moſt part, be thoſe only which are common to that kind of diſorder by which the fever has been produced.

With reſpect to the cure of puerperal fevers, Dr Kirkland adviſes the antiphlogiſtic method when they ariſe from inflammation; but when this method fails of ſucceſs, and a diarrhœa ſupervenes, the diſeaſe has changed its nature, having become more or leſs putrid, and requires a very different treatment.

His obſervations relative to the management of the diarrhœa merit attention. No one, ſays he, would purge and bleed to cure the colliquative fever ariſing from the abſorption of matter in large wounds; and yet the only difference is, that in the puerperal fever the matter abſorbed from the uterus, &c. acts with more violence, becauſe the blood is commonly thinner and the habit in a more irritable ſtate. We ſee, continues he, that abſorbed matter purges as effectually as if any purging medicine had been given by the mouth; and may we not therefore do harm by additional purging, when there has been a large evacuation, eſpecially as purges in this caſe are incapable of entirely removing the *fomes morbi?*

He conſiders the Peruvian bark as the principal remedy, as ſoon as the pulſe ſinks, the heat is leſſened, and the ſtomach will bear it. If the bark increaſe the diarrhœa beyond moderation, he joins with it ſmall doſes of laudanum; but if the diarrhœa ſhould entirely ſtop without the fever going off, in place of laudanum he adviſes a proper quantity of rhubarb. Should the diarrhœa, notwithſtanding the uſe of the medicines propoſed, become ſo violent as to endanger the patient, he joins Mr White in recommending the columbo root, which is a warm cordial, and removes the irritability of the ſtomach and inteſtines more powerfully than any other bitter he knows.

Of this diſeaſe alſo, as it appeared in Derbyſhire and ſome of the adjacent provinces, an account has been publiſhed by Dr Butter. Concerning the cauſes and nature of the diſeaſe, he obſerves, that pregnancy ſeems to add much to the natural ſenſibility of the female conſtitution; becauſe at this period women are often ſubject to a train of nervous ſymptoms, which never moleſt them at other times. During geſtation likewiſe, the appetite is for the moſt part keen, while the digeſtion appears to be impaired; and this weakneſs is increaſed not only by improper food, of which the woman is frequently deſirous, but alſo by the inactivity attending her ſituation. To theſe circumſtances, it is added, that the inteſtinal paſſage being interrupted by the uterine preſſure, coſtiveneſs generally prevails. From the ſeveral obſervations here enumerated, Dr Butter concludes, that the proximate cauſe of the puerperal fever is a ſpaſmodic affection of the firſt paſſages, with a morbid accumulation in their cavity; and upon this ſuppoſition he endeavours to account for the various ſymptoms of the diſeaſe.

In treating of the method of cure, he lays down two indications; the former of which is to promote two, three, or four ſtools daily, in a manner ſuited to the ſtrength of the patient, till ſuch time as they reſume a natural appearance. The ſecond indication is to relieve all uneaſy ſymptoms, ſuch as heat, thirſt, head-ach, &c.

With reſpect to the opinion entertained by Dr Butter of the cauſe of the puerperal fever, it nearly coincides with that of Mr White. But however plauſible it may appear, we are not entirely ſatisfied that a diſeaſe attended with ſo peculiar ſymptoms as the puerperal fever can depend principally upon an irritability, which is not reſtricted either to the pregnant or puerperal ſtate.

The late Dr Thomas Young profeſſor of midwifery in the univerſity of Edinburgh, although he publiſhed nothing on the ſubject of the puerperal fever, wrote a very ingenious diſſertation reſpecting it, which was read in the Philoſophical Society of Edinburgh. In that diſſertation, after giving a very accurate account of the ſymptoms of the diſeaſe, which coincides very nearly with the account given by others, he endeavours to ſhow, that the *puerperal fever*, ſtrictly ſo called; is in every inſtance the conſequence of contagion; but he contends, that the contagious matter of this diſeaſe is capable only of producing its effect, in conſequence of a peculiar prediſpoſition given by delivery and its conſequences. In ſupport of this doctrine, he remarks, that for many years the diſeaſe was altogether unknown in the lying-in ward of the Royal Infirmary at Edinburgh; but that after it was once accidentally introduced into the hoſpital, almoſt every woman was in a ſhort time after delivery attacked with it; although prior to her delivery, ſhe may have lain even for weeks together, not only in the ſame ward with the infected, but even in the very next bed. He remarks, that it was only eradicated from the hoſpital in conſequence of the wards being entirely emptied, thoroughly ventilated, and new painted. After theſe proceſſes, puerperal females in the hoſpital remained as free from this diſeaſe as formerly. The puerperal fever, according to Dr Young, has very generally a ſtrong tendency to the typhoid type; although he allows, that

in

Puerperal Fever.

in the beginning it is not unfrequently attended with inflammatory symptoms, and even with topical inflammation, particularly in the intestinal canal. On this idea, he considers the puerperal fever as admitting of the same variety of treatment with other affections depending on contagion, in which sometimes an inflammatory, sometimes a putrescent tendency, prevails; such, for example, as small-pox or erysipelas. But from the prevailing putrescent tendency in this affection, he considers the free access of cool air, with the liberal use of antiseptics, as being very generally requisite.

It deserves to be remarked, that though the several writers who treat of this subject have conducted their method of cure conformably to their particular idea of the cause of the disease, respecting which their sentiments are very different, they seem to have been equally successful in the treatment of their patients. Indeed the several writers differ less from each other in their method of cure than might be expected, where so great an opposition of theoretical sentiments prevails. For after endeavouring to establish indications correspondent to their particular systems, those who contend for the expediency of promoting the intestinal discharge, dissuade not from a recourse to phlebotomy when the disease is attended with inflammatory symptoms; while, on the other hand, the most strenuous advocates for bleeding admit the utility of the former evacuation. It appears, therefore, that a due regulation of the alvine discharge is necessary through the whole course of the fever, but venesection only sometimes.

405

CEPHALALGIA.
Head-Ach.

The head-ach is symptomatic of very many distempers, but is rarely an original disease itself. Dr Home acquaints us that his report-books only furnish four instances of it; and of these four, three were women. The disease proved fatal to the man; and after death, a considerable effusion of blood was found on the brain, together with some hydatids, and water in the ventricles.

Head-achs appear frequently to be occasioned by effusions of blood or serum; as well as by ulcers, and abscesses of the brain, dura and pia mater. Accretions and ossifications of different parts of the dura mater, falx, and brain, are also frequently discovered. An ossification of the falx, however, does not always produce head-ach: for Dr Home mentions a patient who had the falx ossified without head-ach; but he had been observed to be very furious when drunk. Congestions of blood in the vessels of the brain are also discovered from dissections to be a frequent cause of the head-ach; and nervous irritation alone will frequently produce it, as we see in the *clavus hystericus*.

In the cure of this disease we have little or no power over ossifications, effusions, or ulcerations; and hence the head-ach is frequently incurable. In congestions, and nervous affections, medicines may indeed be of some service. Congestion may be relieved by an evacuation of blood, either general or topical; as venesection, cupping, or leeches: by errhines; which, however, Dr Home thinks are little to be depended upon: by topical evacuations near the head by blisters, issues,

Cephalalgia.

or setons; by purgatives; or by determining the fluids to other parts, by rubefacients applied to the temples, pediluvia, &c.

Nervous irritation may be diminished, 1. By a great quantity of cold water drunk every morning. This is recommended by Hoffman; and will wash off all acrid particles from the stomach, while the cold strengthens and diminishes the sensibility of the part. This remedy was tried for a considerable time in one of Dr Home's patients without any effect. 2. Nervous and tonic medicines; as the bark, valerian, &c. These were tried in two of Dr Home's patients, but also without success. In a third the valerian succeeded. 3. By cold water applied to the head, immersion, or the shower-bath. 4. Cephalics; as lavender, rosemary, &c. In slight cases, the smell of eau de luce, or any strong volatile alkali, will generally prove a cure.

A *Dangerous* Affection *of the* ŒSOPHAGUS. 406

This distemper has only been treated of by Dr Munckley, who reckons it one of the most deplorable diseases of the human body. Its beginning is in general so slight as to be scarce worth notice, the patients perceiving only a small impediment to the swallowing of solid food: they usually continue in this state for many months; during which, all liquid foods, and even solids themselves, when cut small and swallowed leisurely, are got down without much difficulty: by degrees the evil increases, and the passage through the œsophagus becomes so narrow, that not the smallest solid whatever can pass through it; but, after having been detained for some time at the part where the obstacle is formed, is returned again with a hollow noise of a very peculiar kind, and with the appearance of convulsion.

The seat of this malady is sometimes near the top of the œsophagus, and at other times farther down, nearer the superior orifice of the stomach. In this last case, the part of the alimentary tube which is above the obstruction is frequently so dilated by the food which is detained in it as to be capable of containing a large quantity; and the kind of vomiting, by which it is again returned through the mouth, comes on sooner or later after the attempt to swallow, in proportion to the nearness or remoteness of the part affected. In the last stage of this disease, not even liquids themselves can be swallowed so as to pass into the stomach, and the patient dies literally starved to death.

On the dissection of such as have died in this manner, the œsophagus is found to be considerably thickened; and in some so contracted within at the diseased part, as scarcely to admit the passing of a common probe; in others, to adhere together in such a manner as entirely to close up the passage, and not to be separated without great difficulty.

He comes next to show what he has found to be the most efficacious method of treating this disease, which, though not uncommon, yet in general has been considered as incurable.

He claims not the merit of having discovered the method of cure, but hopes that some service may arise from publishing what his experience has confirmed to him; having first received the hint from another eminent physician.

Cephalalgia.

The only medicine, then, from the ufe of which he has ever found any fervice, is mercury; and in cafes which are recent, and where the fymptoms have not rifen to any great height, fmall dofes of mercury given every night, and prevented, by purgative medicines, from affecting the mouth, have accomplifhed the cure.

But where the complaint has been of long ftanding, and the fymptom has come on of the food's being returned through the mouth, a more powerful method of treatment becomes neceffary. In this cafe he has never found any thing of the leaft avail in removing any of the fymptoms, but mercury, ufed in a fuch a manner as to raife a gentle but conftant fpitting: and this method he has purfued with the happieft fuccefs. If this method be commenced before the complaint has gained too much ground upon the conftitution, the cafe is not to be defpaired of; and of thofe who have come under his care in this ftate, by much the greater part have received confiderable benefit from it, and many have been entirely cured.

The complaint itfelf, he obferves, is not very uncommon; but there is no inftance, to his knowledge, recorded, of fuccefs from any other manner of treating it, than that he has recommended.

407

WORMS.

Thofe infefting the human body are chiefly of three kinds: the *afcarides*, or fmall round and fhort white worms; the *teres*, or round and long worm; and the *tænia*, or tape-worm.

The *afcarides* have ufually their feat in the rectum.—The *teretes* or *lumbrici* are about a fpan long, round and fmooth: they are feated for the moft part in the upper fmall inteftines; but fometimes they are lodged alfo in the ftomach, and in any part of the inteftines, even to the rectum.—The tape-worms are from two to forty feet long, according to the teftimony of Platerus; they generally poffefs the whole tract of the inteftines, but efpecially the ileum: they very much refemble a tape in their appearance, whence the name of *tape-worm*: but another fpecies of this genus, from the refemblance of each joint to a gourd feed, has the name of the *gourd-worm*.

In the Medical Tranfactions, Vol. I. Dr Heberden gives a very accurate account of the fymptoms produced by the *afcarides*, from an eminent phyfician who was troubled with them all his life. They brought on an uneafinefs in the rectum, and an almoft intolerable itching in the anus; which fenfations moft ufually came on in the evening, and prevented fleep for feveral hours. They were attended with heat, fometimes fo confiderable as to produce a fwelling in the rectum both internally and externally; and if thefe fymptoms were not foon relieved, a tenefmus was brought on, with a mucous dejection. Sometimes there was a griping pain in the lower part of the abdomen, a little above the *os pubis*. If this pain was very fevere, a bloody mucus followed, in which there were often found afcarides alive. They were alfo fometimes fufpected of occafioning difturbed fleep, and fome degree of head-ach.

On this cafe Dr Heberden obferves, that the general health of the patient did not feem to have fuffered from the long continuance of the difeafe, nor the immediate inconveniences of the diforder itfelf to have increafed. "It is (fays he) perhaps univerfally true, that this kind of worms, though as difficult to be cured as any, yet is the leaft dangerous of all. They have been known to accompany a perfon through the whole of a long life, without any reafon to fufpect that they had haftened its end. As in this cafe there was no remarkable ficknefs, indigeftion, giddinefs, pain of the ftomach, nor itching of the nofe, poffibly thefe fymptoms, where they have happened to be joined with the afcarides, did not properly belong to them, but arofe from fome other caufes. There is indeed no one fign of thefe worms, but what in fome patients will be wanting."

Worms.

The abovementioned patient ufed purging and irritating clyfters with very little fuccefs. One drachm and an half of tobacco was infufed in fix ounces of boiling water; and the ftrained liquor being given as a clyfter, occafioned a violent pain in the lower part of the abdomen, with faintnefs and a cold fweat: this injection, though retained only one minute, acted as a fmart purge, but did little or no good. Lime-water was alfo ufed as a clyfter; which brought on a coftivenefs, but had no good effect. Six grains of falt of fteel were diffolved in fix ounces of water, and injected. This clyfter in a few minutes occafioned an aching in the rectum, griped a little without purging, and excited a tenefmus. Some few afcarides were brought off with it; but all of them were alive. The uneafy fenfation in the rectum did not abate till fome warm milk was thrown up. Whenever the tenefmus or mucus ftools were thought worth the taking notice of, warm milk and oil generally gave immediate relief. If purging was neceffary, the lenient purges, fuch as manna with oil, were, in this particular cafe, made ufe of: rhubarb was found too ftimulating.—But, in general, the moft ufeful purge, and which therefore was moft ufually taken, was cinnabar and rhubarb, of each half a drachm: this powder feldom failed to bring away a mucus as tranfparent as the white of an egg, and in this many afcarides were moving about. The cinnabar frequently adhered to this mucus, which did not come off in large quantities, when a purge was taken without cinnabar. Calomel did no more than any other purge which operates brifkly would have done; that is, it brought away afcarides, with a great deal of mucus. Oil given as a clyfter fometimes brought off thefe animalcules: the oil fwam on the furface of the mucus, and the afcarides were alive and moving in the mucus itfelf, which probably hindered the oil from coming in contact with them and killing them.

The Doctor alfo obferves, that mucus or flime is the proper neft of the afcarides, in which they live, and is perhaps the food by which they are nourifhed; and it is this mucus which preferves them unhurt, though furrounded with many other liquors, the immediate touch of which would be fatal. It is hard to fatisfy ourfelves by what inftinct they find it out in the human body, and by what means they get at it; but it is obfervable in many other parts of nature, as well as here, that where there is a fit foil for the hatching and growth of animals and vegetables, nature has taken fufficient care that their feeds fhould find the way thither. Worms are faid to have been found in the inteftines of infants born dead. Purges, by

Worms.

by lessening this slime, never fail to relieve the patient: and it is not unlikely, that the worms which are not forced away by this quickened motion of the intestines, may, for want of a proper quantity of it, languish, and at last die; for if the ascarides are taken out of their mucus, and exposed to the open air, they become motionless, and apparently die in a very short time. Dr Heberden supposes that the kind of purge made use of is of some consequence in the cure of all other worms as well as ascarides; the animals being always defended by the mucus from the immediate action of medicines; and that therefore those purges are the best which act briskly, and of which a repetition can be most easily borne. Purging waters are of this sort, and jalap especially for children; two or more grains of which, mixed with sugar, are most easily taken, and may be repeated daily.

From the case above-mentioned, and from Dr Heberden's observations, we may easily see why it is so difficult to destroy these animals; and why anthelmintics, greatly celebrated for some cures, are yet so far from being specifics in the disease. As the worms which reside in the cavities of the human body are never exposed to the air, by which all living creatures are invigorated, it is evident, that in themselves they must be the most tender and easily destructible creatures imaginable, and much less will be requisite to kill them than any of our common insects. The most pernicious substances to any of the common insects are oil, caustic fixed alkali, lime, and lime-water. The oil operates upon them by shutting up the pores of their bodies; the lime-water, lime, and caustic alkali, by dissolving their very substance. In the case of intestinal worms, however, the oil can have very little effect upon them, as they are defended from it by the moisture and mucus of the intestines; the like happens with lime-water: and therefore it is necessary that the medicine should be of such a nature as to destroy both mucus and insects together; for which purpose the caustic fixed alkali is at once safe and efficacious; nor is it probable that any case of worms whatever could resist the proper use of this medicine. A very large dose of any salt indeed will also destroy the mucus and destroy the worms; but it is apt to inflame and excoriate the stomach and intestines, and thus to produce worse distempers than that which it was intended to cure. Dr Heberden gives the following remarkable case of a patient cured of worms by enormous doses of common salt, after trying many other remedies in vain. In February 1757, the patient was seized with uncommon pains in his stomach, attended with nausea, vomiting, and constipation of bowels, and an almost total loss of sleep and appetite: He soon became much emaciated, and could neither stand nor walk upright; his belly grew small and hard, and closely retracted, insomuch that the sternum covered the navel, and the latter could scarce be discovered or felt by the finger: his urine was always milky, and soon deposited a thick white sediment; his excrements were very hard and lumpy, resembling those of sheep, only of a brown colour; nor had he ever a stool without some medicine or other to procure it. In this situation he continued four years; during which time he had been in an infirmary, attended by eminent physicians, but was dismissed as incurable. At last he was advised by a neighbour to drink salt and water, as he said he knew one cured by it who had for many years been afflicted with the same kind of pains in the belly and stomach. As his distemper was now almost insupportable, he willingly tried the experiment. Two pounds of common salt were dissolved in as little water as possible, all which he drank in less than an hour. Soon afterwards he found himself greatly oppressed at the stomach, grew extremely sick, and vomited violently; on the fourth straining he brought up about half a pint of small worms, part ascarides, and the rest resembling those worms which are called the *botts*, and frequently met with in the stomach of horses, but much smaller, and about the size of a grain of wheat. The salt soon began to operate downwards, and he had five or six very copious fetid stools, tinged with blood; and in them discharged near an equal quantity of the same kind of worms he had vomited. Being greatly fatigued with the violence of the operations, he fell into a calm sleep, which lasted two hours, during which he sweated profusely, and awoke much refreshed. Instead of his usual pains, he now only complained of a rawness and soreness of his gullet, stomach, and bowels, with an almost unquenchable thirst; to allay which, he drank large quantities of cold water, whey, butter-milk, or whatever he could get. The urine he now passed was small in quantity, and rendered with very great difficulty, being highly saturated with the salt, from whence arose a most troublesome dysuria and strangury. However, these symptoms gradually abated by a free use of the liquors above-mentioned; and on the third morning he was so well recovered, that he took two pounds more of salt, dissolved in the like quantity of water. The effects were nearly similar to the former; only that most of the worms were now burst, and came away with a considerable quantity of slime and mucus. The drought, strangury, &c. returned with their former violence, but soon yielded to the old treatment. He sweated very copiously for three days, slept easily, and by that time could extend his body freely: on the fifth day he left his bed, and, though very weak, could walk upright; his strength and appetite soon returned, and he became robust and well.

The anthelmintic medicines which have been recommended by one person or other, are in a manner innumerable; but the principal are,

1. *Quicksilver.* This is very efficacious against all kinds of worms, either taken in the form of calomel or corrosive sublimate. Even the crude metal boiled in water and the water drunk, has been recommended as an almost certain cure. But this, it is evident, can receive no impregnation from the mercury. If, therefore, it have any effect, it must be from some foreign and accidental impregnation. In most instances there can be no objection to mercury, but only that it is not endowed with any attenuating quality whereby the mucus in which these insects resides can be dissolved. It therefore fails in many cases, though it will most certainly destroy worms where it can get at them.

2. *Powder of tin.* This was for some time celebrated as a specific, and indeed we may reasonably expect good effects from it; as by its weight and

Worms.

grittiness it rubs off the mucus and worms it contains from the coats of the intestinal canal, in which case they are easily evacuated by purgatives. In order to produce any considerable effects, it must be given in a large dose.

3. *Geoffræa inermis, or cabbage bark* This remedy is used by the inhabitants of Jamaica. The first account of it which appeared in this country was published in the Physical and Literary Essays, vol ii. by Mr Duguid surgeon in that island. He acquaints us, that the inhabitants of Jamaica, young and old, white and black, are much infested with worms, especially the long round sort; the reason of which, he thinks, is the quantity of sweet viscid vegetables which they eat. On dissecting a child of seven months old, who died of vomiting and convulsions, twelve large worms were found; one of them filled the *appendix vermiformis*, and three of them were entwisted in such a manner as to block up the *valvula Tulpii*, so that nothing could pass from the small to the great guts.—The cabbage-bark, however, he tells us, is a safe and effectual remedy, and the most powerful vermifuge yet known; and that it frequently brings away as many worms by stool as would fill a large hat. He owns that it has sometimes violent effects; but this he ascribes to the negroes who make the decoction (in which form the bark is used), and not to the remedy itself.

Mr Anderson, surgeon in Edinburgh, has also given an account of this bark and its operation, in a letter to Dr Duncan, published in the Edinburgh Medical Commentaries, volume iv. p. 84. From this account it appears, that there are two different kinds of bark; the one much paler than the other: the pale kind operates much more violently than the other. It often occasions loose stools, great nausea, and such like symptoms, attended with great uneasiness in the belly: in one or two instances it was suspected of inducing syncope. The darker coloured kind resembles the cassia lignea, though it is of a much coarser texture. This kind, Mr Anderson thinks, may be exhibited in any case where an anthelmintic is necessary; the dangerous symptoms might have followed either from the use of the first kind, or from an over-dose of the second. The usual method of preparing the medicine is by boiling two ounces and a half of the bark in two quarts of water to a pint and a half. Of this a tea-spoonful may be given at first in the morning, gradually increasing the quantity till we come to four or five table-spoonfuls in a day. When exhibited in this manner, Mr Anderson informs us, that he never saw it produce any violent symptoms, and has experienced the best effects from it as an anthelmintic. After the use of this decoction for eight or nine mornings successively, a dose of jalap with calomel must be given, which seldom fails to bring away the worms, some dead, some alive. If at any time the decoction produce more than one or two loose stools, a few drops of liquid laudanum may be given; and, in general, Mr Anderson gave 15 or 20 drops of the spirit of lavender with each dose.

In a letter from Dr Rush, professor of chemistry at Philadelphia, to Dr Duncan of Edinburgh, the following account is given of another preparation of this medicine. "It has long (says he) been a complaint among physicians, that we have no *vermifuge* medicine which can be depended upon. Even calomel fails in many cases where there are the most pathognomonic signs of worms in the bowels. But this complaint, it is hoped, is now at an end. The physicians of Jamaica have lately found, that the *cabbage-bark*, as it is called in the West Indies, made into a syrup with brown sugar, is an infallible antidote to them. I have used above 30 pounds of it, and have never found it fail in one instance The syrup is pleasant; it sometimes pukes, and always purges, the first or second time it is given."

Notwithstanding these encomiums, however, the cabbage-bark (A) hath not come into general use in Britain. But diseases from the *teretes*, or *lumbrici* as they are often called, the species of worm against which this bark is employed, much less frequently occur than in some other countries. When they do occur, in almost every instance they readily yield to more gentle and safe anthelmintics; and the worms may not only be expelled by calomel, but by the vegetable bitters; as the powder of the semen santonicum, or the like.

4. *Cowhage*, or *cow-itch*. This is the *Dolichos urens* or *pruriens* of Linnæus; and the principles on which it acts have been already explained under the article DOLICHOS. It is somewhat similar to the powder of tin, but bids fair for being more efficacious. It might at first appear to occur as objections to this medicine, that by the hairs of it entangling themselves with one another, calculi might be formed in the intestines, or obstructions equally bad; or if the sharp points and hooks with which it abounds were to adhere to the nervous coats of the intestines themselves, they might occasion a fatal irritation, which could not be removed by any means whatever. But from the experience of those who have employed it extensively in practice, it would appear, that these objections are entirely theoretical; and that it may be employed with perfect safety. The spiculæ, gently scraped off from a single pod, and mixed with syrup or melasses, are taken for a dose in the morning fasting. It is repeated in this manner for two or three days without any sensible operation; but even a very slight purgative taken afterwards has been found to discharge an almost incredible quantity of worms. And according to Dr Bancroft, who has given a very particular account of its use in his Natural History of Guaiana, it is one of the safest and most certain anthelmintics yet discovered; but, as well as the bark of the *Geoffræa*, it has hitherto been very little used in Britain, probably from its not being necessary.

5. *Indian pink*. This plant, which in the *Spigelia marilandica*

(A) The most accurate account of this vegetable, and its effects, has been given by Dr Wright in the Philosophical Transactions, of which the reader will find a short view under the article *Geoffræa*, in the order of the alphabet.

Worms. *marilandica* of Linnæus, is alfo an American plant, and was firft recommended in the Edinburgh Phyfical and Literary Effays by Dr Garden of Charleftown in South Carolina. He is of opinion that a vomit ought always to precede the ufe of it; and informs us, that half a drachm of it purges as brifkly as the fame quantity of rhubarb. At other times he has known it produce no effect on the belly though given in very large quantity: In fuch cafes it becomes neceffary to add a grain or two of fweet mercury, or fome grains of rhubarb; but then it is lefs efficacious than when it proves purgative without addition. The ufe of it, however, in fmall dofes, is by no means fafe; as it frequently produces giddinefs, dimnefs of fight, convulfions, &c. The addition of a purgative, indeed, prevents thefe effects; but at the fame time, as already obferved, it diminifhes the virtue of the medicine. The Doctor therefore recommends large dofes, as from them he never knew any other effect than the medicine's proving emetic or violently cathartic. The dofe is from 12 to 60 or 70 grains of the root in fubftance, or two, three, or four drachms of the infufion, twice a-day.

This medicine has alfo had its day, and is now very far from being confidered as a fpecific. From what has been already obferved, it muft pretty clearly appear, that powder of tin, cow-itch, or fixed alkaline falts, bid faireft for deftroying worms in all the variety of cafes in which they can occur. Alkalies indeed have been but little tried. We have known one cafe in which all the complaints have been removed by a fingle dofe: we have alfo an inftance of their efficacy, in an extraordinary cafe of a worm bred in the liver, mentioned in the 2d volume of the Medical Obfervations. The patient had a violent pain in the fide, and fometimes in the fhoulder, as the worm fhifted its place; but, on the application of a lixivial poultice, the pain went out of the fide entirely, and kept in the fhoulder for fome weeks.

The long round worms feem to be the moft dangerous which infeft the human body, as they often pierce through the ftomach and inteftines, and thus bring on a miferable death. The common fymptoms of them are naufea, vomiting, loofenefs, fainting, flender intermitting pulfe, itching of the nofe, and epileptic fits. By the confumption of the chyle they produce hunger, palenefs, weaknefs, coftivenefs, tumor of the abdomen, eructations, and rumbling of the inteftines; but it is from the perforation of the inteftines that the difeafe proves fo frequently fatal. A child may be known to have worms from his cold temperament, palenefs of the countenance, livid eye-lids, hollow eyes, itching of the nofe, voracity, ftartings, and grinding of the teeth in fleep; and more efpecially by a very fetid breath. Very frequently, however, they are voided by the mouth and anus, in which cafe there is no room for doubt. In the Medical Commentaries, vol. II. we have an account of the inteftines being perforated by a worm, and yet the patient recovered. The patient was a woman troubled with an inflammation in the lower part of the abdomen. The pain was fo violent, that for fix days fhe flept none at all; the tumor then broke, difcharged upwards of a pound of thin watery fanies, immediately after which the excrements followed. The next day fhe was extremely low; her pulfe could fcarcely be felt; the extremities were cold; and there was a confiderable difcharge from the wound, which had already begun to mortify. She got a decoction of the bark with wine, which alleviated the fymptoms; but in removing the mortified parts a worm was found among them nine inches long, and as thick as an eagle's quill. By proper applications, the difcharge of excrements ceafed, and fhe recovered perfect health. She was fenfible of no accident giving rife to the inflammation; fo that in all probability it arofe entirely from the worm itfelf.

The *tænia*, or *tape-worm*, as it is called, is one of thofe moft difficult to be removed from the human body. It is of two kinds, *tænia folium* and *tænia lata*; for a defcription of which fee the article Tænia.—The reafon of its being fo difficult to cure, is, that though portions of it are apt to break off and be difcharged, it is endowed with a power of reproduction, fo that the patient is little or nothing better. The fymptoms occafioned by it are not different from thofe above defcribed. A fpecific againft the *tænia lata* hath been lately fo much celebrated in France, that the king thought proper to purchafe it from the proprietor (Madam Nouffer), and the account of it has been tranflated into Englifh by Dr Simmons. The patients are required to obferve no particular regimen till the day before they take the fpecific. That day they are to take nothing after dinner till about 7 o'clock; after which, they are to take the following foup: "Take a pint and an half of water, two or three ounces of good frefh-butter, and two ounces of bread cut into thin flices: add to this falt enough to feafon it, and then boil it to the confiftence of panada." About a quarter of an hour after this, they take a bifcuit and a glafs of white-wine, either pure or mixed with water; or even water alone, if they have not been accuftomed to wine. If the patient has not been to ftool that day, (which, however, is not ufual with patients in this way), the following clyfter is to be injected. "Take a fmall quantity of the leaves of mallows, and boil them in a fufficient quantity of water, mixing with it a little falt, and when ftrained off add two ounces of oil olive." Next morning, about eight or nine hours after the fupper above mentioned, the fpecific is to be taken. This is no other than two or three drachms of the root of male fern, *polypodium filix mas* of Linnæus, gathered in autumn, and reduced to fine powder. It is to be taken in any diftilled water, or in common water. This medicine is apt to occafion a naufea: to avoid which, Madam Nouffer allows her patients to chew any thing that is agreeable, but forbids any thing to be fwallowed; or they may fmell to vinegar, to check the ficknefs: but if, notwithftanding this, the fpecific be thrown up, a frefh dofe muft be fwallowed as foon as the ficknefs is gone off, and then they muft try to fleep. About two hours after this the following bolus is to be taken. "Take of the panacea of mercury 14 times fublimed, and felect refin of fcammony, each ten grains; of frefh and good gamboge, fix or feven grains: reduce each of thefe fubftances feparately into powder, and then mix them with fome conferve into a bolus." This compofition is to be fwallowed at two different times, wafhing it down with

Worms. with one or two dishes of weak green-tea, after which the patient must walk about his chamber. When the bolus begins to operate, he is to take a dish of the same tea occasionally, until the worm be expelled; then, and not before, Madame Nouffer gives him broth or soup, and he is directed to dine as is usual after taking physic. After dinner he may either lie down or walk out, taking care to conduct himself discreetly, to eat but little supper, and to avoid every thing that is not of easy digestion.

The cure then is complete; but it is not always effected with the same quickness in every subject. He who has not kept down the whole bolus, or who is not sufficiently purged by it, ought to take, four hours after it, from two to eight drachms of Epsom salt dissolved in boiling water. The dose of this salt may be varied according to the temperament and other circumstances of the patient.

If the worm should not come away in a bundle, but in the form of a thread (which particularly happens when the worm is involved in much tenacious mucus), the patient must continue to sit upon the close stool without attempting to draw it away, drinking at the same time warm weak tea: sometimes this alone is not sufficient, and the patient is obliged to take another dose of purging salt, but without varying his position till the worm be wholly expelled.

It is unusual for patients who have kept down both the specific and purging dose, not to discharge the worm before dinner-time. This, however, sometimes happens when the dead worm remains in large bundles in the intestines, so that the fæces becoming more limpid towards the end of the purging, pass by it without drawing it with them. The patient may in this case eat his dinner; and it has been observed, that the food, joined to the use of a clyster, has brought about the expulsion of the worm.

Sometimes the worm is brought away by the action of the specific alone, before the patient has taken the purging bolus: when this happens, Madame Nouffer gives only two-thirds of it, or substitutes the salt in its stead.

Patients must not be alarmed by any sensation of heat or uneasiness they may feel during the action of the remedy, either before or after a copious evacuation, or just as they are about to void the worm. These sensations are transitory, and go off of their own accord, or by the assistance of the vapour of vinegar drawn in at the nose.

They who have vomited both the specific and bolus, or who have kept down only a part of them, sometimes do not void the worm that day. Madame Nouffer therefore directs them to take again that night the soup, the wine and biscuit; and if circumstances require it, the clyster. If the worm do not come away during the night, she gives them early the next morning another dose of the specific, and, two hours afterwards, six drachms or an ounce of purging salt, repeating the whole process of the preceding day; excepting the bolus, which she suppresses.

She observes, that very hot weather diminishes in some degree the action of her remedy; she therefore prefers the month of September for administering it; but as she has not been always able to choose the season, and has been sometimes obliged to undertake the cure of patients in the hottest days of summer, she then gave her specific very early in the morning; and with this precaution she saw no difference in its effects.

On the day appointed for the trial of this medicine before the commissioners nominated by the king of France, it was exhibited to five different persons; but only one of them was certainly known to have the *tænia lata* by having discharged parts of it before. That person was cured; the second voided a portion of the *tænia solium*; the third some *ascarides*, with a part of the *tænia solium*; the fourth and fifth voided no worms; but the last considered much of the viscid slime he voided to be worms in a dissolved state.

This trial was thought sufficient to ascertain the efficacy of the medicine, and further trials were made by those to whom the secret was communicated. The first voided two tænia, after much vomiting and 18 or 20 stools; the second had no vomiting, but was as violently purged, and discharged two worms; the third had 20 copious stools during the night, and discharged the worm in the morning; and the fifth was effected in much the same manner. Some others who were not relieved, were supposed not to have a tænia.

This specific, however, is not to be considered as a new discovery; the efficacy of fern in cases of tenia having been known long ago. Theophrastus prescribes its root, in doses of four drams, given in water sweetened with honey, as useful in expelling flat worms.—Dioscorides orders it in the same dose, and adds, that its effects are more certain when it is mixed with four oboli (40 grains) of scammony or black hellebore; he particularly requires that garlic should be taken before hand. Pliny, Galen, Oribasius, and Aëtius, ascribe this same virtue to fern; and are followed in this by Avicenna, and the other Arabian physicians. Dorstenius, Valerius Cordus, Dodonæus, Mathiolus, Dalechampius, who commented on Dioscorides, or copied him in many things, all mention the fern-root as a specific against the tænia. Sennertus, and Burnet after him, recommended in similar cases an infusion of this plant, or a dram of its powder for young persons, and three drams for adults. Simon Paulus, quoted by Ray and Geoffroy, considers it as the most efficacious of all poisons against the flat worm, and as being the basis of all the secret remedies extolled by empirics in that disease. Andry (*génér. des Vers, p.* 246, 249) prefers distilled fern-water to the root in powder, or he employs it only in the form of an opiate, or mixed with other substances.

These are not the only authors who have mentioned the tænia; many others have described this worm, the symptoms it excites, and the treatment proper to expel it. Almost all of them mention the fern-root, but at the same time they point out other remedies as possessing equal efficacy. Amongst these we find the bark of the root of the mulberry-tree, the juice of the *auricula murus*, the roots of *chamæleon niger*, ginger, zedoary; decoctions of mugwort, southernwood, wormwood, penny-royal, origanum, hyssop, and in general of all bitter and aromatic plants, &c. Some of them direct the specific to be simply mixed and taken in wine or honey and water; others join to it the use of some purgative remedy, which they say adds to its efficacy. Oribasius, Sylvius, &c. distinguish the specific

cific that kills the worm, from the purgative that evacuates it, and direct them to be given at different times. Sennertus gives a very satisfactory reason for adopting this method. If we give, says he, the purgative medicine and the specific at the same time, the latter will be hastily carried off before it can have exerted its powers on the worm: whereas, if we give the specific first, and thus weaken the worm, it will collect itself into a bundle, and, being brought away by means of the purge, the patient will be cured. The cure will be more speedy if the *primæ viæ* have been previously lubricated. These precautions are all of them essential to the success of the remedy, nor are they neglected by Madame Nouffer in her method of treatment. The panada and injection she prescribes the night before, to lubricate the intestines, and prepare the *primæ viæ*. The fern-root, taken in the morning, kills and detaches the worm: of this the patients are sensible by the cessation of the pain in the stomach, and by the weight that is felt in the lower belly. The purgative bolus administered two hours after this, procures a complete evacuation; it is composed of substances that are at once purgative and vermifuge, and which, even when administered alone, by different physicians, sometimes succeeded in expelling the worm. If this purgative appear to be too strong, the reader is desired to recollect, that it produced no ill effects in either of the cases that came under the observation of the physicians appointed to make the trials; and that in one of those cases, by diminishing the dose, they evidently retarded the evacuations.—Regard however, they observe, is to be had both to the age and the temperament of the patient, and the treatment should always be directed by a prudent and experienced physician, who may know how to vary the proportions of the dose as circumstances may require. If the purgative be not of sufficient strength, the worm, after being detached by the specific, remains too long a time in the intestines, and becoming soon corrupted is brought away only in detached portions: on the other hand, if the purgative be too strong, it occasions too much irritation, and evacuations that cannot fail to be inconvenient.

Madame Nouffer's long experience has taught her to distinguish all these circumstances with singular adroitness.

This method of cure is, as we have seen, copied in a great measure from the ancients: it may be possible to produce the same effects by varying the remedies; but the manner of applying them is by no means indifferent: we shall be always more certain of success, if the intestines be previously evacuated, and if the specific be given some time before the purgative bolus. It is to this method that Madame Nouffer's constant success is attributed.

Her remedy has likewise some power over the *tænia solium*; but as the rings of this worm separate from each other more easily than those of the *tænia lata*, it is almost impossible for it to be expelled entire. It will be necessary therefore to repeat the treatment several times, till the patient cease to void any portions of worms. It must likewise be repeated, if, after the expulsion of one *tænia solium*, another should be generated in the intestinal canal. This last case is so rare, that it has been supposed that no person can have more than one of these worms; and for this reason it has been named *solitary worm*, which, being once removed, could never be renewed or replaced by a second: but experience has proved, that this notion is an ill-founded prejudice, and we know that sometimes these worms succeed each other, and that sometimes many of them exist together. Two living tæniæ have frequently been expelled from the same patient. Dr de Haen (*Rat. Med.* tom. viii. p. 157.) relates an instance of a woman who voided 18 tæniæ at once. In these cases the symptoms are usually more alarming; and the appetite becomes excessive, because these worms derive all their nourishment from the chyle. If too austere and ill judged a regimen deprives them of this, they may be expected to attack even the membranes of the intestines themselves. This evil is to be avoided by eating frequently.

Such are the precautions indicated in this disease. The ordinary vermifuge remedies commonly procured only a palliative cure, perhaps because they were too often improperly administered. But the efficacy of the present remedy, in the opinion of the French physicians, seem to be sufficiently confirmed by experience. To the above account, however, it seems proper to subjoin the following observations by Dr Simmons.

"A Swiss physician, of the name of *Herrenschwand*, more than 20 years ago, acquired no little celebrity by distributing a composition of which he styled himself the *inventor*, and which was probably of the same nature as Madame Nouffer's. Several very eminent men, as Tronchin, Hovius, Bonnet, Cramer, and others, have written concerning the effects of this remedy. It seems that Dr Herrenschwand used to give a powder by way of preparation, the night before he administered his specific. Nothing could be said with certainty concerning the composition either of one or the other. The treatment was said sometimes to produce most violent effects, and to leave the patients in a valetudinary state. Dr De Haen was dissuaded by his friends from using it, because it disordered the patients too much. It will be readily conceived, now that we are acquainted with Madame Nouffer's method, that these effects were occasioned wholly by the purgative bolus. It is not strange, that resin of scammony or jalap, combined with *mercurius dulcis* and gamboge, all of them in strong doses, should in many subjects occasion the greatest disorders. It seems likely, however, that much of the success of the remedy depends on the use of a drastic purge. Some of the ancients who were acquainted with the virtues of the fern-root, observed that its efficacy was increased by scammony. Resinous purges, especially when combined with mercury, have often been given with success in cases of *tænia*. Dr De Haen saw a worm of this sort five ells long expelled by the resin of jalap alone. Dr Gaubius knew a woman who had taken a variety of anthelmintic remedies without any effect, though she had voided a portion of *tænia* an ell and a half long previous to the use of these medicines: but at length, after taking a purge of singular strength, she voided the worm entire. Many other instances of the same kind are to be met with in authors. Other remedies have occasionally been given with success. In Sweden, it has been a practice to drink several gallons

Worms. gallons of cold water, and then to take some drastic purge. Boerhaave says, that he himself saw a *tænia* measuring 300 ells expelled from a Russian by means of the *vitriolum martis*. All these methods, however, have been too often ineffectual."

From some late accounts, there is reason to believe that Dr Herrenschwand's remedy for *tænia* does not so exactly agree with that of Madame Nouffer as Dr Simmons seems to imagine. According to the account given us by a gentleman who had his information from Dr Herrenschwand himself, it consists entirely of gamboge and fixed vegetable alkali.

408

Of POISONS.

These have all been treated of already, except the bites and stings of serpents, scorpions, &c. According to Dr Mead, the symptoms which follow the bite of a viper are, an acute pain in the place wounded, with a swelling, at first red, but afterwards livid, which by degrees spreads farther to the neighbouring parts; with great faintness, and a quick, low, and sometimes interrupted pulse; great sickness at stomach, with bilious convulsive vomitings, cold sweats, and sometimes pains about the navel. Frequently a fanious liquor runs from the small wound, and little pustules are raised about it: the colour of the whole skin in less than an hour is changed yellow, as if the patient had the jaundice. These symptoms are very frequently followed by death, especially if the climate be hot, and the animal of a large size. This is not, however, the case with all kinds of serpents. Some, we are assured, kill by a fatal sleep; others are said to produce an universal hemorrhagy and dissolution of the blood; and others an unquenchable thirst. But of all the species of serpents hitherto known, there is none whose bite is more expeditiously fatal than that of the rattle-snake. Dr Mead tells us, that the bite of a large serpent of this kind killed a dog in a quarter of a minute; and to the human species they are almost equally fatal. Of this serpent it is said, that the bite makes the person's skin become spotted all over like the skin of the serpent; and that it has such a motion as if there were innumerable living serpents below it. But this is probably nothing more than a dissolution of the blood, by which the skin becomes spotted as in petechial fevers, at the same time that the muscles may be convulsed as in the distemper called *hieranosos*, which was formerly thought to be the effect of evil spirits: but it is even not improbable that observers have been somewhat aided by fancy and superstition when they thought that they detected such appearances.

It has justly appeared surprising to philosophers, how such an inconsiderable quantity of matter as the poison emitted by a viper at the time of biting should produce such violent effects. But all inquiries into this matter must necessarily be uncertain; neither can they contribute any thing towards the cure. It is certain that the poison produces a gangrenous disposition of the part itself, and likewise seemingly of the rest of the body; and that the original quantity of poison continues some time before it exerts all its power on the patient, as it is known that removing part of the poisonous matter by suction will alleviate the symptoms. The indications of cure then are three. 1. To remove the poisonous matter from the body: Or, 2. If this cannot be done, to change its destructive nature by some powerful and penetrating application to the wound: And, 3. To counteract the effects of that portion already received into the system. Poisons.

The poisonous matter can only be removed from the body by sucking the wound either by the mouth, or by means of a cupping-glass; but the former is probably the more efficacious, as the saliva will in some measure dilute and perhaps obtund the poison. Mead directs the person who sucks the wound to hold warm oil in his mouth, to prevent inflammation of the lips and tongue: but as bites of this kind are most likely to happen in the fields, and at a distance from houses, the want of oil ought by no means to retard the operation, as the delay of a few minutes might prove of the most fatal consequence; and it appears from Dr Mead's experiments, that the taking the poison of a viper into the mouth undiluted, is attended with no worse consequences than that of raising a slight inflammation. A quick excision of the part might also be of very great service.

The only way of answering the second indication is, by destroying the poisoned part by a red-hot iron, or the application of alkaline salts, which have the power of immediately altering the texture of all animal-substances to which they are applied, provided they are not covered by the skin; and as long as the poison is not totally absorbed into the system, these must certainly be of use.

To answer the third indication, Dr Mead recommends a vomit of ipecacuanha, encouraged in the working with oil and warm water. The good effects of this, he says, are owing to the shake which it gives to the nerves, whereby the irregular spasms into which their whole system might be drawn are prevented. After this the patient must go to bed, and a sweat must be procured by cordial medicines; by which the remaining effects of the poison will be carried off.

It has been confidently asserted by many, that the American Indians are possessed of some specific remedy by which they can easily cure the bite of a rattle-snake. But Mr Catesby, who must have had many opportunities of knowing this, positively denies that they have any such medicine. They make applications indeed, and sometimes the patient recovers; but these recoveries he ascribes to the strength of nature overcoming the poison, more than to the remedies made use of. He says, they are very acute in their prognostics whether a person that is bit will die or not; and when they happen to receive a bite in certain parts of the body, when the teeth of the animal enter a large vein, for instance, they quietly resign themselves to their fate, without attempting any thing for their own relief. Indeed, so violent and quick is the operation of this poison, that unless the antidote be instantly applied, the person will die before he can get to a house. It would seem therefore eligible for those who are in danger of such bites, to carry along with them some strong alkaline ley, or dry alkaline salt, or both, which could be instantly clapt on the wound, and by its dissolving power would destroy both the poison and the infected parts. Strong cordials also, such as ardent spirits, volatile alkali, &c. might possibly excite the languid powers of nature, and enable her to expel

Poison. expel the enemy, which would otherwise prove too powerful. This seems to be somewhat confirmed from the account we have in the Philosophical Transactions of a gentleman bit by a rattle-snake, who was more relieved by a poultice of vinegar and vine-ashes put to his wound than any thing else. The vine-ashes being of an alkaline nature, must have saturated the vinegar, so that no part of the cure could be attributed to it: on the other hand, the ashes themselves could not have been saturated by the small quantity of acid necessary to form them into a poultice; of consequence they must have operated by their alkaline quality.—Soap-ley, therefore, or very strong salt of tartar, may reasonably be thought to be the best external application, not only for the bites of vipers, but of every venomous creature; and in fact we find *dry salt* universally recommended both in the bites of serpents and of mad dogs. Dr Mead recommends the fat of vipers presently rubbed into the wound; but owns that it is not safe to trust to this remedy alone.

Some years ago the volatile alkali was strongly recommended by M. Sage of the French academy, as a powerful remedy against the bite of the viper: and, by a letter from a gentleman in Bengal to Dr Wright, it would appear that this article, under the form of the *eau de luce*, which is very little if any thing different from the *spiritus ammoniæ succinatus* of the London Pharmacopoeia, has been employed with very great success against this affection in the East Indies: but from the trials made with it by the Abbé Fontana, published in his Treatise on the Poison of the Viper, it would appear that it by no means answered his expectation; and the efficacy of this, as well as of the snake pills mentioned under the article HYDROPHOBIA, still requires to be confirmed by further experience.

409

MELÆNE.

THIS is a distemper not very common, but it has been observed by the ancient physicians, and is described by Hippocrates under the name of *morbus niger*. It shows itself by a vomiting and purging of black tar-like matter; which Hippocrates, Boerhaave, and Van Swieten, supposed to be occasioned by atra bilis. But Dr Home, in his Clinical Experiments, shows that it is owing to an effusion of blood from the meseraic vessels, which by its stagnation and corruption assumes that strange appearance. The disease, he says, frequently follows hæmorrhagy; and those of a scorbutic habit are most subject to it. It is an acute disease, and terminates soon; yet is not attended with any great degree of fever. In one of Dr Home's patients the crisis happened on the eighth day by diarrhœa; in another, on the 14th, by sweat and urine; and a third had no evident critical evacuation.

As to the cure, Dr Home observes, that bleeding is always necessary where the pulse can bear it; nor are we to be deterred from it by a little weakness of the pulse, more than in the enteritis. Emetics are hurtful, but purgatives are useful. But the most powerful medicine for checking this hæmorrhagy is the vitriolic acid: and, that this might be given in greater quantity, he mixed it with mucilage of gum arabic; by which means he was enabled to give double the quantity he could otherwise have done. The cold bath was tried in one instance, but he could not determine whether it was of any service or not. The cure was completed by exercise and the bark. Diseases of Children.

Of the DISEASES of CHILDREN. 410

Dr Buchan observes, that from the annual registers of the dead it appears, that about one half of the children born in Great Britain die under twelve years of age; and this very great mortality he attributes in a great measure to wrong management. The particulars of this wrong management enumerated by him are,

1. Mothers not suckling their own children. This, he owns, it is sometimes impossible for them to do; but where it can be done, he affirms that it ought never to be omitted. This, he says, would prevent the unnatural custom of mothers leaving their own children to suckle those of others; on which he passes a most severe censure, and indeed scarce any censure can be severe enough upon such inhumanity. Dr Buchan informs us, "He is sure he speaks within bounds, when he says not one in a hundred of these children live who are thus abandoned by their mothers." For this reason he adds, that no mother should be allowed to suckle another's child till her own be fit to be weaned. A regulation of this kind would save many lives among the poorer sort, and would do no harm to the rich; as most women who make good nurses are able to suckle two children in succession upon the same milk.

2. Another source of the diseases of children is the unhealthiness of parents: and our author insists that no person who labours under an incurable malady ought to marry.

3. The manner of clothing children tends to produce diseases. All that is necessary here, he says, is to wrap the child in a soft loose covering; and the softness of every part of the infant's body sufficiently shows the injury which must necessarily ensue by pursuing a contrary method.

4. A new-born infant, instead of being treated with syrups, oils, &c. ought to be allowed to suck the mother's milk almost as soon as it comes into the world. He condemns the practice of giving wines and spirituous liquors along with the food soon after birth; and says, that if the mother or nurse has a sufficient quantity of milk, the child will need little or no other food before the third or fourth month. But to this it may reasonably be objected, not only that the nursing would thus be very severe on the mother; but if the child be left thus long without food, it will not easily relish it for some time, and its stomach is apt to be easily hurt by a slight change of diet after it has been long accustomed to one thing. Neither can it be shown, that the strongest and most healthy infants are those which get no other food but the mother's milk during the first months of their life. In fact, children are evidently of a weak and lax habit of body, so that many of their diseases must arise from that cause; all directions which indiscriminately advise an antiphlogistic regimen for infants as soon as they come into the world, must of necessity be wrong. Many instances in fact might be brought to show, that by the preposterous method of starving infants, and at the same time treating them with vomits and purges, they are

Diseases of Children.

often hurried out of the world. Animal-food indeed is exceessively agreeable to children, and they ought to be indulged with it in moderation; and this will prove a much better remedy for those acidities with which children are often troubled, than magnesia alba, crab's eyes, or other absorbents, which have the most pernicious effects on the stomachs of these tender creatures, and pall the appetite to a surprising degree The natural appetites of children are indeed the best rule by which we can judge of what is proper or improper for them. They must no doubt be regulated as to the quantity; but we may be assured that what a child is very fond of will not hurt it if taken in moderation. When children are sick, they refuse every thing but the breast; and if their distemper be very severe, they will refuse it also; and in this case they ought not to be pressed to take food of any kind: but when the sickness goes off, their appetite also returns, and they will require the usual quantity of food.

According to Dr Armstrong, *inward fits*, as they are called, are in general the first complaint that appears in children; and as far as he has observed, most, if not all infants, during the first months, are more or less liable to them. The symptoms are these. The child appears as if it was asleep, only the eyelids are not quite closed; and if you observe them narrowly, you will see the eyes frequently twinkle, with the white of them turned up. There is a kind of tremulous motion in the muscles of the face and lips, which produces something like a simper or a smile, and sometimes almost the appearance of a laugh. As the disorder increases, the infant's breath seems now and then to stop for a little; the nose becomes pinched; there is a pale circle about the eyes and mouth, which sometimes changes to livid, and comes and goes by turns; the child starts, especially if you go to stir it though ever so gently, or if you make any noise near it. Thus disturbed, it sighs, or breaks wind, which gives relief for a little, but presently it relapses into the dozing. Sometimes it struggles hard before it can break wind, and seems as if falling into convulsions; but a violent burst of wind from the stomach, or vomiting, or a loud fit of crying, sets all to rights again. As the child increases in strength, these fits are the more apt to go off spontaneously and by degrees; but in case they do not, and if there is nothing done to remove them, they either degenerate into an almost constant drowsiness, (which is succeeded by a fever and the thrush), or else they terminate in vomitings, sour, curdled, or green stools, the watery-gripes, and convulsions. The thrush indeed very often terminates in these last symptoms. Wherefore, as these complaints naturally run into one another, or succeed one another, they may be considered, in a manner, as only different stages of the same disease, and which derive their origin from the same cause. Thus, the inward fits may be looked upon as the first stage of the disorder; the fever, and thrush (when it happens), as the second; the vomitings, sour, curdled, green or watery stools, as the third; and convulsions, as the last.

As to the cause of these complaints, he observes, that in infants the glandular secretions, which are all more or less glutinous, are much more copious than in adults. During the time of sucking, the glands of the mouth and fauces being squeezed by the contraction of the muscles, spue out their contents plentifully; which afterwards mixing with the mucus of the gullet and stomach, render the milk of a slimy consistence, by which means it is not so readily absorbed into the lacteals; and as in most infants there is too great an acidity in the stomach, the milk is thereby curdled, which adds to the load; hence sickness and spasms, which, being communicated by sympathy to the nerves of the gullet and fauces, produce the convulsive motions above described, which go commonly by the name of *inward fits*. The air, likewise, which is drawn in during suction, mixing with the milk, &c. in the stomach, perhaps contributes towards increasing the spasms above-mentioned. Dr Armstrong is the more induced to attribute these fits to the causes now assigned, that they always appear immediately after sucking or feeding; especially if the child has been long at the breast, or fed heartily, and has been laid down to sleep without having first broken wind, which ought never to be done. Another reason is, that nothing relieves them so soon as belching or vomiting; and the milk or food they throw up is generally either curdled, or mixed with a large quantity of heavy phlegm. In case they are not relieved by belching or vomiting, the fits sometimes continue a good while, and gradually abate, according as the contents of the stomach are pushed into the intestines; and as soon as the former is pretty well emptied, the child is waked by hunger, cries, and wants the breast; he sucks, and the same process is repeated.—Thus, some children for the first weeks are kept almost always in a dose, or seemingly so; especially if the nurses, either through laziness or want of skill, do not take care to rouse them when they perceive that it is not a right sleep, and keep them awake at proper intervals. This dozing is reckoned a bad sign amongst experienced nurses; who look upon it as a forerunner of the thrush, as indeed it often is; and therefore, when it happens, we ought to be upon our guard to use the necessary precautions for preventing that disorder.

For these disorders, the only remedy recommended by Dr Armstrong is antimonial wine, given in a few drops, according to the age of the infant. By this means the superabundant mucus will no doubt be evacuated; but at the same time we must remember, that this evacuation can only *palliate*, and not cure the disease. This can only be effected by tonics; and a decoction of the Peruvian bark, made into a syrup, will readily be taken by infants, and may be safely exhibited from the very day they come into the world, or as soon as their bowels are emptied of the meconium by the mother's milk or any other means.

Dr Clarke observes, that *fractures* of the *limbs*, and *compressions* of the *brain*, often happen in difficult labours; and that the latter are often followed by convulsions soon after delivery. In these cases, he says, it will be advisable to let the navel-string bleed two or three spoonfuls before it be tied. Thus the oppression of the brain will be relieved, and the disagreeable consequences just mentioned will be prevented. But if this has been neglected, and fits have actually come on, we must endeavour to make a revulsion by all the means in our power; as by opening the jugular vein, procuring an immediate discharge of the urine and meconium, and applying small blisters to the back, legs, or behind the ears. The semicupium, too, would seem to be useful in this case, by driving the oppressive load of fluids from the head and upper parts.

It

It sometimes happens after a tedious labour, that the child is so faint and weak as to discover little or no signs of life. In such a case, after the usual cleansing, the body should be immediately wrapped in warm flannel, and briskly tossed about in the nurse's arms, in order, if possible, to excite the languid circulation. If this fail, the breast and temples may be rubbed with brandy or other spirits; or the child may be provoked to cry, by whipping, or other stimulating methods, as the application of onion, or salt and spirit of hartshorn, to the mouth and nostrils. But after all these expedients have been tried in vain, and the recovery of the child absolutely despaired of, it has sometimes been happily revived by introducing a short catheter or blow-pipe into the mouth, and gently blowing into the lungs at different intervals. Such children, however, are apt to remain weak for a considerable time, so that it is often no easy matter to rear them; and therefore particular care and tenderness will be required in their management, that nothing may be omitted which can contribute either to their preservation or the improvement of their strength and vigour.

All the disorders which arise from a *retention* of the *meconium*, such as the *red gum*, may easily be removed by the use of gentle laxatives; but the great source of mortality among children is the *breeding* of their *teeth*. The usual symptoms produced by this are fretting; restlessness; frequent and sudden startings, especially in sleep; costiveness; and sometimes a violent diarrhœa, fever, or convulsions. In general, those children breed their teeth with the greatest ease, who have a moderate laxity of the bowels, or a plentiful flow of saliva during that time.

In mild cases, we need only, when necessary, endeavour to promote the means by which nature is observed to carry on the business of dentition in the easiest manner. For this purpose, if a costiveness be threatened, it must be prevented, and the body kept always gently open; and the gums should be relaxed by rubbing them frequently with sweet oils, or other softening remedies of that kind, which will greatly diminish the tension and pain. At the same time, as children about this period are generally disposed to chew whatever they get into their hands, they ought never to be without something that will yield a little to the pressure of their gums, as a crust of bread, a wax-candle, a bit of liquorice-root, or such like; for the repeated muscular action, occasioned by the constant biting and gnawing at such a substance, will increase the discharge from the salivary glands, while the gums will be so forcibly pressed against the advancing teeth, as to make them break out much sooner, and with less uneasiness, than would otherwise happen. Some likewise recommend a slice of the rind of fresh bacon, as a proper masticatory for the child, in order to bring moisture into its mouth, and facilitate the eruption of the teeth by exercising the gums. If these means, however, prove ineffectual, and bad symptoms begin to appear, the patient will often be relieved immediately by cutting the inflamed gum down to the tooth, where a small white point shows the latter to be coming forward. When the pulse is quick, the skin hot and dry, and the child of a sufficient age and strength, emptying the vessels by bleeding, especially at the jugular, will frequently be necessary here, as well as in all other inflammatory cases; and the belly should be opened from time to time by emollient oily or mucilaginous glysters. But, on the contrary, if the child be low, sunk, and much weakened, repeated doses of the spirit of hartshorn, and the like reviving medicines, ought to be prescribed. Blisters applied to the back, or behind the ears, will often be proper in both cases. A prudent administration of opiates, when their use is not forbid by costiveness or otherwise, is sometimes of great service in difficult teething, as, by mitigating pain, they have a tendency to prevent its bad effects, as a fever, convulsions, or other violent symptoms; and often they are absolutely necessary, along with the testaceous powders, for checking an immoderate diarrhœa.

When cathartics are necessary, but the child seems too tender and weak to bear their immediate operation, they should be given to the nurse; in which case they will communicate so much of their virtues to the milk as will be sufficient to purge the infant. This at least certainly holds with regard to some cathartics; such, for example, as the infusion of senna, particularly if a very weak infusion be employed, and not used to such an extent as to operate as a purgative to the nurse.

As most young children, if in health, naturally sleep much, and pretty soundly, we may always be apt to suspect that something is amiss when they begin to be subject to *watching* and *frights*; symptoms which seldom or never occur but either in consequence of some present disorder not yet taken notice of, or as the certain forerunners of an approaching indisposition. We should immediately, therefore, endeavour to find out their cause, that we may use every possible means to remove or prevent it; otherwise the want of natural rest, which is so very prejudicial to persons of all ages, will soon reduce the infant to a low and emaciated state, which may be followed by an hectic fever, diarrhœa, and all the other consequences of weakness and debility. These symptoms, being always the effects of irritation and pain, may proceed, in very young infants, from crudities or other affections of the *primæ viæ* producing flatulencies or gripes; about the sixth or seventh month, they may be owing to that uneasiness which commonly accompanies the breeding of the teeth; and after a child is weaned, and begins to use a different kind of food, worms become frequently an additional cause of watchings and disturbed sleep. Hence, to give the necessary relief on these occasions, the original complaint must first be ascertained from the child's age and other concomitant circumstances, and afterwards treated according to the nature of the case. Women and nurses are too apt to have recourse to opiates in the watchings of children, especially when their own rest happens to be much disturbed by their continual noise and clamour. But this practice is often prejudicial, and never ought to have place when the belly is in the least obstructed.

There is no complaint more frequent among children than that of worms, the general symptoms of which have been already enumerated; but it must be observed, that all the symptoms commonly attributed to worms alone, may be produced by a foulness of the bowels. Hence practitioners ought never to rest satisfied with administering to their patients such medicines

Diseases of Children.

cines as are possessed only of an anthelmintic quality, but to join them with those which are particularly adapted for cleansing the *primæ viæ;* as it is uncertain whether a foulness of the bowels may not be the cause of all the complaints. This practice is still the more advisable, on account of viscid humours in the intestines affording lodgment to the ova of worms; which, without the convenience of such a receptacle, would be more speedily discharged from the body.

The difficulty of curing what is called a *worm fever*, arises, according to Dr Musgrave, from its being frequently attributed to worms, when the cause of the disorder is of a quite different nature. He does not mean to deny that worms do sometimes abound in the human body, nor that the irritation caused by them does sometimes produce a fever; but he apprehends these cases to be much more uncommon than is generally imagined, and that great mischief is done by treating some of the disorders of children as worm cases, which really are not so. Dr Hunter, it is observed, is of the same opinion on this point; and he has, we are told, dissected great numbers of children who have been supposed to die of worm-fevers, and whose complaints were of course treated as proceeding from worms, in whom, however, there appeared, upon dissection, to be not only no worms, but evident proofs of the disorder's having been of a very different nature.

The *spurious worm-fever*, as Dr Musgrave terms it, has, in all the instances he has seen of it, arisen evidently from the children having been indulged with too great quantities of fruit; though a poor cold diet may, he thinks, occasionally give birth to it. Every sort of fruit eaten in excess will probably produce it; but an immoderate use of cherries seems to be the most common cause of it. The approach of this disorder has a different appearance, according as it arises from a habit of eating fruit in rather too large quantities, or from an excessive quantity eaten at one time. In the former case, the patient gradually grows weak and languid; his colour becomes pale and livid; his belly swells and grows hard; his appetite and digestion are destroyed; his nights grow restless, or at least his sleep is much disturbed with startings, and then the fever soon follows, in the progress of which, the patient grows comatose, and at times convulsed; in which state, when it takes place to a high degree, he often dies. The pulse at the wrist, though quick, is never strong or hard; the carotids, however, beat with great violence, and elevate the skin so as to be distinctly seen at a distance. The heat is at times considerable, especially in the trunk; though at other times, when the brain is much oppressed, it is little more than natural. It is sometimes accompanied by a violent pain of the epigastric region, though more commonly the pain is slight, and terminates in a coma; some degree of pain, however, seems to be inseparable from it, so as clearly to distinguish this disorder from other comatose affections.

When a large quantity of fruit has been eaten at once, the attack of the disorder is instantaneous, and its progress rapid; the patient often passing, in the space of a few hours, from apparently perfect health, to a stupid, comatose, and almost dying state. The symptoms of the fever, when formed, are in both cases nearly the same; except that, in this latter sort, a little purulent matter is sometimes discharged, both by vomit and stool, from the very first day. The stools, in both cases, exhibit sometimes a kind of curd resembling curdled milk, at other times a floating substance is observed in them; and sometimes a number of little threads and pellicles, and now and then a single worm.

Strong purgatives, or purges frequently repeated, in this disorder, are greatly condemned by Dr Armstrong, as they in general not only aggravate the symptoms already present, but are sometimes the origin of convulsions. Bloodletting is not to be thought of in any stage of the disorder.

Although frequent purging, however, be not recommended, yet a single vomit and purge are advised in the beginning of the disorder, with a view to evacuate such indigested matter and mucus as happens to remain in the stomach and bowels. These having operated properly, there is seldom occasion for repeating them; and it is sufficient, if the body be costive, to throw up, every second or third day, a clyster, composed of some grains of aloes, dissolved in five ounces of infusion of chamomile.

The principal part of the cure, however, depends upon external applications to the bowels and stomach; and as the cause of the disorder is of a cold nature, the applications must be warm, cordial, and invigorating; and their action must be promoted by constant actual heat.

The following is the form recommended.

"Take of leaves of wormwood and rue, each equal parts: make a saturated decoction in a sufficient quantity of water, with which foment the region of the stomach and abdomen for a quarter of an hour, repeating the fomentation every three or four hours. A poultice of the boiled herbs is to be applied after the fomentation, and constantly renewed as it cools." For internal use, the following is all that has been found necessary. "Take of spirituous and simple cinnamon-water, each half an ounce; oil of almonds, an ounce and an half; balsamic syrup, three drachms. Mix, and shake the vial when used." From two to six drachms are given every third hour.

When any nervous symptoms come on, or remain after the disorder is abated, they are easily removed by giving a pill with a grain or two of asafœtida once or twice a-day.

The diagnostics of worms are very uncertain; but, even in real worm cases, the treatment above recommended would, it is imagined, be much more efficacious than the practice commonly had recourse to. As worms either find the constitution weakly, or very soon make it so, the frequent repetition of purges, particularly mercurials, cannot but have a pernicious effect. Bares-foot is still more exceptionable, being in truth to be ranked rather among poisons than medicines. Worm-seed and bitters are too offensive to the palate and stomach to be long persisted in, though sometimes very useful. The powder of coralline creates disgust by its quantity; and the infusion of pink-root is well known to occasion now and then vertiginous complaints and fits.

Fomenting the belly night and morning with a strong decoction of rue and wormwood, is much recommended. It is a perfectly safe remedy, and, by invigorating the bowels, may thereby have some influence in rendering them capable of expelling such worms

Dif. of children. worms as they happen to contain. After the fomentation, it is advifed to anoint the belly with a liniment, compofed of one part of effential oil of rue, and two parts of a decoction of rue in fweet oil. It is, however, a matter of great doubt whether thefe external applications, in confequence of the articles with which they are impregnated, exert any influence on the worms themfelves.

The diet of children difpofed to worms, fhould be warm and nourifhing, confifting in part at leaft of animal food, which is not the worfe for being a little feafoned. Their drink may be any kind of beer that is well hopped, with now and then a fmall draught of porter or negus. A total abftinence from butter is not fo neceffary, perhaps, as is generally imagined. Poor cheefe muft by all means be avoided; but fuch as is rich and pungent, in a moderate quantity, is particularly ferviceable. In the fpurious worm-fever, the patient fhould be fupported occafionally by fmall quantities of broth; and, at the clofe of it, when the appetite returns, the firft food given fhould be of the kinds above recommended.

The diet here recommended will, perhaps, be thought extraordinary, as the general idea is at prefent, that, in the management of children, nothing is fo much to be avoided as repletion and rich food. It is no doubt an error to feed children too well, or to indulge them with wine and rich fauces; but it is equally an error to confine them to too ftrict or too poor a diet, which weakens their digeftion, and renders them much more fubject to diforders of every kind, but particularly to diforders of the bowels. In regard to the fpurious worm-fever, if it be true that acid fruits too plentifully eaten are the general caufe of it, it follows as a confequence, that a warm nutritious diet, moderately ufed, will moft effectually counteract the mifchief, and fooneft reftore the natural powers of the ftomach. Befides, if the diforder does not readily yield to the methods here directed, as there are many examples of its terminating by an inflammation and fuppuration of the navel, it is highly advifable to keep this probability in view, and, by a moderate allowance of animal-food, to fupport thofe powers of nature, from which only fuch a happy crifis is to be expected.

Of MEDICAL ELECTRICITY.

The application of this fubtile fluid to medicinal purpofes was thought of foon after the difcovery of the electric fhock; and after various turns of reputation, its medical virtues feem now to be pretty well eftablifhed. After giving fo particular a defcription of the electrical apparatus under the proper article, it would here be fuperfluous to fay any thing farther on that head. We fhall only obferve, that Mr Cavallo, who has publifhed the lateft and the beft treatife on Medical Electricity, entirely difapproves of giving violent fhocks, and finds it moft efficacious to expofe the patient to the electrical aura difcharged from an iron or a wooden point; or if fhocks are given, they fhould be very flight, and not exceed 12 or 14 at a time. In this way he recommends it as effectual in a great number of diforders. The patient may be electrified from three to ten minutes; but if fparks are drawn, they fhould not exceed the number of fhocks above mentioned. Medical Electricity.

Rheumatic diforders, even of long ftanding, are relieved, and generally quite cured, by only drawing the electric fluid with a wooden point from the part, or by drawing fparks through flannel. The operation fhould be continued for about four or five minutes, repeating it once or twice every day.

Deafnefs, except when it is occafioned by obliteration or other improper configuration of the parts, is either entirely or partly cured by drawing the fparks from the ear with the glafs-tube director, or by drawing the fluid with a wooden point. Sometimes it is not improper to fend exceedingly fmall fhocks (for inftance, of one-thirteenth of an inch) from one ear to the other.—It has been conftantly obferved, that whenever the ear is electrified, the difcharge of the wax is confiderably promoted.

The toothach, occafioned by cold, rheumatifm, or inflammation, is generally relieved by drawing the electric fluid with a point, immediately from the part, and alfo externally from the face. But when the body of the tooth is affected, electrifation is of no ufe; for it feldom or never relieves the diforder, and fometimes increafes the pain to a prodigious degree.

Swellings in general, which do not contain any *matter*, are frequently cured by drawing the electric fluid with a wooden point. The operation fhould be continued for three or four minutes every day.—It is very remarkable, that in fome cafes of white fwellings, quite cured by means of electricity, the bones and cartilages were in fome meafure disfigured.

Inflammations of every fort are generally relieved by a very gentle electrization.

In inflammations of the eyes, the throwing of the electric fluid by means of a wooden point is often attended with great benefit; the pain being quickly abated, and the inflammation being generally diffipated in a few days. In thefe cafes, the eye of the patient muft be kept open; and care fhould be taken not to bring the wooden point very near it, for fear of caufing any fpark. Sometimes it is fufficient to throw the fluid with a metal point; for in thefe cafes, too great an irritation fhould be always avoided. It is not neceffary to continue this operation for three or four minutes without intermiffion; but after throwing the fluid for about half a minute, a fhort time may be allowed to the patient to reft and to wipe his tears, which generally flow very copioufly; then the operation may be continued again for another half minute, and fo on for four or five times every day.

The *gutta ferena* has been fometimes cured by electrization; but at the fame time it muft be confeffed, it has proved ineffectual in many fuch cafes, in which it was adminiftered for a long time and with all poffible attention. However, it has never been known that any body was made worfe by it. The beft method of adminiftering electricity in fuch cafes, is firft to draw the electric fluid with a wooden point for a fhort time, and then to fend about half a dozen of fhocks of one-twentieth of an inch from the back and lower part of the head to the fore head, very little above the eye.

A remarkable difeafe of the eye was fome time ago perfectly cured by electrization; it was an opacity of the vitreous humour of the eyes.

Medical Electricity.

All the cafes of *fiftula lacrymalis* which Mr Cavallo hath known to have been electrified by perfons of ability for a fufficient time, have been entirely cured. The method generally practifed has been that of drawing the fluid with a wooden point, and to take very fmall fparks from the part. The operation may be continued for about three or four minutes every day. It is remarkable, that in thofe cafes, after curing the fiftula lacrymalis, no other difeafe was occafioned by it, as blindnefs, inflammations, &c. by fuppreffing that difcharge.

Palfies are feldom perfectly cured by means of electricity, efpecially when they are of long ftanding; but they are generally relieved to a certain degree. The method of electrifying in thofe cafes, is to draw the fluid with the wooden point, and to draw fparks thro' flannel, or through the ufual coverings of the part if they are not too thick. The operation may be continued for about five minutes per day.

Ulcers, or open fores of every kind, even of a long ftanding, are generally difpofed to heal by electrization. The general effects are a diminution of the inflammation, and at firft a promotion of the difcharge of properly formed matter; which difcharge gradually leffens, according as the limits of the fore contract, till it be quite cured. In thefe cafes the gentleft electrization muft be ufed, in order to avoid too great an irritation, which is generally hurtful. To draw or throw the fluid with a wooden or even with a metal point, for three or four minutes per day, is fully fufficient.

Cutaneous eruptions have been fuccefsfully treated with electrization: but in thefe cafes it muft be obferved, that if the wooden point be kept too near the fkin, fo as to caufe any confiderable irritation, the eruption will be caufed to fpread more; but if the point be kept at about fix inches diftance, or farther, if the electrical machine be very powerful, the eruptions will be gradually diminifhed, till they are quite cured. In this kind of difeafe, the immediate and general effect of the wooden point is to occafion a warmth about the electrified part, which is always a fign that the electrization is rightly adminiftered.

The application of electricity has perfectly cured various cafes of *St Vitus's dance*, or of that difeafe which is commonly called fo; for it is the opinion of fome very learned phyficians, that the real difeafe called *St Vitus's dance*, which formerly was more frequent than it is at prefent, is different from that which now goes under that name. In this difeafe fhocks of about one-tenth of an inch may be fent through the body in various directions, and alfo fparks may be taken. But if this treatment prove very difagreeable to the patient, then the fhocks muft be leffened, and even omitted; inftead of which, fome other more gentle applications muft be fubftituted.

Scrophulous tumors, when they are juft beginning, are generally cured by drawing the electric fluid with a wooden or metal point from the part. This is one of thofe kinds of difeafes in which the action of electricity requires particularly the aid of other medicines in order to effect a cure more eafily; for fcrophulous affections commonly accompany a great laxity of the habit, and a general cachexy, which muft be obviated by proper remedies.

In *cancers*, the pains only are commonly alleviated by drawing the electric fluid with a wooden or metal point. Mr Cavallo, however, mentions one cafe in which a moft confirmed cancer of very long ftanding, on the breaft of a woman, had been much reduced in fize. It is remarkable, that this patient was fo far relieved by drawing the fluid with a metal point from the part, that the excruciating pains fhe had fuffered for many years did almoft entirely difappear; and alfo, that when the electric fluid was drawn by means of a wooden point, the pains did rather increafe.

Abfceffes, when they are in their beginning, and in general whenever there is any tendency to form matter, are difperfed by electrization. Lately, in a cafe in which matter was formed upon the hip, called the *lumbar abfcefs*, the difeafe was perfectly cured by means of electricity. The *fciatica* has alfo been often cured by it. In all fuch cafes, the electric fluid muft be fent through the part by means of two directors applied to oppofite parts, and in immediate contact either with the fkin, or with the coverings, when thefe are very thin. It is very remarkable, that the mere paffage of the electric fluid in this manner is generally felt by the patients afflicted with thofe diforders, nearly as much as a fmall fhock is felt by a perfon in good health. Sometimes a few fhocks have been alfo given, but it feems more proper to omit them; becaufe fometimes, inftead of difperfing, they rather accelerate the formation of matter.

In cafes of *pulmonary inflammations*, when they are in the beginning, electrization has been fometimes beneficial; but in confirmed difeafes of the lungs, it does not feem to have ever afforded any unqueftionable benefit; however, it feems that in fuch cafes the power of electricity has been but feldom tried.

Nervous headachs, even of a long ftanding, are generally cured by electrization. For this difeafe, the electric fluid muft be thrown with a wooden, and fometimes even with a metal point, all round the head fucceffively. Sometimes exceedingly fmall fhocks have been adminiftered; but thefe can feldom be ufed, becaufe the nerves of perfons fubject to this difeafe are fo very irritable, that the fhocks, the fparks, and fometimes even the throwing the electric fluid with a wooden point kept very near the head, throw them into convulfions.

The application of electricity has often been found beneficial in the *dropfy* when juft beginning, or rather in the tendency to a dropfy; but it has never been of any ufe in advanced dropfies. In fuch cafes, the electric fluid is fent through the part, in various directions, by means of two directors, and fparks are alfo drawn acrofs the flannel or the cloaths; keeping the metal rod in contact with them, and fhifting it continually from place to place. This operation fhould be continued at leaft ten minutes, and fhould be repeated once or twice a-day.—Perhaps in thofe cafes, a fimple electrization (viz. to infulate the patient, and to connect him with the prime conductor whilft the machine is an action), continued for a confiderable time, as an hour or two, would be more beneficial.

The *gout*, extraordinary as it may appear, has certainly been cured by means of electricity, in various inftances. The pain has been generally mitigated, and fometimes the difeafe has been removed fo well as not to

Medical Electricity.

to return again. In thoſe caſes, the electric fluid has been thrown by means of a wooden point, although ſometimes, when the pain was too great, a metal point only has been uſed.

Agues have not unfrequently been cured by electricity, ſo that ſometimes one electrization or two have been ſufficient. The moſt effectual and ſure method has been that of drawing ſparks through flannel, or the cloaths, for about ten minutes or a quarter of an hour. The patients may be electrified either at the time of the fit, or a ſhort while before the time in which it is expected.

The ſuppreſſion of the menſes, which is a diſeaſe of the female ſex that often occaſions the moſt diſagreeable and alarming ſymptoms, is often ſucceſsfully and ſpeedily cured by means of electricity, even when the diſeaſe is of long ſtanding, and after the moſt powerful medicines uſed for it have proved ineffectual The caſes of this ſort in which electrization has proved uſeleſs are ſo few, and the ſucceſsful ones ſo numerous, that the application of electricity for this diſeaſe may be juſtly conſidered as an efficacious and certain remedy. Great attention and knowledge is required, in order to diſtinguiſh the arreſt of the menſes from a ſtate of pregnancy. In the former, the application of electricity, as we obſerved above, is very beneficial; whereas, in the latter, it may be attended with very diſagreeable effects: it is therefore a matter of great importance to aſcertain the real cauſe of the diſeaſe, before the electricity be applied in thoſe caſes. Pregnant women may be electrified for other diſeaſes, but always uſing very gentle means, and directing the electric fluid through other parts of the body diſtant from thoſe ſubſervient to generation. In the real ſuppreſſion of the menſes, ſmall ſhocks, *i. e.* of about one twentieth of an inch, may be ſent through the pelvis; ſparks may be taken through the cloaths from the parts adjacent to the ſeat of the diſeaſe; and alſo the electric fluid may be tranſmitted by applying the metallic or wooden extremities of two directors to the hips, in contact with the clothes; part of which may be removed in caſe they be too thick. Thoſe various applications of electricity ſhould be regulated according to the conſtitution of the patient The number of ſhocks may be about 12 or 14 The other applications may be continued for two or three minutes; repeating the operation every day. But either ſtrong ſhocks, or a ſtronger application of electricity than the patient can conveniently bear, ſhould be carefully avoided; for by thoſe means, ſometimes more than a ſufficient diſcharge is occaſioned, which is not eaſily cured In caſes of uterine hæmorrhagie, it is not known that the application of electricity was ever beneficial. Perhaps a very gentle electrization, ſo as to keep the patient inſulated and connected with the prime conductor, whilſt the electrical machine is in action, may be of ſome benefit.

In reſpect to *unnatural diſcharges* and *fluxus* in general, it may be obſerved, that ſome diſcharges are quite unnatural or adventitious, as the fiſtula lacrymalis, and ſome ſpecies of the venereal diſeaſe; but others are only increaſed natural diſcharges, ſuch as the menſes, perſpiration, &c. Now the power of electricity in general has been found more beneficial for the firſt than for the ſecond ſort of diſcharges, which are moſtly increaſed by it.

In the *venereal diſeaſe*, electrization has been generally forbidden; having commonly increaſed the pains, and other ſymptoms, rather than diminiſhed them. Indeed, conſidering that any ſort of ſtimulus has been found hurtful to perſons afflicted with that diſorder, it is no wonder that electricity has produced ſome bad effects, eſpecially in the manner it was adminiſtered ſome time ago, viz. by giving ſtrong ſhocks. However, it has been lately obſerved, that a very gentle application of electricity, as drawing the fluid by means of a wooden or metal point, is peculiarly beneficial in various caſes of this kind, even when the diſeaſe has been of long ſtanding. Having remarked above, that tumors, when juſt beginning, are diſperſed, and that unnatural diſcharges are gradually ſuppreſſed by a judicious electrization, it is ſuperfluous to deſcribe particularly thoſe ſtates of the venereal diſeaſe in which electricity may be applied; it is only neceſſary to remind the operator to avoid any conſiderable ſtimulus in caſes of this ſort.

The application of electricity has been found alſo beneficial in other diſeaſes beſides thoſe mentioned above; but as the facts are not ſufficiently numerous, ſo as to afford the deduction of any general rules, we have not thought proper to take any particular notice of them.

We may laſtly obſerve, that, in many caſes, the help of other remedies to be preſcribed by the medical practitioner will be required to aſſiſt the action of electricity, which by itſelf would perhaps be uſeleſs; and, on the other hand, electrization may often be applied to aſſiſt the action of other remedies, as of ſudorifics, ſtrengthening medicines, &c.

Of FIXED AIR *as a* MEDICINE. 412

THE antiſeptic qualities of fixed air, or as it is now more generally called of the *aerial* or *carbonic acid*, have of late introduced it as a medicine in caſes of putrid diſorders, and various other complaints.—Dr Percival obſerves, that though fatal if inſpired in a very large quantity, it may in ſmaller quantities be breathed without danger or uneaſineſs. And it is a confirmation of this concluſion, that at Bath, where the waters copiouſly exhale this mineral ſpirit, the bathers inſpire it with impunity. At Buxton alſo, where the bath is in a cloſe vault, the effects of ſuch effluvia, if noxious, muſt certainly be perceived.

Encouraged by theſe and ſome other conſiderations, he has adminiſtered fixed air in more than 20 caſes of the *phthiſis pulmonalis*, by directing his patients to inſpire the ſteams of an efferveſcing mixture of chalk and vinegar through the ſpout of a coffee-pot. The hectic fever has in ſeveral inſtances been conſiderably abated, and the matter expectorated has become leſs offenſive and better digeſted. He has not, however, been ſo fortunate in any one caſe as to effect a cure; although the uſe of mephitic air has been accompanied with proper internal medicines. But Dr Withering has been more ſucceſsful. One phthiſical patient under his care, by a ſimilar courſe, entirely recovered; another was rendered much better; and a third, whoſe caſe was truly deplorable, ſeemed to be kept alive by it

Fixed Air. it more than two months. It may be proper to observe, that fixed air can only be employed with any prospect of success in the latter stages of the *phthisis pulmonalis*, when a purulent expectoration takes place. After the rupture and discharge of a vomica also, such a remedy promises to be a powerful palliative. Antiseptic fumigations and vapours have been long employed, and much extolled, in cases of this kind. The following experiment was made to determine whether their efficacy in any degree depends on the separation of fixed air from their substance.

One end of a bent tube was fixed in a phial full of lime-water; the other end in a bottle of the tincture of myrrh. The junctures were carefully luted; and the phial containing the tincture of myrrh was placed in water, heated almost to the boiling point, by the lamp of a tea-kettle. A number of air-bubbles were separated, but probably not of the mephitic kind; for no precipitation ensued in the lime-water. This experiment was repeated with the *tinct. Tolutana Ph. Ed.* and with *sp. vinos. camph.* and the result was entirely the same. The medicinal action therefore of the vapours raised from such tinctures, cannot be ascribed to the extrication of fixed air; of which it is probable bodies are deprived by chemical solution as well as by mixture.

If mephitic air be thus capable of correcting purulent matter in the lungs, we may reasonably infer it will be equally useful when applied externally to *foul ulcers*; and experience confirms the conclusion. Even the sanies of a cancer, when the carrot-poultice failed, has been sweetened by it, the pain mitigated, and a better digestion produced. But though the progress of the cancer seems to be checked by the fixed air, it is to be feared that a cure will not be effected. A palliative remedy, however, in a disease so desperate and loathsome, may be considered as a very valuable acquisition. Perhaps nitrous air might be still more efficacious. This species of factitious air is obtained from all the metals, except zinc, by means of the nitrous acid; as a sweetener and antiseptic, it far surpasses fixed air.

In the ulcerous *sore throat*, much advantage has been experienced from the vapours of effervescing mixtures drawn into the *fauces*. But this remedy should not supersede the use of other antiseptic applications.

In *malignant fevers*, wines abounding with fixed air may be administered to check the septic ferment, and sweeten the putrid *colluvies* in the *primæ viæ*. If the laxative quality of such liquors be thought an objection to the use of them, wines of a greater age may be given, impregnated with aerial acid.—The patient's common drink might also be medicated in the same way. A putrid diarrhœa frequently occurs in the latter stage of such disorders; and it is a most alarming and dangerous symptom. If the discharge be stopped by astringents, a putrid *fomes* is retained in the body, which aggravates the delirium, and increases the fever. On the contrary, if it be suffered to take its course, the strength of the patient must soon be exhausted, and death unavoidably ensue. The injection of mephitic air into the intestines, under these circumstances, bids fair to be highly serviceable. And in some cases of this kind, the gas emitted from a mixture of chalk and oil of vitriol conveyed into the body by the machine employed for tobacco-clysters, quickly restrained the diarrhœa, corrected the heat and fetor of the stools, and in a short time removed every symptom of danger. Fixed Air.

As a *solvent* of the *calculus*, its virtues have been already mentioned; but the experiments made on that subject do not determine the matter with sufficient accuracy.

Observations on the MEANS *of Preserving* HEALTH.

I. RULES *for the Management of* VALETUDINARIANS. 413

THAT part of the medical system which lays down rules for the preservation of health, and prevention of diseases, termed *Hygeine*, is not to be strictly understood as if it respected only those people who enjoy perfect health, and who are under no apprehensions of disease, for such seldom either desire or attend to medical advice; but should rather be considered as relating to valetudinarians, or to such as, though not actually sick, may yet have sufficient reason to fear that they will soon become so: hence it is that the rules must be applied to correct morbific dispositions, and to obviate the various things that were shown to be the remote or possible causes of diseases.

From the way in which the several temperaments are usually mentioned by systematic writers, it should seem as if they meant that every particular constitution must be referred to one or other of the four; but this is far from being reducible to practice, since by much the greater number of people have constitutions so indistinctly marked, that it is hard to say to which of the temperaments they belong.

When we actually meet with particular persons who have evidently either,

1. Too much strength and rigidity of fibre, and too much sensibility;

2. Too little strength, and yet too much sensibility;

3. Too much strength, and but little sensibility; or,

4. But little sensibility joined to weakness;

we should look on such persons as more or less in the valetudinary state, who require that these morbific dispositions be particularly watched, lest they fall into those diseases which are allied to the different temperaments.

People of the first-mentioned temperament being liable to suffer from continued fevers, especially of the inflammatory species, their scheme of preserving health should consist in temperate living, with respect both to diet and exercise; they should studiously avoid immoderate drinking, and be remarkably cautious lest any of the natural discharges be checked. People of this habit bear evacuations well, especially bleeding: they ought not, however, to lose blood but when they really require to have the quantity lessened; because too much of this evacuation would be apt to reduce the constitution to the second-mentioned temperament, wherein strength is deficient, but sensibility redundant.

Persons of the second temperament are remarkably prone to suffer from painful and spasmodic diseases, and are easily ruffled; and those of the softer sex who have this

Means of preserving Health.

this delicacy of habit, are very much difpofed to hyfterical complaints. The fcheme here fhould be, to ftrengthen the folids by moderate exercife, cold bathing, the Peruvian bark, and chalybeate waters; particular attention fhould conftantly be had to the ftate of the digeftive organs, to prevent them from being overloaded with any fpecies of faburra which might engender flatus, or irritate the fenfible membranes of the ftomach and inteftines, from whence the diforder would foon be communicated to the whole nervous fyftem. Perfons of this conftitution fhould never take any of the draftic purges, nor ftrong emetics; neither fhould they lofe blood but in cafes of urgent neceffity. But a principal fhare of management, in thefe extremely irritable conftitutions, confifts in avoiding all fudden changes of every fort, efpecially thofe with refpect to diet and clothing, and in keeping the mind as much as poffible in a ftate of tranquillity: hence the great advantages which people of this frame derive from the ufe of medicinal waters drunk on the fpot, becaufe of that freedom from care and ferious bufinefs of every kind, which generally obtains in all the places laid out for the reception of valetudinarians.

The third-mentioned temperament, where there is an excefs of ftrength and but little fenfibility, does not feem remarkably prone to any diftreffing or dangerous fpecies of difeafe; and therefore it can hardly be fuppofed that perfons fo circumftanced will either of themfelves think of any particular fcheme of management, or have recourfe to the faculty for their inftructions: fuch conftitutions, however, we may obferve, bear all kinds of evacuations well, and fometimes require them to prevent an over-fulnefs, which might end in an oppreffion of the brain or fome other organ of importance.

But the fourth temperament, where we have weaknefs joined to want of fenfibility, is exceedingly apt to fall into tedious and dangerous difeafes, arifing from a defect of abforbent power in the proper fets of veffels, and from remiffnefs of the circulation in general: whence corpulency, dropfy, jaundice, and different degrees of fcorbutic affection. In order to prevent thefe, or any other fpecies of accumulation and depravation of the animal fluids, the people of this conftitution fhould ufe a generous courfe of diet, with brifk exercife, and be careful that none of the fecretions be interrupted, nor any of the natural difcharges fuppreffed. Thefe conftitutions bear purging well, and often require it; as alfo the ufe of emetics, which are frequently found neceffary to fupply the place of exercife, by agitating the abdominal vifcera, and are of fervice to prevent the ftagnation of bile, or the accumulation of mucous humours, which hinder digeftion, and clog the firft paffages. The free ufe of muftard, horfe-radifh, and the like fort of ftimulating dietetics, is ferviceable in thefe torpid habits

When the general mafs of fluids is accumulated beyond what is conducive to the perfection of health, there arifes what the writers term a *plethora*, which may prove the fource of different difeafes; and therefore, when this overfulnefs begins to produce languor and oppreffion, care fhould be taken in time to reduce the body to a proper ftandard, by abridging the food and increafing the natural difcharges, ufing more exercife, and indulging lefs in fleep.

But in oppofite circumftances, where the fluids have been exhaufted, we are to attempt the prevention of further wafte by the ufe of ftrengthening ftomachics, nourifhing diet, and indulgence from fatigue of body or mind.

Vitiated fluids are to be confidered as affected either with the different kinds of general acrimony, or as betraying figns of fome of the fpecies of morbific matter which give rife to particular difeafes, fuch as gout, rheumatifm, calculus, fcurvy, &c.

During the ftate of infancy, we may fometimes obferve a remarkable acidity, which not only fhows itfelf in the firft paffages, but alfo feems to contaminate the general mafs of fluids. As it takes its rife, however, from weak bowels, our views, when we mean to prevent the ill confequences, muft be chiefly directed to ftrengthen the digeftive organs, as on their foundnefs the preparation of good chyle depends; and hence fmall dofes of rhubarb and chalybeates (either the natural chalybeate waters mixed with milk, or the *flores martiales* in dofes of a few grains, according to the age of the child), are to be adminiftered; and the diet is to be fo regulated as not to add to this acid tendency: brifk exercife is likewife to be enjoined, with frictions on the ftomach, belly, and lower extremities.

Where the fluids tend to the putrefcent ftate, which fhows itfelf by fetid breath, fponginefs, and bleeding of the gums, a bloated look and livid caft, the diet then fhould be chiefly of frefh vegetables and ripe fruits, with wine in moderation, brifk exercife, and ftrengthening bitters.

Where acrimony fhows itfelf by itching eruptions, uncommon thirft, and flufhing heats, nothing will anfwer better than fuch fulphureous waters as the Harrowgate and Moffat in Britain, or the Lucan and Swadlinbar in Ireland; at the fame time ufing a courfe of diet that fhall be neither acrid nor heating.

So far with refpect to thofe kinds of morbific matter which do not invariably produce a particular fpecies of difeafe: but there are others of a fpecific nature, fome of which are generated in the body fpontaneoufly, and feem to arife from errors in diet, or other circumftances of ill management with refpect to the animal economy; and hence it is fometimes poffible, in fome degree if not altogether, to prevent the ill confequences. Thus, there are inftances where returns of the gout have been prevented by adhering ftrictly to a milk diet.

The rheumatifm has alfo been fometimes warded off by wearing a flannel fhirt, or by ufing the cold bath without interruption.

Calculus may be retarded in its progrefs, and prevented from creating much diftrefs, by the internal ufe of foap and lime-water, by foap-lees taken in milk or in veal-broth, or by the ufe of aerated alkaline water, which may perhaps be confidered as being both more fafe and more efficacious, and at the fame time more pleafant, than any of the other practices.

The fcurvy may be prevented by warm clothing and perfeverance in brifk exercife, by drinking wine or cyder, and eating freely of fuch vegetable fubftances as can be had in thofe fituations where this difeafe is moft apt to fhow itfelf.

In conftitutions where there is an hereditary difpo-

Means of preferving Health.

fition to the fcrofula, if early precautions be taken to ftrengthen the folids by cold bathing, a nourifhing courfe of diet, and moderate ufe of wine, the acrimony which gives rife to the difeafe will probably be prevented from producing any very bad effects.

The other kinds of morbific matter, which are of the fpecific nature, are received into the body by infection or contagion.

The infection of a putrid fever or dyfentery is beft prevented by immediately taking an emetic on the firft attack of the ficknefs or fhivering; and if that do not completely anfwer, let a large blifter be applied between the fhoulders: by this method the nurfes and other attendants on the fick in the naval hofpitals have often been preferved. As to other infectious morbific matter, we muft refer to what has already been faid when treating of hydrophobia, poifons, &c.

The ill effects which may arife from the different fpecies of faburra, are to be obviated, in general, by the prudent adminiftration of emetics, and carefully abftaining from fuch kinds of food as are known to caufe the accumulation of noxious matters in the firft paffages.

Crude vegetables, milk, butter, and other oily fubftances, are to be avoided by perfons troubled with a fournefs in the ftomach; brifk exercife, efpecially riding, is to be ufed, and they are to refrain from fermented liquors: the common drink fhould be pure water; or water with a very little of fome ardent fpirit, fuch as rum or brandy. Seltzer and Vahls water are to be drunk medicinally; and aromatic bitters, infufions, or tinctures, with the acid elixir of vitriol, from 10 to 20 drops, will be found ferviceable, in order to ftrengthen the fibres of the ftomach, and promote the expulfion of its contents, thereby preventing the too hafty fermentation of the alimentary mixture. In order to procure immediate relief, magnefia alba, or *creta præparata*, will feldom fail; the magnefia, as well as the chalk, may be made into lozenges, with a little fugar and mucilage; and in that form may be carried about and taken occafionally by people afflicted with the acid faburra.

In conftitutions where there is an exuberance or ftagnation of bile, and a troublefome bitternefs in the mouth, it is neceffary to keep the bowels always free, by taking occafionally fmall dofes of pure aloes, *oleum ricini*, cream of tartar, fome of the common purging falts, or the natural purging waters.

When there is a tendency to the empyreumatic and rancid faburra, people fhould carefully avoid all the various kinds of thofe oily and high-feafoned things generally termed *made-difhes*, and eat fparingly of plain meat, without rich fauces or much gravy; and in thefe cafes the moft proper drink is pure water.

414 II. Rules *for thofe who enjoy perfect* Health.

There can be no doubt, that, in general, temperance is the true foundation of health; and yet the ancient phyficians, as we may fee in the rules laid down by Celfus, did not fcruple to recommend indulgence now and then, and allowed people to exceed both in eating and drinking: but it is fafer to proceed to excefs in drink than in meat; and if the debauch fhould create any extraordinary or diftreffing degree of pain or ficknefs, and a temporary fever fhould enfue, there are two ways of fhaking it off, either to lie in bed and encourage perfpiration, or to get on horfe-back and by brifk exercife reftore the body to its natural ftate. The choice of thefe two methods muft always be determined by the peculiar circumftances of the parties concerned, and from the experience which they may before have had which agrees beft with them.

If a perfon fhould commit excefs in eating, efpecially of high-feafoned things, with rich fauces, a draught of cold water, acidulated with vitriolic acid, will take off the fenfe of weight at the ftomach, and affift digeftion, by moderating and keeping within bounds the alimentary fermentation, and thus preventing the generation of too much flatus. The luxury of ices may be here of real fervice at the tables of the great, as producing fimilar effects with the cold water acidulated. Perfons in thefe circumftances ought not to lay themfelves down to fleep, but fhould keep up and exercife until they are fenfible that the ftomach is unloaded, and that they no longer feel any oppreffive weight about the præcordia.

If a man be obliged to faft, he ought, if poffible, during that time, to avoid laborious work: after fuffering fevere hunger, people ought not at once to gorge and fill themfelves; nor is it proper, after being overfilled, to enjoin an abfolute faft: neither is it fafe to reft totally immediately after exceffive labour, nor fuddenly fall hard to work after having been long without motion: in a word, all changes fhould be made by gentle degrees; for though the conftitution of the human body be fuch that it can bear many alterations and irregularities without much danger, yet, when the tranfitions are extremely fudden, they cannot fail of producing fome kind or degree of diforder.

It is alfo the advice of Celfus to vary the fcenes of life, and not confine ourfelves to any fettled rules: but as inaction renders the body weak and liftlefs, and exercife gives vigour and ftrength, people fhould never long omit riding, walking, or going abroad in a carriage; fencing, playing at tennis, dancing, or other fimilar engagements, which afford both exercife and amufement, as each fhall be found moft agreeable or convenient, are to be ufed in their turns, according to the circumftances and tendency to any particular fpecies of difeafe. But when the weaknefs of old age fhall have rendered the body incapable of all thefe, then dry frictions with the flefhbrufh will be extremely requifite to preferve health, by accelerating the flow of humours through the fmalleft orders of veffels, and preventing the fluids from ftagnating too long in the cellular interftices of the flefhy parts.

Sleep is the great reftorer of ftrength; for, during this time, the nutritious particles appear to be chiefly applied to repair the wafte, and replace thofe that have been abraded and wafhed off by the labour and exercife of the day; but too much indulgence in fleep has many inconveniencies, both with refpect to body and mind, as it blunts the fenfes, and encourages the fluids to ftagnate in the cellular membrane whence corpulency, and its neceffary confequences languor and weaknefs.

The proper time for fleep is the night feafon, when darknefs

Means of preserving Health.

of darkness and silence naturally bring it on: therefore day-sleep in general is not so refreshing; and to some people is really distressful, as creating an unusual giddiness and languor, especially in persons addicted to literary pursuits. Custom, however, frequently renders sleep in the day necessary; and in those constitutions where it is found to give real refreshment, it ought to be indulged.

With regard to the general regimen of diet, it has always been held as a rule, that the softer and milder kinds of aliment are most proper for children and younger subjects; that grown persons should eat what is more substantial; and old people lessen their quantity of solid food, and increase that of their drink.

I N D E X.

Gener-

Stab

Medicines || Medicis.

MEDICINES, whatever substances serve to restore health.—Medicines are either *simple* or *compound*; the former being prepared by nature alone; and the latter owing to the industry of man, by variously mixing the simple together. See PHARMACY.

MEDICINES are likewise distinguished from the manner of using them, into *external* and *internal*; and with regard to their effects, they are said to be *emetic*, *cathartic*, *astringent*, &c. See *MATERIA Medica*.

Pocket MEDICINES, in surgery, those which a surgeon ought always to carry about with him, in a box or convenient case.

Those, according to Heister, are the common digestive ointment, and some detergent ointment, for cleansing and digesting foul ulcers; to which must also be added a plaster or two fitted for defence or adhesion, since one or other of these is almost constantly wanted. Neither should there be wanting a piece of blue vitriol for the taking down luxuriant flesh, and to stop hemorrhagies: but if vitriol is wanting, burnt alum, red precipitate, the infernal stone, or any other corrosive medicine, will supply its place in corrosive intentions; and the last will also serve to open abscesses, to make issues, and perform many other operations of that kind.

With these there should always be kept in readiness also a quantity of scraped lint, that the surgeon may be able to give immediate assistance to wounded persons; since, if he is unprepared for this, they may easily be taken off by an hemorrhagy; a circumstance which ought also to prevail with him to be always provided with suitable bandages.

MEDICIS (Cosmo de), called the *Elder*, son of John de Medicis, was born at Florence Sept. 1389. Altho' in a private station, he appeared with the splendor of the most powerful sovereign; and his fortune, accumulated by successful commerce, was surpassed by the revenue of few princes. He was partial to the sciences, and liberal to men of genius. His library consisted of a vast number of books of his own collecting, and he enriched it with many scarce and valuable manuscripts. Banished from his native country by the envy which his riches inspired, he went to Venice, where he was received with the honours due to a sovereign prince. His countrymen soon perceived their error, and recalled him from banishment. For 34 years he was supreme judge of the republic; and his advice was solicited by the greater part of the cities and sovereignties of Italy. This great man died August 1464, in the 75th year of his age, full of happiness and glory. On his tombstone he is styled, "*Father of the people, and deliverer of his country.*"

MEDICIS (Laurence de), styled the *Great* and the *Father of learning*, was born A. D. 1448. He was the son of Peter, the grandson of Cosmo, and the brother of Julian de Medicis. These two brothers, who were in possession of absolute power at Florence, excited the jealousy of Ferdinand of Naples and Pope Sixtus IV. The first hated them, because they had ruined his influence in Florence; and the second, because they opposed the advancement of his nephew. It was at their instigation that the Pazzi conspired against them. Julian was murdered while he heard mass April 26th 1478; and Laurence, who was only wounded, was carried back to his house in the midst of the shouts and acclamations of the people. Heir to the greater part of his grandfather's virtues, he was, like him, the Mæcenas of his age. It was equally astonishing (says an historian of that country) and foreign to our manners, to see the same man engaged in commerce, and supporting the burden of the public affairs; conversing with factors, and receiving ambassadors; giving shows to the people; affording an asylum to the unfortunate; and adorning his country with many magnificent buildings. He was so much beloved by the Florentines, that they appointed him chief magistrate of the republic. By his unbounded liberality, he drew to his court a great number of learned men. He sent John Lascaris into Greece to recover manuscripts, with which he enriched his library. He cultivated learning himself, and was the author of the following works: 1. *Des Poesies Italiennes*, Venice, 1554, 12mo. 2. *Canzonne à ballo*, 1568, 4to. 3. *La Compagnia del Mantellaccio Beoni*, with the sonnets of

Medicis. *Burchiello*, 1558 or 1568, 8vo. Laurence de Medicis was so universally admired, that the princes of Europe did him the honour to appeal their differences to his decision. It is even reported, that Bajazet emperor of the Turks, to show him a mark of esteem and regard, caused search for the murderers of his brother Julian in Constantinople, and sent back one of them who had concealed himself in that city. Pope Sixtus IV. was the last of his enemies; but he opposed him with so much ability, that he brought him to terms of accommodation. This illustrious man died April 9th 1492, aged 44. His reputation was sullied by his passion for women and by his infidelity. His two sons, Peter who succeeded him and who was expelled from Florence in 1404, and John who went by the name of Pope Leo X. were like their father remarkable for their generosity and their love of learning Peter died in 1594, leaving Laurence, the last male issue of this branch. Laurence was the father of Catharine de Medicis, who married Henry II. king of France.

Medicis (John de), on account of his bravery and knowledge in military affairs was surnamed the *Invincible*. He was the son of John, otherwise called *Jourdain*, de Medicis. His only son Cosmo I. styled the *Great*, was chosen duke of Florence after the murder of Alexander de Medicis, A. D. 1537. He first carried arms under Laurence de Medicis against the duke of Urbino, afterwards under Pope Leo X. Upon the death of Leo, he entered into the service of Francis I. which he quitted to follow the fortunes of Francis Sforza duke of Milan. When Francis I. formed an alliance with the pope and the Venetians against the emperor, he returned to his service. He was wounded in the knee at Governola, a small town in the Mantuan territory, by a musket-ball; and being carried to Mantua, he died the 29th of November 1526, aged 28. Brantome relates, that when his leg was to be cut off, and when he was informed that he needed some person to support him, "Proceed without fear (said he), I need nobody!" and he held the candle himself during the operation. This anecdote is also mentioned by Varchi. John de Medicis was above the middle stature, strong, and nervous. His soldiers, to express their affection for him and their concern for his loss, assumed a mourning dress and standards, which gave the name of *the black band* to the Tuscan troops whom he commanded.

Medicis, (Laurence, or Laurenein de), was descended from a brother of Cosmo the Great, and affected the name of *popular*. In 1537, he killed Alexander de Medicis, whom Charles V. had made duke of Florence, and who was believed to be the natural son of Laurence de Medicis duke of Urbino. He was jealous of Alexander's power, and disguised this jealousy under the specious pretext of love to his country. He loved men of learning, and cultivated literature. His works are, 1. *Lamenti*, Modena, 12mo. 2. *Aridosio Commedia*, Florence 1595, 12mo. He died without issue.

Medicis, (Hypolitus de), natural son of Julian de Medicis and a lady of Urbino, was early remarkable for the brilliancy of his wit and the graces of his person. Pope Clement VII. his cousin, made him cardinal in 1529, and sent him as legate into Germany to the court of Charles V. When that prince went into Italy, Medicis, yielding to his warlike disposition, appeared in the dress of an officer, and advanced before the emperor, followed by several respectable gentlemen of the court. Charles, naturally suspicious, and afraid that the legate intended to do him some ill offices with the pope, sent after him and caused him to be apprehended. But when he understood that it was a mere sally of humour in the young cardinal, he set him at liberty in a few days. The character which Medicis obtained by the happy success of this appointment, was of essential service to him. He was considered as one of the supports of the Holy See; and a little before Clement's death, when the corsair Barbarossa made a descent into Italy to the great terror of Rome, which was only defended by 200 of the pope's guards, Medicis was dispatched to protect the coasts from the fury of the barbarians. On his arrival at the place of destination, he was fortunate enough to find that Barbarossa had withdrawn himself at that critical moment; which allowed him to claim the honour of the retreat without exposing his person or his army. When he returned to Rome, he was of great service in the election of Paul III. who nevertheless refused to make him legate to Ancona, though that office had been promised to him in the conclave. Enraged also that the pope had bestowed the principality of Florence on Alexander de Medicis, supposed to be the natural son of Laurence duke of Urbino, he was prompted by his ambition to believe that he might succeed to that dignity by the destruction of Alexander. He entered into a conspiracy against him, and determined to carry him off by a mine; but the plot was discovered before he had accomplished his purpose. Octavian Zanga, one of his guards, was arrested as his chief accomplice. Hypolitus de Medicis, apprehensive for his own safety, retired to a castle near Trivoli. On his road to Naples, he fell sick at Itri in the territory of Fondi, and died August 13th 1535, in his 24th year, not without suspicion of being poisoned. His house was an asylum for the unfortunate, and frequently for those who were guilty of the blackest crimes. It was open to men of all nations; and he was frequently addressed in 20 different languages. He had a natural son named *Asdrubal de Medicis*, who was a knight of Malta. This anecdote proves that his manners were more military than ecclesiastic. He wore a sword, and never put on the habit of cardinal except on occasions of public ceremony. He was wholly devoted to the theatre, hunting, and poetry.

Medicis, (Alexander de), first duke of Florence in 1530, was natural son of Laurence de Medicis surnamed the *Younger*, and nephew of pope Clement VII. He owed his elevation to the intrigues of his uncle and to the arms of Charles V. This prince having made himself master of Florence after an obstinate siege, conferred the sovereignty of this city on Alexander, and afterwards gave him in marriage Margaret of Austria his natural daughter. According to the terms of capitulation granted to the Florentines, the new duke was to be only hereditary doge, and his authority was tempered by councils; which left them at least a shadow of their ancient liberty. But Alexander,

Alexander, who felt himfelf fupported by the emperor and the pope, was no fooner in poffeffion of his new dignity, than he began to govern like a tyrant; being guided by no law but his own caprice, indulging the moft brutal paffions, and making light of difhonouring families, and of violating even the afylum of the cloifters to gratify his luft. Among the confidants of his debauchery was a relation of his own, Laurence de Medicis. This young man, who was only 22 years of age, at the inftigation of Philip Strozzi, a zealous republican, conceived the defign of affaffinating Alexander, and thereby of delivering his country from oppreffion. From the moment when he firft became attached to him, he tried to gain his confidence, for no other reafon but that he might the better have it in his power to take away his life. A confiderable time elapfed before he found fuch an opportunity as he defired. At length, under pretence of procuring the duke a *tête à tête* with a lady of whom he was deeply enamoured, he brought him alone and unattended into his chamber, and put him under his bed. He went out, under pretence of introducing the object of his paffion; and returned along with an affaffin by profeffion, to whom alone he had entrufted his defign, only to ftab him. This cruel fcene happened on the night betwixt the 5th and 6th of January 1537. Alexander was only 26 years of age. The Florentines derived no advantage from this crime of Laurence, for they failed in their attempt to recover their liberty. The party of the Medicis prevailed, and Alexander was fucceeded by Cofmo; whofe government, it muft be confeffed, was as juft and moderate, as that of his predeceffor had been violent and tyrannical. Laurence de Medicis fled to Venice, to fome of the leaders of the malcontents at Florence, who had taken refuge there; but not thinking himfelf in fufficient fecurity, he went to Conftantinople, whence he returned fome time after to Venice. He was there affaffinated in 1547, ten years after the duke's murder, by two foldiers, one of whom had formerly been in Alexander's guards: And thefe foldiers were generous enough to refufe a confiderable fum of money, which was the price put upon his head.

Medicis (Cofmo de), grand duke of Tufcany, joined Charles V. againft the French, after trying in vain to continue neutral. As a reward for his fervices, the emperor added to the duchy of Tufcany Piombino the ifle of Elba and other ftates. Cofmo foon after received from pope Pius IV. the title of *grand duke*; and had it not been oppofed by all the princes of Italy, this pontiff, who was entirely devoted to Cofmo, becaufe he had thought proper to acknowledge him to be of his houfe, would have conferred on him the title of *king*. There never was a more zealous patron of learning. Ambitious of imitating the fecond Cæfar, he, like him, was fond of learned men, kept them near his perfon, and founded for them the univerfity of Pifa. He died in 1574, at the age of 55, after governing with equal wifdom and glory. In 1562 he inftituted the military order of St Stephen. His fon, Francis Mary, who died in 1587, was the father of Mary of Medicis the wife of Henry the Great, and of Ferdinand I. who died in 1608.

MEDIETAS linguæ, in law, fignifies a jury, or inqueft impanelled, of which the one half are natives of this land and the other foreigners. This jury is never ufed except where one of the parties in a plea is a ftranger and the other a denizen. In petit-treafon, murder, and felony, foreigners are allowed this privilege; but not in high-treafon, becaufe an alien in that cafe fhall be tried according to the rules of the common law, and not by a *medietas linguæ*. A grand jury ought not in any cafe to be of a *medietas linguæ*; and the perfon that would have the advantage of a trial in this way, is to pray the fame, otherwife it will not be permitted on a challenge of the jurors.

MEDIMNUS, in Grecian antiquity, a meafure of Capacity. See Measure.

MEDINA-talnabi, a famous town of Arabia Petræa, between Arabia Deferta and Arabia the Happy; celebrated for being the burial-place of Mahomet. It ftands at a day's journey from the port of Iambo. It is of moderate fize, furrounded by wretched walls, and fituated in the midft of a fandy plain. It belongs to the Scherif of Mecca, although it had of late times a particular fovereign of the family of Dacii Barkad. At prefent, the government is confided by the Scherif to a vizir, who muft be taken from the family of the fovereign. Before Mahomet, this city was called *Iathreb*; but it got the name of *Medinet en Nebbi*, "the City of the Prophet," after Mahomet, being driven from Mecca by the Koreifchites, had taken refuge there, and paffed in it the reft of his days. The tomb of Mahomet at Medina is refpected by Muffulmans, but they are under no obligation to vifit it for the purpofes of devotion. The caravans of Syria and Egypt alone, which on their return from Mecca pafs near Medina, go a little out of their way to fee the tomb. It ftands in a corner of the great fquare, whereas the Kaba is fituated in the middle of that at Mecca. That the people may not perform fome fuperftitious worfhip to the relics of the prophet, they are prevented from approaching the tomb by grates, through which they may look at it. It confifts of a piece of plain mafon-work in the form of a cheft, without any other monument. The tomb is placed between two others, where the afhes of the two firft caliphs repofe. Although it is not more magnificent than the tombs of the greater part of the founders of mofques, the building that covers it is decorated with a piece of green filk ftuff embroidered with gold, which the pacha of Damafcus renews every feven years. It is guarded by 40 eunuchs, who watch the treafure faid to be depofited there. It is feated in a plain abounding with palm-trees, in E. Long. 39. 53. N. Lat. 25. See (*Hiftory of*) *Arabia*.

Medina-Celi, an ancient town of Spain, in Old Caftile, and capital of a confiderable duchy of the fame name; feated near the river Xalon, in W. Long. 2. 9. N. Lat. 41. 15.

Medina-de-las-Torres, a very ancient town of Spain, in Eftramadura, with an old caftle, and the title of a duchy. It is feated on the confines of Andalufia, at the foot of a mountain near Bajadoz.

Medina-del-Campo, a large rich, and ancient town of Spain, in the kingdom of Leon. The great fquare is very fine, and adorned with a fuperb fountain. It is is a trading place, enjoys great privileges, and is feated in a country abounding with corn and wine. W. Long. 4. 20. Nat. Lat. 41. 22.

Medina-del-rio-Secco, an ancient and rich town of Spain, in the kingdom of Leon, with the title of a duchy: feated on a plain, where there are fine paftures. E. Long. 4 33. N. Lat. 42. 8.

MEDINA (Sir John), a very eminent painter, was fon of Medina de L'Afturias, a Spanifh captain who had fettled at Bruffels, where the fon was born in 1660. He was inftructed in painting by du Chatel; under whofe direction he made good progrefs; and applying himfelf to the ftudy of Rubens, made that eminent mafter his principal model. He painted both hiftory and portrait; and was held in extraordinary efteem by moft of the princes of Germany, who diftinguifhed his merit by feveral marks of honour. He married young, and came into England in 1686, where he drew portraits for feveral years with great reputation; as he painted thofe fubjects with remarkable freedom of touch, a delicate management of tints, and ftrong refemblance of the perfons. The earl of Leven encouraged him to go to Scotland, and procured him a fubfcription of 500 l. worth of bufinefs. He went, carrying a large number of bodies and poftures, to which he painted heads. He returned to England for a fhort time; but went back to Scotland, where he died, and was buried in the church-yard of the Greyfriers at Edinburgh in 1711, aged 52. He painted moft of the Scotch nobility; but was not rich, having 20 children. The portraits of the profeffors in the furgeon's-hall at Edinburgh were painted by him, and are commended. At Wentworth-caftle is a large piece containing the firft duke of Argyle and his fons, the two late dukes John and Archibald, in Roman habits; the ftyle Italian, and fuperior to moft modern performers. In furgeon's-hall are two fmall hiftories by him. The duke of Gordon prefented Sir John Medina's head to the great duke of Tufcany for his collection of portraits done by the painters themfelves; the duke of Gordon too was drawn by him, with his fon the marquis of Huntley and his daughter Lady Jane, in one piece. Medina was knighted by the duke of Queenfberry, lord high commiffioner; and was the laft knight made in Scotland before the union. The prints in the octavo edition of Milton were defigned by him; and he compofed another fet for Ovid's Metamorphofis, but they were never engraved.

MEDINE, an Egyptian piece of money, of iron filvered over, and about the fize of a filver threepence.

MEDIOLANUM, an ancient city, the capital of the Infubres, built by the Gauls on their fettlement in that part of Italy. A *municipium*, and a place of great ftrength. The feat of the liberal arts; whence it had the name of *Novæ Athenæ*. Now *Milan*, capital of the Milanefe, fituated on the rivers Olana and Lombro, E. Long. 9. 30. N. Lat. 45. 25.

Mediolanum Aulercorum (anc. geog.), a town of Gallia Celtica, which afterwards took the name of the *Eburovicum Civitas* (Antonine); corrupted to *Civitas Ebroicorum*, and this laft to *Ebroica*; whence the modern appellation *Evreux*, a city of Normandy. E. Long. 1. 12. N. Lat. 49. 21.

Mediolanum Gugernorum (anc. geog.), a town of Gallia Belgica; now the village *Moyland*, not far from Cologne.

Mediolanum Ordovicum (anc. geog.), a town of Britain, now *Llan Vethlin*, a market-town in Montgomeryfhire in Wales.

Mediolanum Santonum (anc. geog.), which afterwards taking the name of the people, was called *Santonica Urbs*; alfo *Santones* and *Santoni*: A town of Aquitain. Now *Saintes*, capital of Saintonge in Guienne, on the river Charente.

MEDIOMATRICI, anciently a territory of Belgica. Now the diocefe of Metz.

MEDITATION, an act by which we confider any thing clofely, or wherein the foul is employed in the fearch or confideration of any truth. In our religion, it is ufed to fignify a confideration of the objects and grand truths of the Chriftian faith.

Myftic divines make a great difference between *meditation* and *contemplation*: the former confifts in difcurfive acts of the foul, confidering methodically and with attention the myfteries of faith and the precepts of morality; and is performed by reflections and reafonings, which leave behind them manifeft impreffions on the brain. The pure contemplative have no need of meditation, as feeing all things in God at a glance, and without any reflection. When a man, therefore, has once quitted meditation, and is arrived at contemplation, he returns no more; and, according to Alvarez, never refumes the oar of meditation, except when the wind of contemplation is too weak to fill his fails.

MEDITERRANEAN, fomething inclofed within land; or that is remote from the ocean.

Mediterranean is more particularly ufed to fignify that large fea which flows between the continents of Europe and Africa, entering by the ftraits of Gibraltar, and reaching into Afia, as far as the Euxine Sea and the Palus Mæotis.

The Mediterranean was anciently called the *Grecian Sea* and the *Great Sea*. It is now cantoned out into feveral divifions, which bear feveral names. To the weft of Italy it is called the *Liguftic* or *Tufcan Sea*; near Venice, the *Adriatic*; towards Greece, the *Ionic* and *Ægean*; between the Hellefpont and the Bofphorus, the *White Sea*, as being very fafe; and beyond, the *Black Sea*, its navigation being dangerous.

The Britifh trade carried on by means of the Mediterranean Sea is of the laft confequence to Great Britain; and the permanent prefervation thereof depends on the poffeffion of the town and fortification of Gibraltar.

The counterfeiting of Mediterranean paffes for fhips to the coaft of Barbary, &c. or the feal of the admiralty office to fuch paffes, is felony without benefit of clergy. Stat. 4 Geo. II. c. 18.

MEDITRINALIA, a Roman feftival in honour of the goddefs Meditrina, kept on the 30th of September. Both the deity and the feftival were fo called a *medendo*, becaufe on this day they began to drink new wine mixed with old by way of medicine. The mixture of wines, on this feftival, was drank with much form and folemn ceremony.

MEDITULLIUM, is ufed by anatomifts for that

Medium || Meduſa.

ſpungy ſubſtance between the two plates of the *cranium*, and in the interſtices of all laminated bones See Anatomy, n° 1, 11.

MEDIUM, in logic, the mean or middle term of a ſyllogiſm, being an argument, reaſon, or conſideration, for which we affirm or deny any thing; or, it is the cauſe why the greater extreme is affirmed or denied of the leſs in the concluſion.

Medium, in arithmetic, or *arithmetical medium* or *mean*, called in the ſchools *medium rei;* that which is equally diſtant from each extreme, or which exceeds the leſſer extreme as much as it is exceeded by the greater, in reſpect of quantity, not of proportion; thus 9 is a medium betwixt 6 and 12.

Geometrical Medium, called in the ſchools *medium perſonæ*, is that where the ſame ratio is preſerved between the firſt and ſecond as between the ſecond and third terms; or that which exceeds in the ſame ratio or quota of itſelf, as it is exceeded: thus 6 is a geometrical medium between 4 and 9.

Medium, in philoſophy, that ſpace or region thro' which a body in motion paſſes to any point: thus æther is ſuppoſed to be the medium through which the heavenly bodies move; air, the medium wherein bodies move near our earth; water, the medium wherein fiſhes live and move; and glaſs is alſo a medium of light, as it affords it a free paſſage. That denſity or conſiſtency in the parts of the medium, whereby the motion of bodies in it is retarded, is called the *reſiſtance of the medium;* which, together with the force of gravity, is the cauſe of the ceſſation of the motion of projectiles.

Subtile or *Ætherial Medium*. Sir Iſaac Newton conſiders it probable, that, beſide the particular aereal medium, wherein we live and breathe, there is another more univerſal one, which he calls an *ætherial medium;* vaſtly more rare, ſubtile, elaſtic, and active, than air; and by that means freely permeating the pores and interſtices of all other mediums, and diffuſing itſelf through the whole creation; and by the intervention hereof he thinks it is that moſt of the great phenomena of nature are effected. See Æther, Electricity, Fire, &c.

Medium, in optics, any ſubſtance through which light is tranſmitted.

MEDLAR, in botany. See Mespilus.

MEDULLA ossium, or *Marrow of the Bones*. See Anatomy, n° 5.

Medulla cerebri and *cerebelli*, denotes the white ſoft part of the brain and cerebellum, covered on the outſide with the cortical ſubſtance, which is of a more dark or aſhy colour. See Anatomy, n° 131—133.

Medulla oblongata, is the medullary part of the brain and cerebellum, joined in one; the fore-part of it coming from the brain, and the hind-part from the cerebellum. See Anatomy, n° 134.

It lies on the baſis of the ſkull, and is continued thro' the great perforation thereof into the hollow of the vertebræ of the neck, back, and loins; though only ſo much of it retains the name *oblongata* as is included within the ſkull. After its exit thence, it is diſtinguiſhed by the name of *medulla ſpinalis*. *Ibid.* n° 135.

MEDUSA (fab. hiſt.), one of the three Gorgons, daughter of Phorcys and Ceto. She was the only one of the Gorgons who was ſubject to mortality. She is celebrated for her perſonal charms and the beauty of her locks. Neptune became enamoured of her, and obtained her favours in the temple of Minerva. This violation of the ſanctity of the temple provoked Minerva; and ſhe changed the beautiful locks of Meduſa, which had inſpired Neptune's love, into ſerpents, the ſight of which turned the beholders into ſtones: but Perſeus, armed with Mercury's ax with which he killed Argus, cut off Meduſa's head, from whoſe blood ſprang Pegaſus and Chryſaor, together with the innumerable ſerpents that infeſt Africa. The conqueror placed Meduſa's head on the ægis of Minerva, which he had uſed in his expedition; and the head ſtill retained the ſame petrifying powers as before.

Meduſa.

Medusa, in zoology, a genus of vermes, belonging to the order of molluſca. The body is gelatinous, roundiſh, and depreſſed; and the mouth is in the centre of the under part of the body. Many ſpecies, on being handled, affect with a nettle-like burning, and excite a redneſs. The ancients, and ſome of the moderns, add that they have an aphrodiſiac property, and in ſeveral languages they are called by an obſcene name. They were known to the Greeks and Romans by the names of Πνευμα Θαλασσιος, and *pulmo marinus*, or ſea-lungs. They attributed medicinal virtues to them. Dioſcorides informs us, that, if rubbed freſh on the diſeaſed part, they cured the gout in the feet, and kibed heels. Ælian ſays, that they were depilatory; and, if macerated in vinegar, would take away the beard. Their phoſphoric quality is well known; nor was it overlooked by the ancients. Pliny obſerves, that if rubbed with a ſtick it will appear to burn, and the wood to ſhine all over. The ſame naturaliſt obſerves, that when they ſink to the bottom of the ſea, they portend a continuance of bad weather.

On Plate CCXCIV, are figured ſeveral ſpecimens, viz. 1. The aurita, or aurited meduſa; which appears, as floating on the water, to be a mere lifeleſs lump of Fig. 3. n° 1.
jelly. It is of a whitiſh colour, with a caſt of bluiſh grey, and is of an orbiculated figure, elevated into a convexity in the middle on the upper ſide, flat on the under, and furniſhed with a fringe of fine and ſomewhat rigid filaments round the edge, reſembling white hairs: on the under ſurface there are four cavities near the centre, each of an arcuated figure, and ſurrounded with an opaque line, formed of about 24 parallel points or dots: from the very centre of the under ſide there ariſe four crooked appendages, which have each a row of hairy filaments on the exterior edge; and on the upper ſurface there is an appearance of fine veſſels of a pale colour. This ſpecies is frequent, floating on the ſurface of the ſea, or adhering to rocks about our own coaſts; and when the ſun ſhines on them, they have a very beautiful lucid appearance. It is called by ſome the *ſea nettle*, it being one of thoſe animals that when touched occaſions a very diſagreeable tingling in the hands. 2. The capillata, or capillated meduſa, is a very Ibid 3 n° 2.
ſingular and odd animal: it ſeems a mere lump of a whitiſh ſemi-pellucid jelly; and is as eaſily broken and deſtroyed by a touch as the common jellies brought to our tables: its ſhape is rounded, riſing into a convexity in the middle, where it is therefore thickeſt, and whence it becomes gradually thinner to the ſides: on the under ſide it is plain, and on this there is viſible a rough, or as it were echinated circle, within which

there run eight pairs of rays from the centre toward the circumference; and from the centre there arise also a number of curled appendages, which are sometimes reddish, but more usually whitish, and a vast number of slender filaments: the edge or the circumference of the body is regularly divided into eight portions, and each of them is emarginated, so that on the whole verge there are 16 sinuses. This species is to be met with in vast abundance floating on the surface of the water about Sheppey island in Kent, and elsewhere on that coast: great quantities of it are destroyed by being thrown on shore with the waves, whence it has no power of getting off again; and in the open seas, many fish skim near the surface, and prey on them. This is the species called by many authors *pulmo marinus*, or the sea lungs. 3. The marsupialis, or purse medusa, is semi-oval, with four tentacula on the edge. It inhabits the Mediterranean.

Fig. 3. n° 3.

Ibid. n° 4.

4. The waved medusa has the edges waved, with fangs on the projecting parts; four orifices beneath, between which rises a stem divided into eight large ragged tentacula.

These animals swim in large companies in search of food, with their tentacula in continual motion, with which they seize their prey, and convey it to their mouths: they vary in size, the largest being generally about eight inches in diameter. They vary likewise in the number of their tentacula; some having only two, others four, six, and some eight, but they rarely exceed that number. So powerful is their embrace, that whatever prey comes within their reach never escapes. They subsist on insects, small fish, &c.

Mr Banks, in his passage from Madeira to Rio de Janeiro, discovered a new species, which, when brought aboard by the casting net, had the appearance of metal violently heated, and emitted a white light. With these animals were taken small crabs of three different species, altogether new, each of which gave as much light as the glow-worm, though the creature was not so large by nine-tenths. These luminous animals are one of the causes of that appearance to the sea which has been mentioned by many navigators, and of which various reasons have been assigned. It appeared to emit flashes of light exactly resembling those of lightning, only not so considerable, but so frequent, that sometimes eight or ten were visible at the same moment.

MEDWAY, a river of England, rises in the Weald of Sussex, and entering Kent near Ashurst, runs by Tunbridge, and thence continues its course towards Maidstone. It is navigable for large ships to Rochester bridge, and thence for vessels and barges to Maidstone, the tide flowing up to that town. The distance between the mouth of this river, where the fort at Sheerness is erected, and Rochester bridge, is between 16 and 18 miles. In this part of the river, the channel is so deep, the banks so soft, and the reaches so short, that it is one of the best and safest harbours in the world; and ships of 80 guns ride a-float at low-water, within musket-shot of Rochester-bridge. Nor is there a single instance upon record, that any of the royal navy ever suffered here by storms, except in that dreadful tempest which happened in November 1703, when the Royal Catharine was driven on shore, where she sunk and was lost. On the shore of this river are two castles, one at Upnor, which guards two reaches of the river, and is supposed to defend all the ships which ride above, between that and the bridge; on the other side of the river is Gillingham castle, built for the same purpose, and well furnished with cannon which commands the river. Besides these, there is a platform of guns at a place called the Swam, and another at Cockham-wood. But the principal fortification on this river is the castle at Sheerness.

MEEREN, or Meer, (John Vander,) called the *Old*, an esteemed painter, was born in 1627; but the master, under whom he learned the art of painting, is not mentioned. His genius directed him to choose for his subjects sea-pieces, landscapes, and views of the sea and its shores; which he painted with great truth, as he had accustomed himself to sketch every scene after nature. The situations of his landscapes are agreeably chosen, frequently they are solemn, and generally pleasing. The forms of his trees are easy and natural, his distances well observed, and the whole scenery has a striking effect, by a happy opposition of his lights and shadows. He also very often painted battles in such a style as met with approbation; as they showed good composition, were touched with spirit, and had a great deal of transparence in the colouring. But the fault imputable to Vander Meer is, that in some of his pictures the back-grounds are a little too blue, and that some of his landscapes have a tint which appears rather too yellowish. He died in 1690.

Meeren, or *Meer*, (John Vander), called *De Jonghe*, an eminent landscape-painter, is supposed to have been the son of the old John Vander Meer, and of whom he learned the first rudiments of the art; but being in his youth deprived of his instructor before he had made any great progress, he became a disciple of Nicholas Berghem, and was accounted the best of those who were educated in the school of that admired master. In the manner of his master, he painted landscapes and cattle; and his usual subjects are cottages, with peasants at their rural occupations and diversions. It is observed of him, that he very rarely introduced cows, horses, or any other species of animals, except goats and sheep; the latter of which are so highly finished, that one would imagine the wool might be felt by the softness of its appearance. His touch is scarce perceptible, and yet the colours are admirably united. He died in 1688. The genuine works of this Vander Meer bear a very high price, and are esteemed even in Italy, where they are admitted into the best collections; but the scarcity of them has occasioned many moderate copies after his works to be passed on the undiscerning for real originals.

MEGALE polis, (anc. geog.) dividedly (Ptolemy, Pausanius); or conjunctly *Megalopolis*, (Strabo): A town of Arcadia, built under the auspices of Epaminondas, after the battle of Leuctra; many inconsiderable towns being joined together in one great city, the better to withstand the Spartans. It was the greatest city of Arcadia, according to Strabo.

MAGALESIA, and Megalenses Ludi, feasts and games in honour of Cybele or Rhea the mother of the gods, kept on the 12th of April by the Romans, and famous for great rejoicings and diversions of various sorts. The Galli carried the image of the goddess along the city, with sound of drums and other music,

music, in imitation of the noise they made to prevent Saturn from hearing the cries of his infant son Jupiter, when he was disposed to devour him.

MEGARA (anc. geog.), a noble city, and the capital of the territory of Megaris, which for many years carried on war with the Corinthians and Athenians. It had for some time a school of philosophers, called the *Megarici*, successors of Euclid the Socratic, a native of Megara. Their dialect was the Doric; changed from the Attic, which it formerly had been, because of Peleponnesian colonists who settled there.

Megara was situated at a distance from the sea. Its port was called *Nisæa*, from Nisus son of Pandion the second, who obtained the Megaris for his portion, when the kingdom of Athens was divided into four lots by his father. He founded the town, which was eighteen stadia or two miles and a quarter from the city, but united with it, as the Piræus with Athens, by long walls. It had a temple of Ceres. "The roof (says Pausanias) may be supposed to have fallen through age." The site (as Dr Chandler informs us †) is now covered with rubbish, among which are standing some ruinous churches. The place has been named from them *Dode Ecclesiais*, "The Twelve Churches;" but the number is reduced to seven. The acropolis or citadel, called also *Nisæa*, was on a rock by the sea-side. Some pieces of the wall remain, and a modern fortress has been erected on it, and also on a lesser rock near it.

† Travels in Greece, 192.

The village Megara (continues the Doctor) consists of low mean cottages, pleasantly situated on the slope of a brow or eminence indented in the middle. On each side of this vale was an acropolis or citadel; one named Caria; the other from Alcathous, the builder of the wall. They related, that he was assisted by Apollo, who laid his harp aside on a stone, which, as Pausanias testifies, if struck with a pebble returned a musical sound. An angle of the wall of one citadel is seen by a wind-mill. The masonry is of the species called Incertum. In 1676 the city-wall was not entirely demolished, but comprehended the two summits, on which are some churches, with a portion of the plain toward the south. The whole site, except the hills, was now green with corn, and marked by many heaps of stones, the collected rubbish of buildings. A few inscriptions are found, with pedestals fixed in the walls and inverted; and also some maimed or mutilated statues. One of the former relates to Atticus Herodes, and is on a pedestal which supported a statue erected to him when consul, A. D. 143. by the council and people of Megara, in return for his benefactions and good-will toward the city. In the plain behind the summits, on one of which was a temple of Minerva, is a large basin of water, with scattered fragments of marble, the remains of a bath or of a fountain, which is recorded as in the city, and remarkable for its size and ornaments, and for the number of its columns. The spring was named from the local nymphs called Sithnides.

The stone of Megara was of a kind not discovered any where else in Hellas; very white, uncommonly soft, and consisting entirely of cockle-shells. This was chiefly used; and, not being durable, may be reckoned among the causes of the desolation at Megara, which is so complete, that one searches in vain for vestiges of the many public edifices, temples, and sepulchres, which once adorned the city.

Megara was engaged in various wars with Athens and Corinth, and experienced many vicissitudes of fortune. It was the only one of the Greek cities which did not re-flourish under their common benefactor Hadrian; and the reason assigned is, that the avenging anger of the gods pursued the people for their impiety in killing Anthemocritus, a herald, who had been sent to them in the time of Pericles. The Athenian generals were sworn on his account to invade them twice a-year. Hadrian and Atticus were followed by another friend, whose memory is preserved by an inscription on a stone lying near a church in the village:— "This too is the work of the most magnificent count Diogenes son of Archelaus, who regarding the Grecian cities as his own family, has bestowed on that of the Megarensians one hundred pieces of gold toward the building of their towers, and also one hundred and fifty more with two thousand two hundred feet of marble toward re-edifying the bath; deeming nothing more honourable than to do good to the Greeks, and to restore their cities." This person is not quite unnoticed in history. He was one of the generals employed by the emperor Anastasius on a rebellion in Isauria. He surprised the capital Claudiopolis, and sustained a siege with great bravery, A. D. 494.

Megara retains its original name. It has been much infested by corsairs; and in 1676 the inhabitants were accustomed, on seeing a boat approach in the day time or hearing their dogs bark at night, immediately to secrete their effects and run away. The Vaiwode or Turkish governor, who resided in a forsaken tower above the village, was once carried off. It is no wonder, therefore, that Nisæa has been long abandoned. The place was burned by the Venetians in 1687.

MEGARA (anc. geog.) formerly called *Hybla*, a town towards the east coast of Sicily; extinct in Strabo's time, though the name Hybla remained on account of the excellence of its honey. It was a colony of Megareans from Greece. *Risus Megaricus* denotes a hoarse-laugh.

MEGARIS (anc. geog.), the country of the Megareans, is described as a rough region, like Attica; the mountain called *Oneian* or the Asinine, now *Macriplayi* or "the long Mountain," extending through it toward Bœotia and mount Cithæron. It belonged to Ionia or Attica, until it was taken by the Peloponnesians in the reign of Codrus, when a colony of Dorians settled in it. This territory had Attica to the east, Bœotia to the north and west, and the Isthmus of Corinth to the south.

MEGARIS, a small island in the Tuscan sea, joined to Naples by a bridge. Now called *Castello dell'Ovo*.

MEGASTHENES, a Greek historian in the age of Seleucus Nicanor, about 300 years before Christ. He wrote about the oriental nations, and particularly the Indians. His history is often quoted by the ancients. What now passes as his composition is spurious.

MEGIDDO (anc. geog.), a town of Galilee, recited (Joshua xvii. 11.) among the cities of Manasseh, in the tribe of Issachar or Asser, on the west side of Jordan. Famous for the defeat of Ahaziah and Josiah, who perished there (2 Kings xxiii. 29.): near it was an an open plain, fit for drawing up an army in battle array. It was situated to the north, contrary to its position in the common maps. The Canaanites, being tributary to the Israelites, dwelt in it, Joshua xvii. — It was rebuilt by Solomon, 1 Kings ix.

MEIBOMIUS, the name of several learned Germans.—*John Henry Meibomius* was professor of physic at Helmstadt, where he was born, and at Lubec; he wrote the *Life of Mæcenas*, published at Leyden in 4to, 1653, with several other learned works. *Henry*, his son, was born at Lubec in 1638; became professor of physic at Helmstadt; and, besides works in his own profession, published *Scriptores rerum Germanicarum*, 3 vol. folio, 1688; a very useful collection, first begun by his father.—*Marcus Meibomius*, of the same family, published a collection of seven Greek authors who had written upon ancient music, with a Latin version by himself; dedicated to Queen Christina of Sweden, who invited him to her court. But she engaging him one day to sing an air of ancient music, while somebody was ordered to dance to it, the immoderate mirth which this occasioned in the spectators so disgusted him, that he immediately left the court of Sweden. His edition of the Greek mythologists, and notes upon Diogenes Laertius in Menage's edition, show him to have been a man of learning; but he suffered no little raillery for his attempt to correct the Hebrew text of the Bible, by a kind of metre he fancied he had found out in those ancient writings.

MEISSEN, a considerable town of Germany, in the electorate of Saxony, and in the margravate of Misnia, with a castle. It formerly belonged to the bishop, but is now secularized, and the inhabitants are Lutherans. In this place is a famous manufactory of porcelain. E. Long. 13. 33. N. Lat. 51. 15.

MEL, HONEY, in the materia medica. See HONEY.

MELA (Pomponius), an ancient Latin writer, was born in the province of Bætica in Spain, and flourished in the reign of the emperor Claudius. His three books of Cosmography, or *De situ orbis*, are written in a concise, perspicuous, and elegant manner; and have been thought worthy of the attention and labours of the ablest critics. Isaac Vossius gave an edition of them in 1658, 4to, with very large and copious notes. To this edition is added, *Julii Honorii oratoris excerptum cosmographiæ*, first published from the manuscript, and *Æthici cosmographia*. Gronovius afterwards published another edition with illustrations by medals. In his last edition are added five books, *De Geographia*, written by some later author; by Jornandes, as Fabricius conjectures.

MELÆNE, or BLACK FLUX, in medicine. See MEDICINE, n° 409.

MELALEUCA, in botany; a genus of the polyandria order, belonging to the polydelphia class of plants. The calyx is quinquepartite, superior; the corolla pentapetalous; the filaments are very numerous, and collected in such a manner as to form five pencils; there is one style; the capsule is half-covered with the calyx, formed like a berry, and is trivalved and trilocular.—This plant has already been noticed under the article (misspelt) MALALEUCA; where also, by mistake, it was said that there is only one species. —The species are five, natives of India and the South Sea islands. The most remarkable species is the LEUCADENDRON, from a variety of which (the *latifolia*, or broad-leaved leucadendron) the Cajeput oil is obtained: a medicine in very high esteem among the eastern nations, particularly in India. It is said to be obtained by distillation from the fruit of the tree. When brought into this country, it is a liquid of a greenish colour, of a fragrant but at the same time a very peculiar odour, and of a warm pungent taste. Some authors, however, represent this oil as being, when of the best quality, a white or colourless fluid; and it has been said by the authors of the *Dispensatorium Brunsvicense*, when prepared in Europe from the seeds sent from India, to be entirely of this appearance. Hitherto the oleum cajeput has been but little employed either in Britain or on the continent of Europe; but in India it is used both internally and externally, and is highly extolled for its medical properties. It is applied externally where a warm and peculiar stimulus is requisite; it is employed for restoring vigour after luxations and sprains, and for easing a violent pain in gouty and rheumatic cases, in tooth-ach, and similar affections; but it has been chiefly celebrated as taken internally, and it is particularly said to operate as a very powerful remedy against tympanitic affections.

MELAMPODIUM, a name given to black hellebore. See HELLEBORUS.

MELAMPODIUM, in botany: A genus of the polygamia necessaria order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is paleaceous and conical; the pappus is monophyllous and valve-like; the calyx pentaphyllous.

MELAMPUS (fab. hist.), a celebrated soothsayer and physician of Argos, son of Amythaon and Idomenea or Dorippe. He lived at Pylos in Peloponnesus. His servants once killed two large serpents who had made their nests at the bottom of a large oak; and Melampus paid so much regard to their remains, that he raised a burning pile and burned them upon it. He also took particular care of their young ones, and fed them with milk. Some time after this, the young serpents crept to Melampus as he slept on the grass near the oak; and, as if sensible of the favours of their benefactor, they wantonly played around him, and softly licked his ears. This awoke Melampus, who was astonished at the sudden change which his senses had undergone. He found himself acquainted with the chirping of the birds, and with all their rude notes, as they flew around him. He took advantage of this supernatural gift, and soon made himself perfect in the knowledge of futurity, and Apollo also instructed him in the art of medicine. He had soon after the happiness of curing the daughters of Prœtus, by giving them hellebore, which from that circumstance has been called *melampodium*; and as a reward for his troubles, he married the eldest of these princesses. The tyranny of his uncle Neleus, king of Pylos, obliged him to leave his native country; and Prœtus, to show himself more sensible of his services, gave him part of his kingdom. About this time the personal charms of Pero, the daughter of Neleus, had gained many admirers; but the father promised his daughter only to him who brought into his hands the oxen of Iphiclus. This condition displeased many; but Bias, who was also one of her admirers, Melampyrum ‖ Melancthon.

mirers, engaged his brother Melampus to steal the oxen and deliver them to him. Melampus was caught in the attempt, and imprisoned; and nothing but his services as a soothsayer and physician to Iphiclus would have saved him from death. All this pleaded in the favour of Melampus; but when he had taught the childless Iphiclus how to become a father, he not only obtained his liberty, but also the oxen; and with them he compelled Neleus to give Pero in marriage to Bias. A severe distemper, which had rendered the women of Argos insane, was totally removed by Melampus; and Anaxagoras, who then sat on the throne, rewarded his merit by giving him part of his kingdom, where he established himself, and where his posterity reigned during six successive generations. He received divine honours after death, and temples were raised to his memory.

MELAMPYRUM, COW-WHEAT: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personatæ*. The calyx is quadrifid; the upper lip of the corolla is compressed, with the edges folded back; the capsule is bilocular and oblique, opening at one side; there are two gibbous seeds. There are four species, all of them natives of Britain, and growing spontaneously among corn-fields. They are excellent food for cattle; and Linnæus tells us, that where they abound the yellowest and best butter is made. Their seeds, when mixed with bread, give it a dusky colour; and, according to some authors, produce a vertigo, and other disorders of the head; but this is denied by Mr Withering, though he allows that they give it a bitter taste.

MELANCHOLY, a kind of delirium attended with gloomy thoughts, heaviness, and sorrow. See MEDICINE, n° 85, 327.

MELANCTHON (Philip), born at Bretten in the Palatinate in 1495, was one of the wisest and most able men of his age among the Reformers, though of a mild temper, and disposed to accommodate rather than to inflame disputes. In his youth he made an admirable progress in learning, and was made Greek professor at Wirtemberg in 1509. Here his lectures upon Homer, and the Greek text of St Paul's Epistle to Titus, drew to him a great number of auditors, and entirely effaced the contempt to which his low stature and mean appearance had exposed him. Melancthon reduced the sciences to systems; and acquired such reputation, that he had sometimes 2500 auditors. He soon entered into an intimate friendship with Luther, who taught divinity in the same university; and in 1519 they went together to Leipsic, to dispute with Eccius. The following years he was continually engaged in various employments; he composed several books; he taught divinity; took several journeys, in order to found colleges and visit churches; and in 1530 drew up a confession of faith, which goes by the name of the *Confession of Augsburg*, because it was presented to the emperor at the diet held in that city. All Europe was convinced, that he was not, like Luther, backward to accommodate the differences between the various sects of Christians. He hated religious disputes, and was drawn into them only through the necessity of the part he was called to act in the world; and therefore would have sacrificed many things to have produced an union among the Protestants. For this reason, Francis I. the French king, wrote to desire him to come and confer with the doctors of the Sorbonne, in order to agree with them about putting an end to all controversies; but though Luther endeavoured to persuade the elector of Saxony to consent to that journey, and though Melancthon himself desired it, that prince, whether he distrusted Melancthon's moderation, or was afraid of quarrelling with the emperor Charles V. would never grant his permission. The king of England also in vain desired to see him. Melancthon, in 1529, assisted at the conferences of Spires. In 1541, he was at the famous conferences at Ratisbon. In 1543, he went to meet the archbishop of Cologn to assist him in introducing the reformation into his diocese; but that project came to nothing: and in 1548, he assisted at seven conferences on the subject of the interim of Charles V. and wrote a censure on that interim, and all the writings presented at these conferences. He was extremely affected at the dissensions raised by Flaccus Illyricus. His last conference with those of the Roman communion was at Worms, in 1557. He died at Wittemburg in 1560, and was interred near Luther. Some days before he died, he wrote upon a piece of paper the reasons which made him look upon death as a happiness; and the chief of them was, that it "delivered him from theological persecutions." Nature had given Melancthon a peaceable temper, which was but ill suited to the time he was to live in. His moderation served only to be his cross. He was like a lamb in the midst of wolves. No body liked his mildness; it looked as if he was lukewarm; and even Luther himself was sometimes angry at it.

Melancthon was a man in whom many good as well as great qualities were wonderfully united. He had great parts, great learning, great sweetness of temper, moderation, contentedness, and the like, which would have made him very happy in any other times but those in which he lived. He never affected dignities, or honours, or riches, but was rather negligent of all these things; too much so in the opinion of some, considering he had a family; and his son-in-law Sabinus, who was of a more ambitious make, was actually at variance with him upon this very article. Learning was infinitely obliged to him on many accounts; on none more than this, that, as already observed, he reduced almost all the sciences which had been taught before in a vague irregular manner, into systems. Considering the distractions of his life, and the infinity of disputes and tumults in which he was engaged, it is astonishing how he could find leisure to write so many books. Their number is prodigious, insomuch that it was thought necessary to publish a chronological catalogue of them in the year 1582. His works indeed are not correct, and he himself owned it: but as he found them useful, he chose rather to print a great number, than to finish only a few; "which however (as Bayle says) was postponing his own glory to the advantage of others." His constitution was very weak, and required great tenderness and management; which made Luther, as hot and zealous as he was, blame him for labouring too earnestly in the vineyard.

MELANIPPIDES, (fab. hist.), a Greek poet about 520 years before Christ. His grandson of the same name flourished about 60 years after at the court of Perdiccas the Second, of Macedonia. Some fragments of their poetry are still extant.

MELANTERIA, in natural history, a very beautiful fossil, of a dense, compact, and regular texture, and of an extremely bright pale yellow, resembling nothing so much as the purest gold. It is remarkably heavy; and is sometimes found in little irregular masses of the bigness of a pigeon's egg, which are broken with a slight blow: but it is usually met with in the form of a fine gold-coloured efflorescence on vitriolic and pyritical bodies; or in loose, shattery, and friable masses of a more dusky yellow; in which latter state it so much resembles a native sulphur, that it is frequently mistaken for one; however, it is not inflammable; but calcines in the fire to a greyish powder, which by burning longer changes to a deep and fine purple.

The Greeks used it externally as a gentle escharotic and a styptic: they made it an ingredient in their ointments for old ulcers, and used to sprinkle the powder of it on fresh wounds in order to stop the hæmorrhagy.

MELASSES. See MOLASSES.

MELASTOMA, the AMERICAN GOOSEBERRY-TREE, in botany: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is quinquefid and campanulated; the petals are five, inserted into the calyx; the berry is quinquelocular, and wrapped in the calyx.—There are a great many species, all of them natives of the warm parts of America, and very beautiful on account of the variegation of their leaves. Most of the leaves are of two different colours on their surfaces; the under side being either white, gold-coloured, or russet, and their upper parts of different shades of green; so that they make a fine appearance in the hot-house all the year round. There are but few of these plants in the European gardens; which may perhaps have been occasioned by the difficulty of bringing over growing plants from the West Indies; and the seeds being small when taken out from the pulp of their fruits, rarely succeed. The best way is to have the entire fruits put up in dry sand as soon as they are ripe, and forwarded by the quickest contrivance to England. They should be immediately taken out when they arrive, and the seeds sown in pots of light earth, and plunged into a moderate hot-bed of tanner's bark. When the plants come up, and are fit to be removed, they must each be planted in a small pot, and plunged into the tan-bed; and afterwards treated as other exotic plants.

MELCHA, a small village of Barbary, situated about 30 miles from the city of Tunis, built on the ruins of CARTHAGE, some of which are still visible.

MELCHITES, in church-history, the name given to the Syriac, Egyptian, and other Christians of the Levant. The Melchites, excepting some few points of little or no importance, which relate only to ceremonies and ecclesiastical discipline, are in every respect professed Greeks; but they are governed by a particular patriarch, who resides at Damas, and assumes the title of *patriarch of Antioch*. They celebrate mass in the Arabian language. The religious among the Melchites follow the rule of St Basil, the common rule of all the Greek monks. They have four fine convents distant about a day's journey from Damas, and never go out of the cloister.

MELCHISEDEC, or MELCHIZEDEK, king of Salem, and priest of the Most High The scripture tells us nothing either of his father, or of his mother, or of his genealogy, or of his birth, or of his death. And in this sense he was a figure of Jesus Christ, as St Paul affirms, who is a priest for ever, according to the order of Melchisedec, and not according to the order of Aaron, whose original, life, and death, are known. When Abraham returned from pursuing the four confederate kings, who had defeated the kings of Sodom and Gomorrah, and had taken away Lot Abraham's nephew along with them (Gen xiv. 17, 18, 19, &c.), Melchisedek came to meet Abraham as far as the valley of Shaveh, which was afterwards named the king's valley, presented him with the refreshment of bread and wine (or he offered bread and wine in sacrifice to the Lord, for he was a priest of the most high God), and blessed him. Abraham, being desirous to acknowledge in him the quality of priest of the Lord, offered him the tythes of all he had taken from the enemy. After this time, there is no mention made of the person of Melchisedec; only the Psalmist (cx. 4.) speaking of the Messiah, says, "Thou art a priest for ever after the order of Melchisedec." St Paul, in his epistle to the Hebrews, unfolds the mystery which is concealed in what is said of Melchisedec in the Old Testament. See Heb. v. 6—10. An infinite number of difficulties and scruples have been started upon the subject of Melchisedec.—St Jerom thought that Salem, of which Melchisedec was king, was not Jerusalem, but the city of Salem near Scythopolis, where they still pretended to show the ruins of the palace of this prince. The greatness and extent of these ruins are a sufficient proof of the magnificence of this ancient building. He thinks it was at this city of Salem or Shalem, that Jacob arrived after his passage over Jordan, at his return from Mesopotamia (Gen xxxiii. 18.) Some believe that Salem, where Melchisedec reigned, is the same as Salim spoken of in the gospel of St John, chap. iii 23. From the time of Epiphanes there were names invented for the father and mother of Melchisedec. To his father was given the name of Heraclas or Heracles, and to his mother that of Ashtaroth or Astaria. It is generally agreed on by the learned, that when the apostle says, he was "without father and without mother," no more is meant, than that he is introduced into the history of Abraham without acquainting us who he was, or whence he came, where he lived, or when he died. Nevertheless, some have taken St Paul's word's literally, and contended that he was not of human but divine nature. Origen and Didymus took him to be an angel; and the author of the *Questions upon the Old and New Testament* pretends, that he was the Holy Ghost, who appeared to Abraham in a human form. The Arabic Catena, upon the ninth chapter of Genesis, makes Melchisedec to be descended from Shem by his father, and from Japheth by his mother.

Melchisedec.

mother. Heraclas or Heraclim his father, was, they fay, fon or grandfon of Phaleg, and fon of Heber; and his mother named Salathiel, was daughter of Gomer fon of Japheth. Cedrenus and others derive Melchifedec from an Egyptian ftock. They fay his father was called Sidon or Sida, and was the founder of the city of Sidon the capital of Phœnicia. Suidas fays he was of the curfed race of Canaan; for which reafon the fcripture does not mention his genealogy. The Jews and Samaritans believed Melchifedec to be the fame with the patriarch Shem; which opinion has been followed by a great number of modern writers. M. Jurieu has undertaken to prove that he is the fame as Cham or Ham. It would be endlefs to fet down all the opinions upon this matter: therefore we fhall only add, that Peter Cunæus and Peter du Moulin have afferted, that Melchifedec who appeared to Abraham was the Son of God, and that the patriarch worfhipped him and acknowledged him for the Meffiah.

About the beginning of the third century arofe the herefy of the Melchifedecians, who affirmed that Melchifedec was not a man, but a heavenly power, fuperior to Jefus Chrift: for Melchifedec, they faid, was the interceffor and mediator of the angels, but Jefus Chrift was fo only for men, and his priefthood only a copy of that of Melchifedec, who was the Holy Ghoft.

We fhall only beg leave to add here one opinion more concerning Melchifedec, which is that of the learned Heidegger, who, as the author of the *Hift. Patriar.* thinks, has taken the right method of explaining the accounts of Mofes and the apoftle Paul relating to this extraordinary perfon. He fuppofes a twofold Melchifedec; the one hiftorical, whereof Mofes gives an account in the xivth chapter of Genefis, as that he was king as well as high-prieft of Jerufalem; the other allegorical, whom St Paul defcribes, and this allegorical perfon is Jefus Chrift.

As the hiftory of this prince and prieft is fo little known, it is no wonder, as Selden obferves, that many fabulous accounts have been invented of him; of which the following may fuffice as a fpecimen. Eutychus patriarch of Alexandria relates, that the body of Adam having been embalmed according to his order, was depofited in a cave under a mountain of the children of Seth; but that Adam before his death had commanded that they fhould take away his remains from that place, and tranfport them to the middle of the earth: that Noah, to follow the orders of his anceftors, had preferved the bodies of Adam and all the patriarchs with him in the ark: that finding himfelf near his death, he ordered his fon Shem to take the body of Adam, to furnifh himfelf with bread and wine for his journey, to take with him Melchifedec the fon of Phaleg, and to go to the place in which an angel would fhow them where to bury the firft man: that Noah added this order, "Command Melchifedec to fix his refidence in that place, and to live unmarried all his lifetime, becaufe God has chofen him to do fervice in his prefence; command him, that he build no temple, nor fhed the blood of birds, nor four-footed beafts, or any other animal; and that he offer no other oblations to God but bread and wine." This is the reafon, according to this author, why Melchifedec, when he met Abraham, brought forth only bread and wine.

Melchifedec, Melcomb-regis.

A Greek author, under the name of Athanafius, relates, that Melchifedec was the fon of an idolatrous king called Melchi and of a queen called Salem.—Melchi, having refolved to offer a facrifice to the gods, fent his fon Melchifedec to fetch him feven calves. In the way the young prince was enlightened by God, and immediately returned to his father, to demonftrate to him the vanity of his idols. Melchi, in wrath, fent him back to fetch the victims. While he was abfent, the king facrificed his eldeft fon, and a great many other children, to his gods. Melchifedec returning, and conceiving great horror at this butchery, retired to mount Tabor, where he lived feven years, without clothes, and fed only on wild fruits. At the end of feven years, God appeared to Abraham, bid him go up to mount Tabor, where he fhould find Melchifedec. He ordered him to cloath him, and to afk his bleffing; which Abraham having done, Melchifedec anointed him with oil, and they came down together from the mountain.

MELCOMB-REGIS, a town of Dorfetfhire, in England, 130 miles from London, is fituated at the mouth of the river Wey, by which it is parted from Weymouth. It appears from the name to have been anciently the king's demefne, and from the records to have paid quit-rent to the crown all along after king Edward I. till it was bought off by the inhabitants before they were united to Weymouth. It lies on the north fide of the haven, on a peninfula furrounded by the fea on all fides except on the north. The ftreets are broad and well paved, and many of the houfes large and high. It fent members to parliament in the reign of king Edward I. before Weymouth had that privilege. It was by parliament appointed a ftaple in the reign of Edward III. In the next reign the French burnt it; and it was thereby rendered fo defolate, that the remaining inhabitants prayed and obtained a difcharge from cuftoms. On account of its quarrels with Weymouth, in the reign of Henry VI. its privileges as a port were removed to Pool: but in that of queen Elizabeth they were reftored to it by act of parliament, which was confirmed in the next reign, on condition that Melcomb and Weymouth fhould make but one corporation, and enjoy their privileges in common; and to this was owing the flourifhing ftate of both. In the two reigns laft mentioned, a wooden bridge with feventeen arches was built from hence to Weymouth; to which, as well as its church, the chief contributors were certain citizens of London; and upon its decay it was rebuilt in 1770. Here is a good market-place and town-hall, to which the members of the corporation of Weymouth come to attend public bufinefs, as the inhabitants do to its church for public worfhip. For feveral years paft the fea has retired from it on the eaft, the priory formerly being bounded by the fea; but there is now a ftreet beyond it, from which it is feveral paces to the high-water mark. The priory was fituated in the eaft part of the town, in Maiden-ftreet, whofe fite occupied about an acre, now covered with tenements. On the fouth fide are the remains of the chapel, now converted into a malt-houfe. Near it are the remains of an ancient building, formerly a nunnery. Here are three meeting-houses and a work-house for the poor. The church, which is in the middle of the town, has a wooden turret for a bell, and had been an old chapel. It was rebuilt in 1605, and made parochial, and is a handsome fabric, with a beautiful altar-piece painted and given by Sir James Thornhill. The port, which generally goes by the name of Weymouth, is said to be the best frequented in the county, and is defended by Sandford and Portland castles. The markets for both towns are Tuesdays and Fridays, but there are no fairs. Melcomb-regis is reckoned bigger, more thriving, and populous than Weymouth. They are both but one corporation and borough, consisting of a mayor, recorder, two bailiffs, an uncertain number of aldermen, and twenty-four capital burgesses. Whoever has been a mayor is ever after an alderman. They send four burgesses to parliament, who are elected by such as have freeholds, whether they inhabit here or not; and the number of voters is near 700. Every elector, as in London, has the privilege of voting for four persons, who when chosen are returned, in two distinct indentures, as the burgesses of Weymouth and the burgesses of Melcomb-Regis.

MELDÆ (anc. geog.), a town of Gallia Celtica, (called *Meldorum Civitas* in the Notitia), on the Matrona. Now *Meaux*, a city in Champaign on the Marne.

MELEAGER (fab. hist.) a celebrated hero, son of Œneus king of Calydonia, by Althæa daughter of Thestius. The Parcæ were present at the moment of his birth, and predicted his future greatness. Clotho said that he would be brave and courageous; Lachesis foretold his uncommon strength and valour; and Atropos said that he should live as long as that firebrand which was on the fire remained entire and unconsumed. Althæa no sooner heard this, than she snatched the stick from the fire, and kept it with the most jealous care, as the life of her son totally depended upon its preservation. The fame of Meleager increased with his years; he signalized himself in the Argonautic expedition, and afterwards delivered his country from the neighbouring inhabitants, who made war against his father at the instigation of Diana, whose altars Œneus had neglected. But Diana punished the negligence of Œneus by a greater calamity. She sent a huge wild boar, which laid waste all the country, and seemed invincible on account of its immense size. It became soon a public concern: all the neighbouring princes assembled to destroy this terrible animal; and nothing is more famous in mythological history, than the hunting of the Calydonian boar. The princes and chiefs that assembled, and which are mentioned by mythologists, were Meleager son of Œneus, Idas and Lynceus sons of Apharcus, Dryas son of Mars, Castor and Pollux sons of Jupiter and Leda, Pirithous son of Ixion, Theseus son of Ægeus, Anceus and Cepheus sons of Lycurgus, Admetus son of Pheres, Jason son of Æson, Peleus and Telamon sons of Æacus, Iphicles son of Amphitryon, Eurytrion son of Actor, Atalanta daughter of Schœneus, Iolas the friend of Hercules, the sons of Thestius, Amphiaraus son of Oileus, Protheus, Cometes, the brothers of Altæa, Hippothous son of Cercyon, Leucippus, Adrastus, Ceneus, Phileus, Echion, Lelex, Phœnix son of Amyntor, Panopeus, Hyleus, Hippasus, Nestor, Menœtius the father of Patroclus, Amphicides, Laertes the father of Ulysses, and the four sons of Hippocoon. This troop of armed men attacked the boar, and it was at last killed by Meleager.—The conqueror gave the skin and the head to Atalanta, who had first wounded the animal. This irritated the rest, and particularly Toxeus and Plexippus the brothers of Althæa, and they endeavoured to rob Atalanta of the honourable present. Meleager defended her, and killed his uncles in the attempt. Mean time the news of this celebrated conquest had already reached Calydon, and Althæa went to the temple of the gods to return thanks for the victory which her son had gained: But being informed that her brothers had been killed by Meleager, she in the moment of resentment threw into the fire the fatal stick on which her son's life depended, and Meleager died as soon as it was consumed. Homer does not mention the firebrand; whence some have imagined that this fable is posterior to that poet's age. But he says, that the death of Toxeus and Plexippus so irritated Althæa, that she uttered the most horrible curses and imprecations upon her son's head.

Meleager, a Greek poet, the son of Eucrates, was born at Seleucia in Syria, and flourished under the reign of Seleucus VI. the last king of Syria. He was educated at Tyre; and died in the island of Coos, anciently called *Merope*. He there composed the Greek epigrams called by us the *Anthologia*. The disposition of the epigrams in this collection was often changed afterwards, and many additions have been made to them. The monk Planudes put them into the order they are in at present, in the year 1380.

MELEAGRIS, in ornithology, the Turky; a genus of birds belonging to the order of gallinæ. The head is covered with spongy caruncles; and there is likewise a membranaceous longitudinal caruncle on the throat.

There is but one (A) species, *viz.* the gallopavo, or North American turky of Ray. It has a caruncle both on the head and throat; and the breast of the male is bearded or tufted. He lives upon grain and insects: when the cock struts, he blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forehead, and the naked parts of the face and neck become intensely red. Barbot informs us that very few turkies are to be met with in Guinea, and those only in the hands of the chiefs of the European forts; the negroes declining to breed any on account of their tenderness, which sufficiently proves them not to be natives of that climate. He also remarks, that neither the common poultry nor ducks are natural to Guinea any more than the turky. Neither is that bird a native of Asia: the first that were seen in Persia were brought

(A) Two others were formerly enumerated; but in the late edition of the *Syst. Nat.* by Gmelin, they have been transferred to a new genus. See Penelope.

Meleagris, Meles.

brought from Venice by fome Armenian merchants. They are bred in Ceylon, but not found wild. In fact, the turky, properly fo called, was unknown to the ancient naturalifts, and even to the old world, before the difcovery of America. It was a bird peculiar to the new continent; and is now the commoneft wild-fowl in the northern parts of that country, where they are frequently met with by hundreds in a flock: in the day-time they frequent the woods, where they feed on acorns; and return at night to the fwamps to rooft, which they do on the trees. They are frequently taken by means of dogs, though they run fafter for a time; but the dogs perfifting in the purfuit, the birds foon grow fatigued, and take to the higheft trees, where they will fuffer themfelves to be fhot one after another if within reach of the markfman. This fowl was firft feen in France in the reign of Francis I. and in England in that of Henry VIII. By the date of the reign of thefe monarchs, the firft turkies muft have been brought from Mexico, the conqueft of which was completed A. D. 1521. Ælian mentions a bird found in India, which fome writers have fufpected to be the turky; but Mr Pennant concludes with Gefner, that it was either the peacock, or fome bird of that genus.

The turky-hen begins to lay early in the fpring, and will often produce a great number of eggs, which are white, marked with reddifh or yellow fpots, or rather freckles. She fits well, and is careful of her young; of which in this climate fhe will often have from fourteen to feventeen for one brood: but fhe fcarce ever fits more than once in a feafon, except allured thereto by putting frefh eggs under her as foon as the firft fet are hatched; for as fhe is a clofe fitter, fhe will willingly remain two months on the neft, tho' this conduct, as may be fuppofed, is faid greatly to injure the bird. Turkies are bred in quantities in fome of the northern counties of England, and are driven up to London towards autumn for fale in flocks of feveral hundreds, which are collected from the feveral cottages about Norfolk, Suffolk, and neighbouring counties, the inhabitants of which think it well worth their while to attend carefully to them, by making thefe birds a part of their family during the breeding feafon. It is pleafing to fee with what facility the drivers manage them, by means of a bit of red rag faftened to the end of a flick, which, from their antipathy to it as a colour, acts with the fame effect as a fcourge to a quadruped.

Of the turky there are feveral varieties, which have arifen from domeftication. The moft common is *dark grey* inclining to black, or barred dufky white and black. There is alfo a beautiful variety of a fine deep *copper* colour, with the greater quills pure white, and the tail of a dirty white; it is when old a moft beautiful bird. A variety with a *pure white* plumage is alfo now not unfrequent, and appears very beautiful. It was once efteemed as a great rarity, and the breed fuppofed originally to have arifen in Holland. In the Leverian Mufeum is alfo a common turky, with a large *tuft* of feathers on its head, much refembling one figured by Albin.

MELES, in zoology. See Ursus.

Meles (anc. geog.), a fine river running by the walls of Smyrna in Ionia, with a cave at its head, where Homer is faid to have written his poems. And from it Homer takes his original name *Melafigenes*, given him by his mother Critheis, as being born on its banks. (Herodotus.)

Meletians || Melica.

MELETIANS, in ecclefiaftical hiftory, the name of a confiderable party who adhered to the caufe of Meletius bifhop of Lycopolis, in Upper Egypt, after he was depofed, about the year 306, by Peter bifhop of Alexandria, under the charge of his having facrificed to the gods, and having been guilty of other heinous crimes; though Epiphanius makes his only failing to have been an exceffive feverity againft the lapfed. This difpute, which was at firft a perfonal difference between Meletius and Peter, became a religious controverfy; and the Meletian party fubfifted in the fifth century, but was condemned by the firft council of Nice.

MELIA, Azaderach, or the *Bead tree*, in botany: A genus of the monogynia order, belonging to the decandria clafs of plants; and in the natural method ranking under the 23d order *Trihilatæ*. The calyx is quinquedentated; the petals five; the nectarium cylindrical, as long as the corolla, with its mouth ten-toothed: the fruit is a plum with a quinquelocular kernel. There are three fpecies, all of them exotic trees of the Indies, rifing near 20 feet high; adorned with large pinnated or winged leaves, and clufters of pentapetalous flowers. They are all propagated by feeds fown on hot-beds.

MELIANTHUS, Honey-flower, in botany: A genus of the angiofpermia order, belonging to the didynamia clafs of plants; and in the natural method ranking under the 24th order *Corydales*. The calyx is pentaphyllous, with the lowermoft leaf gibbous: there are four petals, with the nectarium under the loweft ones. The capfule is quadrilocular. There are two fpecies. 1. The major hath a thick, ligneous, fpreading root; many upright, ligneous, durable ftalks, rifing fix or eight feet high; garnifhed with large pinnated leaves, of four or five pair of ferrated lobes terminated by an odd one; and, from the fides and tops of the ftalks, long fpikes of chocolate-coloured flowers. 2. The minor hath a root like the former; upright, ligneous, foft, durable ftalks, rifing four or five feet high; garnifhed with fmaller pinnated leaves; and from the fides and ends of the branches, long, loofe, pendulous bunches of flowers tinged with green, faffron colour, and red.—Both the fpecies flower about June: but rarely produce feeds in this country. They are very ornamental, both in foliage and flower, and merit admittance in every collection. They are eafily propagated by fuckers and cuttings. They thrive beft in a dry foil, and in a fheltered warm expofure.

MELIBOEA (anc. geog.), an ifland of Syria, at the mouth of the Orontes; which, before it falls into the fea, forms a fpreading lake round it. This ifland was famous for its purple dye. Thought to be a colony of Theffalians; and hence Lucretius's epithet, *Theffalicus*.

MELICA, ropegrass: A genus of the digynia order, belonging to the triandria clafs of plants; and in the natural method ranking under the 4th order *Gramina*. The calyx is bivalved, biflorous, with an embryo of a flower betwixt the two florets. There are three fpecies; of which the moft remarkable is the nutans. It is a native of several parts of Britain, and the adjacent islands; and the inhabitants of some of the western islands make ropes of it for fishing-nets, as it will bear the water for a long time without rotting.

MELICERES, in surgery, a kind of encysted tumors, so called when their contents are of the consistence of honey.

MELICERTA, Melicertes, or *Melicertus* (fab. hist.), a son of Athamas and Ino. He was saved by his mother from the fury of his father, who prepared to dash him against a wall as he had done his brother Learchus. The mother was so terrified that she threw herself into the sea with Melicerta in her arms. Neptune had compassion on the misfortunes of Ino and her son. He changed them both into sea deities. Ino was called *Leucothoë* or *Matuta*; and Melicerta was known among the Greeks by the name of *Palæmon*, and among the Latins by that of *Portumnus*. Some suppose that the Isthmian games were instituted in honour of Melicerta.

MELILLA, an ancient town of Africa in the kingdom of Fez, and in the province of Garet. It was taken by the Spaniards in 1469, but returned back to the Moors. W. Long. 2 9. N. Lat. 35. 20.

MELILOT. See Trifolium.

MELINDA, a kingdom on the east coast of Africa, situated, according to some, between the third and fourth degree of south latitude; though there is great disagreement among geographers as to its extent. It is allowed by all, however, that the coasts are very dangerous; being full of rocks and shelves, and the sea at some seasons very liable to tempests. The kingdom of Melinda is for the most part rich and fertile; producing almost all the necessaries of life except wheat and rice, both which are brought thither from Cambaya and other parts; and those who cannot purchase them make use of potatoes in their stead, which are here fine, large, and in great plenty. They likewise abound with great variety of fruit-trees, roots, plants, and other esculents, and with melons of exquisite taste. They have also great plenty of venison, game, oxen, sheep, hens, geese, and other poultry, &c. and one breed of sheep whose tails weigh between 30 and 40 pounds. The capital city is also called *Melinda*.

MELINUM, in natural history, the name of an earth famous in the earliest ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the three colours with which alone they performed all their works. It is a fine, white, marly earth, of a very compact texture, yet remarkably light; a sort of texture which must render any earth fit for the painter's use that is of a proper colour. It is frequently found forming a stratum in the earth, lying immediately under the vegetable mould. It is of a very smooth but not glossy surface; is very soft to the touch; adheres firmly to the tongue; is easily broken between the fingers; and stains the skin in handling. It melts readily in the mouth, and is perfectly fine; leaving not the least grittiness between the teeth: thrown into water, it makes a loud bubbling and hissing noise, and moulders away into a fine powder. It does not ferment with acids; and suffers no change in the fire. These are the characters by which the melinum of the ancients is distinguished from all other white earths. It is still found in the same place from which the painters of old had it, *viz.* the isle of Milo or Melos, from whence it had its name; and is common in most of the adjacent islands. It has of late been tried here; but is found not to make such a bright paint as the other substances now employed. It is not, however, liable, like them, to turn yellow: hence it would seem to be worth the consideration of persons in the colour-trade; especially as it might be had in any quantities for the carriage.

MELISSA (fab. hist.), a daughter of Melissus king of Crete, who with her sister Amalthæa fed Jupiter with the milk of goats. She first found out the means of collecting honey; whence it has been fabled that she was changed into a bee, as her name is the Greek word for that insect.

MELISSA, Baum: A genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42d order *Verticillatæ*. The calyx is arid, a little plane above, with the upper lip having its dents nearly of equal height: the upper lip of the corolla is arched and bifid; the under one, with the middle lobe, cordated. There are several species; but the most remarkable are the following. 1. The officinalis, or common baum, has fibrous perennial roots; many upright, square, branchy, annual stalks, rising two or three feet high: garnished with oblong, indented, opposite leaves, by pairs, two or three inches long, and half as broad; and from the upper axillas verticillate clusters of small white flowers upon single footstalks. There is also a kind with variegated leaves. 2. The grandiflora, or Hetrurian calamint, hath fibrous perennial roots and annual stalks, rising about a foot high, garnished with oblong, oval, indented, hairy, opposite leaves; and from the upper axillas verticillate clusters of large purple flowers on forked footstalks. 3. The calamintha, or common calamint of the shops, has fibrous perennial roots; upright, square, branchy hairy stalks, rising a foot high; roundish, indented, opposite leaves; and verticillate clusters of small bluish flowers, on forked footstalks as long as the flowers. All these species are easily propagated by offsets.

Medicinal uses. The first species, when in perfection, has a pleasant smell, somewhat of the lemon kind; and a weak, roughish, aromatic taste. The young shoots have the strongest flavour; the flowers, and the herb itself when old or produced in very rich moist soils or rainy seasons, are much weaker both in smell and taste. Baum is appropriated, by the writers on the materia medica, to the head, stomach, and uterus; and in all disorders of these parts is said to do extraordinary service. So high an opinion have some chemists entertained of this plant, that they have expected to find in it a medicine which should prolong life beyond the usual period. The present practice, however, holds it in no great esteem; and ranks it (where it certainly deserves to be) among the weaker corroborants. Infusions of the leaves in water smell agreeably of the herb, but have not much taste, though on being inspissated they leave a considerable quantity of a bitterish austere extract. Infusions of baum do not, like other aromatics, offend

offend the head, as is complained of from sage, &c. Cold infusions in water or spirit are far better than the cohobated distilled water, and are the best preparations from the plant. On distilling the fresh herb with water, it impregnates the first running pretty strongly with its grateful flavour. When large quantities are subjected to the operation at once, there separates and rises to the surface of the aqueous fluid a small portion of essential oil, which some call *ol. Syriæ*, and others *ol. Germanis*. It is of a yellowish colour, and of a very fragrant smell.

MELISSUS of Samos, a Greek philosopher, was the son of Rhagines and the disciple of Parmenides; and lived about 440 B. C. He pretended that the universe is infinite, immoveable, and without a vacuum. Themistocles was among his pupils.

MELITE (anc. geog.), an island referred to Africa by Scylax and Ptolemy; but nearer Sicily, and allotted to it by the Romans: commended for its commodious harbours; for a city well built, with artificers of every kind, especially weavers of fine linen; all owing to the Phœnicians the first colonists. Now *Malta*; remarkable for St Paul's shipwreck. See Malta.

Melite, *Melita*, or *Melitina Infula*; an island on the coast of Illyricum in the Adriatic. The *Catuli Melitæi* (Pliny) were famous. Now *Melede*, the name of the island Samos. See Samos.

Melite (anc. geog.), a town of Ionia, struck out of the number of Ionian towns on account of the arrogance of the people, and Smyrna admitted in lieu of it. The situation not said.

MELITENSIS terra, the *Earth of Malta*: an earth of which there are two very different kinds; the one of the genus of boles, the other of the marles. The latter is that known by medicinal authors under this name; the former is the Malta earth now in use: but both being brought from the same place, are confusedly called by the same name. The Maltese marle, which is the *terra Melitensis* of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture; and, when exposed to the weather, soon falls into fine soft powder: but when preserved and dried, it becomes a loose, light mass, of a dirty white colour, with a greyish cast: it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and stains the hands. Thrown into the water, it swells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstruums. Both kinds are found in great abundance in the island of Malta, and the latter has been much esteemed as a remedy against the bites of venomous animals. The other has supplied its place in the German shops; and is used there as a cordial, sudorific, and astringent.

MELITO (canonized), bishop of Sardis in Lydia, in the second century; remarkable for the apology he presented to the emperor Aurelius, in favour of the Christians; on which Eusebius and the other ancient ecclesiastical writers bestow great praises: but that apology and all Melito's other works are lost.

MELITUS, a Greek orator and poet, the accuser of Socrates. The Athenians, after the death of Socrates, discovering the iniquity of the sentence they had passed against that great philosopher, put Melitus to death, 400 B. C.

MELLAN (Claude), an engraver of considerable note, was a native of Abbeville in Picardy, and born in 1601. His father was the receiver of the customs in that town; and he took great care of the education of his son. His genius for drawing discovering itself very early in life, he was sent to Paris, and placed under the direction of Simon Vouet in order to perfect himself in that art, and his studies promised success; but he was diverted from his application to them by the desire he had of learning the management of the graver, which he acquired with much facility. From Paris, at the age of sixteen, he went to Rome, where he engraved a considerable number of plates, many of which are held in great estimation; particularly those for the Justinian Gallery, the portrait of the Marquis Justinian, and that of Pope Urban VIII. Returning to France, he married at Paris, and settled there in 1654. The king of France being made acquainted with his merit, assigned him apartments in the Louvre, in the double quality of a painter and an engraver. He acquired a competent fortune, and was greatly esteemed by all who knew him. He died in 1688, aged 87.

Florent le Comte tells us, "That Charles II. was so much pleased with his performances, that he invited him to come into England, making him at the same time very advantageous offers. But the love of his country (continues that author) prevented his accepting of them."

It is remarked, that most of the plates which he engraved at Rome, and before he went thither, are executed in the usual manner; that is, with parallel strokes, crossed with second and third strokes, as the depth of the shadows might require. But afterwards he adopted a new mode of working with single strokes only, without any second strokes laid upon them; and the shadows are expressed by the same strokes being made stronger and brought nearer to each other. The effect which he produced by this method of engraving is soft and clear. In single figures and small subjects he succeeded very happily; but in large compositions, where great depth of shadow was required, he has failed. His neatest plates in this style have an unfinished appearance, by no means suitable to large engravings; but at the same time a lightness exceedingly agreeable when confined to small ones. According to Le Comte, the works of this master amount to 342.

MELLER, a lake of Sweden, 80 miles long, and 30 broad; on which stands the city of Stockholm.

MELLI, with the country of the Mundingoes, in Africa. The country formerly called *Melli*, now chiefly inhabited by the Mundingoes, who still retain pretty much of the character ascribed to the people of Melli, lies to the south of the river Gambia; on the west it borders on the kingdom of Kabo; on the south it has *Melli*, properly so called, and the mountains that part it from Guinea; and on the east it extends to the kingdom of Gago. A great part of this country we are little acquainted with; as is the case with regard to most of the inland territories of Africa, but towards the sea-coast this country is a little better known.

The first place of note we meet with is Kachao, a Portuguese colony, situated on the river of St Domingo, which falls into the sea about 26 leagues below this

this town.—About 26 leagues above Kachao, on the same side of the river, is another trading town called *Farini*, where, in the months of October and November, one may trade for about half the quantity of wax and ivory which is traded for at Kachao. Here are also some slaves to be bought.—Bot is a village near the mouth of the river Gesves, where most of the traders buy rice; which is in great plenty there, and very good.—Gesves is a village on a river of the same name, on which the Portuguese have a factory. At Gesves one may trade yearly for 250 slaves, 80 or 100 quintals of wax, and as many of ivory. Near the mouth of the river of Gesves is a village called *Kurbali*, where there is a considerable trade for salt; here are also some slaves and ivory. Rio Grande, or the Great River, runs about 10 or 12 leagues to the south of the river of Gesves. About 80 leagues from the mouth of it is a nation of Negroes, who are good traders in ivory, rice, millet, and some slaves. They are called *Analons*. Over-against the mouth of Rio Grande is a cluster of islands called *Bissago Isles*; the most considerable of which is Cassagut, being about six leagues long and two broad; its soil is very good, and produces millet, rice, and all kinds of pulse, besides orange and palm-trees, and many others. This island, with those of Carache, Canabac, and La Gallina, are the only ones where the Europeans may trade with some security. They trade, however, sometimes at the other islands, but they must be extremely cautious; and yet after all their precautions, they will be robbed and murdered if they venture to go ashore. The river Nunho runs 16 leagues to the south of Rio Grande; it is very considerable, and comes from a vast distance in-land. One may buy here 300 quintals of ivory and 100 slaves a-year. Rice grows here admirably well, and is very cheap. There are every-where sugar-canes which grow naturally; and plants of indigo, which might turn to good account. The trade is carried on here from March till August. In the river of Sierra Leone, the late Royal African company of England had, in the year 1728, two islands; the one, called *Tasso*, a large flat island, near three leagues in circumference, in which the company's slaves had a good plantation; the rest of the island is covered with wood, among which are silk-cotton trees of an unaccountable size. The other island is *Bense*, whereon stood a regular fort. It was formerly the residence of one of the English chiefs.

MELMOTH (William, Esq;), a learned and worthy bencher of Lincoln's Inn, was born in 1666. In conjunction with Mr Peere Williams, Mr Melmoth was the publisher of Vernon's Reports, under an order of the court of chancery. He had once an intention of printing his own Reports; and a short time before his death advertised them at the end of those of his coadjutor Peere Williams, as then actually preparing for the press. They have, however, not yet made their appearance. But the performance for which he justly deserves to be held in perpetual remembrance is, "The Great Importance of a Religious Life;" concerning which it may be mentioned, to the credit of the age, that notwithstanding many large editions had before been circulated, 42,000 copies of this useful treatise have been sold in the last 18 years. It is a somewhat singular circumstance, that the real author of this most admirable treatise should never before have been publicly known (it having been commonly attributed to the first earl of Egmont, and particularly by Mr Walpole in his Catalogue); which is the more surprising, as the author is plainly pointed out in the following short character prefixed to the book itself: "It may add weight, perhaps, to the reflections contained in the following pages, to inform the reader, that the author's life was one uniform exemplar of those precepts which, with so generous a zeal, and such an elegant and affecting simplicity of style, he endeavours to recommend to general practice. He left others to contend for modes of faith, and inflame themselves and the world with endless controversy: it was the wiser purpose of his more ennobled aim, to act up to those clear rules of conduct which revelation hath graciously prescribed. He possessed by temper every moral virtue; by religion every Christian grace. He had a humanity that melted at every distress; a charity which not only thought no evil, but suspected none. He exercised his profession with a skill and integrity which nothing could equal but the disinterested motive that animated his labours, or the amiable modesty which accompanied all his virtues. He employed his industry, not to gratify his own desires; no man indulged himself less: not to accumulate useless wealth; no man more disdained so unworthy a pursuit: it was for the decent advancement of his family, for the generous assistance of his friends, for the ready relief of the indigent. How often did he exert his distinguished abilities, yet refuse the reward of them, in defence of the widow, the fatherless, and him that had none to help him! In a word, few have ever passed a more useful, not one a more blameless life; and his whole time was employed either in doing good or in meditating it. He died on the 6th day of April 1743, and lies buried under the cloister of Lincoln's Inn Chapel. MEM. PAT. OPT. MER. FIL. DIC." The son, by whom this character is drawn, is William Melmoth, Esq; the celebrated translator of Pliny and of Cicero's Letters; and author of those which pass under the name of *Sir Thomas Fitzosborne*.

MELOCHIA, Jews mallow, in botany: A genus of the pentandria order, belonging to the monodelphia class of plants; and in the natural method ranking under the 37th order, *Columniferæ*. The capsule is quinquelocular and monospermous. There are several species; but the only remarkable one is the olitorius, or common Jews-mallow, which is a native of the warm parts of Asia and America.—It is an annual plant, which rises about two feet high, dividing into several branches, garnished with leaves of different sizes and forms: some are spear-shaped, others are oval, and some almost heart-shaped: they are of a deep green, and slightly indented on their edges, having near their base two bristly reflexed segments. They have very long slender footstalks, especially those which grow on the lower part of the branches. The flowers sit close on the opposite side of the branches to the leaves, coming out singly; they are composed of five small yellow petals, and a great number of stamina surrounding the oblong germen, which is situated in the centre of the flower, and afterwards turns to a rough swelling capsule two inches long, ending in a point, and

and having four cells filled with angular greenifh feeds. This fpecies is cultivated about the city of Aleppo in Syria, and in the Eaft Indies, as a pot-herb; the Jews boiling the leaves, and eating them with their meat. It is fuppofed by Rauwolf to be the *olus Judaicum* of Avicenna, and the *corchorum* of Pliny.

MELODUNUM, (anc. geog.), a town of the Cenones in Gallia Celtica above Lutetia; now *Melun*, in the ifle of France, on the Seine.

MELODY, in mufic, a fucceffion of founds ranged in fuch a manner, according to the laws of rhythmus and modulation, that it may form a fentiment agreeable to the ear. Vocal melody is called *finging;* and that which is performed upon inftruments may be termed *fymphonic melody*.

The idea of rhythmus neceffarily enters into that of melody. An air is not an air but in proportion as the laws of meafure and quantity are obferved. The fame fucceffion of founds is fufceptible of as many different characters, as many different kinds of melody, as the various ways by which its emphatic notes, and the quantities of thofe which intervene, may be diverfified; and the change in duration of the notes alone, may difguife that very fucceffion in fuch a manner that it cannot be known. Thus, melody in itfelf is nothing; it is the rhythmus or meafure which determines it, and there can be no air without time. If then we abftract meafure from both, we cannot compare melody with harmony; for to the former it is effential, but not at all to the latter.

Melody, according to the manner in which it is confidered, has a relation to two different principles. When regarded only as agreeable to the proportions of found and the rules of modulation, it has its principle in harmony; fince it is a harmonical analyfis, which exhibits the different gradations of the fcale, the chords peculiar to each mode, and the laws of modulation, which are the fole elements that compofe an air. According to this principle, the whole power of melody is limited to that of pleafing the ear by agreeable founds, as the eye may be pleafed with an agreeable affemblage of fuitable colours. But when confidered as an imitative art, by which we may affect the mind with various images, excite different emotions in the heart, inflame or foothe the paffions; by which, in a word, we produce different effects upon our moral faculties, which are not to be effectuated by the influence of external fenfe alone, we muft explore another principle for melody: for in our whole internal frame there appears to be no power upon which either harmony alone, or its neceffary refults, can feize, to affect us in fuch a manner.

What then is the fecond principle? It is as much founded on nature as the firft; but, in order to difcover its foundation in nature, it will require a more accurate though fimpler obfervation, and a more exquifite degree of fenfibility in the obferver. This principle is the fame which varies the tone of the voice, when we fpeak, according as we are interefted in what we fay, and according to the different emotions which we feel in expreffing it. It is the accent of languages which determines the melody of every nation; it is the accent which determines us to employ the emphafis of fpeaking while we fing, and to fpeak with more or lefs energy according as the language which we ufe is more or lefs accented. That language whofe accents are the moft fenfible, ought to produce a more paffionate and more lively melody; that which has little accentuation, or none at all, can only produce a cold and languid melody, without character and without expreffion. Thefe are the true principles: in proportion as we depart from them, when we fpeak of the power of mufic upon the human heart, we fhall become unintelligible to ourfelves and others; our words will be without meaning.

If mufic does not imprefs the foul with images but by melody, if from thence it obtains its whole power, it muft follow, that all mufical founds which are not pleafing by themfelves alone, however agreeable to harmony they may be, is not an imitative mufic; and, being incapable, even with its moft beautiful chords, either to prefent the images of things, or to excite the finer feelings, very foon cloys the ear, and leaves always the heart in cold indifference. It follows likewife, that notwithftanding the parts which harmony has introduced, and which the prefent tafte of mufic fo wantonly abufes, wherever two different melodies are heard at the fame time, they counteract each other, and deftroy the effects of both, however beautiful each may be when performed alone: from whence it may be judged with what degree of tafte the French compofers have introduced in their operas the miferable practice of accompanying one air with another, as well in finging, which is the native expreffion of pathos and fentiment, as in inftrumental performances; which is the fame thing as if whimfical orators fhould take it in their heads to recite two orations at the fame time, that the elegance of each might derive more force from the other.

So much for Rouffeau The tranflator, however, has reafon to fear, that the caufes by which national melody is diverfified and characterifed, are more profound and permanent than the mere accentuation of language. This indeed may have great influence in determining the nature of the rhythmus, and the place of emphatic notes; but very little in regulating the nature of the emphafis and expreffion themfelves. If Rouffeau's principle be true in its full extent, he muft of neceffity acknowledge, that an air which was never fet or intended for words, however melodious, cannot be imitative: he muft likewife confefs, that what is imitative in one nation cannot be fuch in another: nor can it be denied upon his hypothefis, that the recitative, which is formed upon the mode of fpeaking, is the moft forcible of all melodies; which is abfurd. His other obfervations are at once judicious and profound. Though it is impoffible to exhibit the beauty and variety of harmony by playing the fame melody at the fame time upon different keys, admitting thofe keys to form among themfelves a perfect chord, which will of confequence preferve all the fubfequent notes in the fame intervals; yet this perfect harmony would by no means be uniformly pleafing to the ear. We muft therefore of neceffity introduce lefs perfect chords to vary and increafe the pleafure, and thefe chords in any complex fyftem of mufic muft of neceffity produce diffonances. It then becomes the bufinefs of the compofer to be careful that thefe difcords may arife as naturally from, and return as naturally to, perfect har-

 mony,

Meloe. mony as possible. All these causes must inevitably vary the melody of the different parts; but still, amidst all these difficulties, the artist ought to be zealous in preserving the melody of each as homogeneous with the others as possible, that the result of the whole may be in some measure uniform. Otherwise, by counteracting each other, the parts will reciprocally destroy the effects one of another.

MELOE, in zoology; a genus of insects of the order of coleoptera. The antennæ are jointed, the last joint being oval; the breast is roundish; the elytra are soft and flexible; and the head is inflected, and gibbous. The insects of this genus are divided into two families; one without wings, and having the elytra shorter than the abdomen; the other winged, with elytra shorter than the body and wholly covering the wings.—The most remarkable species are,

1. The proscarabæus; the colour of which is black, but without brightness, though intermixed with a small degree of purple, especially towards the under part of the body. Its head, which is large, is dotted; as is the thorax, which is narrower, round, and without a margin. The elytra are as soft as leather, shagreened, and cover but part of the abdomen. They are, as it were, cut off obliquely from the inner to the outer part, being shorter towards the suture, longer on the sides. There are no wings under the elytra. The abdomen is large, especially that of the female, in which it far exceeds the elytra.—This insect makes its abode on the side of wet roads and in woods. Its food are insects, violet leaves, and delicate herbs. There oozes from its body a fat unctuous matter of an agreeable smell. The males are less than the females.

2. The vesicatorius, or blistering meloe, is nine or ten lines in length, of a shining green colour mixed with azure. It multiplies greatly. They are sometimes seen flying in swarms. A nauseous smell, not unlike that of mice, bespeaks their approach; which scent leads to the discovery of them when they are sought for in order to make a provision. When dried, they are so light, that 50 scarce weigh one dram. They prey upon the leaves of trees and shrubs, and in preference take to those of the ash-tree. The odorous particles exhaled by these insects, are extremely corrosive. Great caution should be used in picking them up. People have been known to be seized with violent heat of urine, voiding of blood, for having gathered a quantity of them during the heat of the sun with their hands bare, or for having fallen asleep under trees where swarms of them had settled. The copulation of these insects is performed during the most intense heat of the day.

There are many other species, differing in size, figure, and colour. Nature has apparelled almost all of them in a splendid manner. Green, azure, and gold, render them dazzling to the eyes. They are most common in the southern parts of the continent. In this genus, as well as in some others, the females court, and in the act take the place of the males. The females deposit their eggs in the ground, whence proceed larvæ, which pass through the state of chrysalids in order to attain to that of meloes.

Uses. Oil in which insects of the *first* species have been infused is said to be an excellent topical for wounds and the scorpion's sting. It enters also into the composition of salve for plague sores. The insects bruised and mixed with oil or honey, Linnæus says, are commended as a remedy in the rabies canina.

The *second* species is the cantharis of the shops; which, when bruised, is universally used as a blistering plaster. The largest and most esteemed of this sort come from Italy. Cantharides are extremely acrimonious: applied to the skin, they first inflame, and afterwards excoriate the part, raising a more perfect blister than any of the vegetable acrids, and occasioning a more plentiful discharge of serum. All the blistering compositions have cantharides for their basis. The external application of cantharides is often followed by a strangury, accompanied with thirst and feverish heat: this inconvenience may be remedied by soft unctuous or mucilaginous liquors liberally drank.

Cantharides taken internally often occasion a discharge of blood by urine, with exquisite pain. If the dose is considerable, they seem to inflame and exulcerate the whole intestinal canal; the stools become mucous and purulent; the breath fetid and cadaverous; intense pains are felt in the lower belly; the patient faints, grows giddy, raving mad, and dies. All these terrible consequences have sometimes happened from a few grains. Herman relates, that he has known a quarter of a grain inflame the kidneys, and occasion bloody urine with violent pain. There are nevertheless cases in which this stimulating fly, given in larger doses, proves not only safe, but of singular efficacy for the cure of diseases that yield little to medicines of a milder class. In cold phlegmatic sluggish habits, where the viscera are overloaded, and the kidneys and ureters obstructed with thick viscid mucous matter, cantharides have excellent effects: here the abounding mucus defends the solids from the acrimony of the fly, till it is itself expelled; when the medicine ought to be discontinued. Groenvelt employed cantharides with great success in dropsies, obstinate suppressions of urine, and ulcerations of the bladder; giving very considerable doses made into boluses with camphor; and interposing large draughts of emulsions, milk, or other emollent liquids: by this means, the excessive irritation, which they would otherwise have occasioned, was in great measure prevented. The camphor did not perhaps contribute so much to this effect as is generally imagined, since it has no sensible quality that promises any considerable abatement of the acrimony of cantharides: nitre would answer all that the camphor is supposed to perform; this, with milk, or emollient mucilaginous liquors, drank in large quantity, are the best correctors. Cantharides, in very small doses, may be given with safety also in other cases. Dr Mead observes, that the obstinate gleetings which frequently remain after the cure of venereal maladies, and which rarely yield to balsamic medicines, are effectually remedied by cantharides; and that no one remedy is more efficacious in leprous disorders; in which last, proper purgatives are to be occasionally taken during the use of the cantharides. The best and safest preparation of cantharides for these purposes, is a spirituous tincture; and indeed, in all cases, the tincture is far preferable, for internal use, to the fly in substance.

The virtues of cantharides are extracted by rectified spirit

Melon. ſpirit of wine, proof ſpirit, and water; but do not ariſe in diſtillation. The watery and ſpirituous extracts bliſter as freely as the fly in ſubſtance; whilſt the fly remaining after the ſeveral menſtrua have performed their office, is to the taſte inſipid, and does not in the leaſt bliſter or inflame the ſkin.

See Cucumis. MELON, in botany, a ſpecies of CUCUMIS *, in the Linnæan ſyſtem. The female flowers have no ſtamina or ſummits, but have a very large oval germen, ſituated below the flower, which turns to an oval fruit with ſeveral cells, filled with oval, acute-pointed, compreſſed ſeeds, incloſed in a ſoft pulp. There is a great variety of this fruit cultivated in different parts of the world, many of them of no value, ſize being regarded too much in the markets. The *Cantaleupe melon*, ſo called from a place in the neighbourhood of Rome, where this fruit has been long cultivated, and whither it was brought from Armenia, is in the greateſt eſteem among the curious in every part of Europe. Beſides this, there are alſo the *romana*, the *ſuccado*, the *Zatte*, the ſmall *Portugal* or *dormer*, and the black *Galloway* melons, moſt of which are cultivated for an early crop.

The proper management and culture of melons are as follow: the ſeeds ſhould be procured from good melons, of the soundeſt ſort and higheſt flavour, produced, as ſome have adviſed, in a diſtant garden; for if ſown on the place where it was raiſed and ripened, it is very apt to degenerate. This ſeed ſhould be kept three years before it is ſown, but not more than ſix; and it ſhould be ſown at two ſeaſons, or if at three it will be ſtill better: the firſt for the early crop, to be raiſed under frames, ſhould be ſown about the middle of February; the ſecond, to be raiſed in the ſame manner, is to be ſown about the middle of March; and thoſe which are deſigned for hand or bell-glaſſes, or to be covered with oil-papers, ſhould not be ſown till about a week in April.

For thoſe of the firſt ſeaſon, the ſeeds may be ſown on the upper ſide of a cucumber-bed, if there be any; or, a proper quantity of new looſe dung muſt be provided, and thrown on a heap to ferment, and turned over, that it may acquire an equal heat; and the plants muſt be raiſed and managed like cucumbers, until they are planted where they are to remain. The beds or ridges, where the plants are to remain, ſhould be placed in a warm ſituation, ſo that they may be defended from all cold and ſtrong winds, and incloſed in a good reed fence. In preparing the earth for theſe plants, the Dutch and German gardeners form a mixture of a third part of hazel loam, a third part of the ſcouring of ditches and ponds, and the ſame quantity of very rotten dung; which they mix up at leaſt one, and often two years, before they make uſe of it, frequently turning it over, ſo that the parts may be well incorporated; but the compoſt in which Mr Miller has found melon plants to ſucceed beſt in England is two-thirds of freſh gentle loam, and one-third of rotten neat's dung: if theſe are mixed together one year before it is wanted, ſo as to have the benefit of a winter's froſt and ſummer's heat, obſerving to turn it over often, and never ſuffering weeds to grow upon it, this will be found equal to any compoſt whatever. Before the plants appear, there ſhould be a quantity of new dung thrown in a heap, allowing about 15 wheelbarrows full to each light; which muſt be turned over two or three times, and in a fortnight it will be fit for uſe; when the trench muſt be dug to receive the dung where the bed is deſigned to be made, which in a dry ground ſhould not be leſs than a foot or a foot and a half deep. The frames ſhould then be placed over the bed to keep out the wet; but no earth ſhould be laid upon it for three or four days, till it is found of a proper temperature of heat. When this is the caſe, the earth may be laid upon it, about two inches thick, except in the middle of each light, where the plants are to be placed, which muſt be raiſed into a hill 15 inches high or more, terminating in a flat cone: in two or three days after the earth is put on the bed, it will be of a proper temper to receive the plants; which ſhould be carefully taken up with a trowel, ſo as to preſerve all the fibres of their roots; or if the beds cannot be ready for them in time, ſoon after the third or rough leaf is put out, it will be a good method to put each plant into a ſmall pot while they are young, and theſe may be plunged into the hot-bed where they were raiſed, or in a cucumber-bed, where there is room; and when the bed is ready, the plants may be turned out of the pots, with the whole ball of earth to their roots: and this is the beſt method for the Cantaleupe melon. When the plants are placed on the tops of the hills, they ſhould be gently watered once or twice, till they have taken good root; and when they are well fixed in the new beds, a greater quantity of earth ſhould be laid on the beds, preſſed down as cloſe as poſſible, and raiſed at leaſt a foot and a half thick upon the dung all over the bed; obſerving alſo to raiſe the frames, that the glaſſes may not be too near the plants, leſt the ſun ſhould ſcorch them. When the plants have four leaves, the top of the plants ſhould be pinched off with the finger and thumb, that they may put out lateral branches for producing the fruit; and when two or more of theſe lateral ſhoots are produced, they muſt alſo be pinched to force out more. The management of theſe beds is much the ſame as that of cucumbers, except that melons require more air and very little water. In five or ſix weeks the plants will ſpread over the bed, and reach to the frames, when the alleys between the beds ſhould be dug out; or in caſe of one bed, a trench ſhould be made on each ſide about four feet wide, as low as the bottom of the bed; and hot dung wheeled in for a lining, to the ſame height as the dung of the bed; this ſhould be trodden down cloſe, and covered with the ſame earth that was laid on the bed, to the thickneſs of a foot and a half or more, treading it down as cloſe as poſſible. In this way the bed will be extended to the width of 12 feet, that the roots of the plants may ſpread quite through it; and the beds will alſo require a freſh warmth, which will be of great ſervice in ſetting of the fruit. When the vines have extended ſo as to fill the frames, and want more room, the frames ſhould be raiſed up with bricks about three inches high, to admit the ſhoots of the vines to run out under them. When the fruit appears, the vines ſhould be carefully looked over three times a week; and one ſhould be choſen upon each runner that is ſituated neareſt the ſtem, having the largeſt foot-ſtalk, and appearing to be the ſtrongeſt fruit; then pinch off all the other fruit which may appear upon the ſame runner, and pinch off the end of the runner at the third joint above the fruit; and if the runner is gently pinched at the next

Melon. joint above the fruit, it will stop the sap and set the fruit. There is also another method practised by some gardeners to set this fruit, which is the taking off some of the male flowers, whose farina is just ripe and fit for the purpose, laying them over the female fruit, and gently striking with the nails the male flowers, to shake the farina into the female flowers; whereby they are impregnated, and the fruit will soon after swell, and manifest visible signs of being perfectly set; so that where the plants are under frames, and the wind excluded from them, which is wanted to convey the farina from the male to the female flowers, this practice may be very necessary. The glasses of the hot-bed should also be raised high, to admit a large share of air to the plants, otherwise the fruit will not set; and if the season should prove very warm, the glasses may be frequently drawn off, especially in an evening, to receive the dews, provided there is little wind stirring: but they should not remain off the whole night, lest the cold should prove too great. When the plants have extended themselves from under the frames, in cold weather their extremities should be covered every night with mats, and the plants should be watered once in a week in dry warm weather, in the alleys between the beds.

For those melons that are raised under bell or hand-glasses, the plants should be raised in the manner already directed, and about the latter end of April, in a forward season, the beds may be made. For this purpose, a sufficient quantity of hot-dung should be provided, allowing eight or nine good wheel-barrows of dung to each glass. For one bed extended in length, the trench should be cut out three-one-half feet wide, and of such a length, that the glasses may not be placed nearer than four feet to each other: in digging the trench, it should be so situated, as to allow for the widening of the bed three or four feet on each side; the depth must depend on the nature of the soil; and when there is no danger of the beds being injured by the wet, the lower it is made the better. When the dung, prepared as before, is laid on the bed, there should be a hill for each plant, one foot and a half high, and the other part need not be covered more than four inches thick; the glasses should then be placed over the hills, and in two or three days after the beds are made they will be fit for receiving the plants, which should be removed in the manner already directed. These plants must be watered at first, to settle the earth to their roots, and shaded every day, till they have taken new root; and if the nights prove cold, it will be proper to cover the glasses with mats, in order to preserve the warmth of the bed. If several beds are made, they should be placed at eight feet distance from each other. When the plants have taken good root, their tops must be pinched off, and the pruning must be the same as for those under frames. In the day-time, when the weather is warm, the glasses should be raised on the opposite side to the wind, to admit fresh air to the plants; and when they reach the sides of the glasses, in favourable weather the glasses must be set up on three bricks, that the vines may have room to run out under them; but when this is done, the beds should be covered all over with earth to the depth of one foot and an half, and trod down as close as possible; and in cold nights, the beds should be covered with mats. And as the vines of the Cantaleupe melons cannot bear wet without injury, it will be necessary to arch the beds over with props to support the mats, that they may be ready for covering at all times when they require it. If the weather should prove cold, hot dung may be laid to these beds in the manner directed for those under frames. Some have lately raised their melons with considerable success under oiled paper; but great care must be taken not to keep these coverings too close over them. And Miller advises to bring up the plants under hand or bell glasses, till they begin to extend themselves under the glasses, and then, instead of the covering of mats, to put over them the paper done over with linseed oil.

The farther management of melons, after their fruit is set, is to keep pulling off all the superfluous fruit, and to pinch off all weak runners; and also to turn the fruit gently twice a-week, that each side may have equal benefit of the sun and air. When the fruit is fully grown, care should be taken to cut it at a proper time; for if it is left a few hours upon the vines, it will lose much of its delicacy; therefore the vines should be looked over at least twice in a day: and if the fruit intended for the table is cut early in the morning, before the sun has warmed it, it will be much better flavoured; but if it should be necessary to cut any afterwards, it should be put into cold spring water or ice to cool it, before it is brought to table; and that cut in the morning should be kept in the coolest place till it is used. The signs of this fruit's maturity is, its beginning to crack near the foot-stalk, and its beginning to smell, which never fail: but the Cantaleupe melons seldom change their colour till they are too ripe.

Mr Reynolds has communicated to the Society of Arts the following method of raising melons without earth, dung, or water. About a month before the seeds are sown, he prepares a bed of cast-off tanner's bark, four feet deep, six feet wide, and twelve feet in length: this he covers with four lights, so as not to admit rain or water. March (he says) is a proper season for this purpose. When the bed becomes warm, which generally happens in about 20 days, a few melon seeds are put into warm milk in an earthen vessel, which is pressed down into the bark-bed, where it remains 36 hours, in order to promote the vegetation of the seeds. Then, at equal distances, he directs to open four holes in the bed, each nine inches in diameter, and five inches deep; having in readiness about a peck of pounded bark, like saw-dust, some of it to be put at the bottom of the holes, to the thickness of three inches: on this bark some of the seeds are to be placed, and pressed down with the fingers; then the seeds are to be covered with two inches more of the powdered bark, pressing the whole down with the hand. When the plants are advanced to a proper size, the best are chosen and the others cast away; those that are reserved are ordered to be properly pruned, and to have as much warm air as possible during the summer. In this way (he says) he has raised as good melons as can be desired.

When a melon is perfectly fine, it is full, without any vacuity: this is known by knocking upon it; and when cut, the flesh must be dry, no water running

 out,

out, only a little dew, which is to be of a fine red colour. Large melons are not to be coveted, but firm and well-flavoured ones. Our gardeners who raife melons for fale, fow the feeds of the larger rather than the good kinds, and they increafe the fize of thefe by much watering the roots; but this fpoils the tafte. Some of the French raife at this time particularly fine melons, by a method kept as a fecret, but which we find, on a ftrict inquiry, is no other than the ingenious Mr Quintiny's of that nation, publifhed near 80 years ago in our Philofophical Tranfactions

The melons particularly proper to be treated in this manner, are thofe which have a thin and fomewhat embroidered fkin, not divided by ribs, and have a red pulp, dry and melting on the tongue, not mealy, and of a high flavour. Thefe are what fucceed in the following method, and are greatly improved in fize and flavour by it.

When the feeds of this melon are placed in the ground, the firft thing that appears is a pair of feminal leaves, or *ears*, as the gardeners call them. Between thefe two leaves there fhoots, fome days after, a leaf called the *firft leaf* or *knot;* and out of the fame place, after fome days more, there fhoots another leaf, called the *fecond knot.* Out of the midft of this ftalk of the fecond knot, there fhoots a third knot; this third knot muft be cut off at its infertion, without hurting the branch of the fecond knot from whence it grows. Out of this place there will grow, after this cutting, a branch, which will be what the gardeners call the *firft arm;* and this arm will, in the fame manner as the firft plant, fhoot out, firft one, then a fecond, and then a third knot; this third knot muft be cut again as before, and thus the third knots are all along to be cut off, and arms or branches will grow up in the places of them all the way in the fame manner as the firft; and it is at thofe arms that the melons will be produced, and they will be always good, if the foot or root be well nourifhed in good earth, and cherifhed by a good hot-bed and the fun. The foot of the melon muft never be fuffered to pafs into the dung, and the earth muft not be watered but moderately, when it is feen to grow too dry; but in this cafe, it muft be moderately moiftened in time, left the fhoot fuffer by it. Twice or thrice a-week is often enough to water in the drieft weather, and this muft always be done about funfet; and when the heat of the fun is too violent, the melons muft be covered with ftraw mats from 11 in the morning to about two in the afternoon. When it rains much, the melons muft alfo be covered, left it hurt them by too much moifture. (Philofoph. Tranf. n° 4[illegible].)—If the root produce too many branches, the weakeft are to be cut off, and only three or four left; and thofe which are left are to be fuch as have their knots clofeft to one another. When the plants are removed from the feed-bed to the places where they are to ftand, if they are very ftrong, they fhould be planted fingle; but if otherwife, two are to be fet in each hole

When they are planted fingle, the two branches, which always grow on each fide from the bafe of the feed leaves, are to be left on; but when two plants are fet together, thefe branches are to be cut off, otherwife all the branches will be too numerous, and they will entangle and fpoil one another.

When the melons are knit, two of them only are to be left upon each foot, choofing thofe which are beft placed, and next to the firft and principal ftalk, that is, to the heart of the foot. None but fair fruits are to be left, and fuch as have a thick and fhort tail; and the foot of the melon muft be fhort, well truffed, and not far diftant from the ground. Melons of a long ftem, and having the ftalk of the leaf too long and flender, are never vigorous. All the fuperfluous branches muft be cut off from time to time, as they fhoot out. There fometimes fhoot out a branch more than is here mentioned, between the two feed-leaves or ears. If this is ftrong and vigorous, it is to be kept on, but if weakly, it is beft to take it off, for it will never bear good fruit.

Water-Melon. See ANGURIA.

MELOS, (anc. geog.), an ifland between Crete and Peloponnefus, about 24 miles from Scyllæum. It is about 60 miles in circumference, and of an oblong figure. It enjoyed its independence for above 700 years before the time of the Peloponnefian war. This ifland was originally peopled by a Lacedemonian colony, 1116 years before the Chriftian era. For this reafon the inhabitants refufed to join the reft of the iflands and the Athenians againft the Peloponnefians. This refufal was feverely punifhed. The Athenians took Melos, and put to the fword all fuch as were able to bear arms. The women and children were made flaves, and the ifland left defolate. An Athenian colony repeopled it, till Lyfander reconquered it and re-eftablifhed the original inhabitants in their poffeffions.

MELOTHRIA, in botany: A genus of the monogynia order, belonging to the triandria clafs of plants; and in the natural method ranking under the 34th order, *Cucurbitaceæ.* The calyx is quinquefid; the corolla campanulated and monopetalous; the berry trilocular and monofpermous. There is only one fpecies, viz. the pendula, a native of Carolina, Virginia, and alfo many of the American iflands. The plants ftrike out roots at every joint, which faften themfelves into the ground, by which means their ftalks extend to a great diftance each way The flowers are very fmall, in fhape like thofe of the melon, of a pale fulphur colour. The fruit in the Weft Indies grows to the fize of a pea, is of an oval figure, and changes to black when ripe: thefe are by the inhabitants fometimes pickled when they are green. In Britain the fruit are much fmaller, and are fo hidden by the leaves that it is difficult to find them. The plants are too tender to be reared in this country without artificial heat

MELPOMENE (fab. hift.), one of the mufes, daughter of Jupiter and Mnemofyne. She prefided over tragedy. Horace has addreffed the fineft of his odes to her, as to the patronefs of lyric poetry. She was generally reprefented as a young woman with a ferious countenance Her garments were fplendid; fhe wore a bufkin, and held a dagger in one hand and in the other a fceptre and crown.

MELROSE, a town of Scotland, in the county of Selkirk, and on the confines of Tweeddale, feated seated on the south side of the river Tweed; with an ancient abbey now in ruins. W. Long. 2. 32. N. Lat. 55. 3-.

This abbey was founded by king David I in 1136. He peopled it with Cistertians brought from Rivale abbey in Yorkshire, and dedicated it to the Virgin Mary. At the reformation James Douglas was appointed commendator, who took down much of the building, in order to furnish materials for a large house to himself, which still remains, and is dated 1590. Nothing is left of the abbey excepting a part of the cloister walls elegantly carved; but the ruins of the church are of most uncommon beauty. Part is at present used for divine service, the rest uncovered; but every part does great honour to the architect.—Alexander II. was buried beneath the great altar, and it is also the place of interment of the Douglases and other potent families.—Its situation is extremely pleasant.

MELT OF FISHES. In the melt of a living cod there are such numbers of those animalcules said to be found in the semen of all male animals, that in a drop of its juice no larger than a grain of sand, there are contained more than 10,000 of them; and considering how many such quantities there are in the whole melt of one such fish, it is not incredible, that there are more animals in one melt of it than there are living men at one time upon the face of the earth. However strange and romantic such a conjecture must appear, a serious consideration and calculation will make it appear very plain. An hundred such grains of sand as those just mentioned will make about an inch in length; therefore in a cubic inch there will be a million of such sands; and if there be 10,000 animals in each of those quantities, there must be in the whole 150,000 millions, which is a number vastly exceeding that of mankind, even supposing the whole as populous as Holland.

MELTING CONE, in essaying, an hollow cone of brass or cast iron, into which melted metalline substances are thrown, in order to free them from their scoriæ. When a small quantity of matter is melted, it will be sufficient to rub the inside of the cone with grease; but when the quantity is very large, especially if it contains any thing sulphureous, this caution of tallowing the moulds is not sufficient. In this case the essayer has recourse to a lute reduced to thin pap with water, which effectually prevents any injury to the cone.

MELTON-MOUBRAY, a town of Leicestershire, 108 miles from London. It is a large built place, in a fertile soil; with a market on Tuesday, the most considerable for cattle of any in this part of the island. It is almost encompassed with a little river called the *Eye*, over which it has two fine bridges; and has a large handsome church, with a free school. Here are frequent horse-races, and three fairs in the year.

MELVIL (Sir James), descended from an honourable Scots family, being the third son of the laird of Kaeth, was born about the middle of the 16th century. He went to France very young, in the capacity of page to Queen Mary, then married to the dauphin; and on the death of her husband, followed her to Scotland, where he was made gentleman of her chamber, and admitted a privy-counsellor. She employed him in her most important concerns, till her unhappy confinement in Lochleven, all which he discharged with the utmost fidelity; and, from his own accounts, there is reason to conclude, that, had she taken his advice, she might have avoided many of her misfortunes. When she was prisoner in England, she recommended him strongly to her son James; with whom he continued in favour and employment until the death of Queen Elizabeth: James would then have taken him to England; but Melvil, now grown old, was desirous of retiring from business, and in his retirement he drew up the memoirs of his past life for the use of his son. These Memoirs were accidentally found in Edinburgh castle in the year 1660, though nobody knew how they came to be deposited there; and were published in folio in 1683.

MEMBERS, in anatomy, the exterior parts, arising from the trunk or body of an animal, like the boughs from the trunk of a tree.

MEMBER, in architecture, denotes any part of a building; as a frieze, cornice, or the like.

MEMBER is sometimes also used for moulding.

MEMBER, in grammar, is applied to the parts of a period or sentence.

MEMBER, is also used to denote some particular order or rank in a state or government: thus we say, "member of a corporation, member of parliament, member of the council," &c.

MEMBRANE, MEMBRANA, in anatomy, a similar part of an animal body; being a thin, white, flexible, expanded skin, formed of several sorts of fibres interwoven together, and serving to cover or wrap up certain parts of the body. See ANATOMY *passim*.

MEMEL, or MEMMEL; a town of Prussia, situated on the northern extremity of the Curische Haf, an inlet of the sea about 70 miles in length, which is here joined to the Baltic by a narrow strait.—It is an ill-built town, with narrow dirty streets; but remarkable for its extensive commerce, being provided with the finest harbour in the Baltic. In 1784, 996 ships, amongst which were 500 English, arrived here. The imports chiefly are, salt, iron, and salted herrings; the exports, which greatly exceed the imports, are amber, corn, hemp, flax, and particularly timber. An English consul resides here. The trade is daily increasing, on account of the high duties which the court of Russia has laid on the imports of Riga

MEMNON (fab. hist.), a king of Ethiopia, son of Tithonus and Aurora. He came with a body of 10,000 men to assist his uncle Priam, during the Trojan war. He behaved with great courage, and killed Antilochus, Nestor's son. The aged father challenged the Ethiopian monarch; but Memnon refused it on account of the venerable age of Nestor, and accepted that of Achilles. He was killed in the combat, in the sight of the Grecian and Trojan armies. Aurora prayed Jupiter to grant her son such honours as might distinguish him from other mortals. The god consented; and immediately a numerous flight of birds issued from the burning pile on which the body was laid, and dividing themselves into two separate bodies, fought with such fury, that above half of them fell down in the fire as victims to appease the manes of Memnon.

These birds were called *Memnonides*; and it has been observed by some of the ancients, that they never failed to return yearly to the tomb of Memnon in Troas, and repeat the same bloody engagement in honour of the hero from whom they received their name. The Ethiopians or Egyptians, over whom Memnon reigned, erected a celebrated statue to the honour of their monarch. This statue had the wonderful property of uttering a melodious sound every day at sunrising like that which was heard at the breaking of the string of a harp when it is wound up. This was effected by the rays of the sun when they fell upon it. At the setting of the sun, and in the night, the sound was lugubrious. This is supported by the testimony of the geographer Strabo, who confesses himself ignorant whether it proceeded from the basis of the statue, or the people that were then around it. This celebrated statue was dismantled by order of Cambyses when he conquered Egypt; and its ruins still astonish modern travellers by their grandeur and beauty.

Memnon of Rhodes, one of the generals of Darius king of Persia, advised that prince to lay waste the country, in order to deprive Alexander the Great's army of support, and afterwards to attack Macedon; but this counsel was disapproved by Darius's other generals. Memnon behaved at the passage of the Granicus like an experienced general. He afterwards defended the city of Miletum with great courage; seized the islands of Chio and Lesbos; spread terror throughout all Greece; and would have put a stop to the conquests of Alexander, if he had not been prevented by death. Barsina, Memnon's widow, was taken prisoner with Darius's wife, and Alexander had a son by her named *Hercules*.

MEMOIRS, in matters of literature, a species of history, written by persons who had some share in the transactions they relate; answering to what the Romans called *Commentarii*. The journals of the proceedings of a literary society, or a collection of matters transacted therein, are likewise called *Memoirs*.

MEMORY, a faculty of the mind, which presents to us ideas or notions of what is past, accompanied with a persuasion that the things themselves were formerly real and present. What we distinctly remember to have perceived, we as firmly believe to have happened, as what is now present to our senses.

The opinions of philosophers concerning the means by which the mind retains the ideas of past objects, and how those ideas carry with them evidence of their objects having been actually perceived, shall be laid before our readers in another place: (see METAPHYSICS, Part I. chap ii.) At present we shall throw together some observations on the Memory, which, being of a practical rather than of a speculative nature, cannot be admitted into the article where the nature of the faculty itself is discussed.

"When we remember with little or no effort, it is called *remembrance* simply, or *memory*, and sometimes *passive memory* *. When we endeavour to remember what does not immediately and (as it were) of itself occur, it is called *active memory*, or *recollection*. A ready recollection of our knowledge, at the moment when we have occasion for it, is a talent of the greatest importance. The man possessed of it seldom fails to distinguish himself in whatever sort of business he may be engaged." It is indeed evident, that when the power of retention is weak, all attempts at eminence of knowledge must be vain; for "memory is the primary and fundamental power †, without which there could be no other intellectual operation. Judgment and ratiocination suppose something already known, and draw their decisions only from experience. Imagination selects ideas from the treasures of remembrance, and produces novelty only by varied combinations. We do not even form conjectures of distant, or anticipations of future, events, but by concluding what is possible from what is past."

Of a faculty so important, many rules have been given for the regulation and improvement; of which the first is, that he who wishes to have a clear and distinct remembrance, should be temperate with respect to eating, drinking, and sleep. The memory depends very much upon the state of the brain; and therefore whatever is hurtful to the latter, must be prejudicial to the former. Too much sleep clouds the brain, and too little overheats it; therefore either of these extremes must of course hurt the memory, and ought carefully to be avoided. Intemperance of all kinds, and excess of passion, have the same ill effects; so that we rarely meet with an intemperate person whose memory is at once clear and tenacious.

"The liveliest remembrance is not so vivid as the sensation that produced it ‡; and ideas of memory do often, but not always, decay more and more, as the original sensation becomes more and more remote in time. Those sensations and those thoughts have a chance to be long remembered which are lively at first; and those are likely to be most lively which are most attended to, or which are accompanied with pleasure or pain, with wonder, surprise, curiosity, merriment, and other lively passions. The art of memory, therefore, is little more than the art of attention. What we wish to remember we should attend to, so as to understand it perfectly, fixing our view particularly upon its importance or singular nature, that it may raise within us some of the passions above-mentioned. We should also disengage our minds from all other things, that we may attend more effectually to the object which we wish to remember. No man will read with much advantage who is not able at pleasure to evacuate his mind, or who brings not to his author an intellect defecated and pure, neither turbid with care, nor agitated with pleasure. If the repositories of thought are already full, what can they receive? If the mind is employed on the past or the future, the book will be held before the eyes in vain.

"It is the practice of many readers, to note in the margin of their books the most important passages *, the strongest arguments, or the brightest sentiments. Thus they load their minds with superfluous attention, repress the vehemence of curiosity by useless deliberation, and by frequent interruption break the current of narration or the chain of reason, and at last close the volume and forget the passages and the marks together. Others are firmly persuaded, that nothing is certainly remembered but what is transcribed; and they, therefore, pass weeks and months in transferring large quotations to a common place-book. Yet, why any part of a book which can be consulted

Memory.

Memory. confulted at pleafure fhould be copied, we are not able to difcover. The hand has no clofer correfpondence with the memory than the eye. The act of writing itfelf diftracts the thoughts; and what is read twice, is commonly better remembered than what is tranfcribed. This method, therefore, confumes time, without affifting the memory. But to write an abridgement of a good book may fometimes be a very profitable exercife. In general, when we would preferve the doctrines, fentiments, or facts, that occur in reading, it will be prudent to lay the book afide, and put them in writing in our own words. This practice will give accuracy to our knowledge, accuftom us to recollection, improve us in the ufe of language, and enable us fo thoroughly to comprehend the thoughts of other men, as to make them in fome meafure our own."

"Our thoughts have for the moft part a connection *; fo that the thought which is juft now in the mind, depends partly upon that which went before, and partly ferves to introduce that which follows. Hence we remember beft thofe things of which the parts are methodically difpofed and mutually connected. A regular difcourfe makes a more lafting impreffion upon the hearer than a parcel of detached fentences, and gives to his rational powers a more falutary exercife: and this may fhow us the propriety of conducting our ftudies, and all our affairs, according to a regular plan or method. When this is not done, our thoughts and our bufinefs, efpecially if in any degree complex, foon run into confufion."

* *Idler.*

As the mind is not at all times equally difpofed for the exercife of this faculty, fuch feafons fhould be made choice of as are moft proper for it. The mind is feldom fit for attention prefently after meals; and to call off the fpirits at fuch times from their proper employment in digeftion, is apt to cloud the brain, and prejudice the health. Both the mind and body fhould be eafy and undifturbed when we engage in this exercife, and therefore retirement is moft fit for it: and the evening, juft before we go to reft, is generally recommended as a very convenient feafon, both for the ftillnefs of the night, and becaufe the impreffions will then have a longer time to fettle before they come to be difturbed by the acceffion of others proceeding from external objects; and to call over in the morning what has been committed to the memory over-night, muft, for the fame reafon, be very ferviceable. For, to review thofe ideas while they continue frefh upon the mind, and unmixed with any others, muft neceffarily imprint them more deeply.

Some ancient writers fpeak of an artificial memory, and lay down rules for attaining it. Simonides the poet is faid firft to have difcovered this, or at leaft to have given the occafion for it. The ftory they tell of him is this: Being once at a feaft, he recited a poem which he had made in honour of the perfon who gave the entertainment. But having (as is ufual in poetry) made a large digreffion in praife of Caftor and Pollux; when he had repeated the whole poem, his patron would give him but half the fum he had promifed, telling him he muft get the other part from thofe deities who had an equal fhare in the honour of his performance. Immediately after, Simonides was told that two young men were without, and muft needs fpeak with him. He had fcarce got out of the houfe, when the room where the company was fell down, killed all the perfons in it, and fo marfhed the bodies, that, when the rubbifh was thrown off, they could not be known one from another: upon which Simonides recollecting the place where every one had fat, by that means diftinguifhed them. Hence it came to be obferved, that to fix a number of places in the mind in a certain order, was a help to the memory: As we find by experience, that, upon returning to places once familiar to us, we not only remember them, but likewife many things we both faid and did in them. This action therefore of Simonides was afterward improved into an art; and the nature of it is this: They bid you form in your mind the idea of fome large place or building, which you may divide into a great number of diftinct parts, ranged and difpofed in a certain order. Thefe you are frequently to revolve in your thoughts, till you are able to run them over one after another without hefitation, beginning at any part. Then you are to imprefs upon your mind as many images of living creatures, or any other fenfible objects which are moft likely to affect you, and be fooneft revived in your memory. Thefe, like characters in fhort-hand, or hieroglyphics, muft ftand to denote an equal number of other words, which cannot fo eafily be remembered. When therefore you have a number of things to commit to memory in a certain order, all that you have to do is, to place thefe images regularly in the feveral parts of your building. And thus they tell you, that, by going over feveral parts of the building, the images placed in them will be revived in the mind; which of courfe will give you the things or words themfelves in the order you defire to remember them. The advantage of the images feems to be this; that, as they are more like to affect the imagination than the words for which they ftand, they will for that reafon be more eafily remembered. Thus, for inftance, if the image of a *lion* be made to fignify *ftrength*, and this word *ftrength* be one of thofe I am to remember, and is placed in the porch; when, in going over the feveral parts of the building, I come to the porch, I fhall fooner be reminded of that image than of the word *ftrength*. Of this artificial memory, both Cicero and Quintilian fpeak; but we know not of any modern orator that has ever made ufe of it. It feems indeed to have been a laborious way of improving the memory, if it ferves that end at all, and fitter for affifting us to remember any number of unconnected words than a continual difcourfe, unlefs fo far as the remembrance of one word may enable us to recollect more. It is, however, in allufion to it, that we ftill call the parts of a difcourfe *places* or *topics*, and fay, *in the firft place*, *in the fecond place*, &c.

But, doubtlefs, the moft effectual way to gain a good memory, is by conftant and moderate exercife of it; for the memory, like other habits, is ftrengthened and improved by daily ufe. It is indeed hardly credible, to what a degree both active and paffive remembrance may be improved by long practice. *Scaliger* reports of himfelf, that in his youth he could repeat

Memory, Memphis. peat above 100 verses, having once read them; and *Berthicus* declares, that he wrote his *Comment upon Claudian* without consulting the text. To hope, however, for such degrees of memory as these, would be equally vain as to hope for the strength of *Hercules*, or the swiftness of *Achilles*. "But there are clergymen who can get a sermon by heart § in two hours, though their memory, when they began to exercise it, was rather weak than strong: And pleaders, with other orators who speak in public and *extempore*, often discover, in calling instantly to mind all the knowledge necessary on the present occasion, and every thing of importance that may have been advanced in the course of a long debate, such powers of retention and recollection as, to the man who has never been obliged to exert himself in the same manner, are altogether astonishing. As habits, in order to be strong, must be formed in early life, the memories of children should therefore be constantly exercised; but to oblige them to commit to memory what they do not understand, perverts their faculties, and gives them a dislike to learning." In a word, those who have most occasion for memory, as orators and public speakers, should not suffer it to lie idle, but constantly employ it in treasuring up and frequently reviving such things as may be of most importance to them; for by these means, it will be more at their command, and they may place greater confidence in it upon any emergency."

§ Idler.

"Men complain of nothing more frequently than of deficient memory ‡: and indeed every one finds, that after all his efforts many of the ideas which he desired to retain have slipped irretrievably away; that acquisitions of the mind are sometimes equally fugitive with the gifts of fortune; and that a short intermission of attention more certainly lessens knowledge than impairs an estate. To assist this weakness of our nature, many methods besides those which we have mentioned have been proposed; all of which may be justly suspected of being ineffectual: for no art of memory, however its effects may have been boasted or admired, has been ever adopted into general use; nor have those who possessed it appeared to excel others in readiness of recollection or multiplicity of attainments." The reader who is desirous to try the effect of those helps, may have recourse to a treatise entitled *A new Method of Artificial Memory*; but the true method of memory is attention and exercise.

‡ Elements of Moral Science.

MEMPHIS, an ancient city, and the royal residence of the kings in the Higher Egypt; distant from the Delta to the south 15 miles, according to Pliny. Called also *Moph* and *Noph*, in scripture.

Though this city is now so completely ruined, that authors greatly disagree concerning its situation; yet Strabo informs that in his time it was the most magnificent in Egypt, next to Alexandria. It was called the capital of the country; and there was an entire temple of Osiris, where the Apis or sacred ox was kept and worshipped. In the same place was an apartment of the mother of the ox; a very magnificent temple of Vulcan; a large Circus or space for fighting bulls; and a great Colossus in the middle of the city, which was thrown down. There was likewise a temple of Venus, and a Serapium in a very sandy place, where the wind heaps up hills of sand very dangerous to travellers; together with a number of Sphinxes, the heads of some of them only being visible, the others covered up to the middle of their body. The same author likewise informs us, that in the front of the city there were many lakes; and that it contained a number of palaces, at that time in ruins. These buildings, he said, formerly stood upon an eminence: they lay along the side of the hill, stretching down to the lakes and groves, 40 stadia from the city. There was likewise a mountain in the neighbourhood, on which were a great number of pyramids, with the sepulchres of the kings, among which were three remarkable, and two of them accounted wonders of the world. From this description, Mr Bruce concludes that the celebrated capital of Egypt stood in the place where the villages of Metrahenny are now situated; in opposition to Dr Shaw's opinion, who thinks it was situated at Geeza or Gisa.

M Savary has also shown, that Gisa was not the situation of the ancient Memphis. This stood, he says, on the western bank of the Nile, on the spot where the village of Memph now stands, which still preserves the name. Large heaps of rubbish are still to be seen there; but the Arabs have transported to Cairo the columns and remarkable stones, which they have disposed, without taste and without order, in their mosques and public buildings. This city extended as far as Saccara; and was almost wholly encompassed by lakes, part of which are still subsisting. It was necessary to cross them to convey the dead to the sepulchre of their fathers. The tombs, hewn out of the rock, were closed up with stones of a proportionable size, and covered with sand. These bodies, embalmed with so much care, preserved with so much respect, are torn from the monuments they repose in, and sold without decency to strangers by the inhabitants of Saccara. This place is called *the plain of mummies*. There too we find *the well of the birds*, into which one descends by means of a rope. It leads to subterraneous galleries, filled with earthen vases, containing the sacred birds. They are rarely met with entire, because the Arabs break them in hopes of finding idols of gold. They do not conduct travellers into the places where they have found more precious articles. They even close them up carefully, reserving to themselves some secret passages by which they descend. In a journey into Egypt made by the duke de Chaulnes, he advanced very far into these winding labyrinths, sometimes crawling, and sometimes scrambling, on his knees. Informed by Mr Edward Wortley Montague, who has carefully visited Egypt, he arrived at one of those passages which had an opening shut up from without by branches of the date-tree interwoven, and covered with sand. He remarked there some hieroglyphics *in relievo*, executed in the highest perfection. But the Arabs resisted every offer he made them to permit him to take drawings of them, or to mold them, in order to preserve their form. The duke de Chaulnes is of opinion that these hieroglyphics, sculptured with so much art that the objects they represent may be discovered at the first sight, might possibly furnish the key of the others, whose contours are simply expressed, and form a sort of alphabet of this unintelligible language. Several pyramids are distinguishable

guishable along the mountains which bound Saccara on the west, the greatest part of which appear as lofty as those of Gisa. See PYRAMIDS.

MENAGE (Fr.), denotes a collection of animals; whence we have derived the word *menagery*.

MENAGE (Giles), in Latin *Ægidius*, a celebrated French writer, born at Angers in 1613. He finished his studies in that city, was made advocate, and pleaded for some time at Angers, Paris, and Poictiers; but, becoming at length disgusted with the bar, turned ecclesiastic, and gave himself up entirely to the study of polite literature. He at length entered into the family of the cardinal de Retz; but disagreeing with some persons belonging to his Eminence, went to live in the cloyster of Notre Dame, where he held an assembly of learned men every Wednesday. He read a great deal; had a prodigious memory; and was incessantly quoting in his conversation verses in Greek, Latin, Italian, French, &c. on which account he was often turned into ridicule by the wits, especially towards the end of his days. His great memory he retained even in his old age; and what is very rare, it returned to him after some interruption. The reputation of his works procured him a place in the academy *della Crusca* at Florence He might have been a member of the French academy at its first institution, if it had not been for his *Requeste des Dictionnaires*: but when that was forgot, he was proposed in 1684 to fill up a vacant place in that academy, and was excluded only by the superior interest of his competitor Mr Bergent; for there was not one member of all those who gave their votes against them, but owned that he deserved the place. He would not suffer his friends to propose him again. He died at Paris in 1692, aged 79. He wrote a great number of books in prose and verse; the principal of which are, 1. Miscellaneous works. 2. The Origin of the French Language. 3. The Origin of the Italian Tongue; the best edition of which is that of Geneva, in 1685, folio. 4. An edition of Malherbe's Poems, with Notes. 5. An edition of Diogenes Laertius, with Observations. 6 Remarks on the French Tongue. 7. Greek, Latin, Italian, and French Poems.

MENANDER, an ancient Greek poet, was born at Athens in the same year with Epicurus, which was the third of the 109th Olympiad. His happiness in introducing the new comedy, and refining an art which had been so gross and licentious in former times, quickly spread his name over the world. Pliny informs us, that the kings of Egypt and Macedon gave a noble testimony of his merit, by sending ambassadors to invite him to their courts, and even fleets to bring him over; but that Menander was so much of a philosopher, as to prefer the free enjoyment of his studies to the promised favours of the great. Of his works, which amounted to above 100 comedies, we have had a double loss, the originals being not only vanished, but the greatest part of them, when copied by Terence, having unfortunately perished by shipwreck before they saw Rome. Yet the four plays which Terence borrowed from him before that accident happened, are still preserved in the Roman habit; and it is chiefly from Terence that most people form their judgment of Menander, the fragments that remain of him not being sufficient to enable them to do it. The ancients have said high things of Menander; and we find the old masters of rhetoric recommending his works as the true patterns of every beauty and every grace of public speaking. Quintilian declares, that a careful imitation of Menander only, will satisfy all the rules he has laid down in his Institutions. It is in Menander that he would have his orator search for a copiousness of invention, for a happy elegance of expression, and especially for that universal genius which is able to accommodate itself to persons, things, and affections.— But Julius Cesar has left the loftiest as well as the justest praise of Menander's works, when he calls Terence only a *Half-Menander*. For while the virtues of the Latin poet are so deservedly admired, it is impossible we should raise a higher notion of excellency than to conceive the great original still shining with half its lustre unreflected, and preserving an equal part of its graces, above the power of the best copier in the world. Menander died in the 3d year of the 122d Olympiad, as we are taught by the same old inscription from which we learn the time of his birth. His tomb, in Pausanias's age, was to be seen at Athens, in the way from the Piræus to the city, close by the honorary monument of Euripides. Quintilian, in his judgement of Afranius the Roman comedian, who imitated him, censures Menander's morals as much as he commends his writings; and his character, according to Suidas, is, that he was a very "mad fellow after women." Phædrus has given him the gait and dress of a most affected fop:

> "Unguento delibutus, vestitu adfluens,
> "Veniebat gressu delicatulo & languido."
>
> *Lib.* v. fab. 2.

MENANDRIANS, the most ancient branch of Gnostics; thus called from Menander their chief, said by some, without sufficient foundation, to have been a disciple of Simon Magus, and himself a reputed magician.

He taught, that no person could be saved, unless he were baptised in his name: and he conferred a peculiar sort of baptism, which would render those who received it immortal in the next world: exhibiting himself to the world, with the phrensy of a lunatic more than the founder of a sect, as a promised saviour. For it appears by the testimonies of Irenæus, Justin, and Tertullian, that he pretended to be one of the Æons sent from the pleroma, or ecclesiastical regions, to succour the souls that lay groaning under bodily oppression and servitude; and to maintain them against the violence and stratagems of the dæmons that hold the reins of empire in this sublunary world. As this doctrine was built upon the same foundation with that of Simon Magus, the ancient writers looked upon him as the instructor of *Menander*. See SIMONIANS.

MENASSEH (Ben Israel), a celebrated rabbi, born in Portugal about the year 1604, was the son of Joseph Ben Israel, and followed his father into Holland. Here he was educated by rabbi Isaac Uziel, under whom he in a short time made such progress in the Hebrew tongue, that at 18 years of age he succeeded him in the synagogue of Amsterdam. In this post he continued several years, and married Rachel of the

the family of the Abarbanels, whom the Jews imagine to be descended from king David. He afterwards went to his brother Ephraim, a rich merchant, who had settled at Basil; by whose advice he entered into trade. Some time after, the hopes of a more agreeable settlement induced him to come into England, under the protectorship of Cromwell; who gave him a very favourable reception, and one day entertained him at his table with several other learned divines. However, he soon after passed into Zealand; and died at Middleburg about the year 1657. The Jews at Amsterdam obtained his body, and interred it at their expence. He was of the sect of the Pharisees; had a lively wit, a solid judgement, great learning, and all the virtues that can adorn private life. He wrote many works in Hebrew, Latin, Spanish, and English. The principal of those published in Latin, are, 1. His *Conciliator*; a learned and curious work, in which he reconciles those passages of Scripture which seem to contradict each other. 2. *De resurrectione mortuorum*. 3. *De termino vitæ*. 4. *Dissertatio de fragilitate humana, ex lapsu Adami, deque Divino in bono opere auxilio*. 5. *Spes Israel*. Dr Thomas Pococke has written his life in English.

MENCKE (Lewis Otto), in Latin *Menckenius*, a learned professor of morality at Leipsic, was born at Oldenburg in Westphalia in 1644. He studied in several universities of Germany; and became an able philosopher, civilian, and divine. He was made professor of morality at Leipsic in 1668; and enjoyed that post to his death. He was five times rector of the university of that city, and seven times dean of the faculty of philosophy. He published several works; but his most considerable, and what alone is sufficient to perpetuate his memory, is the *Acta Eruditorum* of Leipsic, of which he was the first author, and in which he was engaged till his death. The first volume was published at Leipsic, in 4to, in 1682.

Mencke (John Burchard), son to the preceding. After his studies he travelled into England and Holland; and upon his return was appointed professor of history at Leipsic in 1699. He gained great reputation by his lectures as well as his writings. He died in 1732, aged 58. He wrote many pieces. His *De Charlataneria eruditorum declamationes duæ*, is an excellent satire, designed to expose the artifices used by false scholars to raise themselves a name. As he named and pointed at certain persons, it exasperated them, and they procured his book to be seized; but it spread, and editions of it were multiplied. He likewise published *Methodé pour etudier l'Histoire, avec un catalogue des principaux historiens*, &c. He made a great many additions to Mr Lenglet's book, especially with regard to the German historians.

MENDELSHON (Moses), that is, *Moses the son of Mendel*, a Jew of Berlin, and one of the most celebrated writers in Germany, died there in the year 1785 at the age of 57. His first attempt as an author was in 1755, by a work intitled *Jerusalem*; in which, besides other bold and unjustifiable opinions, he maintains, that the Jews have a revealed law but not a revealed religion; that opinions are not subjects of revelation; and that the only religion of the Jewish nation is that of nature. He acquired great honour by his *Phedon*, or "Discourse on the Immateriality and Immortality of the Soul," translated into French 1773, 8vo; in which he unfolds this important truth, the great foundation of all morality, with the wisdom of an enlightened philosopher and the charms of an elegant writer. In consequence of this excellent work, he was styled the *Jewish Socrates* by some of the periodical writers; but he wanted the firmness and courage of the Grecian philosopher. His timidity, and even pusillanimity, defects too common in speculative men, prevented him from being of any essential service to his nation; of which he might have become the benefactor by being the reformer. The pliancy of his character, his soft, modest, and obliging disposition, gained him the esteem alike of the superstitious and of the incredulous. After all, he could never procure admission to the Berlin society, or to the conversation of the king of Prussia. At his death he received from his nation those honours which are commonly paid to their first rabbins. Contrary to an imprudnt custom prevalent among the Jews of burying their dead before sunset, his interment was delayed till 24 hours after he expired. Though Mendelshon was descended from a respectable family, he was very poor. In early life he entered into a counting-house of his own nation, wherein he greatly recommended himself by his capacity and integrity in business: But philosophy and literature soon became his principal occupation; and to the famous Lessing he was indebted for counsels which, without diverting his attention from those pursuits that were necessary to his subsistence, accelerated his progress in his literary career. Even after the death of his benefactor, Mendelshon retained for him the sincerest regard and the most lively gratitude. Notwithstanding the very strict regimen which he observed, he survived him only a few years; for his feeble frame and weak constitution were gradually and insensibly undermined by intense application to study.

MENDEZ Pinto (Ferdinand), was born at Montemor-o-velho in Portugal, and was at first servant to a Portuguese gentleman. In expectation of making a fortune, he embarked for India in 1537. His vessel being taken by the Turks on his passage, he was carried to Mocka, and sold to a Greek renegado, and afterwards to a Jew, in whose possession he continued till he was redeemed by the governor of Ormus, a Portuguese fort. The governor procured him an opportunity of going out to India, agreeable to his first design. During a residence of twenty-one years in that country, he was witness to very important transactions, and experienced many singular adventures. He returned to Portugal in 1558, where he enjoyed the reward of his labours, after having been thirteen times a slave and sixteen times sold. A very curious account of his travels was written by himself, and published at Lisbon, A. D. 1614, in folio. This work was translated into French by Bernard Figuier, a Portuguese gentleman, and printed at Paris 1645, in 4to. It is written in a very interesting manner, and in a style more elegant than might have been expected from a man whose whole life was spent in the camp and in slavery. It elucidates a great variety of particulars relating to the geography, history, and manners of the inhabitants of China, Japan, Pegu, Siam, Achem, Java, &c. Many of his facts appeared fabulous, but their truth has been since ascertained.

Mendicants.

M. de Surgi compiled an interefting hiftory from the moft fingular facts in Mendez Pinto's relation, which he publifhed in the *Viciffitudes de la Fortune*, Paris, 2 vols, 8vo.

MENDICANTS, or BEGGING FRIARS, feveral orders of religious in Popifh countries, who having no fettled revenues, are fupported by the charitable contributions they receive from others.

This fort of fociety began in the 13th century; and the members of it, by the tenor of their inftitution, were to remain entirely deftitute of all fixed revenues and poffeffions; though in procefs of time their number became a heavy tax upon the people. Innocent III. was the firft of the popes who perceived the neceffity of inftituting fuch an order; and accordingly he gave fuch monaftic focieties, as made a profeffion of poverty, the moft diftinguifhing marks of his protection and favour. They were alfo encouraged and patronized by the fucceeding pontiffs, when experience had demonftrated their public and extenfive ufefulnefs. But when it became generally known, that they had fuch a peculiar place in the efteem and protection of the rulers of the church, their number grew to fuch an enormous and unwieldy multitude, and fwarmed fo prodigioufly in all the European provinces, that they became a burden, not only to the people, but to the church itfelf. The great inconvenience that arofe from the exceffive multiplication of the mendicant orders was remedied by Gregory X. in a general council, which he affembled at Lyons in 1272. For here all the religious orders that had fprung up after the council held at Rome in 1215, under the potificate of Innocent III. were fuppreffed; and the extravagant multitude of mendicants, as Gregory called them, were reduced to a fmaller number, and confined to the four following focieties or denominations, viz. the DOMINICANS, the FRANCISCANS, the CARMELITES, and the AUGUSTINS or hermits of St Auguftin.

As the pontiffs allowed thefe four mendicant orders the liberty of travelling wherever they thought proper, of converfing with perfons of every rank, of inftructing the youth and multitude wherever they went; and as thofe monks exhibited, in their outward appearance and manner of life, more ftriking marks of gravity and holinefs than were obfervable in the other monaftic focieties, they arofe all at once to the very fummit of fame, and were regarded with the utmoft efteem and veneration through all the countries of Europe. The enthufiaftic attachment to thefe fanctimonious beggars went fo far, that, as we learn from the moft authentic records, feveral cities were divided or cantoned out into four parts, with a view to thefe four orders; the firft part being affigned to the Dominicans, the fecond to the Francifcans, the third to the Carmelites, and the fourth to the Auguftinians. The people were unwilling to receive the facraments from any other hands than thofe of the mendicants, to whofe churches they crowded to perform their devotions, while living, and were extremely defirous to depofit there alfo their remains after death: nor did the influence and credit of the mendicants end here; for we find in the hiftory of this and of the fucceeding ages, that they were employed, not only in fpiritual matters, but alfo in temporal and political affairs of the greateft confequence, in compofing the differences of princes, concluding treaties of peace, concerting alliances, prefiding in cabinet councils, governing courts, levying taxes, and other occupations, not only remote from, but abfolutely inconfiftent with, the monaftic character and profeffion. However the power of the dominicans and Francifcans greatly furpaffed that of the other two orders: infomuch that thefe two orders were, before the reformation, what the Jefuits have been fince that happy and glorious period, the very foul of the hierarchy, the engines of the ftate, the fecret fprings of all the motions of the one and the other, and the authors and directors of every great and important event, both in the religious and political world. By very quick progreffion their pride and confidence arrived at fuch a pitch, that they had the prefumption to declare publicly, that they had a divine impulfe and commiffion to illuftrate and maintain the religion of Jefus; they treated with the utmoft infolence and contempt all the different orders of the prielthood; they affirmed without a blufh, that the true method of obtaining falvation was revealed to them alone; proclaimed, with oftentation, the fuperior efficacy and virtue of their indulgencies; and vaunted beyond meafure their intereft at the court of heaven, and their familiar connections with the Supreme Being, the Virgin Mary, and the faints in glory. By thefe impious wiles, they fo deluded and captivated the miferable, and blinded the multitude, that they would not intruft any other but the mendicants with the care of their fouls. They retained their credit and influence to fuch a degree, towards the clofe of the 14th century, that great numbers of both fexes, fome in health, others in a ftate of infirmity, and others at the point of death, earneftly defired to be admitted into the Mendicant order, which they looked upon as a fure and infallible method of rendering heaven propitious. Many made it an effential part of their laft wills, that their bodies after death fhould be wrapped in old ragged Dominican or Francifcan habits, and interred among the Mendicants. For fuch was the barbarous fuperftition and wretched ignorance of this age, that people univerfally believed they fhould readily obtain mercy from Chrift, at the day of judgment, if they appeared before his tribunal affociated with the Mendicant friars.

About this time, however, they fell under an univerfal odium; but being refolutely protected againft all oppofition, whether open or fecret, by the popes, who regarded them as their beft friends and moft effectual fupports, they fuffered little or nothing from the efforts of their numerous adverfaries. In the 15th century, befides their arrogance, which was exceffive, a quarrelfome and litigious fpirit prevailed among them, and drew upon them juftly the difpleafure and indignation of many. By affording refuge at this time to the Beguins in their order, they became offenfive to the bifhops, and were hereby involved in difficulties and perplexities of various kinds. They loft their credit in the 16th century by their ruftic impudence, their ridiculous fuperftitions, their ignorance, cruelty, and brutifh manners. They difcovered the moft barbarous averfion to the arts and fciences, and expreffed a like abhorrence of certain eminent and learned men, who endeavoured to open the paths of science to the pursuits of the studious youth, recommended the culture of the mind, and attacked the barbarism of the age in their writings and discourse. Their general character, together with other circumstances, concurred to render a reformation desirable, and to accomplish this happy event.

Among the number of Mendicants are also ranked the Capuchins, Recollects, Minims, and others, who are branches or derivations from the former.

Buchannan tells us, the Mendicants in Scotland, under an appearance of beggary, lived a very luxurious life; whence one wittily called them, not *Mendicant*, but *Manducant* friars.

MENDOZA (Juan Gonzales de), an Augustan friar, of the province of Castile, was made ambassador from the king of Spain to the emperor of China. In 1593, he was made bishop of Liperi in Italy. In 1607 he was made bishop of Chiapa in New Spain, and the next year was removed to the see of Papaian in the West Indies. He wrote a history of China in Spanish, which has been translated into several languages.

MENE, a Chaldæan word, which signifies "he has numbered or counted;" being one of the three words that was written upon the wall by the hand that appeared to Belshazzar, the last king of Babylon, the night that he was put to death. See BELSHAZZAR.

MENECRATES, a physician of Syracuse, who flourished about 360 B. C. is famous for his skill in his profession, but much more for his vanity. He would always be followed by some of the patients he had cured, and with whom he previously stipulated that they should follow him wherever he went. One appeared with the attributes of Hercules, another with those of Apollo, and others again with those of Mercury or Æsculapius; while he, clad in a purple robe, with a golden crown on his head, and a sceptre in his hand, presented himself, to the admiration of the public, under the name of *Jupiter*, and travelled through different countries escorted by these counterfeit deities. He once wrote the following letter to the king of Macedon: Menecrates-Jupiter to Philip, greeting. Thou reignest in Macedonia, and I in medicine; thou givest death to those who are in good health, I restore life to the sick; thy guard is composed of Macedonians; the gods themselves constitute mine." Philip answered him in a word, that he wished him restored to reason. Learning some time after that he was in Macedon, Philip sent for him, and invited him to an entertainment. Menecrates and his companions were placed on rich and lofty couches; before which was an altar, covered with the first fruits of the harvest; and whilst an excellent repast was served up to the other guests, perfumes and libations only were offered to these new gods, who, unable to endure the affront, hastily left the palace, in which they never more made their appearance.

MENEDEMUS, a Greek philosopher, born at Erythreum, was the son of Calisthenes, and one of Phedo's followers. He was in greatest esteem, and enjoyed several important posts, in his own country. He several times defended Erythreum with great bravery, and died of grief when Antigonus became master of it. A person one day saying to him, "It is a great happiness to have what we desire," he replied, "It is a much greater to desire nothing but what we have." He flourished about 300 B. C.

MENELAUS, the son of Atreus, and the brother of Agamemnon, reigned at Sparta, when Paris deprived him of his wife Helen. This rape occasioned the famous war of Troy. See HELEN.

MENELAUS, a mathematician in the reign of the emperor Trajan, wrote three books on the *Sphere*, which have been published by father Marsenne.

MENES, born at This, a town of Thebais in Upper Egypt, was the founder of the Egyptian empire. He had three sons, viz. Athotis, who ruled after him at This and Thebes; Curudes, who in Lower Egypt founded the kingdom of Heliopoli, which afterward was the kingdom of Diospoli; and Necherophes, who reigned at Memphis. It is thought this Menes reigned 117 years after the birth of Pholeg, son of Heber, which was the very year of the dispersion of the people throughout the whole earth. In building Memphis, he stopped the Nile near it, by the invention of a causeway 100 furlongs broad, and caused it to run through the mountains.

MENESTRIER (John Baptist le), a native of Dijon, and one of the most learned and curious French antiquaries of his time, wrote, 1. A Treatise on the Medals, Money, and Ancient Monuments, of the Roman Empresses, in folio. 2. The most famous Medals of the Ancient Roman Emperors and Empresses, in quarto. He died in 1634, aged 70.

MENGS (Anthony Raphael), first painter to the king of Spain, was born at Aussig in Bohemia, A. D. 1728. His father, painter to Augustus III. king of Poland, perceiving his superior talents, carried him from Dresden to Rome in 1741. After having there pursued his art for four years, and copied the principal monuments of that capital, he returned to Dresden, where he executed different works for Augustus with very uncommon success. During his abode in Italy, he became acquainted with Don Carlos king of Naples; and when this prince succeeded to the crown of Spain in 1761, he was careful to engage Mengs in his service, by granting him an yearly pension of 2000 doubloons, together with a house and equipage. He lived, however, chiefly at Rome; where in 1779 he fell a sacrifice to his confidence in a German quack, who pretended to cure him of a disease which he had contracted partly by his intense application, and partly by grief for the loss of his wife. His natural timidity and great ignorance of the world, the distrust which seemed to be expressed in his air and manners, and his melancholy constitution of body, by no means lessened the envy of his rivals. Under this rude appearance, he had a heart full of kindness and humanity. On one occasion, when he perceived that he had offended a certain person by his bluntness (excusable only in a great genius), he was not only sorry for his inattention, but he assisted with his advice the painter whom he had offended. He made no mystery of his art any more than of his sentiments. Clement XIV. submitted to his judgment some pictures of no great value, and in excuse told him that he had bought them at the recommendation of an eminent painter. "This man and I (replied Mengs) are two artists, one of whom praises every thing which he cannot equal, and the other blames every thing which he can surpass." His manners were pure and simple, and enthusiasm for the arts had almost extinguished in him every other passion. He was a good husband and a good father; and his family could reproach him with nothing but want of economy and unbounded generosity. Although he had received during the last 18 years of his life more than 250,000 livres, he hardly left wherewithal to defray the expences of his funeral. The king of Spain adopted his five daughters, and granted pensions to his two sons. His chief works in the line of his profession are at Madrid and at Rome. A catalogue of them is to be found in the account of his life prefixed to his whole works, in 2 vols 4to, published at Parma in 1780 by the Chevalier d'Azara, with notes. The first volume contains, 1. Reflections on the *beautiful*, and on taste in painting. 2. Reflections on Raphael, Corregio, Titian, &c. 3. On the means of promoting the cultivation of the fine arts in Spain.—The second volume contains, 1. Two letters on the group of Niobé. 2. A letter on the origin, progress, and decline of drawing. 3. A letter on the principal paintings at Madrid. 4. Memoirs of the life and works of Correggio. 5. Memoirs concerning the academy of fine arts at Madrid. 6. Practical lessons in painting. Part of his works have been translated into French by M. Doray de Longrais, and published at Paris 1782 in 8vo. A collection of them was lately published in 4to, 2 vols, 1787.—Mengs placed Raphael at the head of modern painters for design and expression, Corregio for gracefulness of attitude and the *claro obscuro*, and Titian for colouring. He formed his own style upon the different excellencies of those three artists. He united the most sublime expression to the truest colouring, and to that knowledge of different effects which captivates the senses at the first impression, and which will bear the most rigid examination. His paintings possess chiefly that grace which one feels without being able to explain. Nobody ever studied the ancients with greater care than he did. The technical part in *l'Histoire de l'Art*, by his friend the Abbé Winckelman, is of his composition. He respected and admired the ancients; but he was destitute of that excessive zeal which makes their votaries conceal those faults which they perceive.

MENIALS, domestic or household servants, who live under their lord or master's roof.

MENINGES, or MENYNGES, in anatomy, a name given to the dura and pia mater of the brain. See ANATOMY, n° 129.

MENINX, an island in the Mediterranean, to the west of the Syrtis Minor. Supposed by Strabo and Polybius to be Homer's country of the Lotophagi; and hence Ptolemy and Eratosthenes denominate the island *Lotophagitis*, with a cognominal town *Meninx*. It was the country of Vibius Gallus the emperor, and of Volusianus. Now called *Gerbi* and *Zarbi*.

MENIPPUS, a cynic philosopher of Phœnicia. He was originally a slave, but obtained his liberty with a sum of money, and became one of the greatest usurers at Thebes. He grew so desperate from the continual reproaches and insults to which he was daily exposed on account of his meanness, that he destroyed himself. He wrote 13 books of satires, which have been lost.

MENIPPEAN (*satira* MENIPPEA), a kind of satire consisting of prose and verse intermixed. It is thus called from Menippus a cynic philosopher who delighted in composing satirical letters, &c. In imitation of him, Varro also wrote satires under the title of *Satiræ Menippeæ*: whence this sort of composition is also denominated *Varronian satire*.

Among the moderns there is a famous piece under this title first published in 1594, against the chiefs of the league, called also the *Catholicon* of Spain. It is esteemed a master-piece for the time.

MENISCUS, in optics, a glass or lens, concave on one side and convex on the other; sometimes also called *lunula*. See OPTICS.

MENISPERMUM, MOONSEED: A genus of the decandria order, belonging to the diœcia class of plants; and in the natural method ranking under the 11th order, *Sarmentaceæ*. The male has four exterior and eight interior petals; there are 16 stamina; the corolla of the female is the same as in the male; there are eight barren stamina, and two monospermous berries. There are three species, all of them climbing plants, rising 14 feet high, and natives of warm climates; but noway remarkable for beauty. The seeds of a kind which grows in the Levant, being formed into a paste, are regarded by the inhabitants as specific against lice and cutaneous eruptions. The same paste is likewise used for the purpose of intoxicating fishes. See *Cocculus Indicus*.

MENNITH, or MINNITH, Judges xi. 33. a town near Heshbon (Jerome), in Arabia Petræa; in a district named *Ecosipolis*, or *twenty-towns*, (Cellarius). There is also a Minnith mentioned Ezekiel xxvii. as being in a good wheat country: but whether the same with the foregoing is uncertain; though some think that the first Minnith lay in the country of Ammon, (Wells).

MENNONITES, a sect in the United Provinces, in most respects the same with those in other places called *Anabaptists*.

They had their rise in 1536, when Menno Simon, a native of Friesland, who had been a Romish priest, and a notorious profligate, resigned his rank and office in the Romish church, and publicly embraced the communion of the Anabaptists.

Menno was born at Witmarsum, a village in the neighbourhood of Bolswert in Friesland in the year 1505, and died in 1561 in the duchy of Holstein, at the country seat of a certain nobleman not far from the city of Oldesloe, who, moved with compassion by a view of the perils to which Menno was exposed, and the snares that were daily laid for his ruin, took him with certain of his associates into his protection, and gave him an asylum. The writings of Menno, which are almost all composed in the Dutch language, were published in folio at Amsterdam in the year 1651. About the year 1637, Menno was earnestly solicited by many of the sect with which he connected himself, to assume among them the rank and functions of a public teacher; and as he looked upon the persons who made this proposal to be exempt from the fanatical phrenzy of their brethren at Munster (though according to other accounts they were originally of the same stamp, only rendered somewhat wiser by their sufferings), he yielded to their intreaties. From this period to the end of his life, he travelled from one country

country to another with his wife and children exercifing his miniftry, under preffures and calamities of various kinds, that fucceeded each other without interruption, and conftantly expofed to the danger of falling a victim to the feverity of the laws. Eaft and Weft Friefland, together with the province of Groningen, were firft vifited by this zealous apoftle of the Anabaptifts; from whence he directed his courfe into Holland, Gelderland, Brabant, and Weftphalia, continued it through the German provinces that lie on the coafts of the Baltic Sea, and penetrated fo far as Livonia. In all thefe places his minifterial labours were attended with remarkable fuccefs, and added to his fect a prodigious number of followers. Hence he is defervedly confidered as the common chief of almoft all the *Anabaptifts*, and the parent of the fect that ftill fubfifts under that denomination. Menno was a man of genius, undirected by a very found judgment; he poffeffed a natural and perfuafive eloquence, and fuch a degree of learning as made him pafs for an oracle in the eftimation of the multitude. He appears, moreover, to have been a man of probity, of a meek and tractable fpirit, gentle in his manners, pliable and obfequious in his commerce with perfons of all ranks and characters, and extremely zealous in promoting practical religion and virtue, which he recommended by his example as well as by his precepts. The plan of doctrine and difcipline drawn up by Menno was of a much more mild and moderate nature than that of the furious and fanatical ANABAPTISTS, whofe tumultuous proceedings have been recited under that article, but fomewhat more fevere though more clear and confiftent than the doctrine of the wifer branches of that fect, who aimed at nothing more than the reftoration of the Chriftian church to its primitive purity. Accordingly he condemned the plan of ecclefiaftical difcipline that was founded on the profpect of a new kingdom, to be miraculoufly eftablifhed by Jefus Chrift on the ruins of civil government and the deftruction of human rulers, and which had been the fatal and peftilential fource of fuch dreadful commotions, fuch execrable rebellions, and fuch enormous crimes. He declared publicly his diflike of that doctrine, which pointed out the approach of a marvellous reformation in the church by the means of a new and extraordinary effufion of the Holy Spirit. He expreffed his abhorrence of the licentious tenets, which feveral of the Anabaptifts had maintained, with refpect to the lawfulnefs of polygamy and divorce; and finally, confidered as unworthy of toleration thofe fanatics who were of opinion that the Holy Ghoft continued to defcend into the minds of many chofen believers, in as extraordinary a manner as he did at the firft eftablifhment of the Chriftian church, and that he teftified this peculiar prefence to feveral of the faithful by miracles, predictions, dreams, and vifions of various kinds. He retained indeed the doctrines commonly received among the Anabaptifts, in relation to the baptifm of infants, the *millennium*, or 1000 years reign of Chrift upon earth, the exclufion of magiftrates from the Chriftian church, the abolition of war, and the prohibition of oaths enjoined by our Saviour, and the vanity as well as the pernicious effects of human fcience. But while Menno retained thefe doctrines in a general fenfe, he explained and modified them in fuch a manner as made them refemble the religious tenets that were univerfally received in the Proteftant churches; and this rendered them agreeable to many, and made them appear inoffenfive even to numbers who had no inclination to embrace them. It however fo happened, that the nature of the doctrines confidered in themfelves, the eloquence, of Menno which fet them off to fuch advantage, and the circumftances of the times, gave a high degree of credit to the religious fyftem of this famous teacher among the Anabaptifts, fo that it made a rapid progrefs in that fect. And thus it was in confequence of the miniftry at Menno, that the different forts of Anabaptifts agreed together in excluding from their communion the fanatics that difhonoured it, and in renouncing all tenets that were detrimental to the authority of civil government, and by an unexpected coalition formed themfelves into one community.

Though the Mennonites ufually pafs for a fect of Anabaptifts, yet M. Herman Schyn, a Mennonite minifter, who has publifhed their hiftory and apology, maintains, that they are not Anabaptifts either in principle or by origin. However, nothing can be more certain than this fact, viz. that the firft Mennonite congregations were compofed of the different forts of Anabaptifts, of thofe who had been always inoffenfive and upright, and of thofe who, before their converfion by the miniftry of Menno, had been feditious fanatics: befides it is alledged, that the Mennonites do actually retain, at this day, fome of thofe opinions and doctrines, which led the feditious and turbulent Anabaptifts of old to the commiffion of fo many and fuch enormous crimes: fuch particularly is the doctrine concerning the nature of Chrift's kingdom, or of the church of the New Teftament, though modified in fuch a manner as to have loft its noxious qualities, and to be no longer pernicious in its influence.

The Mennonites are fubdivided into feveral fects; whereof the two principal are the *Flandrians* or FLEMINGIANS, and the WATERLANDIANS. The opinions, fays Mofheim, that are held in common by the Mennonites, feem to be all derived from this fundamental principle, that the kingdom which Chrift eftablifhed upon earth is a vifible church or community, into which the holy and juft alone are to be admitted, and which is confequently exempt from all thofe inftitutions and rules of difcipline that have been invented by human wifdom, for the correction and reformation of the wicked. This principle, indeed, was avowed by the ancient Mennonites, but it is now almoft wholly renounced: neverthelefs, from this ancient doctrine, many of the religious opinions that diftinguifh the Mennonites from all other Chriftian communities, feem to be derived: in confequence of this doctrine, they admit none to the facrament of baptifm but perfons that are come to the full ufe of their reafon; they neither admit civil rulers into their communion, nor allow any of their members to perform the functions of magiftracy; they deny the lawfulnefs of repelling force by force, and confider war, in all its fhapes, as unchriftian and unjuft; they entertain the utmoft averfion to the execution of juftice, and more

efpecially

especially to capital punishments; and they also refuse to confirm their testimony by an oath. The particular sentiments that divided the more considerable societies of the Mennonites are the following: The rigid Mennonites, called the *Flemingians*, maintain, with various degrees of rigour, the opinions of their founder Menno, as to the human nature of Christ, alledging that it was produced in the womb of the Virgin by the creating power of the holy Ghost; the obligation that binds us to wash the feet of strangers, in consequence of our Saviour's command; the necessity of excommunicating and avoiding, as one would do the plague, not only avowed sinners, but also all those who depart, even in some light instances pertaining to dress, &c. from the simplicity of their ancestors; the contempt due to human learning, and other matters of less moment. However this austere system declines, and the rigid Mennonites are gradually approaching towards the opinions and discipline of the more moderate or *Waterlandians*.

The first settlement of the Mennonites, in the United Provinces, was granted them by William prince of Orange, towards the close of the 16th century; but it was not before the following century that their liberty and tranquillity were fixed upon solid foundations, when, by a confession of faith published in the year 1626, they cleared themselves from the imputations of those pernicious and detestable errors that had been laid to their charge. In order to appease their intestine discords, a considerable part of the Anabaptists of Flanders, Germany, and Friesland, concluded their debates in a conference held at Amsterdam, in the year 1630, and entered into the bonds of fraternal communion, each reserving to themselves a liberty of retaining certain opinions. This association was renewed and confirmed by new resolutions, in the year 1649; in consequence of which the rigorous laws of Menno and his successors were, in various respects, mitigated and corrected.

MENOCHIUS, vulgarly MENOCHIA, (James), a famous lawyer, meanly born at Pavia, but who became so skilful in the law, that he was called the *Baldus* and *Bartholus* of his age; all the princes of Italy soliciting him to their universities. He read at Padua 23 years together; and for love of his country removed to Pavia, and succeeded Nicholas Gratiani. He hath got an immortal fame by his works, *De recuperanda possessione; De adipiscenda possessione; De presumptionibus; De arbitrariis Judicum questionibus & causis conciliorum*, tom. 13. &c. He died in 1607, aged 75.

MENOLOGY, MENOLOGIUM, (from μην, *month*, and λογος, *discourse*), in much the same as martyrology, or callendar, in the Latin.

The Greek menologium is divided into the several months in the year; and contains an abridgement of the lives of the saints, with a bare commemoration of the names of such whose lives were never written. The Greeks have various menologies; and the Romans tax them with inserting divers heretics in their menologies as saints.—Baillet treats of them at large.

MENSA, in law-books, a term that includes in it all patrimony, and necessaries for livelihood.

MENSALS, MENSALIA, in church-history, such livings as were formerly united to the tables of religious houses, and hence called *mensal benefices*. See the article BENEFICE.

MENSES, CATAMENIA, in medicine, the monthly evacuations from the uterus of women not with child or not giving suck. They are so called from *mensis* "month," the period wherein they return. They are also called *flowers*, *courses*, &c. By the Jewish law a woman was unclean while the menstrual blood flowed; and the man who touched her, or the moveables she had touched, was declared unclean.—Levit. xv.

The menses make one of the most curious and difficult phenomena in the whole human body; for the explanation whereof, many hypotheses have been framed, though the matter is yet scarcely ascertained.

It is generally agreed by all, that the necessity women are under for some extraordinary supply to compensate the expence, and support them during the time of gestation, was the final reason why this redundance at other times was given them, which continues whilst this necessity subsists, and ceases when, according to the constitution of the female frame, it is no longer required: but this is all they agree in. Some, not content with this occasion alone, will have the menstruous blood offend in quality more than quantity; which they argue from the pain it gives many women in the evacuation; with many other idle notions.

Others ascribe this effect to an imaginary dominion of the moon over the bodies of women. This was formerly the prevailing opinion; though the smallest reflection would have shown the weakness of it: for, had this purgation been owing to the influence of the moon, all women of the same age and temperament would have found it at the same periods and revolutions of the moon, *i. e.* at the same time; which all experience shows to be false.

There are two other opinions which carry with them great probability, and are argued with a great deal of strength and reason; in both which, the quality of the blood is allowed to be innocent, but they still differ about the reason of its issue. The former is that of Dr Bohn and Dr Freind, who maintain this flux to be the result of a plethora or plenitude; and to be evacuated only for relief against the quantity.

Dr Freind, who has maintained the cause of a plethora with the greatest strength and clearness, supposes, that this plethora arises from a coacervation in the blood-vessels of a superfluity of aliment, which, he thinks, remains over and above what is expended by the ordinary ways; and that women have this plethora, and not men, because their bodies are more humid, and their vessels, especially the extremities of them, more tender, and their manner of living generally more inactive than that of men; and that these things concurring, are the occasion that women do not perspire sufficiently to carry off the superfluous alimentary parts, till they be accumulated in such quantities as to distend the vessels, and force their way thro' the capillary arteries of the uterus. It is supposed to happen to women more than the females of other species, which have the same parts, because of the erect posture of the former, and the

Menses. the vagina and other canals being perpendicular to the horizon; so that the pressure of the blood is directed towards their orifices: whereas in brutes, they are parallel to the horizon, and the pressure wholly is on the sides of those vessels. The discharge, he thinks, happens in this part rather than in any other, as being more favoured by the structure of the vessels; the arteries being very numerous, and the veins sinous and winding, and therefore more apt to retard the impetus of the blood; and consequently, in a plethoric case, to occasion the rupture of the extremities of the vessels, which may last, till, by a sufficient discharge, the vessels are eased of their overload.

This is the substance of Dr Freind's theory; from whence he very mechanically and very philosophically accounts for the symptoms.

To his argument, why women have menses rather than men, we may add from Boerhaave, that, in the former, the *os sacrum* is wider, and stands farther out, and the *os coccygis* farther in; the *ossa innominata* wider, and farther apart, and the lowest of them, as well as the lower eminences of the *os pubis*, farther outwards than in the latter. Hence, in women, the latitude or expansion about these bones, and the capacity of the *pelvis*, is vastly great in proportion to those of men; and yet, in a woman not pregnant, there is not much to fill this expanse. Again, the foreside of the thorax is smoother in women than in men, and the blood-vessels, lymphatics, adipose, and nervous vessels, membranes, and fibres, are much laxer in women than in men: whence all their cavities, cells, vessels, &c. are more easily replenished, and the humours aggregated in them; besides, that they are found to perspire less than men, and to arrive much sooner at their maturity, or ακμη of increase. To which he adds the consideration of the soft pulpous texture of the uterus, and the vast number of veins and arteries with which it is filled. Hence a healthy maid, being arrived at her growth, begins to prepare more nutriment than is required for the support of the body; which, as there is not to be any farther accretion, must of necessity fill the vessels, and especially those of the uterus and breasts, they being the least compressed. These will be dilated more than the others; whence the lateral vascules evacuating their humour into the cavity of the uterus, it will be filled and extended. Hence a pain, heat, and heaviness, will be felt about the loins, pubes, &c. the vessels of the uterus, at the same time, will be so dilated as to emit blood into the cavity of the uterus, and its mouth will be lubricated and loosened, and blood issue out. As the quantity of blood is diminished, the vessels will be less pressed, and will contract themselves again closer, so as again to retain the blood, and let pass the grosser part of the serum; till at length only the usual serum passes. Again, there are more humours prepared, which are more easily lodged in vessels once dilated; and hence the menses go and return at various periods in various persons.

This hypothesis, however plausible, is opposed by Dr Drake, who maintains, that there is no such repletion, or at least that it is not necessary to menstruation; arguing, that, if the menses were owing to a plethora so accumulated, the symptoms would arise gradually, and the heaviness, stiffness, and inactivity, necessary symptoms of a plethora, would be felt long before the periods were completed, and women would begin to be heavy and indisposed soon after evacuation, and the symptoms would increase daily; which is contrary to all experience, many women, who have them regularly and easily, having no warning, nor any other rule to prevent an indecent surprise, than the measure of the time; in which, some that have slipped, have been put to confusion and shifts no ways consistent with the notice a plethoric body would give. He adds, that even in those who are difficultly purged this way, the symptoms, though very vexatious and tedious, do not make such regular approaches as a gradual accumulation necessarily requires. If we consider what violent symptoms come on in an hour, we shall be extremely puzzled to find the mighty accession of matter, which should, in an hour or a day's time, make such great alterations. According to the hypothesis, the last hour contributed no more than the first; and of consequence, the alteration should not be greater in the one than in the other, setting aside the bare eruption.

This is the substance of what is argued against Dr Freind's theory; which, it must be owned, notwithstanding these objections, is still the most rational and consistent that has yet been advanced.

Those who oppose it, give into the doctrine of fermentation, and maintain the evacuation of blood in those parts to be an effect of an effervescence or ebullition of the blood. This opinion has been maintained by many, particularly by Dr Charleton, Bale, De Graaf, and Drake; the two first of whom suppose a ferment peculiar to the women, which produces this flux, and affects that part only, or at least principally. Dr Graaf, less particular in his notion, only supposes an effervescence of the blood, raised by some ferment, without assigning how it acts, or what it is. The sudden turgescence of the blood occasioned them all to think, that it arose from something till then extraneous to the blood, and led them to the parts principally affected to seek for an imaginary ferment, which no anatomical inquiry could ever show, or find any receptacle for, nor any reasoning necessarily infer. Again, that heat which frequently accompanies this turgescence, led them to think the case more than a plethora, and that there was some extraordinary intestine motion at that time.

Dr Drake improves on the doctrine of a ferment; and contends, not only that it is necessary there should be a ferment, but a receptacle also for this ferment; concluding, from the suddenness and violence of the symptoms, that a great quantity must be conveyed into the blood in a short time, and consequently, that it must have been ready gathered in some receptacle, where, while it was lodged, its action was restrained. But he goes farther still, and pretends to ascertain the place, &c. both of the one and the other, making the gall-bladder to be the receptacle, and the bile the ferment. This liquor he thinks well adapted to raise a fermentation in the blood, when discharged into it in a quantity; and, as it is contained in a receptacle that does not admit of a continual issue, it may be there reserved, till in a certain period of time the

Menfes. the bladder becoming turgid and full, through the compreffion of the incumbent vifcera, it emits the gall; which, by the way of the lacteals, infinuating itfelf into the blood, may raife that effervefcence which occafions the aperture of the uterine arteries. To confirm this, he alledges, that perfons of a bilious conftitution have the menfes either more plentifully, or more frequently, than others; and that diftempers manifeftly bilious, are attended with fymptoms refembling thofe of women labouring under difficult menftruation. —If it be objected, that on this principle men fhould have menfes as well as women, he anfwers, that men do not abound in bile fo much as women, the pores of the former being more open, and carrying off more of the ferous part of the blood, which is the vehicle of all the other humours, and confequently a greater part of each is difcharged through them than in women, wherein the fuperfluity muft either continue to circulate with the blood, or be gathered into proper receptacles, which is the cafe in the bile. The fame reafon he gives why menftruation fhould not be in brutes: the pores of thefe being manifeftly more open than thofe of women, as appears from the quantity of hair which they bear, for the vegetation whereof a large cavity, and a wider aperture of the glands, is neceffary, than where no fuch thing is produced: yet there is fome difference between the males and females even among thefe, fome of the latter having their menfes, though not fo often, nor in the fame form and quantity, as women.

He adds, that the feveral phenomena of the menfes, whether in a natural, a regular, or difeafed cafe, flow naturally and readily from this hypothefis; and that whatever may be accounted for from a plethora, or from any particular ferment, may without any ftraining be applied to this.

Females generally begin to menftruate about the age of fourteen or fifteen, and ceafe about fifty; though inftances have occurred of their commencing fooner and continuing longer. There are, therefore, two critical periods in the lives of females which require their particular attention. In order to efcape the chlorofis, and other fimilar difeafes, incident to that period of life when the menfes commence, they fhould avoid indolence and inactivity, and accuftom themfelves to exercife in the open air as much as poffible. Unwholefome food, dulnefs of difpofition, and ftrait cloaths, are very injurious to females at this feafon. The difcharge in the beginning is feldom fo inftantaneous as to furprife them unawares. The eruption is generally preceded by fymptoms that indicate its approach; fuch as a fenfe of heat, weight, and dull pain in the loins; diftenfion and hardnefs of the breafts, head-ach, lofs of appetite, laffitude, palenefs of the countenance, and fometimes a flight degree of fever. When thefe fymptoms occur, every thing fhould be carefully avoided which may obftruct the menftrual flux, and all means ufed to promote it; as fitting frequently over the fteams of warm water, drinking warm diluting liquors, &c. When the menfes have begun to flow, great care fhould be taken to avoid every thing that tends to obftruct them; fuch as fifh, and all kinds of food that are hard of digeftion, and cold acid liquors. Cold is likewife hurtful at this period; as alfo anger, fear, grief, and other affections of the mind. From whatever caufe this flux is obftructed, except in the ftate of pregnancy, proper means fhould be ufed to reftore it; and if exercife in a dry, open, and rather cool air, wholefome diet, generous liquors in a weak and languid ftate of the body, chearful company, and amufement fail, recourfe muft be had to medicine.— When obftructions proceed from a weak relaxed ftate of the folids, fuch medicines as tend to promote digeftion, to brace the folids, and affift the body in preparing good blood, ought to be ufed. See *Medicine-Index.* Menfes.

When the menftrual flux is too great, the patient becomes weak, the colour pale, the appetite and digeftion are bad, and œdematous fwellings of the feet, dropfies, and confumptions, often enfue. This frequently happens to women about the age of forty-five or fifty, and is very difficult of cure. It may proceed from a fedentary life; a full diet, confifting chiefly of falted, high feafoned, or acrid food; the ufe of fpirituous liquors; exceffive fatigue; relaxation; a diffolved ftate of the blood; violent paffions of the mind, &c. In order to reftrain the flux, the patient fhould be kept eafy both in body and mind. If it be very violent, fhe ought to lie in bed with her head low; to live upon a cool and flender diet, as veal or chicken-broths with bread, and to drink decoctions of nettle-roots or the greater comfrey. If thefe fail, recourfe muft be had to ftronger aftringents, &c. See Medicine nº 246.

The difcharge of the menfes is interrupted naturally during pregnancy: but this is not always the cafe, becaufe fome have them three months, fome fix months, and fome during the whole time of geftation, though in lefs quantity than at other times. The menfes are moftly interrupted during the time of giving fuck, though many women have a return about the third or fourth month after delivery, and almoft all have them again in the ninth or tenth month. In cafes of obftruction, the menftrual blood hath difcharged itfelf by other outlets.

It ufually happens that this periodical difcharge ceafes between the age of forty and fifty; and the feafon in which this takes place is critical to the fex.— However, thofe who furvive this period without contracting any chronical difeafe, become more healthy and vigorous than they were before. About this time, fome are afflicted with the well known fymptoms of plethora, heat, flufhings, reftlefs nights, troublefome dreams, and unequal fpirits; others are attacked with inflammations of the bowels, or other internal parts; fpafmodic affections of various parts, ftiffnefs in the limbs, fwelled ancles, with pain and inflammation, the piles, and other effects of plenitude. Thofe of full plethoric habits, accuftomed to copious evacuations, will find great relief by bleeding frequently in moderate quantities, keeping the bowels lax, moderating their diet, and ufing fufficient exercife that is not too heating. If an immoderate flux of the menfes happens at this period, it fhould be reftrained by gentle laxatives, cooling medicines, reft, anodynes, a moft fparing not too liquid diet, rather than by very copious bleedings and aftringents of any kind. Dr Fothergill obferves, that various purgations of aloes, the tinctura facra, pil. Ruffi, elixir proprietatis, and other compofitions of this kind, are recommended as proper purgatives

purgatives to be used on the cessation of the menses. But many inconveniences have arisen from these heating medicines, as the piles, strangury, immoderate discharges of the menses, racking pains in the loins, and other similar complaints. Rhubarb, sena, magnesia, sulphur medicines, small doses of jalap, and various combinations of these, may be substituted in the room of the others, and will supply sufficient variety to the prescriber and patient. When the menses are about to go off, they appear for the most part irregularly both in time and quantity; once in a fortnight, three, five, or six weeks; sometimes very sparingly, at other times in immoderate quantities. Great losses of this kind are often prevented by taking away four or five ounces of blood a few days after the first menstrual suppression. If a patient has in early life been subject to cutaneous eruptions, sore eyes, glandular swellings, or other obvious marks of morbid humours subsisting in the constitution, and all which may have disappeared about the time the menses became regular, an issue is an advisable drain, and may prevent many inconveniences. If at this time ulcerous sores break out about the ancles, or in other parts of the body, they ought to be continued open, or artificial drains substituted in their stead; for those who will have them dried up are soon after carried off by acute diseases, or fall into those of a chronic nature.

MENSORES, among the Romans, were harbingers, whose business it was to go before the emperor, and fix upon lodgings for him when he travelled into any of the provinces. They also marked out encampments, and assigned every regiment its post.

Mensores were also land-surveyors, architects, or appraisers of houses and public buildings. The distributors of provisions in the army were called *mensores frumentarii.* And mensores was also an appellation given to servants who waited at table.

MENSTRUAL, or MENSTRUOUS, a term in medicine, applied to the blood which flows from women in their ordinary monthly purgations. See MENSES.

MENSTRUUM, in chemistry, any body which in a fluid or subtilised state is capable of interposing its small parts betwixt the small parts of other bodies, so as to divide them subtilly, and form a new uniform compound of the two.

MENSURATION, in general, denotes the act or art of measuring lines, superficies, or solids. See GEOMETRY.

MENTHA, MINT, in botany: A genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42d order *Verticillatæ.* The corolla is nearly equal, and quadrifid, with one segment broader than the rest, and emarginated; the stamina are erect, standing asunder. There are many species; but not more than three are cultivated for use, namely, the viridis or common spearmint, the piperita or peppermint, and the pulegium or pennyroyal. All these are so well known as to need no description; and all of them are very easily propagated by cuttings, parting the roots, or by offsets.

Uses. For culinary purposes, the spearmint is preferable to the other two; but for medicine, the peppermint and pennyroyal have in some places almost entirely superseded it. A conserve of the leaves is very grateful, and the distilled waters both simple and spirituous are universally thought pleasant. The leaves are used in spring sallads; and the juice of them boiled up with sugar is formed into tablets. It has been imagined that cataplasms and fomentations of mint, would dissolve coagulations of milk in the breast; but Dr Lewis says, that the curd of milk, digested in a strong infusion of mint, could not be perceived to be any otherwise affected than by common water: however, milk, in which mint-leaves were set to macerate, did not coagulate near so soon as an equal quantity of the same milk kept by itself. Dr Lewis says, that dry mint digested in rectified spirits of wine, gives out a tincture, which appears by day-light of a fine dark green, but by candle-light of a bright red colour. The fact is, that a small quantity of this tincture is green either by day-light or by candle-light, but a large quantity of it seems impervous to common day-light; however, when held betwixt the eye and a candle, or betwixt the eye and the sun, it appears red.

The virtues of mint are those of a warm stomachic and carminative: in loss of appetite, nausea, and continual retching to vomit, there are few simples of equal efficacy. In colicky pains, the gripes to which children are subject, lienteries, and other immoderate fluxes, this plant frequently does good service. It likewise proves beneficial in many hysteric cases, and affords an useful cordial in languors and other weaknesses consequent upon delivery. The best preparation in these cases is a strong infusion of the dried herb in water (which is much superior to the green), or rather a tincture or extract prepared with rectified spirit. These possess the whole virtues of the mint; the essential oil and distilled water contain only the aromatic part; the expressed juice only the astringency and bitterishness, together with the mucilaginous substance common to all vegetables. The peppermint is much more pungent than the others.

Pennyroyal has the same general characters with the mint, but is more acrid and less agreeable when taken into the stomach. It has long been held in great esteem, and not undeservedly, as an aperient and deobstruent, particularly in hysteric complaints and suppressions of the menses. For these purposes the distilled water is generally made use of, or, what is of equal efficacy, an infusion of the leaves. It is observable, that both water and rectified spirit extract the virtues of this herb by infusion, and likewise elevate the greatest part of them by distillation. The expressed juice, with a little sugar, is not a bad medicine in the chincough.

MENTOR (fab. hist.), a faithful friend of Ulysses; a son of Hercules; a king of Sidonia, who revolted against Artaxerxes Ochus, and afterward was restored to favour by his treachery to his allies, &c. *Diod.* 16. An excellent artist in polishing cups and engraving flowers on them. *Plin.* 33. c. 11.—*Mart.* 9. ep. 60. v. 16.

MENTZ, an archbishopric and electorate in Germany. It lies on the banks of the river Mayne, between the electorate of Triers on the west, the Palatinate on the south, Franconia on the east, and the Wetteraw on

Mentz. on the north. It is about 60 miles in length from north-east to south-west, and about 50 in breadth. A considerable part of the elector's revenue arises from the toll on the Rhine and the Mayne, and from the tax on the excellent wines produced in this country. The chief towns of any trade are, 1. Mentz; (see the next article.) In its neighbourhood is Hockheim, so celebrated for good wines, that the best Rhenish is from thence called *old hock*. It is a pretty village, containing about 300 families; and belongs to the chapter of Mentz, the dean of which enjoys the revenue of it: in a good year he makes from twelve to fifteen thousand guilders of his wine He and the Augustines of Mentz and Francfort have the exclusive enjoyment of the best Hockheimer wine, of which, in good years, a piece, consisting of 100 measures, sells for from 900 to 1000 guilders from the press. "This (says the Baron Riesbeck) is certainly one of the dearest wines in the world. Having a desire to taste it on the spot, we were obliged to pay a rix-dollar; it was, however, of the best vintage in this century, viz. that of 1766. Nor should we have had it, but for an advocate of Mentz, to whom the hostess meant to show favour. This was the first German wine I had met with which was entirely without any sour taste: it was quite a perfume to the tongue; whereas the other wine of Hockheim, let it be as good as it may, is not quite clear of vinegar; though for this also, if it has any age, you are forced to pay a guilder and a half." 2. Bingen is a pleasant town, which stands in the district called *Rhinegau*. This town, which, together with the toll on the Rhine, is worth about 30,000 guilders, belongs to the chapter of Mentz, is extremely beautiful, and contains about 4500 inhabitants. A great part of the corn which is carried into the Rhinegau from the neighbouring Palatinate, comes through this place, which, on the other hand, supplies the Palatinate with drugs, and various foreign commodities. This traffic alone would make the place very lively; but besides this, it has very fruitful vineyards. The hill, at the foot of which it lies, and one side of which is made by the gullet, through which the Nahe runs into the Rhine, forms another steep rock behind this gullet parallel to the Rhine and the golden Rudesheimer mountain; it therefore enjoys the same sun as this does, which makes the Budesheimer wine that grows on it little inferior to the Rudesheimer. See Rudesheim. The rising grounds about it produce wines that are esteemed preferable to those of Baccharac, so much in vogue heretofore.—3. Elfeld, five miles west from Mentz, is a strong fortified town, on the north-side of the Rhine, and the chief of the Rhinegau.—Here is Rudesheim, a place noted for the growth of the best wines in these parts. 4. Weisbaden lies between six and seven leagues from Francfort, and about five or six miles north of Mentz: it is the metropolis of a country belonging to the branch of Nassau-Saarbrak, and is famous for its mineral waters.

After the pope, there is no doubt but the archbishop of this place is the most considerable and richest prelate in the Christian world. According to Baron Riesbeck, the see is indebted for its increase of riches to St Boniface, who may be called, with great justice, the apostle of the Germans. It was this man, an Englishman by birth, who in the time of Charlemagne baptized Witikind and the other brave Saxons who had so long resisted baptism with their swords, and spread the empire of the vicar of Jesus Christ as far as the northern and eastern seas. He it was who introduced the Roman liturgy into Germany, and made the savage inhabitants abstain from eating horse's flesh. He raised the papal power to a higher pitch than it had been raised in any other country in Christendom; and, in recompence of his services, the pope made all the new-founded bishoprics in the north of Germany subject to the see of Mentz, which Boniface had chosen for his residence. The provinces, the most considerable in the whole papal dominions, all Swabia, Franconia, Bohemia, and almost all Saxony, with a part of Switzerland, Bavaria, and the upper Rhine, belong to this diocese. Though the reformation, and revenge of the kings of Bohemia, have lessened it one third, it still contains the archbishopric of Sprengel and eleven bishoprics, most of which are the most considerable of Germany, as Wurzburg, Paderborn, Hildesheim, Augsbourg, &c. When the building of the papal monarchy was completed by Gregory VII. the archbishops of Mentz became powerful enough to be at the head of the empire. In the 13th and 14th centuries, they were so eminent as to be able to make emperors without any foreign assistance; and it was to one of them that the house of Hapsburg was indebted for its first elevation. Since the boundaries of the two powers have been more accurately ascertained, and the temporal has so much got the better of the spiritual, the power and influence of the archbishops of this place have of course been much reduced; still, however, they are possessed of very important prerogatives, which they might exert with much more efficacy than they do, were it not that various circumstances have rendered them too dependent on the emperors. They are still the speakers in the Electoral College, have the appointment of the diets under the emperors, and may order a re-examination of the proceedings of the imperial courts. These high privileges are, however, too much subject to the controul of the house of Austria; nor are their spiritual powers any longer what they once were. Their suffragan bishops have taken it into their heads that all bishops are alike as to power, and that the title of archbishop only intitles its possessor to the first place amongst brothers who are equal. The temporals, however, which are still annexed to this chair, make him who sits in it rich amends for the diminution of his spiritual and political splendor. Though he does not absolutely possess the largest, yet he certainly has the richest and most peopled domain of any ecclesiastical potentate in Germany. The country, it is true, does not contain more than 125 German miles square, whereas the archbishopric of Saltzburg contains 210; but then Saltzburg has only 250,000 inhabitants, whereas Mentz has 320,000. The natural riches of the territory of Mentz, and its advantageous situation, make a subject of Mentz much richer than one of Saltzburg, the greatest part of which is only inhabited by herdsmen. In the territory of Mentz there are 40 cities; in that of Saltzburg only seven The tax on vessels which go down the Rhine of itself produces 60,000 guilders, or 6000 l. a year, which is nearly

Mentz. nearly as much as all the mines of Saltzburg put together, excepting only the falt mine at Halle. The tax on wine, here and in the country round, produces the court above 100,000 guilders, or 10,000 l. a-year, in which fum we do not reckon the cuftoms of the countries which lie at a greater diftance. Upon the whole, the income of the prefent archbifhop may be valued at 1,700,000 guilders, or 170,000 l.

If the lands of the elector lay all together, they would produce a fufficiency of corn and all the prime neceffaries of life; but as feveral parts of them lie wide affunder, the people are compelled to purchafe a great deal from foreigners. The capital itfelf, as well as the adjacent Rhinegau, depends on the Palatinate for its corn, notwithftanding the great abundance of that and every other fpecies of grain in its own poffeffions in Wetterau. The nobleft production of the elector's territory on the Rhine is the wine, which is almoft the only true Rhenifh. Connoiffeurs, indeed, allow the wines of Neirftein, Bacharach, and a very few other places out of this country, to be true Rhenifh: but they do not give this name to the wines of the Palatinate, of Bardon, and of Alfatia. There is a great deal of wine made in the countries which lie on the fouth and weft of the Rhine, at Laubenheim, Bodenheim, Budefheim, and Bingen; but the true Rhenifh, that which infpires fo many who are and fo many who are not poets, comes only from the Rhinegau, which lies on the northern banks of the Rhine. See Rhinegau.

The civil lift of the archbifhop (according to Baron Riefbeck), is by much too immoderate and expenfive "He has his minifters, his counfellors of ftate, and eighty or ninety privy counfellors of various denominations. The expence of this eftablifhment is very difproportionate to the revenue of the ftate. This is owing to the large number of poor nobility, who can only accept of employments of this kind. Ignorance of the true principles of government are the caufes of this evil The confequences are, that a great number of perfons, who might be ufefully employed, live in idlenefs Even the military eftablifhment of the country appears to me more calculated for the purpofe of feeding a hungry nobility than for real ufe. At the acceffion of the prefent elector, though the whole army only confifted of 2400 men, there were fix generals. The regular eftablifhment paid for and fupported by the country is 8000 men; but though there are only 2000 men kept up, the money expended for their fupport, particularly that given to numberlefs ufelefs officers, might be made ufe of more for the benefit of the country. The army of the archbifhop confifts of a German guard of 50 men and 25 horfes, a Swifs guard, a fquadron of huffars of 13 men (the moft ufeful troops, as they purge the land of robbers and murderers), a corps of artillery of 104 men, three regiments of infantry of 600 men each, and fome companies belonging to the armies of Franconia and the Upper Palatinate. Of the fortifications of the capital we may fay much the fame as of the army. Were they, indeed, improved and kept up as they ought to be, they would vie with Luxemburg, and be the moft powerful of all the barriers againft France. It is true, that the nature of the ground does not allow of a regular plan; but for fingle parts, I have feen no place of the fame capabilities, where greater advantages have been taken of the ground for the erection of the feveral works. The beauty, as well as fize of them, is indeed an object of great wonder; but though the circle of the Upper Rhine, and even the empire in general, has laid out great fums on the building thefe fortifications, parts of them are not finifhed, and parts of them are ready to fall to pieces. Their extent, indeed, would require a great army to man them. But this, as well as the maintaining and keeping them up, is evidently beyond the power of this court, or indeed of the whole circle of the Upper Rhine united. They are, therefore, alfo to be looked upon as one of the things which ferve more for magnificence than real ufe." Mentz.

Mentz, a confiderable town of Germany, in the circle of the Lower Rhine, and capital of the electorate of the fame name, is fituated on the Rhine near its confluence with the Mayne, 20 miles north-weft of Worms, 15 weft of Francfort, and 75 eaft of Triers, in E. Long. 8. 20. N. Lat. 49. 51. This city claims a right to the invention of the art of printing: (fee *Hiftory of* Printing). Here is a very beautiful quay along the river, defended by feveral works well fortified with cannon. That part of the city which extends towards the river is moft populous. The beft vineyards for Rhenifh wine being in this neighbourhood, Mentz has a flourifhing trade in that commodity more particularly; and its commerce is the brifker, by reafon that all the merchandize which paffes up and down the Rhine ftops in its harbour to change bottoms.

The northern part of the city, in which the archbifhop refides, is full of very regular buildings. Here are three regular ftreets, called the *Bierchen*, which run parallel to each other from the banks of the Rhine to 600 yards within the city, and are cut almoft regularly by very pretty crofs ftreets. The archbifhop's palace has a moft commanding view of thefe ftreets, the Rhine, and the Rhinegau. There are alfo fome good buildings in the old part of the city. The market of beafts is extremely well worth feeing; and you here and there meet with other agreeable fpots. The market in the middle of the town, though not regular, is one of the pretticft places in Germany. The cathedral is well worth notice. It is an immenfe large old Gothic building, the fpire of which was ftruck with lightning about 20 years ago, and entirely laid in afhes. As it was made of a foreft of wood, it burned 14 hours before it was entirely confumed. To prevent thefe accidents for the future, the chapter had the prefent one built to the fame height in ftone, an undertaking which coft them 40,000 guilders or L. 4000. It is a great pity (Baron Riefbeck obferves) that it is overloaded with fmall ornaments; and a ftill greater, that this wonderful edifice is fo choaked up with fhops and houfes as to be hardly more than half vifible. As, however, houfes and fhops are very dear in this part of the town, one cannot be very angry with the chapter for choofing rather to make the moft of its ground, than to fhow off the church to the beft advantage. The rent of a fhop and a fingle room to live in is 150 guilders or L. 15 per annum in this part of the town.

Mentz. There is hardly another church in Germany of the height and length of this cathedral; and the inside of it is decorated with several magnificent monuments of princes and other great personages. Besides the cathedral, the city of Mentz contains several other churches in the modern style, very well worth seeing. St Peter's, and the Jesuits church, though both too much loaded with ornament, are among this number. The church of the Augustines, of which the inhabitants of Mentz are so proud, is a master-piece of bad taste; but that of Ignatius, though little is said about it, would be a model of the antique, if here likewise there had not been too much ornament lavished. Upon the whole, the palaces of the noblesse want that noble simplicity which alone constitutes true beauty and magnificence. In another century the externals of the city will be quite changed. The late prince built a great deal, and the present has a taste for the same sort of expence. The monks and governors of hospitals also have been forced to rebuild their houses; so that when a few more streets are made broader and straighter, the whole will have no bad appearance. The inhabitants, who together with the garrison amount to 30,000, are a good kind of people, and, like all the catholics of Germany, make great account of a good table. Their faces are interesting, and they are not deficient either in wit or activity.

There are few cities in Germany besides Vienna which contain so rich and numerous a nobility as this does: there are some houses here which have estates of 100,000 guilders, or L. 10,000 a-year. The counts of Bassenheim, Schonborn, Stadion, Ingelheim, Elz, Ostein, and Walderdorf, and the lords of Dahlberg, Breitenbach, with some others, have incomes of from 30,000 to 100,000 guilders. Sixteen or eighteen houses have from 15,000 to 30,000 guilders annual revenue.—The nobility of this place are said to be some of the oldest and most untainted in Germany. There are amongst them many persons of extraordinary merit, who join uncommon knowledge to all the duties of active life. Upon the whole, they are far superior to the greater part of the German nobility. Their education, however, is still too stiff. The first minister of the court was refused admittance into their assemblies for not being sufficiently noble; and they think they degrade themselves by keeping company with bourgeois.

The clergy of this place are the richest in Germany. A canonry brings in 3500 Rhenish guilders in a moderate year. The canonry of the provost brings him in 40,000 guilders a-year; and each of the deaneries is worth 2600 guilders. The income of the chapter altogether amounts to 300,000 guilders. Though it is forbidden by the canons of the church for any one to have more than a single prebend, there is not an ecclesiastic in this place but what has three or four; so that there is hardly a man amongst them who has not at least 8000 guilders a-year. The last provost, a count of Elts, had prebends enough to procure him an income of 75,000 guilders. Exclusive of the cathedral, there are several other choirs in which the canonries bring in from 1200 to 1500 guilders a-year. To give an idea of the riches of the monasteries of this place, Baron Riesbeck informs us, that at the destruction of the Jesuits, their wine, which was reckoned to sell extremely cheap, produced 120,000 rixdollars. A little while ago the elector abolished one Carthusian convent and two nunneries, in the holy cellars of which there was found wine for at least 500,000 rixdollars. "Notwithstanding this great wealth (continues our author), there is not a more regular clergy in all Germany. There is no diocese in which the regulations made by the council of Trent have been more strictly adhered to than they have here; the archbishops having made a particular point of it both at the time of the reformation and ever since. One thing which greatly contributes to keep up discipline is the not suffering any priest to remain in the country who has not fixed and stated duties, and a revenue annexed to them. Most of the irregularities in Bavaria, Austria, and other countries, arise from abbés who are obliged to subsist by their daily industry and any masses which they can pick up. These creatures are entirely unknown here. The theological tenets of this court are also much purer than those of any other ecclesiastical prince in Germany. I was pleased to see the Bible in the hands of so many common people, especially in the country. I was told that the reading of it was not forbidden in any part of the diocese; only persons were enjoined not to read it through, without the advice of their confessors. For a long time superstition has been hunted through its utmost recesses; and though it is not quite possible to get entirely clear of pilgrimages and wonder-working images, you will meet with no priest bold enough to exorcise or to preach such nonsense as we hear in the pulpits of other German churches."

Though the trade of this place has been constantly on the increase for these 18 or 20 years past, yet it is by no means what it ought to be from the situation and other advantages. The persons here who call themselves merchants, and who make any considerable figure, are in fact only brokers, who procure their livelihood at the expence of the country or territory round, or who act for the merchants of Franckfort. A few toy-shops, five or six druggists, and four or five manufacturers of tobacco, are all that can possibly be called traders. There is not a banker in the whole town; and yet this country enjoys the staple privilege, and commands by means of the Mayne, Necker, and Rhine, all the exports and imports of Alsatia, the Palatinate, Franconia, and a part of Suabia and Hesse, as far as the Netherlands. The port too is constantly filled with ships, but few of them contain any merchandize belonging to the inhabitants of the place.

Mentzel. MENTZEL (Christian), born at Furstenwall in the Mittel-mark, is celebrated for his skill in medicine and botany, in pursuit of which he travelled through many countries. He had correspondents in the most distant parts of the world. He died A. D. 1701, about the 79th year of his age. He was a member of the academy *des Curieux de la Nature*. His works are, 1. *Index nominum plantarum*, printed at Berlin in folio, 1696; and reprinted with additions in 1715, under the title of *Lexicon plantarum polyglotton universale*. 2. A Chronology of China, in German, printed at Berlin 1696 in 4to. The following manuscripts of his composition are preserved in the royal library at Berlin. 1. *Sur l'Histoire Naturelle du Brasil*, in four volumes folio.

lio. 2. *Sur les Fleurs et les Plantes du Japon*, with coloured plates, two vols folio.

MENUS (anc. geog.), a river of Germany; now the *Maine*, rising in Franconia, and running from east to west into the Rhine at Mentz.

MENUTHIAS (anc. geog.), an island adjoining to the north-east of the promontory Prasum of Ethiopia beyond Egypt. Some take it to be *Madagascar*, or the island *St Laurence*. Isaac Vossius will have it to be *Zanzibar*; Madagascar being at a greater distance from the continent than the ancients ever sailed to, whereas Menuthias was nearer: yet though Zanzibar be nearer the continent, it is however nearer the equator than Ptolemy's Menuthias, placed in south latitude 12½ degrees.

MENYANTHES, MARSH-TREFOIL, or *Buckbean*: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 21st order, *Preciæ*. The corolla is hairy; the stigma bifid; the capsule unilocular. This plant grows wild in moist marshy places in many parts of Britain. It has three oval leaves standing together upon one pedicle, which issues from the root; their taste is very bitter, and somewhat nauseous. According to Mr Lightfoot, the flowers of this plant are so extremely beautiful, that nothing but their native soil could exclude it from a place in every garden. They grow in an elegant spike; are white, dashed with pink, and fringed internally with hairs. The Highlanders esteem an infusion or tea of the leaves as good to strengthen the stomach. According to Dr Withering, an infusion of the leaves is prescribed in rheumatisms and dropsies; a dram of them in powder purges and vomits, and is sometimes given to destroy worms. In a scarcity of hops, the plant is used in the north of Europe to bitter the ale. The powdered roots are sometimes used in Lapland instead of bread, but they are unpalatable. Some people say, that sheep will eat it, and that it cures them of the rot; but from the Upsal Experiments it appears, that though goats eat it, sheep sometimes will not. Cows, horses, and swine, refuse it.—Dr Lewis informs us, that it is an efficacious aperient and deobstruent; promotes the fluid secretions; and, if liberally taken, gently loosens the belly. It has of late gained great reputation in scorbutic and scrophulous disorders; and its good effects in those cases have been warranted by experience. Inveterate cutaneous diseases have been removed by an infusion of the leaves, drank to the quantity of a pint a-day, at proper intervals, and continued for some weeks. Boerhaave relates, that he was relieved of the gout by drinking the juice mixed with whey.

MENZIKOFF (Alexander), was originally an apprentice to a pastry-cook near the palace of Moscow; but by a fortunate circumstance was drawn from that situation in early life, and placed in the household of Peter the Great. Having made himself master of several languages, and being formed for war and for business, he first rendered himself agreeable, and afterwards became necessary, to his master He assisted Peter in all his projects; and was rewarded for his services with the government of Ingria, the rank of prince, and the title of *major-general*. He signalized himself in Poland in 1708 and 1709; but in 1713 he was accused of embezzling the public money, and fined in 300,000 crowns. The Czar remitted the fine; and having restored him to favour, gave him the command of an army in the Ukraine in 1719, and sent him as his ambassador into Poland in 1722. Constantly employed about the means of preserving his influence after the death of his master, who was then evidently on the decline, Menzikoff discovered the person to whom the Czar intended to leave the succession. The emperor was highly offended, and his penetration cost him the principality of Plescoff. Under the Czarina Katharine, however, he was higher in favour than ever; because, on the death of the Czar in 1725, he was active in bringing different parties in Russia to agree to her succession. This princess was not ungrateful. In appointing her son-in-law Peter II. to be her successor, she commanded him to marry the daughter of Menzikoff, and gave the Czar's sister to his son. The parties were actually betrothed; and Menzikoff was made duke of Cozel and grand steward to the Czar. But this summit of elevation was the prelude to his fall. The *Dolgoroukis*, favourites of the Czar, had influence enough to procure his banishment, together with that of his family, to one of his own estates at the distance of 250 leagues from Moscow. He had the imprudence to leave the capital with the splendor and magnificence of a governor going to take possession of his province. His enemies took advantage of this circumstance to inflame the indignation of the Czar. At some distance from Moscow he was overtaken by a detachment of soldiers. The officer who commanded them made him alight from his chariot, which he sent back to Moscow; and placed him and his whole family in covered waggons, to be conducted into Siberia, in the habit of peasants. When he arrived at the place of his destination, he was presented with cows and sheep big with young, and poultry, without knowing from whom he received the favour. His house was a simple cottage; and his employment was to cultivate the ground, or to superintend its cultivation. New causes of sorrow were added to the severities of exile. His wife died in the journey; he had the misfortune to lose one of his daughters by the small-pox; and his other two children were seized with the same disease, but recovered. He sunk under his misfortunes, November 2. 1729; and was buried beside his daughter, in a little chapel which he had built. His misfortunes had inspired him with sentiments of devotion, which, amid the splendor of his former situation, he had altogether neglected. His two surviving children enjoyed greater liberty after the death of their father. The officer permitted them to attend public worship on Sundays by turns. One day when his daughter was returning from the village, she heard herself accosted by a peasant from the window of a cottage, and, to her great surprize, recognised in this peasant the persecutor of her family, Dolgorouki; who, in his turn, had fallen a sacrifice to the intrigues of the court. She communicated this intelligence to her brother, who could not behold, without emotion, this new instance of the vanity and instability of honours and power. Young Menzikoff and his sister were soon after recalled to Moscow by the Czarina Ann; and left Dolgorouki in possession of their cottage. He was made

made captain of the guards, and received the fifth part of his father's possessions. His sister was appointed maid of honour to the Empress, and afterwards married to great advantage.

MENZINI (Benedict), a celebrated Italian poet, born at Florence, was professor of eloquence at the college Della Sapienza at Rome, where he died in 1704. He wrote, 1. The art of poetry. 2. Satires, elegies, hymns, and the Lamentations of Jeremiah. 3. *Academia Tusculana*, a work in verse and prose, which passes for his masterpiece.

MEOTIS, or PALUS MEOTIS, a sea of Turky, which divides Europe from Asia; extending from Crim Tartary to the mouth of the river Don or Tanais.

MEPHITIC, a name expressing any kind of noxious vapour; but generally applied to that species of vapour called *fixed air*. See AIR, FIXED *Air*, GAS, &c.

MEPHITIS FANUM, a temple erected to the goddess Mephitis, near Lacus Amsancti; who was worshipped also at Cremona. Figuratively, *Mephitis* denotes a noisome or pestilential exhalation, (Virgil.)

MEQUINEZ, or MIQUINEZ, the northern capital of the Morocco empire, stands at the extremity of the province of Beni-Hassen, 80 leagues north from the city of Morocco (which is the southern imperial city), and 20 to the east of Salee and the ocean. Maknassa, its founder, built it first at the bottom of a valley; but Muley Ismael extended it considerably over the plain that lies to the west of the valley. It is surrounded with well cultivated fields and hills, adorned with gardens and olive plantations, and abundantly watered with rivulets. Accordingly, fruits and kitchen stuffs thrive here exceedingly, and even the superior urbanity of the inhabitants announces the temperature of the climate. The winter indeed is very inconvenient, on account of the dirtiness of the town, the streets not being paved, and the soil being slimy.

Mequinez is surrounded with walls; the palace itself is fortified with two bastions, on which formerly some small guns were mounted. Muley Ismael, and Muley Abdallah, often in this city resisted the efforts of the Brebes, the sworn enemies of their tyranny. To the west are seen some walls of circumvallation, six feet in height, which were probably mere intrenchments for the infantry; the attacks of the Brebes being only sudden and momentary inroads, which did not require long defence. There is at Mequinez, as well as at Morocco, a walled and guarded suburb for the Jews. The houses are neater here than at Morocco. The Jews here are more numerous; and they can turn their industry to greater account, because the Moors in this city are more polished, and (being nearer to Europe) more visited, than those in the southern parts. Near the Jewry, there is another inclosed and separate quarter, called the *Negro-town*. It was built by Muley Ismael, for the accommodation of those black families which composed his soldiery. This town is now uninhabited, as are all those destined for the same use through the rest of the empire.

At the south-east extremity of the city stands the palace of the emperor, which was built by Muley Ismael. The space occupied by this palace is very great; it includes several gardens, elegantly disposed, and well watered. There is a large garden in the centre, surrounded by a vast and pretty regular gallery, resting on columns, which communicates with the apartments. Those of the women are very spacious, and have a communication with a large chamber which looks into the garden. As you pass from one apartment to another, you find at intervals regular courts paved with square pieces of black and white marble; in the middle of these courts is a marble bason, from the centre of which rises a *jet-d'eau*, and the water falls down into this bason. These fountains are numerous in the palace; they are useful for domestic purposes, and they serve for the ablutions, which the scruples of the Mahometans have exceedingly multiplied. The palaces of the Moorish kings are large, because they are composed only of one range of apartments; these are long and narrow, from 18 to 20 feet high; they have few ornaments, and receive the light by two large folding doors, which are opened more or less as occasion requires. The rooms are always lighted from a square court in the centre, which is generally encompassed with a colonade.

The Moors here are more courteous than those in the southern parts; they are civil to strangers, and invite them into their gardens, which are very neat. The women in this part of the empire are beautiful; they have a fair complexion, with fine black eyes, and white teeth. I have sometimes seen them taking the air on the terraces; they do not hide themselves from Europeans, but retire very quickly on the appearance of a Moor.

MERA-DE-ASTA, formerly a large town of Andalusia, seated on the river Guadaleta, between Arcos and Xeres de la Frontera; but now only a large heap of ruins. Here the Arabs conquered Roderick the last king of the Goths, and by that victory became masters of Spain in 713.

MERCATOR (Gerard), one of the most celebrated geographers of his time, was born at Ruremonde in 1512. He applied himself with such industry to geography and mathematics, that he is said to have frequently forgot to eat and drink. The emperor Charles V. had a particular esteem for him, and the duke of Juliers made him his cosmographer. He composed a chronology, some geographical tables, an Atlas, &c. engraving and colouring the maps himself. He died in 1594. His method of laying down charts is still used, and bears the name of *Mercator's charts*.

MERCATOR (Nicholas), an eminent mathematician in the 17th century, was born at Holstein in Denmark; and came to England about the time of the restoration, where he lived many years. He was fellow of the Royal Society; and endeavoured to reduce astrology to rational principles, as appeared from a MS. of his in the possession of William Jones, Esq. He published several works, particularly *Cosmographia*. He gave the quadrature of the hyperbole by an infinite series; which was the first appearance in the learned world of a series of this sort drawn from the particular nature of the curve, and that in a manner very new and abstracted.

MERCATOR's Sailing, that performed by Mercator's chart. See NAVIGATION.

MERCATORUM

cato- um, han'.

MERCATORUM festum, was a feſtival kept by the Roman merchants on the 15th of May in honour of Mercury, who preſided over merchandiſe. A ſow was ſacrificed on the occaſion, and the people preſent ſprinkled themſelves with water fetched from the fountain called *aqua Mercurii*; the whole concluding with prayers to the god for the proſperity of trade.

MERCHANT, a perſon who buys and ſells commodities in groſs, or deals in exchanges; or that traffics in the way of commerce, either by importation or exportation. Formerly every one who was a buyer or ſeller in the retail way was called a *merchant*, as they ſtill are both in France and Holland; but here ſhopkeepers, or thoſe who attend fairs or markets, have loſt that appellation.

Previous to a perſon's engaging in a general trade, and becoming an univerſal dealer, he ought to treaſure up ſuch a fund of uſeful knowledge as will enable him to carry it on with eaſe to himſelf, and without riſking ſuch loſſes as great ill-concerted undertakings would naturally expoſe him to. A merchant ſhould therefore be acquainted with the following parts of commercial learning. 1. He ſhould write properly and correctly. 2. Underſtand all the rules of arithmetic that have any relation to commerce. 3. Know how to keep books of double and ſingle entry, as journals, a leger, &c. 4. Be expert in the forms of invoices, accounts of ſales, policies of inſurance, charter-parties, bills of lading, and bills of exchange. 5. Know the agreement between the money, weights, and meaſures of all parts. 6. If he deals in ſilk, woollen, linen, or hair manufactures, he ought to know the places where the different ſorts of merchandizes are manufactured, in what manner they are made, what are the materials of which they are compoſed, and from whence they come, the preparations of theſe materials before working up, and the places to which they are ſent after their fabrication. 7. He ought to know the lengths and breadths which ſilk, woollen, or hair-ſtuffs, linen, cottons, fuſtains, &c. ought to have according to the ſeveral ſtatutes and regulations of the places where they are manufactured, with their different prices, according to the times and ſeaſons; and if he can add to his knowledge the different dyes and ingredients which form the various colours, it will not be uſeleſs. 8. If he confines his trade to that of oils, wines, &c. he ought to inform himſelf particulary of the appearances of the ſucceeding crops, in order to regulate his diſpoſing of what he has on hand; and to learn as exactly as he can what they have produced when got in, for his direction in making the neceſſary purchaſes and engagements. 9. He ought to be acquainted with the ſorts of merchandize found more in one country than another, thoſe which are ſcarce, their different ſpecies and qualities, and the propereſt method for bringing them to a good market either by land or ſea. 10. To know which are the merchandizes permitted or prohibited, as well on entering as going out of the kingdoms or ſtates where they are made. 11. To be acquainted with the price of exchange, according to the courſe of different places, and what is the cauſe of its riſe and fall. 12. To know the cuſtoms due on importation or exportation of merchandizes, according to the uſage, the tariffs, and regulations, of the places to which he trades. 13. To know the beſt manner of folding up, embaling, or tunning, the merchandizes for their preſervation. 14. To underſtand the price and condition of freighting and inſuring ſhips and merchandize. 15. To be acquainted with the goodneſs and value of all neceſſaries for the conſtruction and repairs of ſhipping, the different manner of their building; what the wood, the maſts, cordage, cannons, ſails, and all requiſites, may coſt. 16. To know the wages commonly given to the captains, officers, and ſailors, and the manner of engaging with them. 17. He ought to underſtand the foreign languages, or at leaſt as many of them as he can attain to; theſe may be reduced to four, viz. the Spaniſh, which is uſed not only in Spain but on the coaſt of Africa, from the Canaries to the Cape of Good Hope: the Italian, which is underſtood on all the coaſts of the Mediterranean, and in many parts of the Levant: the German, which is underſtood in almoſt all the northern countries; and the French, which is now become almoſt univerſally current. 18 He ought to be acquainted with the conſular juriſdiction, with the laws, cuſtoms, and uſages of the different countries he does or may trade to; and in general all the ordinances and regulations both at home and abroad that have any relation to commerce. 19. Though it is not neceſſary for a merchant to be very learned, it is proper that he ſhould know ſomething of hiſtory, particularly that of his own country; geography; hydrography, or the ſcience of navigation; and that he be acquainted with the diſcoveries of the countries in which trade is eſtabliſhed, in what manner it is ſettled, of the companies formed to ſupport thoſe eſtabliſhments, and of the colonies they have ſent out.

Merchant, Merchet.

All theſe branches of knowledge are of great ſervice to a merchant who carries on an extenſive commerce; but if his trade and his views are more limited, his learning and knowledge may be ſo too: but a material requiſite for forming a merchant is, his having on all occaſions a ſtrict regard to truth, and his avoiding fraud and deceit as corroding cankers that muſt inevitably deſtroy his reputation and fortune.

Trade is a thing of ſo univerſal a nature, that it is impoſſible for the laws of Britain, or of any other nation, to determine all the affairs relating to it: therefore all nations, as well as Great Britain, ſhow a particular regard to the law-merchant, which is a law made by the merchants among themſelves: however, merchants and other ſtrangers are ſubject to the laws of the country in which they reſide. Foreign merchants are to ſell their merchandize at the port where they land, in groſs, and not by retail; and they are allowed to be paid in gold or ſilver bullion, in foreign coin or jewels, which may be exported. If a difference ariſes between the king and any foreign ſtate, the merchants of that ſtate are allowed ſix months time to ſell their effects and leave the kingdom; during which time they are to remain free and unmoleſted in their perſons and goods. See the articles COMMERCE, and *Mercantile Law*.

MERCHET (MERCHETUM), a fine or compoſition paid by inferior tenants to the lord, for liberty to diſpoſe of their daughters in marriage. No baron, or military tenant, could marry his ſole daughter and heir, without ſuch leave purchaſed from the king, *pro*

Mercia. *maritanda filia* And many of our servile tenants could neither send their sons to school, nor give their daughters in marriage, without exprefs leave from the fuperior lord. See Kennet's Gloffary *in Maritagium*. See alfo MARCHET.

MERCIA, the name of one of the feven kingdoms founded in England by the Saxons. Though the lateft formed, it was the largeft of them all, and grew by degrees to be by far the moft powerful. On the north it was bounded by the Humber and the Merfey, which feparated it from the kingdom of Northumberland; on the eaft by the fea, and the territories of the Eaft-Angles and Saxons; on the fouth by the river Thames; and on the weft by the rivers Severn and Dee. It comprehended well nigh 17 of our modern counties, being equal in fize to the province of Languedoc in France; very little, if at all, lefs than the kingdom of Arragon in Spain; and fuperior in fize to that of Bohemia in Germany.

Penda is regarded as its firft monarch; and the kingdom is thought to derive its name from the Saxon word *merc*, which fignifies "a march, bound, or limit," becaufe the other kingdoms bordered upon it on every fide; and not from the river Merfey, as fome would perfuade us. Penda affumed the regal title A. D. 626, and was of the age of 50 at the time of his acceffion; after which he reigned near 30 years. He was of a moft furious and turbulent temper, breaking at different times with almoft all his neighbours, calling in the Britons to his affiftance, and fhedding more Saxon blood than had been hitherto fpilled in all their inteftine quarrels. He killed two kings of Northumberland, three of the Eaft-Angles, and compelled Kenwall king of the Weft-Saxons to quit his dominions. He was at length flain, with moft of the princes of his family, and a multitude of his fubjects, in a battle fought not far from Leeds, by Ofwy king of Northumberland This battle, which the Saxon chronicle tells us was fought at Winwidfield, A. D. 655, made a great change in the Saxon affairs, which the unbridled fury of Penda had thrown into great confufion. He had the year before killed Anna king of the Eaft-Angles in battle, whofe brother Ethelred notwithftanding took part with Penda. On the other hand, Penda the eldeft fon of Penda, to whom his father had given the ancient kingdom of the Mid-Angles, had two years before married the natural daughter of King Ofwy, and had been baptized at his court. At that time it fhould feem that Ofwy and Penda were upon good terms; but after the latter had conquered the Eaft-Angles, he refolved to turn his arms againft the kingdom of Northumberland. Ofwy by no means had provoked this rupture; on the contrary, Bede tells us that he offered large fums of money, and jewels of great value, to purchafe peace: thefe offers being rejected, he was reduced to the neceffity of deciding the quarrel by the fword. The river near which the battle was fought overflowing, there were more drowned than killed. Amongft thefe, as the Saxon chronicle fays, there were 30 princes of the royal line, fome of whom bore the title of *kings*; and alfo Ethelred king of the Eaft-Angles, who fought on the fide of Penda againft his family and country.

His fon Penda, who married the daughter of that conqueror, became a Chriftian, and was not long after murdered, as is faid, by the malice of his mother. His brother Wolfher becoming king of Mercia, embraced in procefs of time the faith of the Gofpel, and proved a very victorious and potent monarch; and is, with no fewer than feven of his immediate fucceffors, commonly ftyled *king of the Anglo-Saxons*, though none of them are owned in that quality by the Saxon chronicle. But though poffibly none of them might enjoy this honour, they were undoubtedly very puiffant princes, maintaining great wars, and obtaining many advantages over the fovereigns of other Saxon ftates, and efpecially the Eaft-Angles, whom they reduced. The extent of the Mercian territories was fo ample as to admit, and fo fituated as to require, the conftituting fubordinate rulers in feveral provinces: to whom, efpecially if they were of the royal line, they gave the title of *kings;* which occafions fome confufion in their hiftory. Befides the eftablifhing epifcopal fees and convents, the Saxon monarchs took other methods for improving and adorning their dominions; and as Mercia was the largeft, fo thefe methods were moft confpicuous therein. Coventry, as being fituated in the centre, was ufually, but not always, the royal refidence. Penda, who was almoft continually in a ftate of war, lived as his military operations directed, in fome great town on the frontiers. Wolfher built a caftle or fortified palace for his own refidence, which bore his name.—Offa kept his court at Sutton Walls near Hereford.

In each of the provinces there refided a chief magiftrate; and if he was of the royal blood, had ufually the title of *king*. Penda, at the time he married Ofwy's daughter, had the title of *king of Leicefter*.—Ethelred made his brother Merowald king of Hereford; who, dying without iffue, bequeathed it to his younger brother Mercelm. The like honours were fometimes conferred upon the princeffes; and hence, in Mercia efpecially, we occafionally read of *vice-queens*. By thefe means the laws were better executed, the obedience of the fubjects more effectually fecured, and the fplendor of thefe refidences conftantly kept up and augmented.

At length, the crown devolving fometimes on minors and fometimes on weak princes, inteftine factions alfo prevailing, the force of this hitherto mighty kingdom began fenfibly to decline. This falling out in the days of Egbert, the moft prudent as well as the moft potent monarch of the Weft-Saxons, he took advantage of thefe circumftances; and having encouraged the Eaft-Angles to make an attempt for the recovery of their independence, he, in a conjuncture every way favourable to his defign, broke with the Mercians, and after a fhort war obliged them to fubmit. But this was not an abfolute conqueft, the kings of Mercia being allowed by him and his fucceffors to retain their titles and dominions, till the invafion of the Danes put an end to their rule, when this kingdom had fubfifted above 250 years; and when the Danes were afterwards expelled by the Weft-Saxons, it funk into a province, or rather was divided into many.

Mercia ‖ Mercurials.

MERCURIAL, fomething confifting of, or relating to, mercury.

MERCURIALIS (Jerom), an eminent Italian phyfician

Mercurialis. physician, born at Forli in 1530, where he first practised; but afterwards was professor of medicine successively at Padua, Bologna, and Pisa. His writings in physic are very numerous; besides giving an edition of Hippocrates in Greek and Latin, with notes, which, however, did not answer the expectations of the learned. He died in 1606; and in 1644 some select pieces of his were published at Venice in one volume folio.

MERCURIALIS, MERCURY, in botany: A genus of the enneandria order, belonging to the dioecia class of plants; and in the natural method ranking under the 38th order, *Tricoccæ*. The calyx of the male is tripartite; there is no corolla, but nine or twelve stamina; the antheræ globular and twin. The female calyx is tripartite; there is no corolla, but two styles; the capsule bicoccous, bilocular, and monospermous. There are three species. 1. The annua, or French mercury, with spiked flowers, male and female. This is an annual plant, with a branching stalk about a foot high, garnished with spear-shaped leaves of a pale or yellowish green colour. The male plants have spikes of herbaceous flowers growing on the top of the stalks: these fall off soon; but the female plants, which have testiculated flowers proceeding from the side of the stalks, are succeeded by seeds, which, if permitted to scatter, will produce plenty of plants of both sexes. 2. The perennis mountain, or dog's mercury, with spiked and testiculated flowers, grows under hedges and in woods in many parts of Britain. This has a perennial root, which creeps in the ground; the stalks are single, and without branches, rising 10 or 12 inches high, garnished with rough leaves, placed by pairs at each joint, of a dark green colour, indented on their edges: these have their male flowers growing in spikes, upon different plants from those which produce seeds. 3. The tomentosa, or shrubby hairy mercury, is a native of the south of France, Spain, and Italy. It has a shrubby branching stalk, growing a foot and an half high, garnished with oval leaves placed by pairs, and covered with a white down on both sides. The male flowers grow in short spikes from the side of the stalks upon different plants from the first. All the species are easily propagated by seeds, and are apt to become troublesome weeds where they have once got a footing.

Properties. The perennis, according to Mr Lightfoot, is of a soporific deleterious nature, noxious both to man and beast. There are instances of those who have eaten it by mistake instead of chenopodium, bonus Henricus, or English mercury, and have thereby slept their last. In the isle of Skye, it is called *lusglen-bracadale;* and an infusion of it is sometimes taken to bring on a salivation; but our author knows not how the experiment answers. Tournefort informs us, that the French make a syrup of the juice of the annua, two ounces of which is given as a purge; and that they use it in pessaries and clysters, mixing one quantity of honey to one and a half of the juice. Mr Withering differs greatly from Lightfoot concerning the qualities of the perennis. "This plant (says he), dressed like spinach, is very good eating early in the spring, and is frequently gathered for that purpose; but it is said to be hurtful to sheep. Mr Ray relates the case of a man, his wife, and three children, who experienced highly deleterious effects from eating it fried with bacon; but this was probably when the spring was more advanced, and the plant become acrimonious. Steeped in water, it affords a fine deep blue colour. Sheep and goats eat it; cows and horses refuse it.

Mercurification, Mercury.

MERCURIFICATION, in metallurgic chemistry, the obtaining the mercury from metallic minerals in its fluid form. For the effecting this, those who have been engaged in these researches have proposed three methods. The first is by means of a certain mercury, so prepared as to have a dissolving power, by which it could take up the mercuries of metals in the same manner as water dissolves salt from ashes. The second is by means of certain regenerating salts, such as sal ammoniac, which are to detain the more earthy parts of metals, and leave their mercuries separate or separable from them by sublimation or otherwise; and the third method is by means of a large lens or burning-glass, in the focus whereof, if any metal be applied, its mercurial part is said to separate and go off in fume, which when collected and condensed, appears to be running mercury.

The first of these methods would be very easy if the proper mercury were to be readily produced; the second is extremely laborious, and requires much patience and reiteration. But the third seems easy enough, and practicable to advantage, when a glass of three or four feet in diameter is at hand, the sky serene, and the sun shines strong.

For other processes, the reader may consult Junker's Conspectus Chemiæ. But these mercurified metals, or their mercurial principle rendered sensible, are a kind of philosophical mercury, which, although they resemble ordinary mercury, are nevertheless said by persons exercised in such studies, to differ from it considerably, by having a greater specific gravity, by more effectually penetrating and dissolving metals, by a stronger adhesion to these, and by a less volatility.

MERCURY, in natural history. See CHEMISTRY, *Index*. See also METALLURGY, and QUICKSILVER.

The use of mercury in medicine seems to have been little known before the 15th century. The ancients looked upon it as a corrosive poison, tho' of itself perfectly void of acrimony, taste, and smell: there are examples of its having been lodged for years in cavities both in bones and fleshy parts, without its having injured or affected them. Taken into the body in its crude state, and undivided, it passes through the intestines unchanged, and has not been found to produce any considerable effect. It has indeed been recommended in asthmas and disorders of the lungs; but the virtues attributed to it in these cases have not been warranted by experience.

Notwithstanding the mildness and inactivity of crude quicksilver undivided; yet, when resolved by fire into the form of fume, or otherwise divided into very minute particles, and prevented from re-uniting by the interposition of proper substances, or combined with mineral acids, it has very powerful effects; affording the most violent poisons, and the most excellent remedies with which we are acquainted.

The mercurial preparations, either given internally or introduced into a habit by external application, seem

Mercury. seem to forward circulation through even the minutest and most remote vessels of the body; and may be so managed as to promote excretion through all the emunctories. Hence their common use in inveterate chronic disorders, and obstinate obstructions of the excretory glands; in scrophulous and cutaneous diseases; and in the venereal lues. If their power be not restrained to certain emunctories, they tend chiefly to affect the mouth; and occasion a plentiful evacuation from the salival glands.

The salutary effects of mercurials do not depend on the quantity of sensible evacuation. This medicine may be gradually introduced into the habit, so as, without occasioning any remarkable discharge, to be productive of very happy effects. To answer this purpose, it should be given in very small doses, in conjunction with such substances as determine its action to the kidneys or the pores of the skin. By this method, inveterate cutaneous and venereal distempers have been cured, without any other sensible excretion than a gentle increase of perspiration or urine. Where there are ulcers in any part, they discharge for some time a very fetid matter, the quantity of which becomes gradually less, and at length the ulcer kindly heals. If the mercury should at any time, from cold, or the like, affect the mouth, it may be restrained by omitting a dose, and by warmth, or suitable medicines promoting the perspiration.

Cooling purgatives are also often employed with advantage; but perhaps the most effectual means of giving with safety a sudden check to a mercurial salivation, is by the application of a large blister to the back.

Mercury, as used in medicine, has been employed in a vast variety of different forms. But there is reason to believe, that every useful purpose to be answered by mercury may be obtained from a very few. The mercurial preparations in general, with a view to their use both externally and internally, may be divided into two great classes, the mild and the acrid. Almost every purpose to be answered by the former, may be accomplished by the unguentum hydragyri and pilulæ ex hydrargyro of the London and Edinburgh pharmacopœias; while most of the effects to be obtained from the latter may be derived from the proper use of those preparations, hitherto generally known under the title of *calomel*, and *corrosive sublimate mercury*.

The marks of pure mercury are, its globules not losing their spherical figure when poured on wood; its not communicating a tinge to water, or sweetness to vinegar, when rubbed with them; its evaporating entirely in an iron spoon over the fire; and its having a shining appearance without any pellicle on its surface. Mercury is best purified by distillation in an iron pot, with a long neck bent and immersed in vinegar.

Quicksilver has sometimes been used in its pure metallic state, with the view of removing obstructions in the alimentary canal, from an idea that it would operate by its weight. But it is seldom attended with a good effect, and sometimes it must do harm.

Whole volumes have been written respecting its operation and use in different diseases, and particularly in venereal affections. Some refer its operation to an evacuant power, others to its operating as a peculiar stimulus, and a third set to its possessing a power of destroying or neutralizing the venereal virus. Of these opinions, the latter is the most generally received, and perhaps the best founded. But for a more full view of the controversy, we may refer our readers to late publications on the venereal disease, and on mercury, by Mr John Hunter, Dr Schwediauer, and Dr Duncan.

In virulent gonorrhœa, it is doubted whether mercury be necessary. This disease is commonly treated like any similar inflammation: and the chief things attended to are cleanliness of the parts, a regular belly, and an abstinence from every thing stimulant in food, drink, &c. An injection of oil with calomel, or white precipitate, is much used, and some prefer a watery solution of opium. The more active injections have sometimes very disagreeable consequences.

When the constitution is affected, which is known by ulcers on the glands, buboes, ulcers in the mouth or throat, copper-coloured spots and ulcers on the surface, nodes, &c. mercury is thrown into the body either by friction or by the mouth. The general rule is, to keep up a slight soreness of the gums for some short time after the symptoms disappear; at the same time it is to be remembered, that mercury sometimes continues gleets, and induces ulcers, that are difficultly distinguished from venereal ones; and that these last only yield to warm bathing, diaphoretic diluents, opiates, country air, and milk diet. Corrosive sublimate is sometimes used, as more speedily arresting disagreeable, spreading, or dangerous ulcers; but the completion of the cure should always be trusted to the mild preparations alone. Mercury is also used in rabies canina, in worms, in hydrocephalus internus, in tetanus, and is by some considered as an antidote to the variolous matter.

Mercury, in the heathen mythology. See Hermes.

Most of the actions and inventions of the Egyptian Mercury have likewise been ascribed to the Grecian, who was said to be the son of Jupiter and Maia, the daughter of Atlas. No one of all the heathen divinities had so many functions allotted to him as this god: he had constant employment both day and night, having been the common minister and messenger of the whole Pantheon; particularly of his father Jupiter, whom he served with indefatigable labour, and sometimes indeed in a capacity of no very honourable kind. Lucian is very pleasant upon the multitude of his avocations; and, according to the confession of the emperor Julian, Mercury was no hero, but rather one who inspired mankind with wit, learning, and the ornamental arts of life, than with courage. The pious emperor, however, omits some of his attributes; for this god was not only the patron of trade, but also of theft and fraud.

Amphion is said, by Pausanias, to have been the first that erected an altar to this god; who, in return, invested him with such extraordinary powers of music (and masonry), as to enable him to fortify the city of Thebes in Bœotia, by the mere sound of his lyre.

Horace gives us the best part of his character.

Thou god of wit, from Atlas sprung,
Who by persuasive pow'r of tongue,

And

And graceful exercife, refin'd
The favage race of human kind,
Hail! winged meffenger of Jove,
And all th' immortal pow'rs above.
Sweet parent of the bending lyre,
Thy praife fhall all its founds infpire.
Artful and cunning to conceal
Whate'er in fportive theft you fteal,
When from the god who gilds the pole,
E'en yet a boy, his herds you ftole;
With angry voice the threat'ning pow'r
Bade thee thy fraudful prey reftore;
But of his quiver too beguil'd,
Pleas'd with the theft, Apollo fmil'd.
You were the wealthy Priam's guide,
When fafe from Agamemnon's pride,
Through hoftile camps, which round him fpread
Their watchful fires, his way he fped.
Unfpotted fpirits you confign
To blifsful feats and joys divine;
And, pow'rful, with thy golden wand,
The light, unbodied crowd command;
Thus grateful does thy office prove
To gods below, and gods above. *Francis.*

This ode contains the fubftance of a very long hymn to Mercury, attributed to Homer. Almoft all the ancient poets relate the manner in which the Grecian Mercury difcovered the lyre; and tell us that it was an inftrument with feven ftrings; a circumftance which makes it effentially different from that faid to have been invented by the Egyptian Mercury, which had but three. However, there have been many claimants befides Mereury to the feven-ftringed lyre. See Lyre.

His moft magnificent temple was on mount Cylene, in Arcadia. He is defcribed by the poets as a fair beardlefs youth, with flaxen hair, lively blue eyes, and a fmiling countenance. He has wings fixed to his cap and fandals, and holds the caduceus (or ftaff furrounded with ferpents with two wings on the top) in his hand; and is frequently reprefented with a purfe, to fhow that he was the god of gain. The animals facred to him, were the dog, the goat, and the cock. In all the facrifices offered to him, the tongues of the victims were burnt; and thofe who efcaped imminent danger facrificed to him a calf with milk and honey.

Mercury, ☿ in aftronomy. See Astronomy, *Index*.

This planet is brighteft between his elongations and fuperior conjunction, very near to which laft he can generally be feen. He becomes invifible foon after he has found his elongation, going towards his inferior conjunction; and becomes vifible again a few days before his next elongation The brightnefs of this planet alters fometimes very confiderably in 24 hours. It has been obferved when lefs than three degrees diftant from the fun, and may, perhaps, fometimes be feen even in conjunction with it.

Mercury and Venus appear brighteft and moft beautiful in the oppofite parts of their orbits: the firft, between his elongations and fuperior conjunction; and the other, between her elongations and inferior conjunction. Therefore, Venus is feen in great perfection as a crefcent, particularly in her inferior conjunction, whilft Mercury is feldom feen in fuch perfect phafes. Mercury fhould be always obferved on or near the meridian. When fartheft from the fun, he always appears with a very faint light; and when he has a great fouth declination, or the atmofphere is not perfectly clear, he feldom can be feen in thofe parts of his orbit, where he only begins to recover his brightnefs, or where it is much diminifhed. He has frequently been feen on the meridian even with a fmall telefcope and fmall power; and it appears from the above ftatement that he may be obfcured in a clear day rather more than half his orbit, or near one hundred and fourfcore days in the year.

Mercury, in heraldry, a term ufed in blazoning by planets, for the purple colour ufed in the arms of fovereign princes.

MERCY, a virtue that infpires us with compaffion for our brethren, and which inclines us to give them affiftance in their neceffities. Mercy is alfo taken for thofe favours and benefits that we reeeive either from God or man, particularly in the way of forgivenefs of injuries or of debts. Nothing can be more beautiful than the defcription of mercy given us by Shakefpear, in the pleading between Portia and the Jew:

Por. Then muft the Jew be merciful.
Shy. On what compulfion muft I? tell me that.
Por. The quality of mercy is not ftrain'd;
It droppeth as the gentle rain from heav'n
Upon the place beneath. It is twice blefs'd:
It bleffeth him that gives, and him that takes.
'Tis mightieft in the mightieft; it becomes
The throned monarch better than his crown:
The fceptre fhows the force of temporal power,
The attribute to awe and majefty,
Wherein doth fit the dread and fear of kings;
But mercy is above this fcepter'd fway,
It is enthroned in the hearts of kings;
It is an attribute to God himfelf,
And earthly power doth then fhow likeft God's,
When mercy feafons juftice. Therefore, Jew,
Though juftice be thy plea, confider this,
That in the courfe of juftice none of us
Should fee falvation. We do pray for mercy;
And that fame prayer doth teach us all to render
The deeds of mercy. *Merchant of Venice*, act iv.

MERCY-SEAT, or Propitiatory, in Jewifh antiquity, the covering of the ark of the covenant.—The Hebrew name of this cover, which we tranflate mercy-feat, is *Capporeth* (Exod. xxv. 17. 22.), from *Cappor*, which fignifies *to cover*, *to fhut up*, *to expiate*, *to pay*. This cover was of gold, and at its two ends were fixed the two cherubims of the fame metal, which by their wings extended forwards, feemed to form a throne for the majefty of God, who in fcripture is reprefented to us as fitting between the cherubims, and the ark itfelf was as it were his footftool. It was from hence that God gave his oracles to Mofes, or to the high prieft that confulted him, (Exod. xxv. 22. Numb. vii. 89.)

MERETRIX, among the Romans, differed from the *proftibula*. The *proftibulæ* were common courtezans, with bills over their doors, fignifying their profeffion, and

Merganser. Mergus. and were ready at all times to entertain cuftomers; whereas the *meretrices* entertained none but at night.—The *meretrices* differed in their drefs from the *matrons*; the former wore the *toga* and fhort *tunics*, like thofe of the men: the latter wore the *palla* and the *ftola* of fuch a length as to reach to their feet.

MERGANSER. See Mergus.

MERGUS, in ornithology, a genus of birds of the order of anferes; diftinguifhed by having the beak of a cylindrical figure, and hooked at the extremities, and its denticulations of a fubulated form.

1. The cucullatus, or crefted diver of Catefby, has a globular creft, white on each fide; and the body is brown above and white below. This elegant fpecies inhabits North America. It appears at Hudfon's Bay the end of May, and builds clofe to the lakes.—The neft is compofed of grafs, lined with feathers from the breaft; the number of eggs from four to fix. The young are yellow, and are fit to fly in July.—They all depart from thence in autumn. They appear at New York, and other parts as low as Virginia and Carolina, in November, where they frequent frefh-waters. They return to the north in March; and are called at Hudfon's Bay *Omifka fheep*. Plate CCXCIV.

2. The merganfer, or goofander, weighs four pounds: its length is two feet four inches; the breadth three feet four. The bill is three inches long, narrow, and finely toothed or ferrated; the colour of that and of the irides is red. The *dun-diver*, or female, is lefs than the male: the head and upper part of the neck is ferruginous; the throat white: the feathers on the hind part are long, and form a pendent creft: the back, the coverts of the wings, and the tail, are of a deep afh-colour: the greater quill-feathers are black, the leffer white; the breaft and middle of the belly are white, tinged with yellow. The goofander feems to prefer the more northern fituations to thofe of the fouth, not being feen in the laft except in very fevere feafons. It continues the whole year in the Orkneys; and has been fhot in the Hebrides in fummer. It is common on the continent of Europe and Afia, but moft fo towards the north. It is found alfo in Iceland and Greenland, and breeds there, retiring fouthward in winter, at which time it is found about the lake Baikal. It is frequent in America; inhabits the province of New York in winter; retires from thence in April, probably to Hudfon's Bay; and, if it be the bird called a *Fifherman-duck*, found alfo in Carolina.

3. The ferrator, or red-breafted merganfer, weighs about two pounds: the length is one foot nine inches, the breadth two feet feven; the bill is three inches long; the lower mandible red; the upper dufky; the irides a purplifh red: head and throat a fine changeable black and green: on the former a long pendent creft of the fame colour; the tail fhort and brown; the legs orange-coloured The head and upper part of the female are of a deep rufh-colour, and the tail afh-coloured. Thefe birds are moft frequent in the northern parts of Great Britain. They are obferved to breed on Loch Mari, in the county of Rofs, and in the ifle of Iflay. The fpecies is common in moft parts of the north of Europe, on the continent; and as high as Iceland, where it is called *Vatus-ond*: alfo in the Ruffian dominions, about the great rivers of Sibiria, and the lake Baikal. It is likewife frequent in Greenland in the fummer, where it breeds on the fhores. The eggs are like thofe of a wild duck, but fmaller and whiter. It dives well, and is very active in the water; but the Greenlanders often take it by darts thrown at it, efpecially in Auguft, being the time when it is in moult. It is frequent in Newfoundland, and often appears at Hudfon's Bay in large flocks, but is obferved to be of a larger fize there than in Europe. They generally come in pairs the beginning of June, as foon as the ice breaks up; make the neft foon after their arrival, chiefly on dry fpots of ground in the iflands, and lay from eight to thirteen white eggs, the fize of thofe of a duck: the neft made of withered grafs, and lined with the down of the breaft. The young are of a dirty brown, like young goflings. They all depart fouth in October to the lakes, where they may have open water. They are known at Hudfon's Bay by the name of *As-fick*. Mergus. Merian.

4. The albellus, or fmew, weighs about 34 ounces: the length 18 inches, the breadth 26; the bill is near two inches long, and of a lead colour; the head is adorned with a long creft, white above and black beneath: the head, neck, and whole under part of the body, are of a pure white; the tail is of a deep afh-colour, the legs a bluifh grey. The female, or *lough diver*, is lefs than the male: the back, the fcapulars, and the tail, are dufky; the belly is white. The fmew is feen in England only in winter, at which feafon it will fometimes be met with at the fouthern parts of it; as alfo in France, in the neighbourhood of Picardy, where it is called la Piette: fimilar to this, we have heard it called in Kent by the name of *Magpie-diver*. On the continent we find it as far fouth as Carniola; frequents alfo Iceland, at which place, or fome other arctic region, it paffes the fummer; and where it in courfe breeds, probably along with the other Merganfers; as it has been obferved to migrate, in company with thofe birds, feveral kinds of ducks, &c. in their courfe up the Wolga, in February. It alfo inhabits America, having been fent from New-York, where it is probably a migratory fpecies, as in Europe.

5. The minutus, or redheaded fmew, weighs about 15 ounces; the length one foot four inches, the breadth one foot eleven: the bill is of a lead colour: the head flightly crefted, and of a ruft colour: the hind part of the neck is of a deep grey, the forepart clouded with a lighter colour of the fame kind: the back and tail are of a dufky afh-colour, the legs of a pale afh-colour.—It is a native of Europe. Birds of this genus (Mr Latham obferves) "are in general not fo well-flavoured as thofe of the duck kind; yet we have often met with the laft fpecies in the London markets, and by fome they are thought to be very little inferior to the wild duck; which laft now and then partakes of the *fifhy haut gout*, a flavour not difagreeable to the palates of the connoiffeurs in good eating."

MERIAN (Maria Sibylla), a celebrated paintrefs, born at Frankfort in 1647, was the daughter of Matthias Merian, a noted engraver and geographer.—As fhe fhowed a very early fondnefs for painting, fhe was inftructed by Abraham Mignon; from whom fhe learned great neatnefs of handling and delicacy of colour.

lour. Her genius particularly led her to paint reptiles, flowers, and insects, which she designed after nature, and studied every object with a most curious and inquisitive observation; so that her works rose every day more and more into reputation. Frequently she painted her subjects in water-colours on vellum, and finished an astonishing number of designs, as she was equally indefatigable in her work and in her inquiries into the curiosities of nature. She drew the flies and caterpillars in all the variety of changes and forms in which they successively appear from their quiescent state till they become butterflies; and also drew frogs, toads, serpents, ants, and spiders, after nature, with extraordinary exactness and truth. She even undertook a voyage to Surinam, to paint those insects and reptiles which were peculiar to that climate; and at her return to her own country published two volumes of engravings after her designs, which are well known to the curious. She died in 1717. Her daughter Dorothea Henrietta Graff, who painted in the same style, and had accompanied her mother to Surinam, published a third volume collected from the designs of Sibylla; which complete work has been always admired by the learned, as well as by the professors of painting.

MERIDA, a strong town of Spain, in Estremadura, built by the Romans before the birth of Christ. Here are fine remains of antiquity, particularly a triumphal arch, but not now what it was formerly. It is seated in an extensive and fertile plain, 47 miles east of Elva, and 45 south by east of Alcantara. W. Lon. 6.4. N. Lat. 38.42.

MERIDA, a town of North America, in New Spain, and capital of the province of Yutacan, where the bishop and the governor of the province reside. It is inhabited by Spaniards and native Americans; is 30 miles south of the sea, and 120 N. E. of Campeachy. W. Lon. 89. 25. N. Lat. 20. 15.

MERIDA, a town of South America, in the kingdom of New Granada, seated in a country abounding with all kinds of fruits, 130 miles N. E. of Pampeluna. W. Lon. 71. 0. N. Lat. 8. 30.

MERIDEN, or MIREDEN, a town of Warwickshire, 97 miles from London, in the London road, near Coventry. It is pleasantly situated, though in a wet clayey situation, and is not ill built. The church stands on an elevated spot, and contains some good monuments. There is an inn here, about half way from St Clement's forest to Coventry, one of the finest in this part of England, being built like a nobleman's seat.

MERIDIAN, in geography, a great circle supposed to be drawn through any part on the surface of the earth, and the two poles; and to which the sun is always perpendicular at noon. See GEOGRAPHY.

In astronomy, this circle is supposed to be in the heavens, and exactly perpendicular to the terrestrial one. See ASTRONOMY.

MERIDIANI, in antiquity, a name which the Romans gave to a kind of gladiators who entered the arena about noon after the bestiarii (who fought in the morning against beasts) had finished. They were thus called from *meridies*, i. e. *noon*, the time when they exhibited their shews. The meridiani were a sort of artless combatants, who fought man with man, sword in hand. Hence Seneca takes occasion to observe, that the combats of the morning were full of humanity compared with those which followed.

MERIDIONAL DISTANCE, in navigation, the same with departure, or easting and westing; being the difference of longitude between the meridian, under which the ship now is, and any other meridian which she was under before.

MERIDIONAL parts, miles, or minutes, in navigation, are the parts by which the meridians in a Mercator's chart do increase, as the parallels of latitude decrease.

MERIONETHSHIRE, a county of North-Wales, is bounded on the north by Caernarvonshire and Denbighshire; on the east by Montgomeryshire; on the west by St George's channel, or the Irish sea; and on the south by the river Dyffi, which parts it from Cardiganshire; extending 40 miles in length and 36 in breadth. It is divided into six hundreds, in which are four market-towns, 37 parishes, about 2590 houses, and 17,100 inhabitants. It lies in the diocese of Bangor, and sends one member to parliament. The air is very sharp in winter, on account of its many high barren mountains; and the soil is as bad as any in Wales, it being very rocky and mountainous. However, this county feeds large flocks of sheep, many goats, and large herds of horned cattle, which find pretty good pasture in the valleys. Besides these, among their other commodities may be reckoned Welch cotton, deer, fowl, fish, and especially herrings, which are taken on this coast in great plenty.

MERIT, signifies *desert*. This term is more particularly applied to signify the moral goodness of the actions of men, and the rewards to which those actions intitle them.

MERLIN (Ambrose), a famous English poet and reputed prophet, flourished at the end of the 5th century. Many surprising and ridiculous things are related of him. Several English authors have represented him as the son of an incubus, and as transporting from Ireland to England the great stones which form Stonehenge on Salisbury plain. Extravagant prophecies and other works are also attributed to him, on which some authors have written commentaries.

MERLIN, in ornithology. See FALCO.

MERLON, in fortification, is that part of a parapet which is terminated by two embrasures of a battery.

MERLUCIUS, the HAKE, in ichthyology. See GADUS.

MERMAID, or MERMAN, a sea-creature frequently talked of, supposed half human and half a fish.

However naturalists may doubt of the reality of *mermen* or *mermaids*, we have testimony enough to establish it; though, how far these testimonies may be authentic, we cannot take upon us to say. In the year 1187, as Laray informs us, such a monster was fished up in the county of Suffolk, and kept by the governor for six months. It bore so near a conformity with man, that nothing seemed wanting to it but speech. One day it took the opportunity of making its escape; and plunging into the sea, was never more heard of. *Hist. de Angleterre*, P. I. p. 403.

In the year 1430, after a huge tempest, which broke down the dikes in Holland, and made way for the

Mermaid,
||
Merodach.

the sea into the meadows, &c. some girls of the town of Edam in West-Freezeland, going in a boat to milk their cows, perceived a mermaid embarrassed in the mud, with a very little water. They took it into their boat, and brought it with them to Edam, dressed it in womens apparel, and taught it to spin. It fed like one of them, but could never be brought to offer at speech. Some time afterwards it was brought to Haerlem, where it lived for some years, though still showing an inclination to the water. Parival relates, that they had given it some notion of a Deity, and that it made its reverences very devoutly whenever it passed by a crucifix. *Delices de Hollande.*

In the year 1560, near the island of Manar, on the western coast of the island of Ceylon, some fishermen brought up, at one draught of a net, seven mermen and mermaids; of which several Jesuits, and among the rest F. Hen. Henriques and Dimas Bosquez, physicians to the viceroy of Goa, were witnesses. The physician, who examined them with a great deal of care, and made dissection thereof, asserts, that all the parts both internal and external were found perfectly conformable to those of men. See the *Hist. de la compagnie de Jesus*, P. II. T. IV. n° 276. where the relation is given at length.

We have another account of a merman, seen near the great rock called *Diamond*, on the coast of Martinico. The persons who saw it, gave in a precise description of it before a notary. They affirmed that they saw it wipe its hand over its face, and even heard it blow its nose.

Another creature of the same species was caught in the Baltic in the year 1531, and sent as a present to Sigismond king of Poland, with whom it lived three days, and was seen by all the court. Another very young one was taken near Rocca de Sintra, as related by Damian Goes. The king of Portugal and the grand master of the order of St James, are said to have had a suit at law to determine which party these monsters belong to.

In Pontopidan's Natural History of Norway, also, we have accounts of mermaids; but not more remarkable or any way better attested than the above.

MERNS, or KINCARDINSHIRE, a county of Scotland, stretching 27 miles in length and 20 in breadth, is bounded on the east by the German ocean, on the south by the river of North Esk, on the west by Angus, and on the north by the river Dee and Aberdeenshire. The country is pretty plain and level, fruitful in corn and pasturage, producing an infinite number of fir-trees, besides a great number of agreeable plantations; and along the sea-coasts there are many convenient creeks and harbours.—The people are Lowlanders, civil, hospitable, and industrious.—The name *Merns* is by some derived from that of a valiant nobleman, who, subduing the country, received it in reward from Kenneth II. Cambden supposes it to retain part of the ancient name of *Vernicones*. The other name is derived from *Kincardin*, its ancient capital, now an inconsiderable village. The stocking-trade employs the natives from the banks of the Dee to Stone-hive; from thence to the North Esk they are wholly employed in weaving.

MERODACH was an ancient king of Babylon, who was placed among the gods, and worshipped by the Babylonians. Jeremiah (chap. l. 2.), speaking of the ruin of Babylon, says, "Babylon is taken, Bel is confounded, Merodach is broken in pieces, her idols are confounded, her images are broken in pieces." We find certain kings of Babylon, in whose names that of Merodach is contained: for example, Evilmerodach and Merodach-baladan. Evilmerodach was the son of Nebuchadnezzar the Great, and had for his successor the wicked Belshazzar. Merodach-baladan, son of Baladan king of Babylon, having heard that Hezekiah had been cured miraculously (Isa. xxxix.), and that the sun had gone backwards to give him an assurance of his recovery, sent him presents, and made him compliments upon the recovery of his health. Ptolemy calls him *Mardocempadus*; and says, that he began to reign at Babylon 26 years after the beginning of the era of Nabonassar, that is, in the year of the world 2283.

Meroe.

MEROE (anc. geog.), an island of Ethiopia beyond Egypt, in the Nile; with a cognominal town, the metropolis of the Ethiopians.

The Jesuits have endeavoured to prove, that the province of Gojam in Abyssinia is the Meroë of the ancients; but this is strongly contested by Mr Bruce, who is of opinion that it must be looked for somewhere between the source of the Nile and its union with the Atbara. The latter, he thinks, is very plainly the Astaboras of the ancients; and Pliny says that this stream incloses the left side of Meroë as the Nile does the right, in which case we must suppose him looking southward from Alexandria, otherwise the words would not apply.

We are told by Diodorus Siculus, that Meroë had its name from a sister of Cambyses king of Persia, who died there in the expedition undertaken by that prince against the Ethiopians. His army perished with hunger and thirst in the deserts beyond Meroë; which could not have happened if they had reached Gojam, the latter being one of the most plentiful countries in the world. A further proof that Gojam cannot be the ancient Meroë is, that the latter was inclosed between the rivers Nile and Astaboras, while Gojam is almost entirely surrounded by the Nile. If the ancients were acquainted with Gojam, they must also have been acquainted with the fountains of the Nile, which we certainly know they were not. Pliny says that Meroë, the most considerable of all the islands of the Nile, was called *Astaboras*, from the name of its left channel, which cannot be supposed any other than the junction of the Nile and Atbara. He informs us moreover, that the sun was vertical twice in the year, *viz.* when proceeding northward he entered the 18th degree of Taurus, and when returning he came to the 14th degree of Leo; but this could never be the case with Gojam, which lies in about 10 degrees north latitude.

Again the poet Lucan describes Meroë by two circumstances which cannot apply to any other than the peninsula of Athara. One is, that the inhabitants were black; which was the case with the Gymnosophists and first inhabitants, and which has been the case with all the rest down to the Saracen conquest: but the inhabitants of Gojam, as well as the other Abyssinians, are fair, at least greatly different in complexion from the blacks; they are also long haired.

and

Meroe, Merom.

and nobody imagined that they ever had philosophers or science among them, which was eminently the case with the ancient inhabitants of Meroë. The other circumstance is, that the ebony tree grew in the island of Meroë, which at this day grows plentifully in the peninsula of Atbara, and part of the province of Kuara, but not in Gojam, where the tree could not subsist on account of the violent rains which take place during six months of the year. Mr Bruce mentions another circumstance quoted from the poet Lucan, which likewise tends to prove the identity of Meroë and Atbara; viz. that though there are many trees in it, they afford no shade. This our traveller found by experience, when returning from Abyssinia through Atbara. "The country (says he) is flat, and has very little water. The forest, though thick, afforded no sort of shade, the hunters for the sake of their sport, and the Arabs for destroying the flies, having set fire to all the dry grass and shrubs; which passing with great rapidity in the direction of the wood from east to west, though it had not time to destroy the trees, did yet wither, and occasion every leaf that was upon them to fall, unless in those spaces where villages had been and where water was. In such spots a number of large spreading trees remained full of foliage; which from their great height and being cleared of underwood, continued in full verdure, loaded with large, projecting, and exuberant branches. But even here the pleasure that their shade afforded was very temporary, so as to allow us no time for enjoyment. The sun, so near the zenith, changed his azimuth so rapidly, that every few minutes I was obliged to change the carpet on which I lay, round the trunk of the tree to which I had fled for shelter; and though I lay down to sleep perfectly screened by the trunk or branches, I was presently awakened by the violent rays of a scorching sun, the shade having passed beyond me. In all other places, though we had travelled constantly in a forest, we never met with a tree that could shade us for a moment, the fire having deprived them of all their leaves." The heat of Atbara is excessive, the thermometer having been observed at $119\frac{1}{2}°$: two of Mr Bruce's company died of thirst, or at least of the consequences of drinking after extreme thirst. The inhabitants live in the greatest misery, and are continually in danger from the neighbouring Arabs, who, by destroying and burning their corn, are able to reduce them to a starving condition. Notwithstanding all their disadvantages, however, they have a manufacture of coarse cotton towels, of a size just sufficient to go round the waist, which pass current as silver money throughout the whole country.

MEROM, (anc. geog.) The waters of Merom, at which place Jabin and the other confederate kings met to fight Joshua (xi. 5.), are generally supposed by the learned to be the lake Semechon, which lies between the head of the river Jordan and the lake Gennesareth; since it is agreed on all hands, that the city Hazor, where Jabin reigned, was situated upon this lake. But others think, that the waters of Merom or Merome were somewhere about the brook Kishon, since there is a place of that name mentioned in the account of the battle against Sisera (Judg. v. 21.) And it is more rational to think, that the confederate kings advanced as far as the brook Kishon, and to a pass which led into the country, to hinder Joshua from penetrating it, or even to attack him in the country where he himself lay encamped, than to imagine that they waited for him in the midst of their own country; leaving all Galilee at his mercy, and the whole tract from the brook Kishon to the lake Semechon.

Merope, Merops.

MEROPE (fab. hist.) one of the Atlantides. She married Sisyphus the son of Æolus, and like her sisters was changed into a constellation after death. It is said that in the constellation of the Pleiades the star of Merope appears more dim and obscure than the rest, because she, as the poets observe, married a mortal, while her sisters married some of the gods or their descendants.

MEROPS (fab. hist.) a king of the island of Cos, who married Clymene, one of the Oceanides. He was changed into an eagle, and placed among the constellations. Also a celebrated soothsayer of Percosus in Troas, who foretold the death of his sons Adrastus and Amphius, who were engaged in the Trojan war. They slighted their father's advice, and were killed by Diomedes.

MEROPS, in ornithology, a genus belonging to the order of picæ. The bill is crooked, flat, and carinated; the tongue is jagged at the point; and the feet are of the walking kind. 1. The apiaster, or bee-eater, has an iron-coloured back; the belly and tail are of a bluish green; and the throat is yellow. This bird inhabits various parts of Europe, on the continent, though not in England; yet is said to have been seen in Sweden, and flocks of them have been met with at Anspach in Germany in the month of June. They are now and then seen in Lorraine, though only in pairs; and are not unfrequent in other parts, since Kramer talks of their building the nest in the sandy crags of the Danube. They are met with in Italy and the south of France; and in Candia and other islands of the Mediterranean, they are in plenty, as well as in Palestine and Arabia, being very common in the woods about Yemen, where they are called Schæghagha. It takes the name of *bee-eater* from its being very fond of those insects; but, besides these, it will catch gnats, flies, cicadæ, and other insects, on the wing, like the swallow. Willoughby tells us, from Belon, "that its singular elegancy invites the Candy boys to hunt for it with cicadæ, as they do for those greater swallows called *swifts*, after this manner:—Bending a pin like a hook, and tying it by the head to the end of a thread, they thrust it through a cicada (as boys bait a hook with a fly), holding the other end of the thread in their hands: the cicada, so fastened, flies nevertheless in the air; which the Merops spying, flies after it with all her force; and catching it, swallows pin and all, wherewith she is caught."—This bird is said to be in most plenty in the isle of Candia; and, in defect of insects, to eat seeds of many kinds; and Ray supposes, from its similarity to the kingsfisher, it may possibly feed on fish. Most probably some think it good to eat, as Willoughby saw many of them exposed for sale in the markets of Rome. These birds make their nests in deep holes in the banks of rivers, like the sand martin and kingsfisher, at the end of which the female lays from five to seven white eggs, rather less than those of a blackbird. The neſt itſelf is compoſed of moſs. 2. The viridis, or Indian bee-eater, is green, with a black belt on the breaſt; and the throat and tail are black. It inhabits Bengal. 3. The congener is yellowiſh, with a green rump. It inhabits the ſouth of Europe. 4. The ſuperciliosus is green, with a white line both above and below the eyes, and a yellow throat. It is found in Madagaſcar, where the natives give it the name of *Patirich Tirich*. 5. The cinereus is variegated with red and yellow, with the two longeſt quill-feathers of the tail red. It is a native of Mexico. 6. The erythropterus, or red-winged bee-eater, is in length ſix inches; the bill is one inch, and black: the upper parts of the head, body, wings, and tail coverts, are green brown, deepeſt on the head and back, lighteſt on the rump and tail coverts: behind the eye is a ſpot of the ſame, but of a very deep colour: the quills and tail are red, tipped with black; the laſt two inches in length: the throat is yellow; the under parts of the body are a dirty white; and the legs black.—This inhabits Senegal, from which place a well-preſerved ſkin was brought by M. Adanſon. (See fig. A.) 7. The wattled bee-eater (fig. B.) is the ſize of a cuckow, in length about $14\frac{1}{2}$ inches. The feathers on the upper part of the head, being longer than the reſt, give the appearance of a creſt; thoſe of the under part are ſmooth; the plumage for the moſt part is brown; the feathers are long and pointed, and each feather has a ſtreak of white down the middle; under the eye, on each ſide, is a kind of wattle, of an orange colour; the middle of the belly is yellow; the tail is wedge-ſhaped, ſimilar to that of the magpie, and the feathers are tipped with white; the bill and legs are brown.—This bird is ſuppoſed to be peculiar to New Holland. There are 14 or 15 other ſpecies.

Plate CCXCIV.

MEROVINGIAN CHARACTER, derives it name from Meroüée, the firſt king of France of that race, which reigned 333 years, from Pharamond to Charles Martel. This race is ſaid by ſome to have terminated in Childeric III. A. D. 751. There are many MSS. in the French libraries ſtill extant in this character.

MEROZ, (anc. geog.), a place in the neighbourhood of the brook Kiſhon, whoſe inhabitants refuſing to come to the aſſiſtance of their brethren when they fought with Siſera, were put under an anathema (Judges v. 23.) "Curſe ye Meroz, ſays the angel of the Lord; curſe ye bitterly the inhabitants thereof: becauſe, &c." Some have thought that Meroz is the ſame as Merrus or Merom; and this F. Calmet thinks the moſt probable opinion in this matter. Others will have it, that Meroz was a mighty man, who dwelt near the Kiſhon, and not caring to come to the aſſiſtance of Barak and Deborah, was excommunicated by the angel of the Lord by the ſound of 400 trumpets. The angel of the Lord, according to ſome, was Barak, the general of the Lord's army; but according to others he was the high-prieſt for the time being, or a prophet.

MERSA, a town of Barbary, pleaſantly ſituated about 11 miles from the city of Tunis, and two from Melcha the ſite of ancient Carthage. The Bey has here two country-houſes, one of them very coſtly work, built by Haſſan Bey ſurnamed the *Good*. From theſe are orange gardens reaching almoſt to the ſea-ſhore; on the edge of which is a famous well of ſweet water, eſteemed the beſt and lighteſt in the kingdom. Cloſe to this is a coffee-houſe, whether numbers of people from the neighbouring places reſort to drink coffee, and a glaſs of this natural luxury ſo peculiarly enjoyed in the eaſtern countries. In the middle of the court is a large mulberry-tree, under the ſhade of which they ſit and ſmoke and play at cheſs; inhaling the comfortable ſea-breeze that refreſhes this delightful ſpot. The water is drawn up by a camel with the Perſian wheel.

Here are the remains of an ancient port, or cothon, (ſuppoſed to be an artificial one), built by the Carthaginians after Sapii had blocked up the old port, nothing but the turret or light-houſe being left.

MERS or MERSE, a county of Scotland, called alſo *Berwickſhire*. This laſt name it derives from the town of Berwick, which was the head of the ſhire before it fell into the hands of the Engliſh, and obtained the appellation of *Mers* or *March*, becauſe it was one of the borders towards England. It is waſhed on the ſouth and eaſt by the river Tweed and the German Ocean, bounded on the weſt by Tweedale, and on the north by Lothian. It extends 24 miles from eaſt to weſt, and the breadth amounts to 16. The face of the country is rough and irregular, exhibiting hills, moors, and moſſes, with intermediate valleys, which are pleaſant and fruitful. It is watered by many ſtreams; and particularly by the famous Tweed, which, riſing from the ſame hills that give birth to the Clyde and Annan, runs with a rapid courſe through Tweedale foreſt and Teviotdale, and after a courſe of 50 miles diſembogues itſelf into the German Ocean. Notwithſtanding the length of its courſe, it is not navigable above Berwick, where there is a noble bridge over it, conſiſting of 15 arches. There is another fine one, called the *Union Bridge*, at Coldſtream. There is a third at Melroſe, a fourth at Peebles, and a fifth at Kelſo. The ſhire of Berwick is generally diſtinguiſhed into the three diviſions of Mers, Lammermuir, and Lauderdale. The Mers is low, pleaſant, and tolerably fruitful in corn. Lammermuir is a hilly country, abounding with game, and yielding good paſture for ſheep and black cattle. Lauderdale is a tract of land lying on each ſide of the river Lauder, agreeably varied with hill, dale, and foreſt, producing good ſtore of corn and paſturage, and giving the title of earl to the family of Maitland: but the moſt fruitful and populous parts of Berwickſhire, are thoſe that lie along the Tweed, and on both ſides of the leſſer rivers White Water, Black Water, and Eye. The ſeats of noblemen and gentlemen abound in this county.

MERSENNE (Marin), in Latin *Merſennus*, a learned French author, born at Oyſé, in the province of Maine, anno 1588. He ſtudied at La Fleche at the ſame time with Des Cartes; with whom he contracted a ſtrict friendſhip, which laſted till death. He afterwards went to Paris, and ſtudied at the Sorbonne; and in 1611 entered himſelf among the minims. He became well ſkilled in Hebrew, philoſophy, and mathematics. He was of a tranquil, ſincere, and engaging temper; and was univerſally eſteemed by perſons illuſtrious for their birth, their dignity, and their learning.

learning. He taught philofophy and divinity in the convent of Nevers, and at length became fuperior of that convent; but being willing to apply himfelf to ftudy with more freedom, he refigned all the pofts he enjoyed in his order, and travelled into Germany, Italy, and the Netherlands. He wrote a great number of excellent works; the principal of which are, 1. *Quæftiones celeberrimæ in Genefim.* 2 *Harmonicorum libri.* 3. *De fonorum natura, caufis, & effectibus.* 4. *Cogitata phyfico-mathematica.* 5. *La verité des Sciences.* 6. *Les queftions inouies.* He died at Paris in 1648. He had the reputation of being one of the beft men of his age. No perfon was more curious in penetrating into the fecrets of nature, and carrying all the arts and fciences to their utmoft perfection. He was in a manner the centre of all the men of learning, by the mutual correfpondence which he managed between them. He omitted no means to engage them to publifh their works; and the world is obliged to him for feveral excellent difcoveries, which, had it not been for him, would perhaps have been loft.

MERSEY, a river of England, that runs through the counties of Lancafter, York, and Chefter, and empties itfelf into the Irifh fea at Liverpool. By the late inland navigation, it has communication with the rivers Dee, Ribble, Oufe, Trent, Darwent, Severn, Humber, Thames, Avon, &c.; which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancafter, Weftmoreland, Chefter, Stafford, Warwick, Leicefter, Oxford, Worcefter, &c.

Mersey-Ifland, an ifland of Effex, at the mouth of the Coln, fouth of Colchefter. It was feized by the Danes in the reign of King Alfred, for their winter-quarters. It had eight parifhes, now reduced to two, viz. eaft and weft Merfey. The ifland had a block-houfe; and, in the Dutch war, the parliament put 1000 men in it.

MERULA (George), an Italian of extraordinary parts and learning, born at Alexandria in the duchy of Milan about the year 1420. He taught youth at Venice and Milan for 40 years, and laboured abundantly in reftoring and correcting ancient authors. He wrote, and addreffed to Lewis Sforza, *Antiquitates Vicecomitum;* or "The Actions of the Dukes of Milan," in 10 books; with fome other things in the fame way. His death, in 1494, is faid not to have grieved any body; as he lived in a ftate of war with, and abufed, almoft all his cotemporary fcholars.

MERULA (Paul), born at Dort in Holland, a famous lawyer, hiftorian, and linguift, was profeffor of hiftory in the univerfity of Leyden after Lipfius. He wrote, 1. Commentaries on Ennius; 2. The life of Erafmus and Junius; 3. A cofmography; 4. A treatife of law; and died in 1607.

Merula, or *Blackbird*, in ornithology. See Turdus.

MERUS, (anc. geog.), a mountain of the Hither India, hanging over the city Nyffa, built by Bacchus, and fituated between the rivers Cophen and Indus. The name, denoting the *thigh*, gave rife to the fable of Bacchus being inferted into Jupiter's thigh, and being born twice; becaufe in this mountain he and his army are faid to have been preferved, when difeafe and peftilence raged in the plains below.

MESARAIC-vessels, in the general fenfe, are the fame with Mesenteric.

In common ufe, mefaraic is more frequently applied to the veins, and mefenteric to the arteries, of the mefentery. See Anatomy.

MESCHED, a confiderable town of Perfia, and in the province of Khoraffan; fortified with feveral towers, and famous for the magnificent fepulchre of Iman Rifa, of the family of Ali, to whom the Perfians pay great devotion. It is feated on a mountain near this town, in which are fine torquife-ftones; in E. Long. 59. 25. N. Lat. 37. c.

MESEMBRYANTHEMUM, Fig-marigold, in botany: A genus of the pentagynia order, belonging to the icofandria clafs of plants; and in the natural method ranking under the 13th order, *Succulentæ.* The calyx is quinquefid; the petals are numerous and linear; the capfule is flefhy, inferior, and monofpermous. There are between 40 and 50 fpecies; all African plants, from the Cape of Good Hope; near 40 of which are retained in our gardens for variety. Of thefe only one is annual, and the moft remarkable of them all. It is called the *cryftallinum, diamond ficoides,* or *ice-plant.* It rifes with a fhort, thick, fucculent ftalk, dividing low into many trailing, very fpreading, fucculent branches, befpangled all over with icy pimples; very pellucid and glittering; oval, undulate, alternate, papulofe or pimply, glittering leaves; and from the fides of the branches, numerous, almoft clofe fitting, white flowers, tinged with red or crimfon; fucceeded by plenty of feed in autumn This fingular and curious plant, being clofely covered with large pellucid pimples, full of moifture fhining brilliantly like diamonds, is in great efteem. It is a very tender plant while young; and is raifed annually from feed by means of hot-beds. In June it will endure the open air till October, when it perifhes; but if placed in a hot-houfe in autumn, it will often live all winter. It is commonly planted in pots for the conveniency of removing from place to place; but if planted in the full ground, it grows confiderably ftronger, even to luxuriance: however, when confined in pots, it flowers more abundantly.

The other fpecies are moft durable in ftem and foliage. Some are fhrubby; others pendulous, with loofe ftraggling ftems, and branches inclining to the ground; while others have no ftalks at all: their leaves are univerfally very thick, fucculent, flefhy; and of many various fhapes, fituations, and directions; while fome are curioufly punctured, or dotted with tranfparent points, and fome have pellucid pimples, as already mentioned: they afford a very agreeable variety at all times in the year, and merit a place in every collection. They are green-houfe plants, and are propagated by cuttings of their ftalks and branches.

MESENTERIC, or Mesaraic, an epithet given to two arteries arifing from the defcending aorta, and proceeding to the mefentery. See Mesentery.

MESENTERITIS, or *Inflammation of the* Mesentery. See Medicine, n° 191.

MESENTERY, Mesenterium, (formed of μεσο- *middle,*

middle, and *εντερον inteftine*), in anatomy, a fatty membranous body, thus called as being placed in the middle of the inteftines, which it connects to one another. See ANATOMY, n 94.

MESHES *of* NETS, the openings or interftices between the threads.

MESN, or MESNE, a term in law, fignifying him who is lord of a manor, and fo hath tenants holding of him; yet he himfelf holds of a fuperior lord.

The word is properly derived from *maifne, quafi minor natu*; becaufe his tenure is derived from another, from whom he holds.

MESN alfo denotes a writ, which lieth where there is lord mefn and tenant; and the tenant is diftrained for fervices due from the mefn to the fuperior lord.

This is in the nature of a writ of right; and in this cafe the tenant fhall have judgment to be acquitted or indemnified by the mefne lord; and if he makes default therein, or does not appear originally to the tenant s writ, he fhall be forejudged of his mefnalty, and the tenant fhall hold immediately of the lord paramount himfelf.

MESOCHRI, were muficians among the ancients who prefided in concerts, and by beating a wooden defk regularly with their feet, directed the meafure of the mufic. For the purpofe of beating time, they wore wooden clogs, called by the ancients *crupezia*, which occafioned the found to be better heard.

MESOCOLON, in anatomy, that part of the mefentery, which, having reached the extremity of the ileum, contracts and changes its name. See ANATOMY, n° 94.

MESOLOGARITHMS, according to Kepler, are the logarithms of the co-fines and co-tangents; the former of which were called by Baron Napier *anti-logarithms*, and the latter *differentials*.

MESOPOTAMIA, the ancient name of the province of DIARBECK, in Turky in Afia. It is fituated between the rivers Euphrates and Tigris; having Affyria on the eaft, Armenia on the north, Syria on the weft, and Arabia Deferta with Babylonia on the fouth. The Hebrews called it *Padan-aram* (Gen. xxviii. 2. &c.), and *Aram Naharaim* (title of Pfal. lx.) or Aram *of the two rivers*, becaufe it was firft peopled by Aram father of the Syrians, and is fituated between the two rivers already mentioned. This country is much celebrated in fcripture, as being the firft dwelling of men both before and after the deluge; and becaufe it gave birth to Phaleg, Heber, Terah, Abraham, Nahor, Sarah, Rebekah, Rachel, Leah, and to the fons of Jacob. Babylon was in the ancient Mefopotamia, till, by vaft labour and induftry, the two rivers of the Tigris and Euphrates were united into one channel. The plains of Shinar were in the fame country. Often they gave it the name of Mefopotamia (Deut. xxiii 4. &c.) and fometimes that of Syria, (Hofea xii. 12.) Balaam fon of Beor was of Mefopotamia, Deut. xxiii. 4. Chufhan-rifhathaim king of Mefopotamia kept the Hebrews in fubjection fome time after the death of Jofhua, Judg. iii. 8.

MESOPTERYGIUS, in ichthyology, a term applied to fuch fifhes as have only one back-fin, and that fituated in the middle of the back.

MESPILUS, the MEDLAR, in botany: A genus of the pentagynia order, belonging to the icofandria clafs of plants; and in the natural method ranking under the 36th order, *Pomaceæ*. The calyx is quinquefid; the petals are five; the berry is inferior and pentafpermous. There are feven fpecies, viz.

1. The Germanica, German mefpilus, or common medlar, rifes with a deformed tree-ftem, branching irregularly 15 or 20 feet high; fpear-fhaped leaves, downy underneath; and large clofe fitting, white flowers, fingly from the fides of the branches; fucceeded by large roundifh brown fruit, the fize of middling apples, which ripen in October, but are not eatable till beginning to decay. The varieties are, common great German medlar—fmaller Nottingham medlar—fpear-fhaped Italian medlar. This fpecies and varieties are all cultivated in the Englifh gardens for the fruit: but the German or Dutch medlar, and the Nottingham kind, are the moft comm n; and the latter of which two, though a fmaller fruit, is rather preferable for richnefs and poignancy of flavour. Thefe kinds of fruit are never eatable until they begin to rot; for when firm and found, they are of a fingularly auftere difagreeable tafte; yet having lain fome time after being gathered, till they begin to affume a ftate of decay and become foft, they acquire a delicious flavour, extremely agreeable to many, though to others altogether unpalatable.—All thefe forts ripen in the latter end of October, or beginning of November; when being gathered, fome fhould be laid in moift bran, in feveral layers, to forward their decay; others on ftraw in the fruitery: thofe in the bran will begin to be ready for ufe in about a fortnight, and thofe laid on ftraw will come gradually forward in fucceffion.

2. The arbutifolia, arbutus-leaved mefpilus, hath a fhrubby ftem, branching erectly five or fix feet high; lanceolate, crenated, alternate leaves, downy underneath; and from the fides and ends of the branches, fmall white flowers in clufters; fucceeded by fmall, roundifh, purple fruit, like haws.

3. The amelanchier, or fhrubby medlar, with black fruit, rifes with feveral fhrubby, flender, hairy ftems, branching moderately about four feet high, having purplifh branches; oval, ferrated leaves, downy underneath; and fmall white flowers, in clufters at the ends of the branches: fucceeded by fmall black fruit.

4. The chamæ-mefpilus, or dwarf medlar, commonly called *baftard quince*, hath a fhrubby, flender, fmooth ftem, branching weakly four or five feet high, having purplifh branches; oval, ferrated, fmooth leaves, on long foot-ftalks; and from the axillas, purple flowers, collected into round heads, with narrow, purplifh, deciduous bracteæ; fucceeded by fmall red fruit.

5. The cotoneafter, commonly called *dwarf quince*, rifes with a fhrubby, fmooth ftem, branching four or five feet high, the branches flender and reddifh; oval entire leaves on fhort foot-ftalks; and from the axillas, fmall clofe-fitting purple flowers, two or three together; fucceeded by fmall roundifh, bright-red fruit.

6. The Canadenfis, Canada fnowy mefpilus, hath a fhrubby, fmooth ftem, branching four or five feet high, with fmooth, purplifh branches; oval-oblong, ferrated, fmooth leaves, on long footftalks; and all the

the branches terminated by clusters of snowy-white flowers; succeeded by small, purplish fruit, like haws.

7. The pyracantha, or ever-green thorn, rises with a shrubby, spinous stem, branching diffusely 12 or 14 feet high, the branches slender and flexible, with a dark greenish bark, armed with long sharp spines; spear-shaped-oval, crenated, ever-green leaves; and all the shoots terminated by numerous clusters of whitish flowers; succeeded by large bunches of beautiful red berries, remaining all winter, and exhibiting a very ornamental appearance.

All these seven species of mespilus are of the tree and shrub kind; the first six sorts are deciduous, the seventh an ever-green; the leaves are universally simple; those of the mespilus Germanica very large, the others mostly of moderate size, and which in most of the sorts grow upon short footstalks. They all flower abundantly every summer, the flowers universally hermaphrodite, and consisting each of five large roundish petals, 20 stamina, and five styles. They are all very hardy, and succeed in any common soil and situation, and their propagation and culture is very easy.

The first sort and varieties are cultivated as fruit-trees, principally as standards, sometimes also as espaliers for variety. The other species are very proper furniture for any ornamental plantation, where they will make an agreeable variety with their different foliage; and their flowers make a fine appearance, as also their fruit in autumn and winter, which, if not devoured by birds, remain long on the branches, and afford a fine variety in those seasons. The pyracantha, being rather of flexible growth, is most commonly trained against walls or the fronts of houses, both for the support of its flexible branches, and that it may exhibit its berries more ornamentally.

When it is designed to have any of the common medlars as fruit-trees, they may be trained either as dwarfs, for dwarf standards, or for espaliers, or trained as half or full standards, and managed in either of those modes of training nearly as other fruit-trees, particularly the apple and pear; and are raised either by seed, by grafting, or by budding; but either of the two latter methods are the most certain for continuing the sorts without variation: observing, after shortening their first shoots from the graft or bud, where it shall seem necessary to force out a proper supply of wood to form a head, to train the branches afterwards principally at full length, and let the standards branch out in their own way.

MESS, in a military sense, implies a number of soldiers, who, by laying away a certain proportion of their pay towards provisions, mess together: six or eight is generally the number of each mess. Experience proves, that nothing contributes more to the health of a soldier, than a regular and well chosen diet, and his being obliged every day to boil the pot: it corrects drunkenness, and in a great measure prevents gaming, and thereby desertion.

MESSALINA (Valeria), a daughter of Messala Barbatus. She married the emperor Claudius, and disgraced herself by her cruelties and incontinence. Her husband's palace was not the only seat of her lasciviousness, but she prostituted herself in the public streets, and few men there were at Rome who could not boast of having enjoyed the favours of the impure Messalina. Her extravagancies at last irritated her husband, who commanded her to appear and answer all the accusations which were brought against her: upon which she attempted to destroy herself; and when her courage failed, one of the tribunes who had been sent to her dispatched her with his sword. It is in speaking of her debaucheries and lewdness that Juvenal says,

Et lassata viris, necdum satiata, recessit.

Her name has become a common appellation to denote a woman of shameless and inordinate lust.

MESSANA, (anc. geog.), the first town of Sicily on crossing over from Italy, situated on the strait now called the *Faro*, (Italicus). Anciently called *Zancle*, according to Diodorus Siculus, from king Zanclus; or, according to others, from the Sicilian term *Zanclon*, denoting a sickle, alluding to the curvity of the coast: a name appropriated by the poets; and hence *Zanclæi*, the people, (Herodotus, Pausanias). The other name *Messana* is from the *Messenii* of Peloponnesus, (Strabo). Thucydides ascribes its origin to Anaxilas the Messenian, tyrant of Rhegium, who received all comers, calling the town after the name of his country. The Greeks always call it *Messene*; the Romans *Messena* constantly, to distinguish it from *Messene* of Peloponnesus. Now MESSINA, lately ruined by earthquakes.

MESSENA, or MESSENE, an inland town, and the capital of Messenia, a country of Peloponnesus; erroneously placed by Ptolemy on the coast. It was built by Epaminondas, who recalled all the Messenian exiles, and gave the town the name of *Messene*. A place vying in point of strength and situation with Corinth, according to Strabo; and therefore Demetrius Phalerius advised Philip, father of Perseus, that if he wanted to have Peloponnesus in his power, he should make himself master of these two towns, as thus he would have the ox by both horns.

MESSENGERS, are certain officers chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all kinds of dispatches foreign and domestic. They also, by virtue of the secretaries warrants, take up persons for high treason, or other offences against the state. The prisoners they apprehend are usually kept at their own houses, for each of which they are allowed 6s. 8d. *per* day by the government: and when they are sent abroad, they have a stated allowance for their journey, viz. 30l. for going to Paris, Edinburgh, or Dublin; 25l. for going to Holland; and to other places in the same proportion; part of which money is advanced for the expence of their journey. Their standing salary is 45l *per annum*; and their posts, if purchased, are esteemed worth 300l. The messengers wait 20 at a time, monthly, and are distributed as follows, viz. four at court, five at one secretary's office, five at another, two at the third for North Britain, three at the council-office, and one at the lord chamberlain's of the household.

MESSENGERS, in Scotland. See LAW, Part III. p. 651, par. 16.

MESSENGERS of the Exchequer, are four officers who attend the exchequer, in the nature of pursuivants, and carry the lord treasurer's letters, precepts, &c.

MESSENGER of the Press, a person who, by order of

Messenia. of the court, searches printing-houses, booksellers shops, &c. in order to discover the printers or publishers of seditious books, pamphlets, &c.

MESSENIA, a country in the south of Peloponnesus, mostly maritime, situated between Elea to the west, and Laconica to the east. Anciently a part of Laconica under Menelaus, and called *Messene* by Homer; interpreted by the scholiast, *Messenæa Regio*. *Messenii*, the people, reduced to a state of slavery and subjection by the Spartans; *Messenius*, the epithet.

This country is famous in history, on account of the resistance made by the Messenians against the Spartans, and the exploits of their hero Aristomenes. The first hostilities commenced about the year 652 B. C. on what occasion is uncertain. Though the Messenians were inferior in the knowledge of the art of war to the Spartans; yet, by keeping for some time on the defensive, they improved so much, that in three years time they found themselves in a capacity of giving battle to their enemies in the open field; nor did they appear to be in any degree inferior either in courage or conduct: the war was therefore protracted, with various success, on both sides. At last, both consulted the oracle at Delphi; and received for answer, "that whoever should first dedicate 100 tripods in the temple of Jupiter at Ithome, a strong-hold of the Messenians, should be masters of the country." The inhabitants of Messenia, on hearing this, having no money to make the tripods of brass, fell to cutting them out in wood; but before this could be accomplished, a Spartan having got into the city by stratagem, dedicated 100 little tripods of clay: which threw the Messenians into such despair, that they at last submitted to the Spartans.

The new subjects of Sparta were treated with the utmost barbarity by these cruel tyrants; so that a new war commenced under Aristomenes, a man of unconquerable valour, and enthusiastically fond of liberty. He perceived that the Argives and Arcadians, who were called the *allies* of the Lacedæmonians, adhered to them only through fear of their power; but that in reality they hated them, and wished to revenge the injuries they had done them. To these Aristomenes applied; and receiving an answer conformable to his wishes, he engaged his countrymen unanimously to take up arms. About a year after the revolt began, and before either party had received any auxiliaries, the Spartans and Messenians met at a village called *Deræ*, where an obstinate engagement ensued. Aristomenes was conceived to have performed more than mortal atchievements: in gratitude therefore, respect being also had to his royal descent, his countrymen unanimously saluted him *king*: which title he modestly waved, alleging, that he took up arms to set them free, and not to make himself great: he consented, however, to accept the title of *general*, with a power of doing whatsoever he thought requisite for the service of the public. Knowing well the superstition of the age in which he lived, he resolved to intimidate the Spartans, by showing them what he was sure they would take for an ill omen. Disguising himself therefore, he went privately to the city, where, in the night, he hung up a shield on the wall of the temple of Minerva, with this inscription: *Aristomenes dedicates this, out of the spoils of the Spartans, to the goddess.* It was easily perceived that this war would be both long and bloody; the Lacedæmonians therefore sent deputies to Delphi, to inquire of the oracle concerning its event: the answer they received was, *That it behoved the Spartans to seek a leader from Athens.* The Athenians, naturally envious of the Spartans, granted their request indeed, but in such a manner as manifested their spite; for they sent them for a general Tyrtæus, a schoolmaster and poet, lame of one foot, and who was suspected to be a little out of his wits. But here their skill failed them; for this captain, notwithstanding his despicable appearance, proved of great consequence to Sparta, teaching them how to use good, and how to bear up under evil fortune.

In the mean time, Aristomenes had drawn together a mighty army, the Eleans, Argives, Sicyonians, and Arcadians, having sent troops to his assistance; the Spartans in this, as in the former war, having no ally but Corinth. The Spartan kings, according to the custom of their city, no sooner took the field, than, notwithstanding their inferiority in number, they offered the enemy battle, which Aristomenes readily accepted.—It was long, obstinate, and bloody; but in the end the Messenians were victorious, and the Lacedæmonians put to flight with a great slaughter. It is scarce to be conceived how much the Spartans were struck with this defeat: they grew weary of the war, dissatisfied with their kings, diffident of their own power, and in a word sunk into a state of general uneasiness and want of spirit. It was now that the Athenian general convinced them, that he was capable of fulfilling all the promises of the oracle; he encouraged them by his poems, directed them by his counsels, and recruited their broken armies with chosen men from among the Helotes. Aristomenes, on the other hand, acted with no less prudence and vigour. He thought it not enough to restore the reputation of the Messenians, if he did not also restore their wealth and power: he therefore taught them to act offensively against their enemies; and, entering the territories of Sparta, he took and plundered Pharæ, a considerable borough in Laconia, putting all such as made any resistance to the sword, carrying off at the same time an immense booty. This, however, was an injury which the Spartans could not brook with patience; they therefore sent immediately a body of forces to overtake the Messenians, which accordingly they did: but Aristomenes routed these pursuers, and continued to make a mighty slaughter of them, till such time as he was disabled by having a spear thrust in his side, which occasioned his being carried out of the battle. His cure, which took up some time, being finished, he resolved to carry the war even to the gates of Sparta; and to that purpose raised a very great army: but, whether he found his design impracticable, or was really diverted by some dream, he gave out, that Castor and Pollux, with their sister Helena, had appeared to him, and commanded him to desist. A short time after this retreat, going with a small party to make an incursion, and attempting to take prisoners some women who were celebrating religious rites near Egila, a village in Laconia, those zealous matrons fell upon him and his soldiers with such fury, that they put them to flight, and took him prisoner:

Meſſenia. priſoner: however, he ſoon afterwards made his eſcape, and rejoined his forces. In the third year of the war, the Spartans with a great force entered Meſſenia, whither Ariſtocrates king of Arcadia was come, with a great body of troops, to the aſſiſtance of his allies: Ariſtomenes therefore made no difficulty of fighting when the Spartans approached; but they entering privately into a negociation with Ariſtocrates, engaged him with bribes and promiſes to betray his confederates. When the battle began, the deceitful Arcadian repreſented to the forces under his command the mighty danger they were in, and the great difficulty there would be of retreating into their own country, in caſe the battle ſhould be loſt: he then pretended, that the ſacrifices were ominous; and, having terrified his Arcadians into the diſpoſition of mind fitteſt to ſerve his purpoſe, he not only drew them off from both wings, but, in his flight, forced through the Meſſenian ranks, and put them too in confuſion. Ariſtomenes and his troops, however, drew themſelves into cloſe order, that they might defend themſelves the beſt they could: and indeed they had need of all their valour and ſkill; for the Lacedæmonians, who expected this event, immediately attacked and ſurrounded them on all ſides. Fortune was, on this occaſion, too powerful either for the courage or the conduct of the Meſſenians; ſo that, notwithſtanding their utmoſt efforts, moſt of their army were cut to pieces, and amongſt them the chief of their nobility. Ariſtomenes, with the poor remains of his ſhattered forces, retired as well as he could; and, perceiving that it was now impoſſible to maintain the war againſt the Lacedæmonians upon equal terms, he exhorted his countrymen to fortify mount Era, and to make the beſt diſpoſitions poſſible for a long defence. He likewiſe placed garriſons in Pylus and Methone on the ſea-coaſts; and to theſe three places he gathered all the inhabitants, leaving the reſt of Meſſenia to the mercy of the Spartans. They, on the other hand, looked on the war as now in a manner finiſhed; for which reaſon they divided the lands among their citizens, and cauſed them to be carefully cultivated, while they beſieged Era. But Ariſtomenes quickly convinced them that the war was far from being over: he choſe out of all the Meſſenians 300 men, with whom he ravaged all the adjacent country; carried off a prodigious booty; and, when Meſſenia could no longer ſupply the wants of his garriſon, penetrated into Laconia, and bore away corn, wine, cattle, and whatever elſe was neceſſary to the ſubſiſtence of his countrymen ſhut up in Era: ſo that at laſt the Spartans were conſtrained to iſſue a proclamation, forbidding the cultivation, not only of the Meſſenian territory in their hands, but alſo of Laconia in its vicinity; whereby they diſtreſſed themſelves more than their enemies, inducing at laſt a famine in Sparta itſelf, which brought with it its uſual attendant, ſedition. Here again all things had gone wrong, if the wiſdom of the poet Tyrtæus had not ſupported the Spartan courage; nor was it without much difficulty that he influenced them to continue the blockade of Era, and to maintain a flying camp for the ſecurity of the country.

Ariſtomenes, in ſpite of all theſe precautions, committed terrible depredations with his ſmall corps of 300 men. Amongſt other places which he plundered, the city of Amyclæ was one; from whence he carried not only a great quantity of riches, but alſo many carriages laden with proviſions. The kings of Sparta lying with their troops in its neighbourhood, as ſoon as they heard of this expedition, marched after Ariſtomenes with the utmoſt diligence; and, as the Meſſenians were encumbered with their booty, came up with them before they could reach Era. In this ſituation of things, Ariſtomenes, prompted rather by deſpair than prudence, diſpoſed his troops in order of battle; and, notwithſtanding they were ſo few, made a long and vigorous reſiſtance againſt the whole Lacedæmonian army. At length, however, numbers prevailed: the greateſt part of the Meſſenians were ſlain on the ſpot; and Ariſtomenes, with about 50 of his men who ſurvived the ſlaughter, were taken priſoners; that chief having received ſo many wounds, that he was ſenſeleſs when they carried him away. The Lacedæmonians expreſſed the loudeſt joy at the ſight of this illuſtrious captive; who for ſo many years, by his ſingle abilities, had enabled his exhauſted country to defend itſelf againſt the the whole force of Sparta. When he was recovered of his wounds, they decreed him and all his fellow-priſoners to be thrown together into a deep cavern, which was the common puniſhment of the loweſt kind of offenders. This judgment was executed with the utmoſt ſeverity, excepting that Ariſtomenes had leave to put on his armour. Three days he continued in this diſmal place, lying upon and covered over with dead bodies. The third day, he was almoſt famiſhed through want of food, and almoſt poiſoned with the ſtench of corrupted carcaſes, when he heard a fox gnawing a body near him. Upon this he uncovered his face, and perceiving the fox juſt by him, he with one hand ſeized one of its hind-legs, and with the other defended his face, by catching hold of its jaw when it attempted to bite him. Following as well as he could his ſtraggling guide, the fox at laſt thruſt his head into a little hole; and Ariſtomenes then letting go his leg, he ſoon forced his way through, and opened a paſſage to the welcome rays of light, from which the noble Meſſenian had been ſo long debarred. Feeble as he was, Ariſtomenes wrought himſelf an outlet with his nails; and travelling by night with all the expedition he could, at length arrived ſafe at Era, to the great joy and amazement of his countrymen. When this news was firſt blazed abroad, the Spartans would have had it paſs for a fiction; but Ariſtomenes ſoon put the truth of it out of doubt, by falling on the poſts of the Corinthians, who, as allies of the Spartans, had a conſiderable body of troops before Era. Moſt of their officers, with a multitude of private men, he ſlew; pillaged their camp; and, in ſhort, did ſo much miſchief, that the Spartans, under the pretence of an approaching feſtival, agreed to a ceſſation of arms for 40 days, that they might have time to bury their dead. On this occaſion, Ariſtomenes for the ſecond time celebrated the *hecatomphonia*, or the ſacrifice appointed for thoſe who had killed 100 of the enemy with their own hands. He had performed the ſame before and after his ſecond battle; and he lived to do it a third time: which muſt appear wonderful to the reader, when he is informed, that, notwithſtanding this truce, certain Cretan archers in the ſervice of the Spar-

Messenia. tans seized Aristomenes as he was walking without the walls, and carried him away a prisoner. There were nine of them in all; two of them immediately flew with the news to Sparta, and seven remained to guard their prize, whom they bound, and conducted to a lone cottage inhabited only by a widow and her daughter. It so fell out, that the young woman dreamt the night before, that she saw a lion without claws, bound, and dragged along by wolves; and that she having loosed his bonds, and given him claws, he immediately tore the wolves to pieces. As soon as Aristomenes came into the cottage, and her mother, who knew him, had told her who he was, she instantly concluded that her dream was fulfilled; and therefore plied the Cretans with drink, and, when they were asleep, took a poinard from one of them, cut the thongs with which Aristomenes was bound, and then put it into his hands. He presently verified her vision, by putting all his guards to death; and then carried her and her mother to Era, where, as a reward for her service, he married the young woman to his son Gorgus, then about 18 years of age.

When Era had held out near eleven years, it fell into the hands of Sparta by an accident: the servant of one Empiramus, a Spartan commander, driving his master's cattle to drink at the river Neda, met frequently with the wife of a Messenian, whom he engaged in an amour. This woman gave him notice, that her husband's house was without the wall; so that he could come to it without danger, when the good man was abroad; and she likewise gave him intelligence when her husband was upon duty in the garrison. The Spartan failed not to come at the time appointed; but they had not been long in bed before the husband returned, which put the house into great confusion: the woman, however, secured her gallant; and then let in her husband, whom she received in appearance with great joy, inquiring again and again by what excess of good fortune she was blessed with his return. The innocent Messenian told her, that Aristomenes being detained in his bed by a wound, the soldiers knowing that he could not walk the rounds, had a grant to retire to their houses, to avoid the inclemency of the season. The Spartan no sooner heard this, than he crept softly out of doors, and hastened away to carry the news to his master. It so happened, that the kings were at this time absent from the camp, and Empiramus had the chief command of the army. As soon as he received this information, he ordered his army to begin its march, though it rained excessively, and there was no moon-light. The fellow guided them to the ford, and managed matters so well that they seized all the Messenian posts: yet, after all, they were afraid to engage; darkness, an high wind, heavy rain, together with the dread of Aristomenes, keeping them quiet in the places they had seized. As soon as it was light, the attack began; and Era had been quickly taken, if only the men had defended it; but the women fought with such fury, and by their mingling in the fray, brought such an accession of numbers, as made the event doubtful. Three days and two nights this desperate engagement lasted: at last, all hopes of preserving the city being lost, Aristomenes drew off his wearied troops. Early the fourth morning, he disposed the women and children in the centre, the Messenian youth in the front and rear, the less able men in the main body: himself commanded the van; the rear-guard was brought up by Gorgus and Manticlus, the former the son of Aristomenes, the latter of Theocles, a Messenian of great merit, who fell with much glory in this attack, fighting valiantly in the cause of his country. When all things were ready, Aristomenes caused the last barrier to be thrown open; and, brandishing his spear, marched directly towards the Spartan troops, in order to force a passage. Empiramus, perceiving his intent, ordered his men to open to the right and left, and fairly gave them a passage; so that Aristomenes marched off in triumph, as it were, to Arcadia. Messenia.

The Arcadians, when they heard that Era was taken, were very desirous of succouring their old confederates in this deep distress: they therefore intreated their king Aristocrates to lead them into Messenia. But he, corrupted by the Lacedæmonians, persuaded them that it was too late; that the Messenians were all cut off; and that such a step would only expose them to the fury of the conquerors. When the thing appeared to be otherwise, and it was known that Aristomenes was on the frontiers of Arcadia, they went in crowds to carry him provisions, and to testify their readiness to afford him and those under his command all the assistance in their power. Aristomenes desired to be heard before a general assembly; which being accordingly convoked, he there opened one of the boldest and best-laid schemes recorded in history: he said, that he had yet 500 undaunted soldiers, who, at his command, would undertake any thing; that it was very probable most of the Spartans were employed in pillaging Era, and that therefore he determined to march and surprise Sparta; which appeared so sensible, that all the assembly loudly commended his great capacity and unshaken courage. Aristocrates, however, took care to betray him; having, by various pretences, retarded the execution of the project. The Arcadians, who began to suspect him, waited for and surprised the messengers as they came back. They took the letters from him, and read them openly in the assembly. The purport of them was, that they acknowledged his great kindness both now and in the battle; and promised, that the Lacedæmonians would be grateful. As soon as the letters were read, the Arcadians fell to stoning their king, frequently calling upon the Messenians to assist them; which, however, they did not, waiting for Aristomenes's orders; who, far from triumphing in this spectacle, stood still, with his eyes fixed on the ground, which he wet with his tears, his soul pierced with sorrow to see a crowned head so shamefully and so deservedly put to death. The Arcadians afterwards erected a monument over him, with an inscription to perpetuate his infamy. As for the Messenians under the command of Gorgus and Manticlus, they passed over into Sicily; where they founded the city of Messene, one of the most famous in the island. Aristomenes remained, however, in Greece; where he married all his daughters, except the youngest, to persons of great rank. A prince of Rhodes, inquiring of the oracle at Delphi whom he should espouse, that his subjects might be happy under his posterity, was directed

Meſſiah.

directed to marry the daughter of the moſt worthy of the Greeks; which anſwer was immediately underſtood to point at the virgin daughter of Ariſtomenes. Her therefore he demanded, and received; Ariſtomenes accompanying him back to his dominions, where he formed a ſcheme of uniting the Lydians and Medes againſt the Spartans, reſolving with this view to go into Media, and to the court of Sardis; but while he meditated theſe great things, death ſurpriſed him, and thereby freed Lacedæmon from the moſt formidable enemy ſhe ever had.

MESSIAH, a word ſignifying one *anointed*, or inſtalled into an office by unction. It was uſual among the Jews to anoint kings, high-prieſts, and ſometimes prophets, at the deſignation or inſtallment of them, to ſignify emblematically the mental qualifications neceſſary for diſcharging theſe offices. Saul, David, Solomon, and Joaſh, kings of Judah, received the royal unction. Aaron and his ſons received the ſacerdotal, and Eliſha the diſciple of Elijah received the prophetic unction.—The name MESSIAH, *Anointed*, or *Chriſt* (Χριστος), was given to the kings and high-prieſts of the Jews. The patriarchs and prophets are alſo called by the name of *Meſſiahs*, or the *Lord's anointed*. See 1 Sam. xii. 3, 5. 1 Chron. xvi. 22. Pſ. cv. 15.

But this name MESSIAH was principally and by way of eminence given by the Jews to their expected great Deliverer, whoſe coming they ſtill vainly wait; and is a name the Chriſtians apply to *Jesus Chriſt*, in whom the prophecies relating to the Meſſiah were accompliſhed. The ſum of theſe prophecies is, That there ſhould be a glorious perſon named *Meſſiah*, deſcended from Abraham, Iſaac, and Jacob, who ſhould be born at Bethlehem, of a virgin of the family of David, then in its decline, before the Jews ceaſed to be a people, while the ſecond temple was ſtanding, and about 500 years after Ezra's time; who, though appearing in mean circumſtances, ſhould be introduced by a remarkable forerunner, whoſe buſineſs it ſhould be to awaken the attention and expectation of the people. That this illuſtrious perſon called *Meſſiah* ſhould himſelf be eminent for the piety, wiſdom, and benevolence of his character, and the miraculous works he ſhould perform: yet that, notwithſtanding all this, he ſhould be rejected and put to death by the Jews; but ſhould afterwards be raiſed from the dead, and exalted to a glorious throne, on which he ſhould through all generations continue to rule, at the ſame time making interceſſion for ſinners. That great calamities ſhould for the preſent be brought on the Jews for rejecting him: whereas the kingdom of God ſhould by his means be erected among the Gentiles, and diſperſe itſelf even unto the ends of the earth; wherever it came, deſtroying idolatry, and eſtabliſhing true religion and righteouſneſs. In a word, That this glorious perſon ſhould be regarded by all who believed in him as a divine teacher, an atoning ſacrifice, and a royal governor: by means of whom God would make a covenant with his people, very different from that made with Iſrael of old; in conſequence of which they ſhould be reſtored to, and eſtabliſhed in, the divine favour, and fixed in a ſtate of perpetual happineſs. See *Jesus Chriſt*, and CHRISTIANITY.

The Jews, as was already obſerved, ſtill wait for the coming of the *Meſſiah*, being infatuated with the notion of a temporal *Meſſiah*, who is to be a mighty conqueror, and to ſubdue all the world. Moſt of the modern rabbins, according to Buxtorf, believe that the *Meſſiah* is already come, but that he keeps himſelf concealed, and will not manifeſt himſelf becauſe of the ſins of the Jews. Some of the Jews, however, in order to reconcile thoſe prophecies that ſeem to contradict each other as to the character and condition of the *Meſſiah*, have had recourſe to the hypotheſis of two *Meſſiahs*, who are yet to ſucceed each other; one in a ſtate of humiliation and ſuffering; the other of glory, ſplendor, and power. The firſt, they ſay, is to proceed from the tribe of Ephraim, who is to fight againſt Gog, and to be ſlain by Annillus, Zech. xii. 10. The ſecond is to be of the tribe of Judah, and lineage of David, who is to conquer and kill Annillus, and reſtore the kingdom of Iſrael, reigning over it in the higheſt glory and felicity.

Jeſus Chriſt aſſerts himſelf the *Meſſiah*. In St John iv. 25. the Samaritan woman ſays to Jeſus, *I know that when* Meſſiah *comes, who is called the* Chriſt; *he will tell us all things. Jeſus anſwered her, I that ſpeak to thee am he.*

There are ſeveral impoſtors, who have endeavoured to paſs for *Meſſiahs*, as Chriſt himſelf predicted. J. Lent, a Dutchman, has written a hiſtory *De Pſeudo-meſſiis*, "Of Falſe Meſſiahs." The firſt he mentions was one Barcochab, who appeared under the empire of Adrian. The laſt was rabbi Mordecai, who began to be talked of in 1652. A little before him, viz. in 1666, appeared Sabbethai Sebi, who was taken by the Turks, and turned Mahometan.

Meſſiah, Meſſina.

MESSINA, an ancient, large, handſome, and ſtrong city of Sicily, and in the Val-di-Demona, with a citadel, ſeveral forts, a fine ſpacious harbour, and an archbiſhop's ſee. It is ſeated on the ſea-ſide, 110 miles eaſt of Palermo, 260 ſouth by eaſt of Rome, and 180 ſouth-eaſt of Naples. E. Long. 15. 50. N. Lat. 38. 10. The public buildings and the monaſteries were numerous and magnificent, and it contained about 60,000 inhabitants; the harbour is one of the ſafeſt in the Mediterranean, and extremely deep; the viceroy of Sicily reſides here ſix months in the year; and it was a place of great trade in ſilk, oil, fruit, corn, and excellent wine, eſpecially ſince it was declared a free port. This city in the beginning of the year 1783 ſuffered moſt dreadfully by the earthquakes, which ſhook great part of Calabria and Sicily to their foundations, overturned many rich and populous towns, and buried thouſands in their ruins: (ſee CALABRIA and EARTHQUAKE.)—The following account of Meſſina, as it ſtood before the above period, is extracted from Mr *Swinburne's Travels in Sicily*

A large chain of mountains preſſes upon the ſhore, and part of the city ſtands upon elevated ground. The mountains are many of them nobly wooded; the hills before them finely chequered with groves and fields. As the town runs in a ſweep along the edge of a declivity, every building of conſequence is ſeen to advantage, while the leſs noble parts are hidden by the Palazzata. This is a regular ornamental range of lofty houſes, with 19 gates, anſwering to as many ſtreets; it follows the ſemicircular bend of the port for one mile and five poles, and would have been the handſomeſt line of buildings in Europe had the deſign been com-

Messina. completed; but a considerable part of the extent is not finished, except merely in the front wall, and that seems to be in a very ruinous condition. Philibert Emmanuel of Savoy, viceroy of Sicily, in 1622 began this princely work. Before it is a broad quay, decorated with statues and fountains; ships of any burden can moor close to the parapet in great depth of water. At the west extremity is a small fort and a gate; the other end is closed by the governor's house and the citadel, a modern pentagonal fortress, built on the point where the isthmus or *braccio di San Ranicro* issues from the main land. On this slip of low ground, which with the Palazzato forms the circular harbour of Messina, are placed the light-house *(lazaretto)*, and on the point the old castle of St Salvatore. The circumference of the port is four miles: it probably owes its formation to an earthquake, which opened an immense chasm, and then filled it with water. Near the light-house is a kind of whirlpool in the sea, shown as the Charybdis of the ancients.

The inner part of Messina is dirty, though it contains a considerable number of neat churches and large substantial dwellings. The cathedral is Gothic, enriched with Saracenic mosaics on the altars and shrines; the front of the high altar is particularly splendid: Gagini has embellished the pulpit and some tombs with excellent specimens of his art.—In the treasury of this church is preserved the palladium of Messina, a letter from the Virgin Mary to its citizens (A). This is the title upon which the Messinese build their pretensions to pre-eminence over the whole island, nay over the whole world; to its virtues and patronage they attribute every piece of good fortune, and to their own unworthiness all sinister events that have befallen them. The authenticity of this epistle has been seriously impugned, and of course vigorously defended by many Sicilian divines and disputators.

There is another church in this city that deserves particular notice, not so much on account of its architecture or ornaments, as for its being the last refuge of the Greek liturgy, which was once the predominant service of the island, but gradually abolished by different conquerors. It is dedicated to the Virgin Mary de Grapheo, or of the *Letter*, which denomination may perhaps have furnished Lascaris with the idea of his letter. It is known at present by the name of *la Cattolica*. According to the Greek canons, the entrance of monastic churches was reciprocally forbidden to each sex, and the cathedrals were the only places of worship where a daily sacrifice was offered up by the bishop and clergy, and where both men and women were present at the same time, but in different parts of the church. From this general admittance the building acquired the title of *Catholic* or *universal*.

Messina is all paved with lava, cut into large flags of two feet square: a material which the vicinity of lavas render it easy to procure, and which being very hard resists friction better than any other

During a series of ages, notwithstanding the various revolutions and calamities to which it has been exposed, this city has still maintained its original situation; while most other cities have shifted their ground more or less from the place where they were first founded. But its situation enjoys advantages which have still tempted such of its inhabitants as escaped from the ravages of war and the desolation of earthquakes, to prefer it to every other spot, however delightful or secure. It is of very ancient origin; it has been under many different races of monarchs; and its name has been repeatedly changed: It has been at different times called *Zancle*, *Mamertina*, *Messana*. Its first name *Zancle*, which in the old language of Sicily meant "a sickle;" alluding, as some authors suppose, to the form of the port; or, according to others, to the

(A) The story is as follows: After St Paul had made some stay at Messina (a circumstance of his travels unnoticed by St Luke), the Messinese prevailed upon him to return to Jerusalem with an embassy of four persons sent by the city to the Virgin Mary. Their excellencies were graciously received by her, and brought back a letter written with her own hand in the Hebrew tongue, which St Paul translated into Greek. By the irruption of the Saracens this invaluable treasure was lost, and utterly forgotten till the year 1467, when Constantine Lascaris, a refugee Greek, found a copy of it, and turning it into Latin, made it known to the citizens, and then to all the Catholic world. Its authenticity is now so well established at Messina, that Regna the historian candidly acknowledges, that whoever was to confess even a doubt on the subject in that city would be treated as an infidel.

This curious epistle is conceived in these terms:—Maria Virgo Joachim filia, Dei humillima Christi Jesu crucifixi Mater, ex tribu Judæ stirpe David, Messanensibus omnibus salutem, et Dei patris omnipotentis benedictionem. Vos omnes fide magna legatos ac nuncios per publicum documentum ad nos misisse constat. Filium nostrum Dei genitum Deum et hominem esse fatemini, et in cœlum post suam resurrectionem ascendisse, Pauli apostoli electi prædicatione mediante viam veritatis agnoscentes. Ob quod vos et ipsam civitatem benedicimus cujus perpetuam protectricem nos esse volumus. Anno filii nostri XLII. Indict. I. III. Nonas Junii, luna XXVII. feria V. ex Hyerosolymis.

Thus translated:—"The Virgin Mary, daughter of Joachim, most humble mother of God, Jesus Christ crucified, of the tribe of Juda and the family of David, health and the blessing of God the Father Almighty to all the people of Messina. Out of the abundance of your faith, you have, in consequence of a public deliberation, sent a deputation to me; and since you acknowledge that my Son is both God and man, and that he ascended into heaven after his resurrection, as you have learned from the preaching of St Paul the apostle, I give my blessing to you and all your city, and agree to become your protectress. In the 42d year of my Son, the 1st of the Indiction, the 3d day of June, and the 27th of the moon, at Jerusalem."

Not to dwell upon the astronomical blunders in these dates, let it suffice to observe, that Lascaris was not aware that Denis the Little, a Syrian monk in the 6th century, was the first who made use of the era that commences at our Saviour's birth.

the fertility of the country. Allured by the advantages of its fituation, the Cumæans, a commercial and enterprifing people, invaded the ifland and drove the Siculi from this fettlement; they were in their turn overpowered by a band of Samian adventurers, who made way for a colony of citizens of Meffene, and under thefe mafters it changed its name to *Meffana*. Their government was of fhort duration; for in the 289th year before Chrift it was deftroyed by the Mamertines, a warlike unprincipled nation inhabiting the fouth part of Brutium. Thefe foldiers being received into Meffana on their return to Italy from Syracufe, where they had ferved as mercenaries in the army of Agathocles, took an opportunity of maffacring the inhabitants and ufurping their poffeffions. The city was now called *Mamertina:* and, in order to fupport themfelves againft the refentment of the Sicilian powers, the Mamertines implored the protection of the Romans, who, eager to extend their dominion beyond the limits of Italy, and jealous of the growing power of Carthage, made no fcruple to fuccour thefe affaffins with a confular army. This ftep brought on the firft Punic war. The Mamertines reaped no other fruit from the alliance but a more honourable degree of flavery; for fuch was the real nature of their connection with Rome, whatever name it might be difguifed under.

Meffina was, however, always diftinguifhed by particular attentions and favours from the fenate; and, excepting a fhort period during the wars of the triumvirate, appears to have tafted all the fweets of Roman profperity, without partaking of the bitter draughts of adverfity. Its fate, in the ruin of the empire, was fimilar to that of the reft of Sicily. In 829 Meffina fell into the hands of the Saracens, but obtained very honourable terms of capitulation; for half the city was left to the Chriftians, where they were to be governed by their own laws, and profefs their own religion undifturbed. In the other refided the bey of one of the five provinces into which the Arabian conquerors had divided the ifland. Notwithftanding this indulgence, Meffina was the firft to caft off the yoke in 1037, when George Maniaces landed an army of Greeks and Normans on the fhore of the Faro. It afterwards held out againft the whole Muffulman force, till the feeble ftate of a diftracted empire fhut out all hopes of affiftance from Conftantinople. This unfortunate city then opened its gates to the army of the caliph, and felt very feverely the weight of his refentment: but it did not long groan under the yoke; for in lefs than 20 years Roger the Norman took it by furprife and delivered it from Mahometan oppreffion. During the crufado our Richard Cœur de Lion and Philip Auguftus king of France wintered here in their way to Paleftine; a fojourn marked by continual quarrels, conflagration, and bloodfhed. The Meffinefe were particularly tardy in entering into the national confpiracy of 1282, but afterwards exceeded the reft of the infurgents in deeds of cruelty: This and the importance of their fituation fingled them out for the firft objects of Charles's vengeance He invefted their city very clofely, and declared fo openly his determination to refufe all terms whatever to the befieged, that they faw no hopes of fafety but in an obftinate defence. Their courage, perfeverance, and fufferings, were exceffive; at length their ftrength and refources began to fail rapidly, and every circumftance feemed to denounce their fpeedy deftruction, when Roger Lauria appeared off the harbour with the Arragonian fleet, forced the king to retire with precipitation acrofs the ftraits, and in his fight defeated and deftroyed his naval armament. Robert, grandfon of Charles I. alfo made a fruitlefs attack; but in the difturbed reign of Frederick III. Meffina was delivered up to Louis king of Naples and his confort queen Joan, who entered it in triumph. In a few years it returned to its former poffeffors. The year 1672 was remarkable for the revolt of the Meffinefe.—They threw off the Spanifh yoke, and fwore allegiance to Louis XIV. king of France. They were for fome time vigoroufly affifted by the French; but before the Spaniards had gained the leaft advantage to excite any hopes of recovering fo valuable a poffeffion, Louis found himfelf neceffitated from motives of political intereft to defert his new fubjects, and leave them to the mercy of their old incenfed mafters. The horror of being thus abandoned, and the chaftifement inflicted by Spain, broke the fierce fpirit of the Meffinefe; they were ftill ftunned with the remembrance and effects of this blow, when the plague in 1743 was introduced from the Levant and fwept away more than half the inhabitants. From this chain of calamities, the opulence, trade, and population of Meffina, have been gradually finking; and unlefs very favourable circumftances happen, will every year fall lower. The number of its inhabitants does not now exceed 30,000.

The following particulars are added from M. Houel, who vifited this city fince the late earthquakes, which completed its deftruction.

On the front of the cathedral there is a fquare, which, though not regular, is far from being mean. This was not the largeft fquare in Meffina before its overthrow; but it was the moft elegant, the moft fplendidly adorned, and the beft frequented. There ftands in this fquare an equeftrian ftatue of Charles II. of Spain, in bronze, which has been fpared by the earthquake. It ftands on a marble pedeftal, in the middle of the fquare. Oppofite to this ftatue is an elegant marble fountain, ornamented with a variety of figures, reprefenting men and other animals, all of them fpouting out water in great abundance; which ufed, in fummer, to fpread an agreeable and refrefhing coolnefs over the fquare, that induced company to affemble here. Seven ftreets terminated here. The cathedral forms a part of the fquare. It is dedicated to the bleffed Virgin; the occafion of which has been already mentioned.

There is an aniverfary feaft celebrated in Meffina, which is called *the feaft of the Letter*. A lock of the Virgin's hair, which fhe fent to the Meffenians at the fame time with the letter, is carried through the city in proceffion in a cryftal veffel. She made alfo a prefent of her picture to the Meffenian deputies. It is placed over the tabernacle. None but the canons of the cathedral are permitted to touch, or take up on their fhoulders, the filver fhrine in which the cryftal veffel with the Virgin's hair is depofited. Eight of thofe canons, with mitres on their heads, bear this fhrine in the proceffion. The canopy fufpended over it is fupported by fix fenators in their robes. The picture

Messina. picture and the hair are shown to strangers. This procession and the other religious ceremonies of this festival are followed by horse races. The spirits of the people being already elevated by their religious exercises, they engage with amazing eagerness in these and the other diversions with which they are accompanied; a tumultuous joy reigns over the city; and the evening concludes with illuminations and fire-works. The ships in the harbour pay the citizens the compliment of entertaining them with a discharge of their guns on the occasion.

Through a square called *the Square of the Great Hospital*, runs a large and impetuous torrent, the *Porto delle Legni*. It is precipitated from those lofty mountains which overlook this city on the south side. The channel which it has cut out for itself is at times entirely full. It would, on such occasions, overflow the square and other parts of the city, were it not confined by walls which have been built on both sides to prevent such accidents.—Another stream of a similar origin, called the *Torrent of La Boccetta*, runs through another part of the city; it is also confined within the walls to prevent it from overflowing.

The *Square of St John of Malta* is one of the largest in Messina. In the middle of this square is a fine marble fountain, ornamented with a variety of sculptured figures and jets d'eau. Beside the fountain there used to stand a large reservoir for horses to drink out of.

In the time of the annual festivals, there used to be exhibited on the waters of the reservoir a galley, or rather a fictitious representation of a galley, with galley-slaves, soldiers, officers, and a commander on board, all in arms, and the galley properly equipped as a ship of war. This galley was decorated with great art; and by night the masts, and every other suitable part, were hung with lamps, which illumined it in a very splendid manner. Every thing around was so artificially disposed, that when the fire-works were played off, the spectator was led to think, though he perceived only one galley, that the noise which he heard was produced by a naval combat; and that the other ships were concealed from his view by the smoke occasioned by the guns and fire-works. This, when properly conducted, was a noble spectacle. The senate repaired thither from the cathedral, attended with a guard and a numerous company. In one carriage sat six senators, the governor of the city, and sometimes the archbishop. It was exceedingly large, and drawn by six white horses very richly harnessed. Other carriages followed, with the train who attended the governor and the senators.

Almost all festivals owe their origin to some extraordinary event, or some singular story either true or false. It is said, that when the splendor with which the feast of *the assumption de la Bara* was celebrated at Messina, first began to attract foreigners to the city, on that occasion such crowds repaired thither as to alarm the inhabitants with the fears of a famine: But one year, when the number of strangers was greater than usual at the time of this festival, the magistrates were very much at a loss how to supply them with provisions; and at length, every other resource failing, no hopes of relief remained but from the kindness of the Blessed Virgin. Fervent prayers were addressed to their patroness: and next morning by day-break three brigantines appeared entering the harbour with full sails. They proved to be loaded with corn. It was eagerly purchased: and the people of the city hasted to appease their hunger. But when they came after refreshing themselves to pay the corn-merchants their money, neither ships nor merchants could be found. After their first emotions of surprise had subsided, they naturally concluded that such a seasonable supply must undoubtedly be a present from the Virgin, who, being pleased with the zeal of her Messenian votaries, and desirous to prevent the concourse of strangers who attended the festival from diminishing, had interposed in this miraculous manner to save them from the distresses of famine. A new festival was celebrated in gratitude to their generous benefactress. Three small vessels of silver were made, and dedicated to the Virgin in memory of the event; and these are at present used as lamps in the cathedral. The senate likewise decreed, that the clergy should pay annually a small tax, to be laid out in constructing a small galley to swim on the fountain, and in defraying the expences of the fire-works. The profits of the clergy are so considerable on the occasion of the festival, that they may be supposed to pay the tax with great cheerfulness.

In Messina, as in the other cities of Sicily, the women wrap themselves in a large black mantle above the rest of their dress. The stuffs are richer or plainer according to rank and circumstances. People who are not rich enough to have fine cloaths of their own, hire them at so much an hour. There are women who make a livelihood by lending out their cloaths. The mantle covers the wearer from head to foot.—It reduces the old and the young, the ill-shaped and the handsome, pretty much to an equality in point of appearance. This must naturally appear very unfavourable to the influence of beauty. But yet, on proper occasions, at church or in a public walk, the ladies of Messina find means to open and adjust the mantle so as to display all their beauties of face and shape, and to attract the affections of lovers, perhaps more powerfully than if their dress were suited to display their charms in a more ostentatious manner.

Between Messina and the tower of Faro there stands a small church called the *Madona of the Grotto*. It was anciently a temple of a round structure, and ornamented with columns like the temple of the sun at Rome. Modern columns now supply the place that was occupied by the ancient. There are large niches in the rock adjoining to the temple, which are thought to be of equal antiquity. These contain no sculptured figures; but in Pagan times they might possibly contain some.

Messina being situated between mount Ætna and the gulph of Charybdis, and being likewise at no great distance from the volcanoes of Lipari and Stromboli, must have been in all ages liable to suffer by earthquakes. Such terrible events, however, appear to have been more unfrequent in ancient than in modern times, and have actually alarmed the present age oftener than any other. In the 1693 a fourth part of the cities of Sicily was destroyed by an earthquake. Messina merely felt the shock: all its buildings, however, suffered. In the year 1742 it suffered another equally violent. A plague which followed in 1743 retarded the repairs necessary after the earthquake. In the year

Messina. year 1780 this city continued, for more than six months, to suffer from a new earthquake.

Were the state of the elements, previous to these dreadful events, carefully examined, it might perhaps be found to undergo certain changes which might be considered as prognosticating them.

The autumn of the year 1782 was unusually cold and rainy. Fahrenheit's thermometer was often as low as 56 degrees. The succeeding winter was dry; and the mercury never fell under 25 degrees: And, what is uncommon in that season, storms were now and then observed to arise from the west. The pilots in the channel observed that the tides no longer rose at the usual periods, and the gulph of Charybdis raged with extraordinary fury.

On the 5th of February 1783, the air was heavy and calm; the sky obscured with thick clouds, and the atmosphere seemingly all in a flame. About half after twelve at noon, the earth began to shake with a dreadful noise. The shocks continually increased, and became at length so violent as to open the ground, and to overturn in two or three minutes a considerable part of the buildings.

A long white cloud appeared to the north-west; and soon after another, very dark, in the same quarter of the heavens. The latter in a moment spread over the whole horizon, and deluged the city with rain and hail, accompanied with dreadful claps of thunder. The inhabitants fled in the utmost terror to the fields and the ships in the harbour.

From mid-day till five in the afternoon the earthquake continued almost without interruption. The shocks then became somewhat less frequent. The cries of the dying; the shrieks of those who were half-buried under the ruins; the wild terror with which others, who were still able, attempted to make their escape; the despair of fathers, mothers, and husbands, bereft of those who were dearest to them; then formed altogether a scene of horror, such as can but seldom occur in the history of the calamities of the human race. Amid that awful scene, instances of the most heroic courage and the most generous affection were displayed. Mothers, regardless of their own safety, rushed into every danger to snatch their children from death. Conjugal and filial affection prompted deeds not less desperate and heroic. But no sooner did the earthquake cease, than the poor wretches who had escaped began to feel the influence of very different passions. When they returned to visit the ruins, to seek out the situation of their fallen dwellings, to inquire into the fate of their families, to procure food and collect some remains of their former fortunes—such as found their circumstances the most wretched became suddenly animated with rage, which nothing but wild despair could inspire. The distinction of ranks, and the order of society were disregarded, and property eagerly violated. Murder, rapine, and lawless robbery, reigned among the smoking ruins.

About one in the morning another shock of the earthquake was felt, which overturned most of the houses that were still standing. Most of those whom want, or avarice, or humanity, still detained among the ruins, now shared the same fate with their friends whom the former shocks had buried under them.

The succeeding day scarce alleviated the distress of this dismal night: the few wretches who still survived found themselves destitute of every necessary. At length order was in some degree re-established; and in two days after every person was supplied at least with some small portion of the necessaries for subsistence. Messina.

None yet thought of returning to take up their abode among the ruins. The common people fixed their residence on the plain of Porto Salvo, near the town of Salleo. The nobles, magistrates, and merchants, took up their abode on another plain, on the other side of the stream Porta de Legno; the soldiers at Terra Nuova.

Some violent shocks which were again felt on the 7th of February and the 28th of March completed the destruction of the city. The corn magazines, however, escaped without damage; and the public ovens and the aqueducts were but little injured. From these facts it may perhaps be inferred, that had not the houses of Messina been, in general, hastily built at the first, and afterwards carelessly repaired, fewer of them would have been overthrown by the earthquake.

The neighbouring villages having suffered but little, were the first to relieve the remaining inhabitants of Messina in their distress. Maltese galleys for some days supplied necessaries to the poor and the sick with a generosity which merits the highest praise. They brought surgeons and whatever was needful for the cure of the wounded. The supplies sent by the king of France were refused, for what reason we know not. What money was needed for the support of the people was taken from the treasury of the city of Messina; for what the king of Naples sent was seized and spent by the garrison.

It is said that not more than 800 or 900 persons perished by this earthquake. The sea during that convulsion of the land was slightly agitated in the harbour. Farther out the sea was more violently agitated; but none of the ships in the harbour were dashed to pieces. The waters rose so high as to be injurious in a very considerable degree to Pharo, as well as along the coast of Scylla and Bagnara.

This earthquake was not of a momentary duration, like that by which Lisbon was destroyed, and like many others: for more than sixty days, from the 5th of February to the beginning of April, Messina continued to be shaken; and in that time felt more than 200 shocks. And ever after that period the alarm was again and again renewed. Not only the magistrates, the soldiers, and the people, but the priests likewise, with their tabernacle and altar, retired to the barracks. The nuns, too, deserted their cloister, and sought a retreat without the walls. Some of them confined themselves to the gardens of their convents; others mixed indiscriminately with the people.

The chief damage which the public buildings within the city suffered was the fall of the dome of the church of Purgatory. Only the walls were left standing: and even these had suffered considerably One half of the steeple of the cathedral was beaten to the ground. The magazines of Porto Franco were likewise very much shattered. The fort of St Salvator, being built on an artificial foundation, the side next the sea is there fallen down; but on the other side, where it is founded

Meffina || Metacarpus.

founded on a rock, it has ftood unmoved by all the fhocks of the earthquake.

On the 5th of February, when the earthquake was more violent than at any time afterwards, a ftrong fmell of fulphur was felt. The earth was affected fomewhat in the fame way as if it had been borne upon a fluid; and feemed to reel with the fhocks much like a fhip toffed with the waves. This tremulous motion was felt all over Sicily; but towards Pharo it became weaker. On the following days the fky was cloudy; the mountains of Sicily and the fhores of Calabria continued covered with a thick fog like fmoke. North and north-eaft winds raged with the moft violent impetuofity.

The difaftrous year of this earthquake was fcarce concluded, the chafms which it had opened in the ground were ftill yawning, and the poor inhabitants of the adjacent country ftill trembled with terror, when the elements again renewed their fury to ravage this miferable land.

On Tuefday the 6th of January 1784, about funrife, the wind began to blow foftly from the northeaft. The fea gradually fwelled, rofe beyond its bed with rapid impetuofity, overflowed the quay of Meffina, and lafhed with its billows the ruins of the Palazzata. It loofened and difplaced many of the ftones of the mole, fpread over the whole ftreet, and attacked the pedeftals of the ftatues which had been fpared by the earthquake, and ftill ftood firm among the ruins. The fame furious wind which fwelled the fea in fo extraordinary a manner, ravaged the whole coaft from Meffina all the way to Syracufe.

MESSUAGE, Messuagium, in law, a dwelling-houfe, with fome land adjoining affigned for its ufe. By the name of *meffuage* may a garden, fhop, mill, cottage, chamber, cellar, or the like, pafs.—In Scotland, *meffuage* denotes what is called in England the *manor houfe*, viz. the principal dwelling-houfe within any barony.

MESOPORPHYRON, a name given by the Greeks to the Roman *laticlave*; becaufe that garment, being edged on each fide, where it opened before, with purple, appeared when clofed with two purple ftripes down the middle. The fame term was alfo applied to the *anguficlave*.

META, in the Roman circus, was a pile of ftones of a pyramidical form, intended as a boundary of the *ftadium*, or chariot-courfe.—When the meta was paffed the feventh time, the race was concluded. The greateft art and management were required in avoiding the meta, and yet going as near it as poffible. If they went too near, they were in the greateft danger of breaking the chariot to pieces; and if they took too large a circuit in the turn, they gave their rivals an opportunity of getting within them, befides lofing a great deal of ground. The boundary of the Grecian *ftadium*, or courfe, was called τελος, τερμα, γραμμη and αργα γραμμη; to which laft name Horace probably alludes in calling death, "*ultima linea rerum*."

The *metæ* at Rome were firft of wood, afterwards of ftone; but the emperor Claudius made them of gold, or rather gilded them. In the Roman circus there were two *metæ*, one at the entrance of the courfe, and the other at the end of it. An egg was placed upon the top of the *metæ*.

METACARPUS, or Metacarpium, (from μετα *behind*, and καρπος, *hand*), in anatomy, that part of the hand between the wrift and the fingers. See Anatomy, n° 55.

Metagitnion, Metal

METAGITNION, the fecond month of the Athenian year, anfwering to the latter part of our July and the beginning of Auguft, and fo called from *metagitnia*, a feftival in honour of Apollo, which was kept in it. The Bœotians called this month *panemus*, and the Syracufans, *carnius*.

METAL, in natural hiftory, a fimple, ponderous, fhining, fixed, opake body, that fufes and becomes fluid by fire, and by cold coagulates and hardens into a folid mafs, capable of being diftended under the hammer. See Metallurgy, and Chemistry.

Metal, in heraldry. There are two metals ufed in heraldry, by way of colours, viz. gold and filver, in blazon called *or* and *argent*.

In the common painting of arms thefe metals are reprefented by white and yellow, which are the natural colours of thofe metals. In engraving, gold is expreffed by dotting the coat, &c. all over; and filver, by leaving it quite blank.

It is a general rule in heraldry, never to place metal upon metal, nor colour upon colour: fo that if the field be of one of the metals, the bearing muft be of fome colour; and if the field be of any colour, the bearing muft be one of the metals.

Metals, Solution of. See Chemistry-*Index*.

On this fubject Mr Keir has fome curious obfervations in the Philofophical Tranfactions for 1790. He takes notice, that the word *folution* has two meanings; one expreffive of the act of diffolving, as when we fay that "folution is a chemical operation;" and the other, when it is put for the fubftance diffolved in the acid, as "a folution of filver in the nitrous acid." To avoid confufion, therefore, he ufes the word *folution* to exprefs the fubftance diffolved, together with its folvent; *diffolution* being the term made ufe of when the act of diffolving is meant. He continues the ufe of the terms *phlogifticated* and *dephlogifticated* to exprefs certain ftates of the acids, but without reference to theory of any kind.

In diffolving metals, our author obferves, that the properties of the feveral acids have been inveftigated with confiderable fuccefs; and even one compound, viz. that of fpirit of nitre and fpirit of falt, commonly called *aqua regis*, is well known on account of its quality of diffolving gold. A vaft field, however, yet remains for examination in the other acids, whether mixed together, or poffeffing various degrees of concentration, temperature, or phlogiftication. Thus, tho' no two fubftances are more frequently in the hands of chemifts than vitriolic acid and nitre, yet the properties of the mixture had not been inveftigated before Mr Keir made his experiments; and upon trial he found, that this mixture poffeffed certain properties which neither the vitriolic nor nitrous acids fingly poffefs. The refults of his experiments on this fubject are as follow.

1. In a long-necked retort containing 1400 grain meafures, 100 grains of oil of vitriol of the fpecific gravity of 1.844 were put along with 100 grains of pure nitre, and the falt diffolved in the acid by means of a water-bath. On applying a boiling heat, the filver began to diffolve, and the folution affumed a purple or

Metal.

or violet colour; but no air was extricated. An end was put to the operation (by the rushing in of the water used in the pneumatic apparatus applied to the retort) when 39 grains of silver had been dissolved.

2. To 100 grains of nitre previously dissolved in an equal quantity of vitriolic acid, 200 grains of standard silver were added; of which 92 grains were dissolved without the production of any air or gas: but upon pouring in 200 grains of water into the retort, a violent effervescence took place, and 3100 measures of nitrous gas were thrown off; and on adding 200 grains more, a farther emission of 600 grain measures ensued; but no more was emitted on the addition of more water, nor did any farther dissolution of the metal take place than two grains. The same phenomena took place in various proportions, according to the different quantities of acid and metal made use of.

On substituting tin for silver, none of the metal was dissolved or calcined by mixtures in the proportion of 200 grain measures of oil of vitriol to as much nitre, nor by 200 of the vitriolic acid to 150 of nitre: but with a proportion of 200 measures of the acid to 100 grains of nitre, the tin soon began to be acted upon, and diffused through the liquor; but no gas was extricated till the digestion had been continued in boiling water for two hours. The tin was still only calcined, not dissolved; 8500 grain measures of nitrous gas were extricated, and 73 grains of the metal reduced to a white powder. On pouring into the retort 200 grains of fresh water, a new effervescence took place betwixt the water and white powder, by which 4600 grain measures of nitrous gas were thrown off. The action of the menstruum was greatly promoted by augmenting the quantity of oil of vitriol, and adding water to the mixture.

By this mixture quicksilver was calcined to a grey powder, nickel was also partly calcined and partly dissolved; but no other metal was much affected, tho' the surfaces of some of them were tarnished. The mixtures themselves were very apt to congeal, especially where there was a large proportion of nitre; and their properties are much altered by the addition of water. Thus, in their concentrated state, they do not act upon iron; but by adding water, it acquires the property of acting upon that metal, and in different degrees according to the quantity of water added. Thus, by adding two measures of the compound acid to one of water, the liquor is rendered capable of calcining iron, and forming with it a white powder, but without any effervescence. An equal measure of water produces effervescence; and with a larger proportion of water the iron acquires a yellow or brown colour, such as phlogisticated nitrous acid acquires from iron, or communicates to a solution of martial vitriol in water. Dilution with water renders this compound acid capable of dissolving copper and zinc, neither of which it will touch in its concentrated state.

From this property of the compound acid not dissolving copper, but very readily silver, we have an easy method of separating the two metals from each other. This might be useful in many cases; but is particularly so in Birmingham, where great numbers of copper vessels covered with silver are manufactured. Thus there are always a great number of cuttings or small bits called *scraps*, which are of no use but to separate the two metals from one another. The easiest method of doing this is an object of some consequence. Two methods have been generally practised for this purpose: one is by melting the whole mass of metal with lead, and separating them by means of eliquation and testing; the other is by dissolving both metals in vitriolic acid, and then separating the solution of copper from the vitriol of silver. The disadvantage of the former method is, the quantity of lead and copper wasted; and of the latter, that of vitriolic acid. The virtues of a mixture of oil of vitriol and nitre were some time ago communicated by Mr Keir to an artist at Birmingham; and it is now generally used there to effect the separation of the two metals. The method of using it is very easy; nothing more being requisite than to put the pieces of plated metal into a glazed earthen pan, and to pour upon them some of the acid liquor, which may contain about one pound of nitre to eight or ten of oil of vitriol. Stir them about, and assist the action by an heat from 100 to 200 of Fahrenheit's scale. When the liquor is nearly saturated, the silver may be precipitated in the form of *luna cornea* by common salt; or it may be obtained in its metallic form by adding to the liquor some pieces of copper, and as much water as will enable it to act upon them. He is of opinion, that the menstruum may be useful in all separations of silver from other metals. The name he seems to wish to impose upon it is *aqua regina*. The following are the conclusions drawn from the experiments on these mixtures by our author.

1. A mixture of the vitriolic and nitrous acids dissolves silver plentifully.

2. It acts upon tin, and mostly calcines it, as well as mercury and nickel; having little or no action upon other metals.

3. The quantity of gas produced while the metal is dissolving, is greater, relatively to the quantity of the metal dissolved, when the proportion of nitre to the vitriolic acid is small, than when it is large; and when the metals are dissolved by mixtures containing much nitre with a small production of gas, the solution itself, or the metallic salt formed in it, yields abundance of gas when mixed with water.

4. Dilution with water renders the concentrated mixture less capable of dissolving silver, but more so of acting upon other metals.

5. This mixture of highly concentrated vitriolic and nitrous acids, acquires a purple or violet colour when phlogisticated, either by the addition of inflammable substances as sulphur, or by its action on metals, or by very strong impregnation of oil of vitriol with nitrous gas.

6. By means of this phlogistication the mixture acquired a property of dissolving, though in small quantities, copper, iron, zinc, and regulus of cobalt.

7. Water expels a vast quantity of nitrous gas from a concentrated mixture of vitriolic acid and nitre impregnated with it; but this fluid unites with a mixture of oil of vitriol and nitre without any considerable effervescence.

By adding to the mixture of oil of vitriol and nitre a solution of common salt, a very powerful *aqua regia* is formed, capable of dissolving gold and platina; and which, Metal. which, though perfectly free from all metallic matter, acquires at once a deep yellow colour. Dry common salt added to the concentrated mixture produces an effervescence, but no yellow colour.

Metalepsis Metallisation.

METALEPSIS. See ORATORY, n° 59.

METALLISATION, the natural process by which metals are formed in the bowels of the earth. See METALLURGY, sect. i.

METALLURGY.

METALLURGY, according to Boerhaave, comprehends the whole art of working metals, from the glebe or ore to the utensil; in which sense essaying, smelting, refining, parting, smithery, gilding, &c. are only branches of metallurgy. But, in the present work, Gilding, Parting, Purifying, Refining, Smithery, &c. are treated under their proper names. With others, therefore, we have chosen to restrain *Metallurgy* to those operations required to separate metals from their ores for the uses of life. These operations are of two kinds: the smaller, or Essaying; and the larger, or Smelting. But a particular description of the ores themselves seemed likewise necessary to be given; and to this place, too, we have referred a general account of metals, metallisation, mines, and ores, as a proper introduction to the subject. Hence the following division into three parts. The *first* treating, 1. Of metals and metallisation. 2. Of mines and ores in general. 3. Of the pyrites. 4 Of the essaying of ores in general. The *second*, Of the particular ores, and the methods of essaying them. The *third*, Of smelting of ores, or the methods of extracting metals from large quantities of ores for the purposes of commerce or manufacture.

PART I.

SECT. I. *Of Metals and Metallisation.*

UNDER the general name *metal*, we comprehend here not only the metals properly so called, but also the *semimetals*, or all matters which have the essential metallic properties which we shall here recount. Thus the word *metal* and *metallic substance* will be synonymous in this article.

Metallic substances form a class of bodies, not very numerous, of very great importance in chemistry, medicine, arts, and the ordinary affairs of life. These substances have very peculiar properties, by which they differ from all other bodies.

The natural bodies from which metals differ the least are, earthy and pyritous matters, on account of their solidity and density. Metals and stones are, nevertheless, very different; the heaviest stones which are unmetallic being much lighter than the lightest metals. A cubic foot of marble weighs 252 pounds; and an equal bulk of tin, the lightest of metals, weighs 516 pounds. The difference is much greater when the weight of such stone is compared with that of gold, a cubic foot of which is 1326 pounds.

Opacity is another quality which metals possess eminently, the opacity of metals being much greater than that of any unmetallic substance.

This great opacity of metals is a consequence of their density; and these two properties produce a third, peculiar also to metals, namely, a capacity of reflecting much more light than any other body: hence metals whose surfaces are polished, form mirrors representing the images of bodies more clearly than any other matter. Thus looking-glasses produce their reflection merely by the silvering, which is a covering of metal on their surfaces. To this reflective property metals owe their peculiar lustre, called the *metallic lustre*.

Although the several metallic substances differ considerably in hardness and fusibility, we may say in general, that they are less hard and less fusible than pure earths

Metals cannot unite with any earthy substance, not even with their own earths, when these are deprived of their metallic state: hence, when they are melted, they naturally run into globes, as much as the absolute gravity of their mass, and their pressure upon the containing vessels, will allow. Accordingly, the surface of a metal in fusion is always convex. A metal in that state always endeavours to acquire a spherical form, which it does more perfectly as the mass is less. This effect is very sensible in quicksilver, which is nothing but a metal habitually fluid or fused. A mass of several pounds of mercury, contained in a shallow wide-mouthed vessel, is so spread out, that its upper surface is almost flat, and the convexity is not very sensible but at its circumference: on the contrary, if we put very small masses of mercury into the same vessel, as, for instance, masses weighing a grain each, they become so round as to seem perfect globes. This effect is partly occasioned by the inaptitude of metals to unite with the vessels containing them when in fusion, by which quality the whole affinity which subsists betwixt the integrant parts of these metals is capable of acting; and partly also by this affinity, which disposes the integrant parts to come as near to each other as they can, and consequently to form a sphere.

This property is not peculiar to melted metals, but to all fluids, when contiguous to bodies solid or fluid, with which they have no tendency to unite. Thus, for instance, masses of water upon oily bodies, or oily masses upon bodies moistened with water, assume always a form so much nearer to the spherical as they are smaller. Even a large drop of oil poured upon a watery liquor, so that it shall be surrounded with this liquor, becomes a perfect sphere.

All metals are in general soluble by all acids; but often these solutions require particular treatment and circumstances, which are mentioned under CHEMISTRY. With acids, they form a kind of neutral salts, which have

have all more or less causticity. The affinity of metals is less than of absorbent earths and alkaline salts to acids; and therefore any metal may be separated from any acid by these substances.

Alkaline salts are capable of acting upon all metallic substances, and by proper management will keep them dissolved.

Metals may in general be united with sulphur and liver of sulphur. With sulphur they form compounds resembling the peculiar substance of ores, which are generally nothing else than natural combinations of sulphur and metal. Metals have less affinity with sulphur than with acids; hence sulphur may be separated from them by acids. Some exceptions from these general rules, concerning the affinity of metals to sulphur and liver of sulphur, and concerning their separation from sulphur by acids, may be seen under the articles of the several metals. But these exceptions do probably take place, only because we have not yet found the method of surmounting some obstacles which occur in the ordinary methods of treating certain metals.

All metals may in general be united with each other, with which they form different allays which have peculiar properties; but this rule also is not without some exceptions.

Metals have a strong affinity with the inflammable principle, and are capable of receiving it superabundantly.

Lastly, oily substances seem to be capable of acting upon all metals. Some metals are easily and copiously dissolved by oils; and perhaps they might all be found to be entirely soluble in oils, if the methods known in chemistry were tried for the accomplishment of these solutions.

The properties above mentioned agree in general to all metallic substances: but, besides the properties peculiar to each metal, some properties are common to a certain number of them; and hence they have been divided into several classes.

Those metallic matters which, when struck by a hammer, or strongly compressed, are extended, lengthened, and flattened, without being broken (which property is called *ductility* or *malleability*), and which also remain fixed in the most violent and long continued fire, without diminution of weight, or other sensible alteration, are called *perfect metals*. These perfect metals are three; *gold, silver, platina*.

The metallic matters which are ductile and fixed in the fire, to a certain degree, but which are destroyed by the continued action of fire, that is, changed into an earth deprived of all the characteristic properties of metals, are called *imperfect metals*. Of this kind are four; *copper, iron, tin, lead*.

The metallic substances which, as well as the imperfect metals, lose their metallic properties by exposure to fire, but which also have no ductility nor fixity, are distinguished from the others by the name of *semi-metals*. Of this class are seven; *regulus of antimony, bismuth, zinc, nickel, regulus of cobalt, regulus of arsenic*, and of *manganese*.

Lastly, *mercury*, which has all the general properties of metals, makes a class separate from the others; because in purity and gravity it is similar to the perfect metals, and in volatility to the semi-metals. Its fusibility also so far surpasses that of any other metallic matter, that it is sufficient to distinguish it from all, and to give it a distinct class. We have enumerated, therefore, in all, 15 metallic substances; four of which were unknown to the ancients, namely, platina, regulus of cobalt, of manganese, and nickel.

As chemists can compound bodies by being capable of separating the principles of such bodies, and even of re-uniting their principles so as to reproduce such compounds as they were originally; and as hitherto they have not been able to accomplish any such decomposition upon the perfect metals: hence, if all the other metallic substances were equally unalterable, we should be very far from having certain notions concerning metals in general: but if we except gold, silver, and platina, all the other metallic matters are susceptible of decomposition and of recomposition, at least to a certain degree; and experiments of this kind have thrown much light on the subject.

We may observe, that even if we had not been able to decompose any metallic substance, we might still, by reflecting on the essential properties of metals, discover sufficiently well the nature of their principles.

The solidity, the consistence, and especially the gravity, which they possess in a degree so superior to all other bodies, would not have allowed us to doubt that the earthy element, of which these are the characteristical properties, enters largely into their composition, and makes their basis.

The facility with which they combine with almost all inflammable matters, and with all those which have great affinity with phlogiston, such as acids; joined to their incapacity of being allayed with meagre matters that are purely earthy or purely watery, which have no disposition to unite with phlogiston; would also have furnished very strong motives to believe, that the inflammable principle enters largely into the composition of metals.

The destructible metals present exactly the same phenomena as all other bodies containing the inflammable principle do, in the state of combustion. When exposed to fire, without access of air, that is, in close vessels, they become red-hot, melt, or sublime, according to their nature: but they receive no alteration in their composition from fire applied in this manner, and they are afterwards found to be exactly in the same state as before. In this respect, they resemble perfectly all bodies which contain no other inflammable matter than pure phlogiston.

But when imperfect metals are exposed to fire, with access of air, as, for instance, under a muffle in a furnace which is made very hot, then they burn more or less sensibly, as their inflammable principle is more or less abundant, or more or less combined. Some of them, as iron and zinc, burn with a very lively and brilliant flame; but this flame is of the same nature as that of charcoal, of sulphur, of all bodies, the combustible principle of which is pure phlogiston, and is not in an oily state, that is, furnishes no soot capable of blackening.

The imperfect metals detonate with nitre, and their phlogiston is consumed by this method much more quickly and completely than by ordinary calcination or combuſtion. Their flame is alſo much more lively and brilliant: and ſome of them, as iron and zinc, are uſed in compoſitions for fireworks from their very vivid and beautiful flame.

Nitre is alkaliſed by theſe metallic detonations exactly in the ſame manner as in its detonation by coals.

Laſtly, imperfect metals being treated with acids which have an affinity with phlogiſton, that is, with the vitriolic and nitrous acids, are deprived by theſe acids of a more or leſs conſiderable part of their inflammable principle; they give a ſulphureous quality to vitriolic acid, and are even capable of producing ſulphur with that acid.

Although the experiments now mentioned were the only proofs of the exiſtence of an inflammable principle in metallic ſubſtances, they would be ſufficient to eſtabliſh it inconteſtably. But we ſhall ſee, when we continue to examine the phenomena attending the decompoſition of metals, that thoſe are not the only proofs.

If the inflammable matter which ſhows itſelf ſo evidently in the burning of metals, is really one of their conſtituent parts, their eſſential properties muſt be altered in proportion to the quantity of it taken from them: and this evidently happens upon trial: for the reſiduum of metallic matters, after calcination, departs from the metallic character, and approaches to the nature of mere earth. The opacity, brilliancy, ductility, gravity, fuſibility, volatility, in a word, all the properties by which metallic ſubſtances differ from ſimple earths, diminiſh or entirely diſappear, by taking from them their inflammable principle; ſo that when their calcination has been carried as far as is poſſible, they reſemble mere earths, and have no longer any thing in common with metals. Theſe earths can no longer be combined with acids or with metals, but are capable of uniting with pure earths. They are then called *calxes* or *metallic earths*. See CHEMISTRY.

We muſt obſerve concerning the decompoſition of metals, 1. That when a ſmall quantity of inflammable principle is taken from metals, only a ſmall quantity of calx is formed, and the remaining part continues in the metallic ſtate: hence, as the portion of calcined matter can no longer remain united with that which is deſtroyed, it ſeparates in form of ſcales from the ſurface of the metal when the calcination has been performed without fuſion, as generally happens to iron and to copper: or theſe ſcales float upon the ſurface of the melted matter when the calcination is performed during fuſion, becauſe the calx is ſpecifically lighter than the metal; as happens to the very fuſible metals, as tin, lead, and moſt of the ſemimetals.

2. The imperfect metals are not all equally eaſily and completely calcinable. In general, as much of their phlogiſton may be eaſily taken from them, as is ſufficient to deprive them of their metallic properties; but the remaining portion of their phlogiſton cannot be ſo eaſily driven off. Some of them, as copper, reſiſt the firſt calcination more than the reſt; and others, as lead and biſmuth, may be very eaſily calcined, but only to a certain degree, and retain always obſtinately the laſt portions of their inflammable principle; laſtly, others, as tin and regulus of antimony, may not only be eaſily and quickly calcined, but alſo much more completely. All the other metals partake more or leſs of theſe properties relating to their calcination. In general, if we except the labours of alchemiſts, which are not much to be depended upon, we have not yet made all the proper efforts to arrive at a perfect calcination of the ſeveral metallic ſubſtances; which, however, is abſolutely neceſſary, before we can arrive at a complete knowledge of the nature of their earths, as we ſhall afterwards ſee.

When metallic earths have loſt but little of their phlogiſton, and are expoſed to ſtrong fire, they melt, and are reduced to compact maſſes, ſtill heavy and opake; although much leſs ſo than the metals, and always brittle and abſolutely unmalleable. If the calcination has been more perfect, the metallic earths are ſtill fuſible by fire, but leſs eaſily, and convertible into brittle and tranſparent maſſes poſſeſſed of all the properties of glaſs, and are accordingly called *metallic glaſſes*. Theſe glaſſes do not poſſeſs any of the properties of their metals, excepting that they are ſpecifically heavier than other glaſſes, that they are capable of being attacked by acids, and that the glaſſes of the ſemimetals are ſomewhat leſs fixed than unmetallic glaſſes. Laſtly, when the calcination of metals has been carried to its greateſt height, their earths are abſolutely fixed, and unfuſible in the fire of our furnaces, and poſſeſs no longer the ſolubility in acids by which metals are characteriſed.

Theſe are the principal changes which metals ſuffer by loſing their phlogiſton. They are thus changed into ſubſtances which have no properties but thoſe of earth. This is a certain proof that the inflammable principle is one of their conſtituent parts. But we have alſo other proofs of this important truth. The reduction of metallic calxes into metal, by the addition of phlogiſton alone, completes the proof; and the whole forms one of the cleareſt and moſt ſatisfactory demonſtrations in all the ſciences. This reduction is effected in the following manner:

If the earth of a metal be mixed with any inflammable matter, which either is or can be changed into the ſtate of coal, together with ſome ſalt capable of facilitating fuſion, but which, from its quantity or quality, is incapable of receiving the inflammable principle; and if the whole be put into a crucible, and the fuſion promoted by a fire gradually raiſed; then an effervescence will happen, accompanied with a hiſſing noiſe, which continues a certain time, during which the fire is not to be increaſed; afterwards, when the whole has been well fuſed, and the crucible taken from the fire and cooled, we ſhall find at the bottom, upon breaking it, the metal, the earth of which was employed for the operation, poſſeſſed of all the properties which it had before calcination and reduction.

We cannot doubt that this transformation of an earthy ſubſtance into a metal, is ſolely cauſed by the phlogiſton paſſing from the inflammable matter to the metallic earth. For, firſt, in whatever manner and with whatever ſubſtance metallic earths be treated, they cannot be ever reduced into metals without a concurrence of ſome ſubſtance containing phlogiſton. 2dly, The nature of the ſubſtance which is to furniſh phlogiſton is quite indifferent, becauſe this principle is the ſame in all bodies containing it. 3dly, If, after the

Of Metallisation.

the operation, the substance furnishing the phlogiston be examined, we shall find that it has lost as much of that principle as the metallic earth has received. See Phlogiston.

The facts related concerning the decomposition and the recomposition of metals, prove incontestably that they are all composed of earth and phlogiston. But we do not yet certainly know whether these two be the only principles of metals. We might affirm this, if we could produce metals by combining phlogiston with some matter which is certainly known to be simple earth. But this hitherto has not been accomplished; for if we try to treat any earth, which has never been metallic, with inflammable matters, we shall perceive that the simple earths are not combinable with phlogiston so as to form metals. We shall even perceive that the metallic earths resist this combination, and are incapable of reduction into metal, when they have been so much calcined as very nearly to approximate the nature of simple earths.

These considerations, added to this, that we cannot easily conceive how, from only two certain principles, so many very different compounds as the several metallic substances are, should result, are capable of inducing a belief that some other principle is added to these two already mentioned in the composition of metals.

Many great chemists, and particularly Becher and Stahl, seem to be of this opinion. Chiefly from the experiments concerning the mercurification of metals, they believe that this third principle exists copiously in mercury; that it is of a mercurial nature; that it also exists in marine acid, to which it gives its specific character; that, by extracting this mercurial principle from marine acid, or any other body containing it copiously, and by combining it with simple earths, these may acquire a metallic character, and be rendered capable of receiving phlogiston, and of being completely metallised.

These chemists admit also, and with probability, a different proportion of metallic principles in the several metals; and believe, that particularly the principle which they call *mercurial earth*, exists more copiously and sensibly in certain metals than in others. The most mercurial metals, according to them, are mercury, silver, lead, and arsenic. Most chemists distinguish them from the other metals, which they call *white metals*, *lunar metals*, or *mercurial metals*.

All these considerations being united, and others too many to be mentioned, give some probability to the existence of the mercurial principle in metals. We must however acknowledge, that the existence of this principle is merely probable; and, as Stahl observes, is not nearly so well demonstrated as that of the inflammable principle: we may even add, that we have strong motives to doubt of its existence.

To produce metals artificially has justly been reckoned one of the most difficult problems in chemistry.

Metallic substances, although they resemble each other by their general properties, differ nevertheless from each other very evidently by the properties peculiar to each. Do these differences proceed from the different proportion, and from the more or less intimate connection of the inflammable principle with the earthy principle, supposing that this latter should be essentially the same in all metals? or ought they to be attributed to the difference of earths, which in that case would be distinct and peculiar to each metal? or, lastly, do metals differ from each other, both by the nature of their earths, and by the proportion and intimacy of connection of their principles? All these things are entirely unknown; and we may easily perceive, that till they are known, we cannot discover what method to pursue in our attempts to accomplish the combinations we are now treating of.

The most essential point then is, to arrive at a knowledge of the true nature of the earths which are in metals; and the only method of arriving at this knowledge is, by reducing them to their greatest simplicity by a perfect calcination. But this cannot be accomplished but by long and difficult operations. We have seen above, that all metals are not calcinable with equal ease; that the perfect metals have not been hitherto calcined truly by any process; and that, in general, the last portions of phlogiston adhere very strongly to calcinable metals.

Some metals, however, as tin and regulus of antimony, may be easily calcined so as to be rendered irreducible. By carrying the calcination still further, we might obtain their earths so pure, that all their essential properties may be discovered, by which they might be easily compared together. This comparison would decide whether their nature be essentially different or not.

If they were found to be composed of earths essentially the same, we might next proceed to compare metallic with unmetallic earths. If the former were found similar to some of the latter kind, we should be then assured that the earth of metals is not peculiar to them, and that ordinary unmetallic earths are susceptible of metallisation. From some late experiments, it was imagined that lime and magnesia alba were capable of being converted into metallic substances, but the processes are now found to be erroneous.

The greater the number of metals operated upon, the more general and certain the consequences resulting from these would be: so that, for instance, if the operation were extended to all calcinable metals; and if the result of each of these operations were, that the calxes, when perfectly dephlogisticated, do not differ from each other, and are similar to earths already known; we might conclude from analogy, and we should be almost certain, that the earths of the perfect metals are also of the same nature.

They who know the extent and difficulties of chemical operations, will easily perceive that this would be one of the most considerable. Nevertheless, after having determined this essential point, we should only have done half our work: For a knowledge of the nature of the earth of metals, and where it is to be found, would not be sufficient; we must further endeavour to find a method of combining with this earth a sufficient quantity of phlogiston, and in a manner sufficiently intimate, that a metal might be formed by such a combination. But this second difficulty is perhaps greater than the former.

We must observe here, that some famous chemical processes have been considered by many as metallisations, but which are really not so. Such is Becher's famous experiment of the *minera arenaria perpetua*, by which that chemist proposed to the States-General to extract gold from any kind of sand. Such also is the process of Becher and of Geoffroy, to obtain iron from

Of Metallization.

from all clays by treating them with linseed oil in close vessels. In these, and many other such processes, we only obtain metal that was already formed. Every earth and sand, as the intelligent and judicious Cramer observes, contains some particles of gold. Clays do not commonly contain iron ready formed: but all of them contain a ferruginous earth, naturally disposed to metallisation. (See CLAY.) Accordingly we must conclude, that, by Mr Geoffrey's experiment, iron is only reduced or revived, but is not produced.

The great difficulties which occur in attempting to give a metallic quality to simple earths have induced a belief, that the nature of metals ready formed might be more easily changed, and the less perfect brought to a more perfect state. To effect this, which is one of the principal objects of alchemy, and is called *transmutation*, numberless trials have been made. As we have not any certain knowledge of what occasions the specific differences of metallic substances, we cannot decide whether transmutation be possible or not. In fact, if each metallic substance have its peculiar earth, essentially different from the earths of the others, and consequently if the differences of metals proceed from the differences of their earths; then, as we cannot change the essential properties of any simple substance, transmutation of metals must be impossible. But if the earths and other principles of metals be essentially the same, if they be combined in different proportions only, and more or less strictly united, and if this be the only cause of the specific difference of metals; we then see no impossibility in their transmutation.

Whatever be the cause of the differences of metals, their transmutation seems to be no less difficult than the production of a new metallic substance; and perhaps it is even more difficult. Alchemists believe that transmutation is possible, and they even affirm that they have effected it. They begin by supposing that all metals are composed of the same principles; and that the imperfect metals do not differ from gold and silver, but because their principles are not so well combined, or because they contain heterogeneous matters. We have then only these two faults to remedy, which, as they say, may be done by a proper coction, and by separating the pure from the impure. As we have but very vague and superficial notions concerning the causes of the differences of metals, we confess that we cannot make any reasonable conjecture upon this matter; and we shall only advise those who would proceed upon good principles, to determine previously, if metals have each a peculiar earth, or only one common to them all. In the second place, if it should be demonstrated that the earthy principle is the same in all metals, and if that be demonstrated as clearly as the identity of the inflammable principle in metals is proved; they must then determine whether these two be the only principles in metals, whether the mercurial principle exists, and whether it be essential to all metals or to some only, and what is the proportion of these two or three principles in the several metallic substances. When we shall clearly understand these principal objects, we may then be able to determine concerning the possibility of transmutation; and if the possibility should be affirmed, we shall then begin to discover the road which we ought to pursue.

We have no reason to believe that any other principle enters into the composition of metals than those above-mentioned; no vestige is perceptible of either air or water. Some chemists have nevertheless advanced that they contain a saline principle. If that were true, they would also contain a watery principle. But all the experiments adduced to prove this opinion are either false, or only show the presence of some saline particles extraneous to the metals, or contained unknown to the chemists in the substances employed in the experiments. For metals perfectly pure, subjected to all trials with substances which do not contain and which cannot produce any thing saline, do not discover any saline property. We must however except arsenic, and even its regulus, these being singular substances, in which the saline are as sensible as the metallic properties.

Arsenic seems to be one of those intermediate substances which nature has placed in almost all its productions betwixt two different kinds, and which partake of the properties of each kind. Arsenic thus placed betwixt metallic and saline substances has properties common to both these kinds of substances, without being either entirely a metal or salt. See ARSENIC.

As water seems to act to a certain degree upon iron, even without the concurrence of air, as the operation of *martial ethiops* shows, we might thence suspect something saline in that metal. Nevertheless, what happens in that operation has not been so well explained, that any certain consequences can be deduced. 1. The water employed ought to be perfectly pure; that is, distilled rain-water. 2. The iron employed ought also to be perfectly pure, and such is very difficultly to be procured. 3. The operation ought to be performed in a bottle accurately closed, that we may be assured that the air contributes nothing to the action upon the iron. 4. After the water has remained a long time, suppose a year, upon the iron, it ought to be carefully filtrated and examined, to ascertain whether it really has dissolved any part of the metal.

In the mean time, we may conclude that metals do not seem to contain any saline principle. And when we consider well their general properties, they seem to be nothing else than earths combined more or less intimately with a large quantity of phlogiston. Although we can demonstrate that their inflammable principle is not in an oily state, and that it is pure phlogiston, they have nevertheless an oily appearance, in this circumstance, that they adhere no more than oils to earthy and aqueous substances, and that they always assume a globular figure when supported by these substances entirely free from phlogiston.

This resemblance is so sensible, that chemists, before they knew the nature of phlogiston, believed that metals contained an oily and fat matter. The cause of this quality of metals is the quantity of phlogiston which they contain. Sulphur, phosphorus, oils, and even fats, have this appearance merely from the inflammable principle which enters into their composition: for this property is communicated by that principle to every compound which contains a certain quantity of it. See PHLOGISTON.

When the phlogiston combines copiously and intimately with earthy matters so as to form metals, it

Of Metallization.

probably so disposes them, that the primitive integrant parts of the new compound, that is, of the metal, approximate and touch each other much more than the integrant parts of simple earths can. This is proved by the great density or specific gravity, and other general properties, of metals.

In fact, as we cannot conceive that a body should be transparent, unless it have pores and interstices through which rays of light can pass; therefore the more dense a body is, that is, the fewer such interstices it has, the less transparent it will be; so that the densest bodies ought to be the most opaque as in metals. The disposition of the pores of bodies contributes also much to their greater or less transparency; and bodies, the pores of which are continued and straight, are more transparent than those whose pores are interrupted, transverse, or oblique; so that a body may be much more transparent than another which is less dense, as we see that glass is more transparent than charcoal. But when other circumstances are equal, the densest bodies are the most opaque. Therefore the opacity of bodies is proportionable to their density, and to the deviation of their pores from right and parallel lines.

From the great opacity of metals, they probably possess both these qualities in an eminent degree. We have seen, at the beginning of this article, that the lustre of metals, and their property of reflecting light much better than any other substance, are necessary consequences of their opacity. This is also self-evident, because the fewer rays any body can transmit, the more it must reflect.

Lastly, the ductility of metals proceeds also from their density, from the disposition of their pores, and from the action of latent heat; for even the most brittle bodies, such as glass, sealing-wax, &c. become ductile by heat. The softness, fusibility, and volatility, of which all metals partake more or less, and which many of them possess in a superior degree, being properties entirely contrary to those of the earthy principle, probably proceed from the inflammable principle.

The order in which metals compared with each other possess most eminently their principal properties, is the same as that in which they are here enumerated, beginning always with that metal in which the property is most considerable.

1. *Specific gravity* or *density*. Platina, gold, mercury, lead, silver, copper, iron, and tin.

2. *Opacity*. We cannot well compare metals with each other in this respect, because it is so considerable in all, that it seems complete. If, however, they differ in this respect, the same order will serve for opacity as for density.

3. *Metallic lustre* or *brilliancy*. The same observation which was made concerning the last mentioned property is applicable to this also. We must, however, observe that as by polish bodies are rendered brighter, and that as whiteness contributes much to the reflexion of light, the whitest and hardest metals therefore reflect best. Hence, according to Mr Macquer, platina ought to be placed first; and then iron, or rather steel, silver, gold, copper, tin, lead.

Hardness of metals may contribute much to the duration of their polish; but certainly soft metals, if their texture be equally compact, are no less capable of receiving a polish than hard metals. Some hard metallic allays have been found to be less liable to tarnish than softer compounds, and have for this reason also been chiefly used for speculums. The property of reflecting light seems chiefly to depend on the closeness of the particles or on the density, on the smoothness of the surface, and on the colour being most similar to the colour of the light to be reflected. The white metals, silver, mercury, tin, reflect light more abundantly than others. Gold, being the densest metal next to platina, and perhaps because the colour of solar light has a slightly yellowish tinge, does also reflect light very copiously. Hence speculums made of leaf-gold have been found to be very powerful. Iron or steel reflects much less light than any of the above-mentioned metals, although Mr Macquer has considered it as capable of a greater reflective power. Platina is generally in so small grains, that its reflective power cannot easily be determined. The precise degrees of that power which ought to be assigned to each of the above-mentioned metals, cannot without accurate experiments be ascertained. Perhaps, however, their reflective powers will be found to be more nearly in the following order, than in that above mentioned from Mr Macquer. Silver, quicksilver, tin, gold, copper, iron, lead.

4. *Ductility*. Gold, silver, copper, iron, tin, lead. The ductility of mercury and that of platina are not yet determined.

5. *Hardness*. Iron, platina, copper, silver, gold, tin, and lead.

6. *Tenacity*. By tenacity we understand the force with which the integrant parts of metals resist their separation. This force appears to be in a compound ratio of their ductility and hardness. The comparative tenacity of metals is measured by the weight which wires of the same diameter, made of the several metals, can sustain without breaking. Gold is the most tenacious; then iron, copper, silver, tin, lead. The tenacity of mercury is unknown: that of platina is not yet determined, but is probably considerable.

7. *Fusibility*. Mercury, tin, lead, silver, gold, copper, iron, and lastly platina, which cannot be fused by the greatest fire of our furnaces, but only by the solar focus, or by a fire excited by dephlogisticated air.

Sect. II. *Of Mines and Ores in general.*

The substances found naturally combined with metals in the earth, are, particularly, sulphur and arsenic, sometimes separately, but generally conjointly. Metals combined with these substances are called *metals mineralised by sulphur*, or *by arsenic*, or *by sulphur and arsenic*; and these matters are called *mineralising* substances.

Besides the sulphur and arsenic with which metals are strictly combined in the mineral state, they are also pretty intimately combined with earthy substances, of different natures, and more or less divided.

These different matters united together form masses which are compact, heavy, brittle, and frequently possessed of much metallic lustre. These substances are properly called *ores*, or the matter of mines.

These ores are found in earths and stones of different kinds, as sands, flints, crystals, slates, indurated clays, according to the ground in which they are contained. But two kinds of stones in particular seem to accompany ores; and have therefore been considered by several mineralogists as matrixes in which metals are formed. One of these stones is a kind of crystal, generally white, milky, and semi-opaque, striking fire with steel, and of the class of vitrifiable earths. It is called QUARTZ.

The other stone is less hard, which does not strike fire with steel, and is sometimes milky like quartz; sometimes transparent and of different colours, consisting of rhomboidal crystals, which are composed of plates and faces. This stone becomes more soft and friable by being exposed to fire. It is called *spar*. Spar is more like to gypseous stones than to any other, but it differs from gypseous stones in possessing a much greater density. Some spars are so heavy, that they exceed in this respect all other stones. See SPAR.

These earthy and stony substances form the *matrix of the ore*.

Ores are natural compounds, containing metals allayed with different substances.

Excepting gold, and a very small quantity of each of the other metals found in some places so pure as to possess all their characteristic properties, nature exhibits to us metals and semimetals differently allayed not only with each other, but also with several heterogeneous substances, which so alter and disguise their qualities, that in this state they cannot serve for any of the purposes for which they are proper when they are sufficiently pure.

Ores consist, 1. Of metallic substances *calcined*; or, 2. Of these substances combined with other matters, with which they are said to be *mineralised*.

Calcined metallic substances, or *calciform ores*, are metallic substances deprived of phlogiston, and in the state of a calx or metallic earth. Such are all *ferruginous ochres*, which are calces of iron.

Mineralised ores, are, 1. *Simple*, containing only one metallic substance: or, 2. *Compound*, containing two or more metallic substances.

Of the simple, and also of the compound ores, four kinds may be distinguished.

1. Ores consisting of metallic substances mineralised by *sulphur*. Such is the lead-ore called *galena*, composed of lead and sulphur.

2. Ores consisting of metallic substances mineralised by *arsenic*. Such is the *white pyrites*, containing iron and arsenic.

3. Ores consisting of metallic substances mineralised *by sulphur and by arsenic*. Such is the *red silver-ore*, containing silver, arsenic, and sulphur.

4. Ores consisting of metallic substances mineralised by *saline matters*. Such are the *native vitriols*. Such also is probably the *corneous silver-ore*, which, according to Mr Cronstedt's opinion, is a luna cornea, or silver combined with marine acid. Of this kind of ores, or native metallic salts, is perhaps the *sedative salt of borax*, which from Mr Cadet's experiments, published in the Memoirs of the Royal Academy for the year 1766, is conjectured to be copper combined with marine acid, and which has been said to be found native. To this class also may be referred the *silver mineralised by an alkaline substance*, which Mr Von Justi pretends to have discovered.

Henckel, and after him Cramer, and the author of the Dictionary of Chemistry, pretend, that in mineralised ores, besides the above mentioned metallic and mineralising substances, are also contained a metallic and an unmetallic earth. But Wallerius affirms, that the existence of such earths cannot be shown, and that sulphur is incapable of dissolving unmetallic earths, and even the calces of all metallic substances, excepting those of lead, bismuth, and nickel.

Metals and *metalliferous ores* are found in various places.

I. *Under water*; in beds of rivers, lakes, and seas, and chiefly at the flexures of these: such are the auriferous and ferrugineous sands, grains of native gold, ochres, and fragments of ores washed from mines.

II. *Dissolved in water*: such are the vitriolic waters containing iron, copper, or zinc.

III. *Upon the surface of the earth*. Such are many ochres; metalliferous stones, sands, and clays; and lumps of ores Mr Gmelin says, that in the northern parts of Asia ores are almost always found upon or near the surface of the ground.

IV. *Under the surface of the earth*. When the quantity of these collected in one place is considerable, it is called a *mine*.

Subterranean metals and ores are differently disposed in different places.

1. Some are *infixed in stones and earths*, forming *nodules* or *spots* diversely coloured.

2. Some are equably and *uniformly diffused through the substance of earths and stones*, to which they give colour, density, and other properties. Such are the greatest part of those earths, stones, sands, clays, crystals, flints, gems, and fluors, which are coloured.

3. Some form *strata* in mountains. Such are the slates containing pyrites, copper-ore, lead-ore, silver-ore, or blend. These lie in the same direction as the strata of stones betwixt which they are placed; but they differ from the ordinary strata in this circumstance, that the thickness of different parts of the same metalliferous stratum is often very various; whereas the thickness of the stony strata is known to be generally very uniform.

4. *Fragments of ores* are frequently found accumulated in certain subterranean cavities, in fissures of mountains, or interposed betwixt the strata of the earth. These are loose, unconnected, frequently involved in clay, and not accreted to the contiguous rocks or strata immediately, nor by intervention of spar or of quartz, as the ores found in veins are. Tin and iron mines are frequently of the kind here described.

5. Large entire masses of ores are sometimes found in the stony strata of mountains. These are improperly called *cumulated veins*, because their length, relatively to their breadth and depth, is not considerable.

6. Some instances are mentioned of *entire mountains* consisting of ore. Such is the mountain Taberg in Smoland; and such are the mountains of Kerunavara and Luosavara in Lapland, the former of which is 1400 perches long and 100 perches broad. These mountains consist of iron-ore.

7. Lastly, and chiefly, metals and ores are found in oblong

Pyrites. oblong tracts, forming maffes called *veins*, which lie in the ftony ftrata compofing mountains. See the article MINE.

SECT. III. *Of the Pyrites.*

PYRITE is a mineral refembling the true ores of metals, in the fubftances of which it is compofed, in its colour or luftre, in its great weight, and, laftly, in the parts of the earth in which it is found, fince it almoft always accompanies ores. It is, like ores, compofed of metallic fubftances, mineralized by fulphur or by arfenic, or by both thefe matters, and of an unmetallic earth intimately united with its other principles.

Notwithftanding the conformity of pyrites with ores properly fo called, fome chemifts and metallurgifts diftinguifh the former from the latter minerals; becaufe the proportion and connection of the materials compofing the pyrites differ much from thofe of ores. Thus, although fometimes pyrites contains more metal than fome ores, yet generally it contains lefs metal, and a larger quantity of mineralifing fubftances, fulphur and arfenic, and particularly of unmetallic earth. The connection of thefe matters is alfo much ftronger in pyrites than in ores, and they are accordingly much harder; fo that almoft every pyrites can ftrike fparks from fteel.

From the above property of ftriking fparks from fteel, they have been called *pyrites;* which is a Greek word fignifying *fire-ftone*. Pyrites was formerly ufed for fire-arms, as we now ufe flints; hence it was called *carabine-ftone*. It is ftill named by fome *marcafite*. Perhaps no other kind of natural body has received fo many names. Perfons curious to know the other names lefs ufed than thofe we have mentioned, may find them in *Henckel's Pyritologia*. We think, with that celebrated chemift, that the fubject has been perplexed by this multiplicity of names; for before his great and excellent work, the notions concerning pyrites were very confufed and inaccurate.

Pyrite differs alfo from ores by its forms and pofitions in the earth. Although pyritous metals generally precede, accompany, and follow veins of ores; they do not, properly fpeaking, themfelves form the oblong and continued maffes called *veins*, as ores do; but they form maffes fometimes greater and fometimes fmaller, but always diftinct from each other. Large quantities of them are often found unaccompanied by ores. They are formed in clays, chalk, marles, marbles, plafters, alabafters, flates, fpars, quartz, granites, cryftals, in a word, in all earths and ftones. Many of them are alfo found in pit-coals and other bituminous matters.

Pyrites is alfo diftinguifhable from ores by its luftre and figure; which is almoft always regular and uniform, externally or internally, or both. Some ores indeed, like thofe of lead, many ores of filver, and fome others, have regular forms, and are in fome manner cryftallized; but this regularity of form is not fo univerfal and fo confpicuous in ores as in pyrites. The luftre of pyrites feems to be caufed by its hardnefs, and the regularity of its form by the quantity of mineralifing fubftances which it contains.

By all thefe marks we may eafily, and without analyfis, diftinguifh pyrites from true ores. When we fee a mineral that is heavy, poffeffed of metallic luftre, and of any regular form, the mafs of which appears evi- Of Pyrites. dently to be entire, that is, not to have been a fragment of another mafs, and which is fo hard as to be capable of ftriking fparks from fteel, we may be affured that fuch a mineral is a pyrites, and not an ore.

The clafs of pyrites is very numerous, various, and extenfive. They differ one from another in the nature and proportions of their component parts, in their forms, and in their colours. The forms of thefe minerals are exceedingly various. No folid, regular or irregular, can eafily be conceived, that is not perfectly imitated by fome kind of pyrites. They are fpherical, oval, cylindrical, pyramidal, prifmatical, cubic; they are folids with 5, 6, 7, 8, 9, 10, &c. fides. The furface of fome is angular, and confifts of many bafes of fmall pyramids; while their fubftance is compofed of thefe pyramids, the points of which all unite in the centre of the mafs.

Pyritous minerals differ alfo in their component fubftances. Some of them are called *fulphureous*, *martial*, *cupreous*, *arfenical*, as one or other of thefe fubftances predominate. We muft obferve with Henckel, whofe authority is very great in this fubject, that in general all pyrites are martial; as ferruginous earth is the effential and fundamental part of every pyrites. This earth is united with an unmetallic earth, with fulphur or arfenic, or with both thefe matters; in which cafe, the fulphur always predominates over the arfenic, as Henckel obferves. He confiders thefe as the only effential principles of pyrites; and believes that all the other matters, metallic or unmetallic, which are found in it, are only accidental; amongft which he even includes copper, although fo much of it exifts in fome kinds of pyrites, that thefe are treated as ores of copper, and fometimes contain even 50lb. of copper each quintal. Many other metals, even gold and filver, are fometimes combined in pyrites; but thefe are lefs frequent, and the precious metals always in very fmall quantities; they are therefore juftly to be confidered as accidental to pyrites. The different fubftances compofing pyrites fenfibly affect its colours. Henckel diftinguifhes them in general into three colours, white, yellowifh, or a pale yellow, and yellow. He informs us, that thefe three colours are often fo blended one with another, that they cannot be eafily diftinguifhed unlefs when compared together.

The white pyrites contain moft arfenic, and are fimilar to cobalt and other minerals abounding in arfenic. The Germans call them *mifpickle*, or *mifpilt*. Iron and arfenic form the greateft part of this pyrites. As arfenic has the property of whitening copper; fome pyritous minerals almoft white, like that of Chemnitz in Mifnia, are found to contain 40 pounds of copper per quintal, and which are fo much whitened by the arfenic, that they are very like white pyrites. But Henckel obferves, that thefe pyritous matters are very rare, and are never fo white as the true white pyrites, which is only ferruginous and arfenical.

Yellowifh pyrites is chiefly compofed of fulphur and iron. Very little copper and arfenic are mixed with any pyrites of this colour, and moft of them contain none of thefe two metallic fubftances. This is the moft common kind of pyrites: it is to be found almoft every where. Its forms are chiefly round, fpherical, oval, flattened, cylindrical; and it is compofed internally of needles

Of Pyrites. needles or radii, which unite in the centre, or in the axis of the solid.

Yellow pyrites receives its colour from the copper and sulphur which enter into its composition. Its colour, however, is inclined to a green; but is sufficiently yellow to distinguish it from the other two kinds of pyrites, particularly when they are compared together. To make this comparison well, the pyrites must be broken, and the internal surfaces must be placed near each other. The reason of this precaution is, that the colour of minerals is altered by exposure to the air.

Persons accustomed to these minerals can easily distinguish them. The chief difficulty is, to distinguish white pyrites from cobalt and other minerals; which also contain some copper and much arsenic.

Hence then we see, that arsenic is the cause of whiteness in pyrites, and is contained in every pyrites of that colour; that copper is the principal cause of the yellow colour of pyrites; and that every pyrites which is evidently yellow contains copper; that sulphur and iron produce a pale-yellow colour, which is also produced by copper and arsenic; hence some difficulty may arise in distinguishing pyrites by its colours. We may also observe, that sulphur and arsenic, without any other substance, form a yellow compound, as we see from the example of orpiment or yellow arsenic. Thus, although the colours of the pyrites enable us to distinguish its different kinds, and to know their nature at first sight, particularly when we have been accustomed to observe them; yet we cannot be entirely certain concerning the true nature of these minerals, and even of all minerals in general; that is, to know precisely the kinds and proportions of their component substances, but by chemical analysis and decomposition.

Besides the above-mentioned matters which compose pyrites, it also contains a considerable quantity of unmetallic earth; that is, an earth which cannot by any process be reduced to metal. Henckel, Cramer, and all those who have examined this matter, mention this earth, and prove its existence.

We ought to observe, that this earth is combined with the other principles of the pyrites, and not merely interposed betwixt its parts. It must therefore be distinguished from other earthy and stony matters mixed accidentally with pyrites, and which do not make a part of the pyrites, since they may be separated by mechanical means, and without decomposing that mineral: but the earth of which we now treat is intimately united with the other constituent parts of the pyrites, is even a constituent part of pyrites, and essential to the existence of this mineral, and cannot be separated but by a total decomposition of it.

According to Henckel, this unmetallic earth abounds much in the white pyrites, since he found from the analyses which he made, that the iron, which is the only metal existing in these pyrites, is only about $\frac{1}{70}$th part of the fixed substance that remains after the arsenic has been expelled by torrefaction or sublimation.

A much larger quantity of iron is in the pale-yellow pyrites, according to Henckel. The proportion of iron is generally about 12 pounds to a quintal of pyrites, and sometimes 50 or 60 pounds: this is therefore called *martial pyrites*. It contains about one-fourth of its weight of sulphur, and the rest is unmetallic earth.

The quantity of unmetallic earth contained in the yellow or cupreous pyrites, which are also martial, since, as we have observed, iron is an essential part of every pyrites, has not yet been determined. They probably contain some of that earth, though perhaps less of it than the others.

The nature of this unmetallic earth of pyrites has not been well examined. Henckel thinks that it is an earth disposed already by nature to metallisation, but not sufficiently elaborated to be considered as a metallic earth. This opinion is not improbable; but as alum may be obtained from many pyrites, may we not suspect that this unmetallic earth is of the nature of the basis of alum or argillaceous earth? Perhaps also this earth is different in different kinds of pyrites. The subject deserves to be well examined.

Although pyrites are not so valuable as true ores, because in general it contains less metal, and but exceedingly little of the precious metals; and because its metallic contents are so difficult to be extracted, that, excepting cupreous pyrites, which is called *pyritous copper ore*, it is not worked for the sake of the contained metal; yet it is applied to other purposes, and furnishes us with many useful substances; for from it we obtain all our green and blue vitriols, much sulphur, arsenic, and orpiment. *See the principal processes by which these substances are extracted from pyrites, under the* section SMELTING *of* ORES.

As all pyrites contain iron, and most of them contain also sulphur; as the pyrites most frequently found contains only these two substances with the unmetallic earth; and as iron and sulphur have a singular action upon each other when they are well mixed together and moistened; hence many kinds of pyrites, particularly those which contain only the principles now mentioned, sustain a singular alteration, and even a total decomposition, when exposed during a certain time to the combined action of air and water. The moisture gradually penetrates them, divides and attenuates their parts; the acid of the sulphur particularly attacks the martial earth, and also the unmetallic earth; its inflammable principle is separated from it, and is dissipated. While these alterations happen, the pyrites changes its nature. The acid of the sulphur which is decomposed, forms with the fixed principles of the pyrites, vitriolic, aluminous, and selenitic salts; so that a pyrites, which was once a shining, compact, very hard mineral, becomes in a certain time a greyish, saline, powdery mass, the taste of which is saline, austere, and styptic.

Lastly, if this mass be lixiviated with water, crystals of vitriol, and sometimes of alum, according to the nature of the pyrites employed, may be obtained by evaporation and crystallization.

This alteration and spontaneous decomposition of pyrites, is called *efflorescence* and *vitriolization;* because the pyrites become covered with a saline powder, and because vitriol is always formed. This vitriolization is more or less quickly accomplished in pyrites according to its nature. It is a kind of fermentation excited by moisture amongst the constituent parts of these minerals; and it is so violent in those which are most disposed

Pyrites. posed to it, that is, in the pale yellow pyrites, which contain chiefly sulphur and iron, that when the quantity of these is considerable, not only a sulphureous vapour and heat may be perceived, but also the whole kindles and burns intensely. The same phenomena are observable, and the same results are formed, by mixing well together, and moistening a large quantity of filings of iron and powdered sulphur; which experiment Lemeri has made, to explain the causes of subterranean fires and volcanoes.

We cannot doubt that, as the earth contains very large masses of pyrites of this kind, they must undergo the same changes when air and moisture penetrate the cavities containing them; and the best natural philosophers agree, that very probably this surprising decomposition of pyrites is the cause of subterranean fires, of volcanoes, and of mineral waters, vitriolic, aluminous, sulphureous, hot and cold.

No other pyrites is subject to this spontaneous decomposition when exposed to humid air, but that which is both martial and sulphureous; that is, the pale-yellow pyrites. The arsenical pyrites, or that which contains little or no sulphur, is not changed by exposure to air. This latter kind is harder, heavier, and more compact, than the former. The pyrites which is angular and regularly shaped, is chiefly of this kind. Mr Wallerius, in his Mineralogy, proposes to distinguish this kind of pyrites by the name of *marcasite*. When cut, it may be polished so well as to give a lustre almost equal to that of diamonds, but without refracting or decomposing the light; for it is perfectly opaque. It has been employed some years past in the manufacture of toys, as of buckles, necklaces, &c. and is called in commerce *marcasite*.

We cannot, however, concur with Mr Macquer (from whom the above is taken), in thinking that there is sufficient reason for considering the minerals called *pyrites*, as a distinct class of substances from ores. They have indeed no mark by which they can certainly and constantly be distinguished from these. The hardness or property of striking ignited sparks from steel is not common to all the substances generally called *pyrites*; for we find some of these enumerated by mineralogists which have not that property. Wallerius even mentions a pyrites which contains no iron, altho' that metal is thought by Henckel to be essential to pyrites. The distinction of pyrites from ores has been chiefly introduced by miners; because the greatest part of the former minerals contain so little metal, and so much of the mineralising substances, sulphur, or arsenic, that they are seldom smelted. Nevertheless, some kinds of pyrites are found which contain so much copper, that they are smelted with great profit. Accordingly, some later mineralogists consider the cupreous yellow pyrites as an ore of copper, the pale-yellow martial pyrites as an ore of iron; and the white arsenical pyrites as an ore of arsenic. See *Ores* of *Copper*, *Iron*, and of *Arsenic*, below.

Sect. IV. *Essaying of Ores in general.*

Essays are chemical operations made in small, to determine the quantity of metal or other matter which is contained in minerals; or to discover the value or purity of any mass of gold or silver. The former kind is the subject of the present section; the latter is treated under the word Essays, in the order of the alphabet.

Essaying of Ores.

Before essays of ores can be well made, a preliminary knowledge of the nature of the several metallic minerals ought to be attained. Each metal has its proper and improper ores, which have peculiar characters and appearances: hence persons accustomed to see them, know pretty nearly by the appearance, weight, and other obvious qualities, what metal is contained in a mineral. A good essayer ought to be very intelligent in this matter, that he may at once know what the proper operations are which are requisite to the essay of any given mineral.

As metals are very unequally distributed in their ores, we should be apt to make false and deceitful essays, if we did not use all possible precautions that the proportionable quantity of metal produced by an essay shall be nearly the medium contained in the whole ore. This is effected by taking pieces of the mineral from the several veins of the mine if there be several, or from different places of the same vein. All these minerals are to be shaken together with their matrixes. The whole is to be well mixed together, and a convenient quantity of this mixture is to be taken for the essay. This is called the *lotting* of the ore.

As essays, particularly the first, are generally made in small, essayers have very small weights corresponding to the weights used in the great; that is, to the quintal or hundred pounds weight, to pounds, ounces, drams, &c. The essay quintal and its subdivisions vary according to the difference of weights in different countries; and this occasions some confusion when these weights are to be adjusted to each other. Tables of these weights are found in treatises of essaying; and particularly in that written by Schlutter, and translated and rendered more complete by Hellot, which contains all the details necessary for the subject.

The custom is to take, for the essay quintal, a real weight of a gros, or dram, which in France is equal to 72 grains; but as the whole dram represents 100 pounds, each grain represents a pound and a fraction of a pound; and hence some difficulty and confusion arise in making the subdivisions. A better method is that of Mr Hellot, which is to make the fictitious or essay quintal equal to 100 real grains, and then each grain represents a real pound. This essay quintal is sufficiently exact for ores of lead, tin, copper, iron, antimony, bismuth, and mercury. But for ores of silver and gold, another representation is convenient: for these metals, as Mr Hellot says, are generally in so small quantity, that the button or small piece of metal obtained in the essay could not be accurately weighed if 100 real grains were made to represent a quintal; and the difficulty of separating the gold from so small a quantity would be still greater. These motives have induced Mr Hellot to use for these ores a fictitious quintal 16 times bigger; that is, equal to 1600 real grains, which represent 1600 ounces; that is, 100 lb. or quintal. The ounce being represented by a grain, its several subdivisions must be represented by fractions of

Essaying of Ores.

† The pounds, of which 100 are here supposed to make a quintal, are called *Paris pounds*, one of which contains 1260 Troy grains.

of a grain. Thus 12 grains of the fictitious quintal correspond with $\frac{5}{28}$ of a real grain (B); and this latter quantity may be accurately weighed in essay-balances: which when well made are sensible to a much less weight. See *(Essay)*-BALANCE.

When a quintal of an ore to be essayed has been weighed, and lotted, as we described above, it is to be roasted in a test under a muffle. It is to be washed, if necessary; and, in short, the same operations are to be made in small which are usually done in great. Additions also are to be made, and in proper proportions, according to the peculiar nature of the ore. The fluxes generally mixed with the essays in ore are three, four, or five parts of black flux; one, two, or three parts of calcined borax; and one half of that quantity of decrepitated common salt. The more refractory the ore is, the more necessary is the addition of these fluxes: then the whole mixture is to be fused either in a forge or in a melting or essay furnace.

To make essays well, all possible attention and accuracy are to be employed. This object cannot be too much attended to; for the least inaccuracy in weighing, or loss of the smallest quantity of matter, might cause errors, so much greater as the disproportion betwixt the weights employed and those represented is greater. The most minute accuracy therefore is necessary in these operations. For instance, the essay-balances ought to be small, and exceedingly just. The ore ought not to be weighed till it has been reduced to gross powder fit for roasting; because some of it is always lost in this pulverization. When the ore is roasted, it ought to be covered with an inverted test; because most ores are apt to crackle and disperse when first heated. To make the fusion good and complete, the precise degree of fire which is requisite ought to be employed; and when it is finished, the crucible ought to be struck two or three times with some instrument, to facilitate the disengagement of the parts of the regulus from the scoria, and to occasion their descent and union into one button of metal. The crucible ought not to be broken, nor its contents examined, till it is perfectly cold.

Upon breaking the crucible, we may know that the fusion has been good, if the scoria be neat, compact, and equal; if it has not overflowed or penetrated the crucible; if it contain no metallic grains; and if its surface be smooth, and hollowed in the middle. The regulus or button ought to be well collected, without holes or bubbles, and to have a neat convex surface; it is then to be separated from the scoria, well scraped and cleaned; and, lastly, is to be weighed. If the operation has been well made, its weight shows the quantity of metal which every real quintal of ore will yield in the great. If the perfect success of this essay be in any respect doubtful, it ought to be repeated; but the best method at all times is, to make several essays of the same ore. Some small differences are always found, however well the essays may have been made. By taking the medium of the results of the several operations, we may approach as nearly as possible the true product of the ore.

Lastly, as mines are not worked, nor founderies established (which cannot be done without considerable expence), till the ore has been essayed, 10 or 12 real pounds of the ore ought to be previously essayed; and essayers ought to be furnished with necessary furnaces and instruments for these larger essays.

In Part II. to the several articles of the ores of metals, we shall add the most approved methods of essaying these ores. We shall here only further observe in general, that the methods commonly practised for essaying ores of imperfect metals, and semimetals especially, are insufficient to procure the whole quantity of metal contained in ores, or even so much as is obtained in the smelting of large quantities of ores; and that therefore the result of essays is not to be considered as the precise quantity contained in an ore, but generally only as an inaccurate approximation to that quantity. M. Gellert ascribes one cause of the want of success of these operations to the alkaline salts employed as fluxes to the ores, by which most metallic calces are partially soluble, but more especially so when any of the sulphur of the ore remains; which, by uniting with these salts, forms a hepar of sulphur which is the most powerful of all solvents. He proposes therefore to omit the black flux, and other alkaline salts, and to add nothing to the ore but powder of charcoal and some fusible glass. This method, he says, he learned from Mr Cramer, and has himself used with much success in the essays of iron and copper: but finding that other imperfect metallic substances could not sustain the heat necessary to effect the fusion and vitrification of the unmetallic parts of the ore without being partly dissipated, he found it necessary to add in the essays of these latter metallic matters some borax, by which the fusion might be completed with less heat. As we consider this as a considerable improvement in the art of essaying ores, we shall, to the articles of the several ores, add not only the processes commonly prescribed, but all those of Mr Gellert, according to the method here mentioned.

PART II.

Containing a summary Description of the principal ORES of each METAL, and the Methods of Essaying them.

SECT. I. *Ores of Gold.*

§ 1. PROPERLY speaking, no ores of gold exist: for as this metal cannot be allayed with arsenic, nor with sulphur, it is never found directly mineralised by these substances, as the other metals are. In the second place, if it be mineralised indirectly by the union it contracts with other metals naturally combined with sulphur and arsenic, so small a quantity of it only is found in these ores, that they

Ores of Gold

they scarcely even deserve the name of *improper ores of gold*.

Hence gold is found either in its natural state, of a certain degree of purity, possessed of all its properties; or engaged with some other metals in certain minerals.

The gold which is found alone is called *native* or *virgin gold*. This is generally incrusted, and fixed in different kinds of stones, principally in flints and quartz. Mr Cramer says, that the yellow brilliant spots of the blue stone called *lapis lazuli*, are native gold; but these are very small.

Gold is also found in fat and muddy earths; and Mr Cramer affirms, that scarcely any sand can be found which does not contain gold; but he acknowledges, at the same time, that the quantity is too small to compensate for the expence of obtaining it.

Lastly, the largest quantity of native gold is to be found in the sands of some rivers. It is chiefly collected in hollows at the bottom of these rivers, and at their several bendings. The gold is collected in these places by a natural operation, similar to that of washing of ores.

A considerable quantity of gold is in the sands of several rivers in France: so that persons who collect it find enough to compensate their trouble. Mr Reaumur, in a memoir that he gave in the year 1718 concerning the rivers of France which contain gold, enumerates ten of them; namely, the Rhine, the Rhone, the Doux, the Ceze, and the Gardon; the Arriege; the Garonne; two streams which flow into the Arriege, called *Ferriet* and *Benagues*; lastly, the Salat, the source of which is in the Pyrenean mountains.

The Ceze is the river which furnishes the largest quaintity of gold at certain times. Mr Reaumur observes, that its particles are larger than those of the Rhine and of the Rhone; and says, that in some days a peasant will find gold to the value of a pistole, and in others will scarcely find any.

The native gold found in rivers or elsewhere is never perfectly pure, or of 24 karats. It always contains a certain quantity of allay, which is generally silver. The gold of the French rivers, according to Mr Reaumur's trials, was found to be from 18 to 22 karats, that of the Ceze being the lowest, and that of the Arriege being the purest.

Although gold, however, as above observed from Macquer, cannot be directly dissolved by sulphur, yet it probably may be mineralised by the intervention of other metallic matters. Thus, although no proper ore of gold exists, yet it is found in several mineral substances, in which it is always accompanied, as Cramer affirms, with a much larger quantity of silver; to which latter metal that author attributes its mineralised state. The minerals containing gold are blend, cupreous and arsenical pyrites, ore of antimony, cinnabar, white ore of arsenic, vitreous and other silver ores, and the lead-ore called *galena*.

Gold is more frequently imbedded in quartz than in any other matrix, but it is also found in limestone and in hornblend. Gold mines are in general very precarious, as they do not form regular veins, nor is the gold uniformly distributed through a matrix.

Essaying of Ores of Gold.

Becher and Cramer think, that no sand is entirely free from gold. The yellow, red, black, and violet-coloured ferruginous sands, are said to contain most gold. Mr Hellot relates, that in 11 essays of one kind of sand, from a quintal, or 921,600 grains, were obtained each time from 848 to 844 grains of noble metal, exclusive of the gold which remained in the scoria; and that of the metal thus obtained two thirds were gold, and the remaining third was silver. He says, that parcels of sand taken up at very small distances from each other contained very unequal proportions of gold.

The gold found in sands is generally less pure than that which is imbedded in a solid matrix. Reaumur says, that a piece of gold, weighing 448 ounces, was shown to the Royal Academy at Paris, which was found upon essay to have different fineness in different parts of the mass.

§ 2. *Ores and earths containing gold may be essayed* by the methods directed for the extraction of gold from large quantities of these auriferous matters, (see Part III.): or they may in general be essayed by being fused in a cupel or test, placed under the muffle of an essay-furnace, or in a crucible placed in an air furnace, with eight or ten times their quantity of lead if they be easily fusible, and with a larger quantity of lead if they be difficultly fusible; and by scorifying the earthy matters, while the lead becomes impregnated with the noble metals. These operations are entirely similar to those employed for the separation of silver from its ores by precipitation with lead; *a detail of which see subjoined under the section* Ores *of* Silver, [*Processes* I. III. IV. V. VI.]. These metals are afterwards to be separated from the lead by cupellation, in the manner directed in the article Essay (*of the value of silver and of gold*). The gold is then to be separated from the silver by the processes described in the article Parting.

The quantity of lead to be added to the ore in this essay must be such as renders the scoria very thin, that the whole gold may be imbibed by the lead. Some iron ores containing gold cannot be reduced into a scoria sufficiently thin with 16 times their quantity of lead, unless the heat be at the same time considerably increased. When the ore is exceedingly refractory, the scorification ought to be promoted by adding to it four times its quantity of tartar, twice its quantity of nitre, and four times its quantity of litharge. This mixture is to be put into a good essay-crucible, and covered with the sea-salt. The crucible is to be set in a forge-hearth, and exposed gradually to heat, till the scoria has acquired sufficient fluidity, and the lead has imbibed the noble metal.

See the methods which have been used for essaying auriferous sands, under Part III.

Sect. II. *Ores of Platina.*

Platina is very rare, and has been but lately discovered. As, like gold, it cannot be allayed with sulphur or with arsenic, probably no *ore*, properly so called, exists of this metal. Accordingly in the only mines of platina which we know, namely, the gold mines of Santafe near Carthagena, the platina is found native like the gold, and in its metallic state.

Ores of Silver.

Sect. III. *Ores of Silver.*

§ 1. Next to gold, ſilver is the metal moſt frequently found in its metallic ſtate, that is, not mineraliſed by ſulphur or by arſenic. This ſilver, called alſo *native* or *virgin*, generally affects ſome regular form, and conſiſts of filaments or vegetations of various figures. It is found in form of plates, of fibres, or of grains, or cryſtallized. It lies generally in quartz, flint, ſpar, ſlate, cobalt, and in ſilver-ores. It is ſometimes enveloped in a thin ſtony cruſt. It is generally allayed with ſome gold: but ſilver, like all the other metals, is much more frequently found mineraliſed by ſulphur and by arſenic.

Three principal proper ores of ſilver are known, which are very rich, but very rare. Theſe are:

1. The *vitreous ſilver ore.* This ore has no determinate figure, and has nearly the colour, ſoftneſs, and fuſibility of lead. It is very heavy, and contains three quarters of its weight of pure ſilver. In this ore the ſilver is mineraliſed by ſulphur alone. Some expert artiſts imitate it very well by combining ſulphur with ſilver by fuſion in a crucible.

This ore, according to Cronſtedt, is either in form of plates or of fibres, or is cryſtallized, or has no determinate figure. It may be imitated by adding about five parts of ſulphur to one part of melted ſilver; in which operation moſt of the ſulphur is conſumed; or it may be imitated by expoſing a plate of ſilver red-hot to the fumes of burning ſulphur.

2. The *horny* or *corneous ſilver ore.* This ore is ſo called from its colour and ſemitranſparency, by which it reſembles horn or colophony. When ſuddenly heated, it crackles, as almoſt all ores do, and melts with a gentle heat. Two-thirds of it are ſilver, which is mineraliſed by ſulphur and arſenic. This ore is very rare. Wallerius ſays, after Woodward, that it is found at Johann-Georgen-Stadt in Saxony.

Corneous ore has various colours; white, pearly, brown, yellow, greeniſh, or reddiſh. It is foliated and ſemitranſparent. It is ſomewhat ductile, and fuſible with the flame of a candle. When heated, it emits, as Wallerius ſays, a ſulphureous and blue flame, and, according to Cramer, alſo a very ſmall quantity of an arſenical fume. Wallerius ſays, that it contains two-thirds of ſilver, with a conſiderable quantity of ſulphur, and a ſmall quantity of arſenic. Lehman thinks that it is ſilver united with a little arſenic. But Mr Cronſtedt ſays, that it is a luna cornea, or ſilver combined with marine acid; and that it is incapable of being decompoſed but by ſubſtances which can unite with that acid. This latter opinion ſeems to be the moſt probable; as the ore, according to its deſcription, is ſimilar to luna cornea, and as it cannot be imitated by any mixture of ſulphur and of arſenic with ſilver. The blue flame, and the ſmell ſlightly arſenical, which are emitted from heated corneous ore, are alſo obſervable from every combination of marine acid with a ſubſtance containing phlogiſton.

3. *Red ſilver ore*, called alſo *roſiclare*. Its colour is more or leſs red; it is ſometimes cryſtallized, very heavy, and is fuſible like the above-mentioned ores. In this ore the ſilver is mineraliſed by arſenic and by ſulphur, but chiefly by the former. It alſo contains a little iron, and furniſhes two-thirds of its weight of ſilver. Its red colour may proceed either from the iron it contains; or from the mixture of arſenic and ſulphur; or, laſtly, from the particular manner in which the arſenic is united with the ſilver, an example of which we have in the red precipitate of ſilver made by the neutral arſenical ſalt.

Red ſilver ore is either plated or ſolid, or cryſtallized, and frequently ſemitranſparent. Its colour is various, from a dark grey to a deep red, according to the proportions of the two mineraliſing ſubſtances. It crackles and breaks in the fire, exhales an arſenical fume, and is readily fuſed. It is found generally in quartz, ſpar, cryſtal, hornblend.

Beſides the three ſilver ores above deſcribed, the following ores contain ſilver mixed with other metals.

1. *Grey ſilver ore.* This contains copper and ſilver mineraliſed by arſenic and ſulphur, and generally more of the former than of the latter metal; but as it is valued chiefly for the ſilver, it has been generally enumerated amongſt ſilver ores.

2. *White ſilver ore* is an arſenical pyrites containing ſilver.

3. *Black ſilver ore* contains ſulphur, arſenic, copper, iron, ſometimes lead, and about a fourth part of ſilver, according to Wallerius.

4. *Plumoſe ſilver ore* is white or black, ſtriated like plumb-alum, or like ore of antimony. It is ſilver mineraliſed by ſulphur, arſenic, and antimony.

5. *Pech-blend.* In this blend ſilver, gold, and zinc, are mineraliſed by ſulphur, probably by intervention of iron, by which the gold and zinc are rendered capable of uniting with the ſulphur.

6. Silver is frequently found in *galena*; and ſometimes in *martial pyrites*; in the *red ore of arſenic*; in various *ores of copper, lead, tin, iron*, and eſpecially *cobalt*; in *blends*; in *yellow* or *red earths*; in *black* and *blue baſaltes*; and alſo in *ſtrata of ſtones* which do not appear externally to contain any mineral ſubſtance.

7. *Liquid ſilver ore* or *guhr of ſilver*, is a grey or whitiſh liquid maſs, which contains, as Wallerius ſays, either native ſilver, or ſome fluid ſubſtance capable of producing it. Mr Cronſtedt mentions, in the Swediſh Memoirs, a water flowing through a mine in Norway containing ſilver. Another inſtance is alſo mentioned of a ſilver guhr, in the *Act. Erud. Upſal.* 1720.

8. Mr Von Juſti pretends, that he has found ſilver mineraliſed by an *alkaline ſubſtance*; but he has not ſpoken ſufficiently diſtinctly concerning it, to know whether he means a ſaline or earthy alkaline matter. Henckel alſo pretends, that by treating calcareous earth or certain clays with pyrites, ſilver may be obtained.

§ 2. *Ores of ſilver may be eſſayed* by the ſame methods which are employed for the extraction of that metal from large quantities of ores; which methods are different, and ſuited to the different qualities of the different ores. See Part III. Or, in general, ores and earths containing ſilver may be eſſayed by the following proceſſes, which are copied from Dr Mortimer's English

Essaying of Ores of Silver.

English edition of *Cramer's Art of Essaying Metals, Part II. Process* 1.

PROCESS I.

To precipitate Silver by means of Lead from fusible Ores.

"Pound the ore in a very clean iron mortar into fine powder: of this weigh one docimastical centner or quintal, and eight of the like centners of granulated lead.

"Then have at hand the docimastical test, which must not as yet have served to any operation: pour into it about half of the granulated lead, and spread it with your finger through the cavity of it.

"Put upon this lead the pounded ore; and then cover it quite with the remainder of the granulated lead.

"Put the test thus loaded under the muffle of an essay-furnace, and in the hinder part of it: then make your fire, and encreafe it gradually. If you look thro' the holes of either of the sliders, you will soon see that the pounded ore will be raised out of the melted lead, and swim upon it. A little after, it will grow clammy, melt, and be thrown towards the border of the test: then the surface of the lead will appear in the middle of the test like a bright disc, and you will see it smoke and boil: so soon as you see this, it will be proper to diminish the fire a small matter for a quarter of an hour; so that the boiling of the lead may almost cease. Then again, increase the fire to such a degree, that all may turn into a thin fluid, and the lead may be seen, as before, smoking and boiling with great violence. The surface of it will then diminish by degrees, and be covered over with a mass of scorias. Finally, have at hand an iron hook ready heated, wherewith the whole mass must be stirred, especially towards the border; that in case any small parcels of the ore not yet dissolved should be adherent there, they may be brought down, taking great care not to stir any the least thing out of the test.

"Now, if what is adherent to the hook during the stirring, when you raise it above the test, melts quickly again, and the extremity of the hook grown cold is covered with a thin, smooth, shining crust; it is a sign that the scorification is perfect; and it will be the more so as the said crust adherent to the hook shall be coloured equally on every side: but in case, while the scorias are stirred, you perceive any considerable clamminess in them, and when they adhere in good quantity to the hook, though red-hot, and are inequally tinged, and seem dusty or rough with grains interspersed here and there; it is a sign that the ore is not entirely turned into scorias. In this case, you must with a hammer strike off what is adherent to the hook, pulverize it, and with a laddle put it again into the test, without any loss or mixture of any foreign body, and continue the fire in the same degree till the scoria has acquired its perfection and the above-mentioned qualities. This once obtained, take the test with a pair of tongs out of the fire, and pour the lead, together with the scoria swimming upon it, into a cone made hot and rubbed with tallow. Thus will the first operation of the process be performed, which does not commonly indeed last above three quarters of an hour.

"With a hammer strike the scorias off from the regulus grown cold, and again examine whether they have the characteristics of a perfect scorification; if they have, you may thence conclude, that the silver has been precipitated out of the ore turned to scorias, and received by the lead.

"When the scorification lasts longer than we mentioned, the lead at last turns to scorias or litharge, and the silver remains at the bottom of the vessel: but the fire must be moderately supplied, and the vessels be extremely good, to produce this effect; for they seldom resist to the strength of the scorias long enough; so that the whole scorification may be brought to an end; which has afterwards this inconveniency, that the silver is dissipated by grains in the small hollows of the corroded ore, and can hardly be well collected again, when the ore has but little silver in it. Nay, there is still more time to be consumed to obtain the perfect destruction of the lead, by means of the combined actions of the fire and air, because the scorias swimming at the top retard it considerably.

"In this process, the sulphur and the arsenic of the silver-ore, when the ore is broken small, and extended widely in a small quantity, are in part easily dissipated by the fire, and in part absorbed by the lead; the lighter part of which, swimming upon the heavier, becomes very clammy by means of the sulphur which is in the ore; but when this is dissipated by the violence of fire, it turns into glass or scorias: but when arsenic is predominant in the ore, the plumbeous part turns immediately into a very penetrating and very fusible glass, having a dissolving efficacy, unless the arsenic lies hidden in a white pyrites or cobalt. For this reason, the fixed part of the ore, which is no silver, is dissolved by that glass, melts, and assumes the form of scorias. The unmetallic earths and the pure copper or lead ores thereto adherent are of this kind. The silver then remains immutable; and being freed of these heterogeneous bodies, which are partly dissipated and partly melted, it is precipitated and received by the remaining regulus of lead. Therefore this process is completed by three distinct operations; viz. 1. By roasting. 2. By scorification. 3. By the melting precipitation of the silver, which is the result of the two former operations.

"The ore must be pulverised very fine, in order to increase the surface, that the dissipation of the volatiles and the dissolution by litharge may be sooner effected. This pulverising must then be done before the ore is weighed, because there is always some part of the ore adherent to the mortar or iron plate on which it is made fine; which part being lost, the operation is not exact. Erker was in the right when he prescribed eight centners of lead for the subduing of fusible ores. Nevertheless, it must be owned, that this quantity is superfluous in some cases. However, as the fluxibility of the silver-ore depends upon the absence of stones, pyrites, &c. it is easy to see, that there are an infinite number of degrees of fluxibility which it would be needless to determine exactly, and most commonly very difficult to determine by the bare sight. Besides, a little more lead does not render the process imperfect; on the contrary, if you use too small fmall a quantity of lead, the fcorification is never completely made. Nay, there are a great many ores, containing fulphur and arfenic in plenty, that deftroy a confiderable quantity of lead: fuch are the red filver-ore, and that wherein there is a great deal of the fteel-grained lead-ore. If the fire muft be fometimes diminifhed in the middle of the procefs, it is in order to hinder the too much attenuated litharge, which is continually generated out of the lead, from penetrating the pores of the teft, and from corroding it; which is eafily done when the fire is over-ftrong; for then the furface of the veffel which is contiguous to the lead contracts cavities, or, being totally confumed by fmall holes, lets the regulus flow out of it. The veffels that are moft fubject to this inconvenience are thofe in the materials of which lime, plafter, and chalk are mixed. Nay, thefe bodies, which are in their nature refractory, being eroded during their fcorification, at the fame time communicate a great clamminefs to the fcoria; fo that a great quantity of the mafs remains adherent to the teft, in the form of protuberances, when you pour it out; whereby a great many grains of the regulus are detained."

PROCESS II.

The regulus obtained by the procefs I. contains all the filver of the ore, and the unfcorified part of the lead. The filver may be afterwards feparated from the lead, and obtained pure by *cupellation;* which procefs is defcribed under the article Essay *(of the value of Silver.)*

PROCESS III.

If the filver-ore cannot be wafhed clean, or if it be rendered refractory by a mixture of unmetallic earths and ftones, the fcorification of thefe earthy matters frequently cannot be completed by the procefs I. Cramer therefore directs, that fuch ores fhall be treated in the following manner.

"Bruife the ore into an impalpable powder, by grinding in a mortar; to a docimaftical centner of it add a like quantity of glafs of lead finely pulverifed; for the more exactly thefe two are mixed together, the more eafily the fcorification afterwards fucceeds. Put this mixture, together with 12 centners of lead, into the teft, according to procefs I. then put the teft under the muffle.

"Make firft under it a ftrong fire, till the lead boils very well; when you fee it fo, diminifh the violence of the heat, as was directed in the firft procefs; but keep it thus diminifhed a little longer: then, finally, again increafe the fire to fuch a degree, till you perceive the figns of a perfect fcorification and fufion. *See the whole procefs I.* Now this procefs lafts a little longer than the foregoing, and requires a greater fire towards the end.

"It fometimes happens that a very refractory ore cannot be diffolved by litharge; and that a mafs, which has the clamminefs of pitch, fwims upon the regulus and upon the fcorias themfelves which are already fubdued in part: when you fee this, fhut the vents of the furnace to diminifh the fire; then gently touch this refractory body with a fmall iron cold hook, to which it will immediately ftick; take it off foftly, not to lofe any thing; pound it into a fine powder, adding a little glafs of lead, and put it again into the teft; then continue the fcorification till it is brought to its perfection. But you muft always examine the fcoria of your refractory ore, to fee whether there may not be fome grains of regulus difperfed in it: for fometimes the fcorias that grow clammy retain fomething of the metal; which if you fufpect, pound the fcorias into a fine duft, and thus the grains of metal will appear if there are any left, becaufe they can never be pounded fine. The filver is feparated from this regulus by cupelling, as in Procefs II.

"All earths and ftones are refractory in the fire: for although fome of them melt naturally in the fire, as thofe that are vitrifiable do; neverthelefs all the others, a very few excepted, melt much more difficultly than metals, and never become fo thin in the fufion as is required for the fufficient precipitation of a precious metal. But litharge itfelf does not conveniently diffolve thefe refractory matters by the help of fire alone, unlefs you add fome mechanical mixture to them; for the very moment the faid litharge penetrates through the interftices of the refractory ore, and begins to diffolve it, a tenacious mafs is produced, which hardly admits any farther dilution by the litharge. You may fee it plain, if you make coloured glaffes with metallic calces: if you pour carelefsly upon them a calx that gives a colour, you will never obtain that they may be equally dyed on every fide, even although you fhould torture them for whole days together in a great fire. Nay, glafs already made can never be diluted by only pouring falts and litharge upon it. Wherefore, you muft ufe the artifice of glafs-makers, who, in the making of the moft perfect glaffes, take great care, before they put the fpecies of their ingredients into the fire, to have a mechanical mixture precede, or at leaft accede, during the fufion itfelf, which is done here by pounding glafs of lead mixed with the ore: but if you think that your glafs of lead is not fufficiently fufible, you may add to it litharge melted firft, and then pounded into a fine powder.

"As this fcorification requires a longer and a greater fire than the foregoing, and as a greater quantity of litharge is moreover requifite to fubdue the refractory fcoria; it is eafy to fee why a much greater quantity of lead muft be ufed here than in Procefs I.; and, although lefs lead is often fufficient, it is neverthelefs proper always to ufe the greateft quantity that can be neceffary; left, for inftance, it fhould be neceffary to try fo many times the lead alone, to make it evident how much filver the lead when alone leaves in the coppel. Nor need you fear left any thing of the filver be taken away by the lead, provided the coppels be good, and the coppelling duly put in execution: for you can hardly collect a ponderable quantity of filver out of the collected fume of the lead, which rifes during the coppelling, as well as out of the litharge that is withdrawn into the coppel."

PROCESS IV.

If the ore be rendered refractory by pyrites, Cramer directs that the filver fhould be precipitated by lead in the following manner. *(Art of Affaying,* Part II. proc. 4.)

"Break

Essaying of Ores of Silver.

"Break your ore into a rough powder, and put a centner of it into the test: put upon this another test in the manner of a tile; put it under the muffle hardly red-hot: increase the fire by degrees. There will always be a crackling: which being ended, take away the upper-test; for when the vessels have been red-hot about one minute, the ore ceases to split. Leave the ore under the muffle till the arsenic and the sulphur are for the most part evaporated; which you will know from the cessation of the visible smoke, of the smell of garlic, or the acid; then take away the test, and leave it in a place not too cold, that it may cool of itself.

"Pour out, without any dissipation, the roasted ore, and with a knife take away what is adherent to the vessel; pound it to a most subtile powder, and grind it together with an equal weight of glass of lead; and, finally, scorify the whole collected ore in the same test wherein the testing was made, unless it has contracted chinks, as was described in Process III.

"*Remarks.* "Yellow pyrites-ores contain a very great quantity of sulphur, even greater than is necessary to saturate the metal that lies hidden in them.—For which reason this superfluous sulphur dissipates in a middling fire; but if it had been mixed with lead, it would have rendered it refractory, nor could it afterwards be dissipated from it without a considerable destruction of the lead. The white arsenical pyrites turn also a great quantity of lead into glass, on account of the abundance of the arsenic they contain. For which reason these ores must be previously roasted, that the sulphur and arsenic may be dissipated. Nor need you fear lest any part of the silver be carried away with the arsenic; for when arsenic is separated from any fixed body, by a certain degree of fire, it carries nothing of that body away with it."

PROCESS V.

Silver may be precipitated from its ore by cupellation only, in the following Process, given by Cramer. [*Art of Assaying, Part* II. *Proc.* 9.]

"Pound one centner of ore; roast it in the manner directed in the last process; beat it to a most subtle powder; and if it melts with difficulty on the fire, grind it together with one centner of litharge, which is not necessary when the ore melts easily: then divide the mixture or the powder of the ore alone into five or six parts, and wrap up every one of them severally in such bits of paper as can contain no more than this small portion.

"Put a very large coppel under the muffle; roast it well first, and then put into it sixteen centners of lead: when the lead begins to smoke and boil, put upon it one of the said portions with the small paper it was wrapt up in, and diminish the fire immediately, in the same manner as if you would make a scorification in a test, but in a lesser time. The small paper, which turns presently to ashes, goes of off itself, and does not sensibly increase the mass of the scorias. The ore proceeding therefrom is cast on the border, and turns to scorias very soon. Increase the fire again immediately, and, at the same time, put another portion of the ore into the coppel, as was just now said. The same effects will be produced. Go on in the same manner, till all the portions are thrown in and consumed in the lead. Finally, destroy the remaining lead with a stronger fire.

"The silver that was in the ore and in the lead will remain in the coppel. If you deduct from it the bead proceeding from the lead, you will have the weight of the silver contained in the ore. If the ore employed was easy to be melted, all the scoria vanishes; but if it was refractory or not fusible, all the scoria does not always go away, but there remains something of it now and then in the form of dust. A great many ores and metals may be tried in this way, except only such as split and corrode the coppels.—There are likewise some of them which must be previously prepared in the same manner as is required to render them fit for going through a scorification.—*See the foregoing Processes.*

"*Remarks.* The ore thrown at several times upon lead boiling in a coppel may be dissolved without the foregoing scorification; but this is very far from having an equal success with all kinds of ores; for there are ores and metals which resist very much their dissolution by litharge; and which being on thi account thrown on the border, are not sufficiently dissolved; because the litharge steals away soon into the coppel. Nevertheless, there are some others which vanish entirely by this method, except the silver and gold that was contained in them.

"A previous roasting is necessary, first, for the reasons mentioned, and then because the ore thrown upon boiling lead should not crackle and leap out; for, having once passed the fire, it bears the most sudden heat."

PROCESS VI.

Silver may be precipitated out of the same bodies as were mentioned in the foregoing processes by scorification in a crucible. [*Cramer, Proc.* 15.]

"The body out of which you intend to precipitate silver must be previously prepared for a scorification by pounding and roasting, as mentioned in the former processes. Then, in the same manner, and with the same quantity of lead, put it into a crucible strictly examined, that it be entire, solid, not speckled with black spots, like the scoria of iron, especially at its inferior parts, and capable of containing three times as much. Add besides glass gall and common salt, both very dry, and enough, that when the whole is melted, the salts may swim at top at the height of about half an inch.

"Put the crucible thus loaded into a wind-furnace; shut it close with a tile; put coals round it, but not higher than the upper border of the crucible. Then light them with burning coals, and increase the fire till the whole melts very thin, which will be done by a middling fire, maintained always equal, and never greater; leave it thus for about one quarter of an hour, that the scorification may be perfectly made. Take off the tile and stir the mass with an iron wire, and a little after pour it out into the mould. When the regulus is cleaned from scorias, try it in a test by coppelling it.

"*Remarks.* The scorification of any ore whatever, or of any body fetched out of ores, may indeed be

Amalgamation of Silver and Gold Ores.

be made by this apparatus, as well as in a test under a muffle: but it serves chiefly to the end that a greater quantity of metal may be melted from it with profit. For you may put many common pounds of it at one single time into the crucible; but then you need not observe the proportion of lead prescribed in the foregoing process; nay, a quantity of lead two or three times less is sufficient, according to the different qualities of the object. But the mass will certainly be spilt, unless you choose a very good crucible; for there is no vessel charged with litharge that can bear a strong fire having a draught of wind, without giving way through it to the litharge.

"You add glass-gall and common salt, that they may forward the scorification, by swimming at top; for the refractory scoria rejected by the litharge, and adhering between this and the salts that swim at top, is soon brought to a flux, and the precipitation of the silver is thereby accelerated. They also hinder in a manner a small burning coal fallen into the crucible, from setting the litharge a boiling, which troubles the operation; for the litharge or glass of lead, especially that which is made without any addition, so soon as the phlogiston gets into it, rises into a foamy mass, consisting of a multitude of small bubbles very difficult to be confined, unless the phlogiston be entirely consumed, and the litharge reduced to lead, which sometimes rises above the border of the vessel."

The *corneous ore*, if it really be, as Cronstedt says, a luna cornea, ought to be treated in some of the methods directed for the reduction of luna cornea. See *Chemistry-Index*.

PROCESS VII.

Silver and gold may be extracted from their ores by mercury.

A new method of extracting the precious metals by means of amalgamation with mercury has lately been introduced into Germany. The attraction between these has indeed been known from the most remote antiquity: Vitruvius informs us, that by this means gold might be recovered from embroidery and old cloaths; and Pliny mentions the gilding of brass and other metals by the same means. From time immemorial mercury has been made use of in the streaming for gold, in order to purify and collect together the gold dust which is dispersed in the sands; and almost all nations who practise this use the same process. The gold sand, after being washed, is triturated with quicksilver, and the superfluous metal separated by straining through leather. By the miners it was used in a similar manner; the stones containing gold being first pounded and then triturated in mills along with the mercury. But it was soon found, that in these mills there was a large quantity left behind in the residuum, so that it was necessary to subject what was left to the action of fire; on which account the mills were deemed unnecessary, and are now almost every where disused. The process of extracting gold and silver by amalgamation, however, was looked upon to be essentially deficient, by reason of an opinion which prevailed among the chemists, that mercury could not dissolve either of these metals except in their pure and perfect state; whence it was supposed, that a great quantity which fire could have extracted was left by the mercury. This opinion was supported by the most celebrated metallurgists, as Schlutter, Gellert, Wallerius, and Kramer; whence it became generally believed, that amalgamation would never answer in great operations. But of late Baron Inigo Born has not only demonstrated that this can be done to great advantage, but has actually introduced it, notwithstanding that some difficulties were thrown in his way. The following is an account of the methods which have been practised for separating gold and silver from their ores by means of quicksilver.

Baron Born's New Process, translated by Raspe, 4to, 179[illegible]

This process was introduced into some of the mines of Mexico in 1566 by Don Pedro Fernandez de Velasco, and in 1571 into some of those of Peru by the same person; and from thence it quickly spread thro' all the mines in the south and north-east parts of America, insomuch that it is almost the only method used in that part of the world for extracting these metals. The richer ores, however, are purified by fusion with lead; and our author informs us, that formerly the poorer kinds of ores were certainly thrown away, and when the method of amalgamation was introduced into Peru, the old barrows were searched for the ores which had been rejected as useless, but were now put to the quicksilver.

In the year 1588, Don Juan de Corduba, a Spaniard, applied to the court of Vienna, proposing to extract silver from its ores, whether poor or rich, by mercury, and in a short space of time. He made some experiments upon different kinds of ore, which on a small scale succeeded very well, but on attempting it with 20 quintals of it he failed; and as Lazarus Erker, who was employed to give in a report concerning it, disapproved of the method, it was not pursued any farther. The reasons alleged in Baron Born's book for this failure are, that he did not calcine his ore; that he did not use any salt; and that the weather was too cold; though this last circumstance might have been remedied had Corduba attended to it.

Another Latin and anonymous account of the mode of amalgamation is preserved among the records of the aulic chamber. It is directed to the emperor, but the year in which it was written is not mentioned. According to the account given by the author of this paper, he had examined the mines of Guatimala in New Spain, and made some useful regulations for them. He directs the ore to be calcined in furnaces like limekilns, the fire being kept up according to the nature of the ores, after which they are to be reduced to powder in mills or stamps. The pulverised matter is then passed through fine iron sieves, and put into earthen or copper vessels by 10 or 20 quintals at a time; more or less salt being mixed with it according to circumstances. The light-coloured ore requires 50 lb. to every thousand, and the darker somewhat more. To this mixture are to be added five pounds of dry tartar, two pounds of pulverized horn, and three pounds of brick-dust. Some kinds of ores require but a small quantity of these additions.

After the mixtures are put into the boilers, as much water is added as will make the whole of the consistence of paste moderately thick; the vessels must be exposed to sunshine, or kept in a place warmed artificially, adding more water when the matter begins to dry; and it must

Amalgamation of Silver and Gold Ores.

must be stirred up three or four times a-day. At the expiration of three or four days, various colours appear upon the surface. After this 15lb. of brimstone is to be added to every thousand pounds of ore, and the whole worked over again; but this addition is by the baron considered as quite superfluous. Lastly, 100lb. or less of quicksilver is added, according to the nature of the ore; the whole mass is carefully worked over, and left at rest for 10 hours. A fire must next be kindled under the boiler, and the matter it contains triturated or stirred for two days together; keeping it always sufficiently diluted by a proportionable quantity of water. It is, lastly, allowed to rest for 12 hours, and then dried.

When this operation is successfully performed, if the ores be rich, particles of amalgam will be seen in it: these are collected, washed out, and kept for further use, the leavings being carried to a place fit for washing over. This place ought to be on the slope of an hill, where a kind of pit is dug out and lined with brick and mortar, and ought to be large enough to contain 25 quintals. A stream of water is then made to run upon it, and the matter stirred without intermission. The superfluous water runs over the rim of the pit, and carries off the lighter stony and earthy particles, the heavy amalgam remaining at bottom. This is then to be mixed with the small clots already mentioned, which were taken out of the mass originally, and pressed through a cloth made of hemp or coarse linen. The quicksilver, which comes through clean, is kept for farther use; the remainder distilled off in proper vessels, and the remaining silver melted into ingots. By this method it is said that even very poor ores are worked to advantage, the expence being very moderate.

The following method of extracting gold from its ores is very much recommended by our author: "The auriferous sand, which contains gold grains and gold-dust, is concentrated by washing; and without any calcination goes to the above mentioned washing-pit, which for this purpose need not be so large. On its upper part is fixed a square launder, about 12 feet long, covered in the bottom with a woollen cloth, in order to retain any part of the gold-dust which may be carried over with the water and stuff gently stirred in the pit. When the water carries off no more mud, but runs clear, the farther supply is to be stopped; the water in the pit is pumped or taken out with buckets; the coarser sand in the bottom is separated or scraped off by hands; and the finer heaviest sand at the bottom is mixed with quicksilver. Then it is squeezed through a piece of cloth; the quicksilver comes off without any gold, which separated from the sand remains as an amalgam, and is pure after the remaining quicksilver has been evaporated. The sand and heavier dust remaining on the launder is washed and treated in the same manner.

"The auriferous ores and loadstones, however, which rise from different mines, are calcined like silver ores, more or less as the nature of their matrixes will direct. Then they are ground and sifted; and the auriferous stuff, thus prepared, is put into heaps, exposed to the sunshine, and worked and turned about for three or four days. It requires no salt. Afterwards sulphur, and at last quicksilver, are added and mixed with it. There is no occasion for fire under the vessel in which it is triturated, except in winter; and two days after, though not dried, it is immediately carried to the washing-pit, and treated like the amalgam of silver.

"This method of extracting gold and silver is so certain and safe, that when other methods of amalgamation extract only one ounce of gold and silver, this produces three or four from the poorest ores in a shorter time and with less expence."

P. Joseph Acosta tells us, that at Potosi 6000 or 7000 quintals of quicksilver are annually consumed in the dressing of the ore, not to mention what is recovered from the leavings of the first washing. These leavings, called *lamas*, are burnt in particular furnaces in order to extract the remaining quicksilver; and there are upwards of 50 such furnaces near Potosi and Tarapaja. The ore refined there amounts, according to the best information, to the immense quantity of 300,000 quintals. Only about 2000 quintals of the quicksilver are recovered, which shows a loss of about two pounds of quicksilver on every quintal of ore. The ores are of different natures, and in proportion to the silver they contain require more or less quicksilver. That which contains most, requires naturally the greatest quantity of quicksilver; though some of the workmen pretend that there is a kind which contains very little silver, and yet requires a great deal of mercury: but whether this be owing to the ignorance of the workmen, or to the mercury being absorbed by some other matter, is not generally known. The ore is first pulverised in mills, and then passed through iron or brass sieves. The mills will grind, when properly regulated, 30 quintals in the space of 24 hours. The pulverised matter is put into heaps in the open air, and salt is mixed with it in the proportion of 5 to 50 quintals of the ore, in order to macerate and cleanse it of its impurities, that the quicksilver may the more readily amalgamate with the metal. Upon these heaps, and while they are stirring, the quicksilver is pressed through a cloth. Before the invention of fire-places, the ore was repeatedly kneaded with quicksilver in wooden troughs, and formed into large round masses, which were left in that form for two days; after which they were worked again, until the metals appeared to be embodied together, which took from 9 to 20 days; but it was afterwards found that heat assisted the operation so far, that by means of proper ovens the same might be accomplished in five or six days. When the quicksilver has taken up the silver, and wholly separated it from its matrix the lead and the copper, the ovens are opened, the matter is taken out, and the quicksilver expelled and recovered in the following manner. The mixture is put into water troughs, and stirred therein by means of mills and water-wheels, by which the earthy and extraneous particles are washed away, and the amalgam settles at the bottom. The sediment looks like sand. It is further washed over in flat plates, and perfectly cleansed; what goes off with the water is collected for further use under the name of *relaves*. When the amalgam is become clean and bright by this method, it is put into a cloth and squeezed out. The uncombined quicksilver

Amalgamation of Silver and Gold Ores.

silver runs off, and the remaining body of amalgam contains five parts of quicksilver and one of solid metal. It is made into masses named *pinnas*, having the form of a sugar loaf, hollow within, and weighing about 100 pounds. They are exposed to a strong fire in order to expel the quicksilver, after being put into pots covered with earthen heads. The silver still appears in the form of amalgam, but is reduced to one sixth of the former weight. Its texture is spongy, and the quality of the metal so fine, that the silversmiths cannot work it, neither can it be formed into coin, without an alloy. Baron Born observes, however, that it is only cold amalgamation which produces silver of such uncommon fineness; by hot amalgamation it is generally alloyed with copper, which cannot be parted from it without cupellation.

The most circumstantial account of the amalgamation of silver ore is that of Alonzo Barba. He divides the ores into two classes: 1. those which are best treated by fire and fusion; and, 2. such as are most fit for amalgamation. Those called *pacos* and *tacana*, may be amalgamated; but that none of their richer contents may be lost, it will be best to combine them with lead, and proceed by cupellation. The former of these ores has no lustre or brightness. It is said to be of a reddish-yellow, soft and friable; seldom rich in silver, and mostly valuable on account of its being easily got from the mine. Tacana is a rich silver ore, of a black colour, sometimes of a grey or of an ash-colour; or a brown, rich, silvery earth. 3. The *plomo* is too rich for pulverisation and amalgamation, and is therefore simply melted down with the tacana. This seems to be the same with the horn-silver ore; and is described as almost entirely consisting of native silver, of a black, grey, or greenish-white colour. Barba says that they found at Potosi some plomo of a cinnabar colour, which they had not seen any where else; but Baron Born thinks that here he has mistaken the red silver ore for another species. Frezier asserts, that in what he calls the *plomo ronco*, the native silver appears upon rubbing or scratching it, and that it gives white and very pure silver by simple fusion without any amalgamation. In the imperial cabinet at Vienna, there is a specimen weighing about a pound, of black horn silver ore from Potosi, on the polished surface of which the virgin silver appears very plainly. 4. The *machacado* (virgin silver or gold grown in the matrix in the form of wire or hair), is amalgated in the mortar. 5. The *soroches* (lead ores containing silver), are melted along with the *rosicler* and *conchiso*, two kinds of red silver ore. 6. The *negrillos* (grey copper and white silver ores) may be refined by amalgamation, though they are more fit for fire.

Besides this classification into such as are fit for fire, and those for amalgamation, the ores require further to be sorted into such as require the addition of particular substances for their amalgamation. Vitriol is generally hurtful, especially when salt is added to the vitriolic ores; and it requires the addition of iron, tin, lead, and lime, in order to counteract its effects; but in some cases it is of service, and promotes amalgamation. The calcination of vitriolic ores is of no service, but rather the contrary, as it disengages the vitriol, and brings on a vitriolic efflorescence. It may, however, be separated by washing till the water comes off tasteless and sweet. The amalgamation is disturbed by sulphur, bitumen, and antimony, only by the smoothness and needle-like figure of the particles, which reduce the quicksilver to a kind of dust. The ores mixed with these always run into reguli, and must therefore be put into a strong calcining fire; if melted without calcination, they would run entirely into dross and scoria.

The finer the ores are pounded so much the better; and after putting the powder thro' a fine sieve, the coarser part goes again to the mill: they ought to be previously burnt, in order to assist the operation of grinding. The best method of obtaining fine powder is by washing over; but as this is very apt to pack and turn clammy, it ought to be mixed with sand.

The ores are known to be sufficiently calcined by their change of colour and loss of brightness. Barba tells us, that all bright ores must be calcined, but with great care, that no vitriol may be disengaged, as that proves injurious to the amalgamation; but baron Born says, that one of the greatest objects in the calcination of the Hungarian ores is to decompose the sulphur into vitriol, as promoting the decomposition of the salt. The amalgamation is likewise promoted by burning and calcination, in as far as it promotes the pulverization of the ore, and assists the action of the quicksilver; but it is chiefly useful in the black and grey silver ores. It can only be determined by circumstances whether it be better to pulverize the ores before or after calcination. Their value is best known by pounding them previous to calcination. The stuff must be constantly stirred during the time it is calcining, and some powder taken from the mass to be tried with quicksilver and salt. The thickening of the quicksilver, and the grain of the stuff, show what additions are necessary, or whether the calcination be completed or not. When ores are calcined in lumps, the fire does not act equally upon all their parts; though this method is attended with the advantage of losing much less dust, as well as saving the expence of stamps and mills.

Ores cannot be calcined in reverberatory furnaces, as the heat would run it together, and part of the metals themselves would be carried off by the strong current of air and the violent smoke. Barba recommends a furnace of an oblong square figure, with three vaults over each other; the fire is put into the lowermost, and the ore into the two upper ones. The heat circulates by means of lateral openings in the walls, and is let out on the back without a flue. The heat is graduated by registers and dampers on the outside.—Whatever kind of furnace, however, is used, some of the ore will have clotted, and must therefore be ground to a fine powder; but to prevent as much as possible these inconveniences, the hard ores ought to be calcined before they go to the mill, and the soft ones after, but with proper additions. The irony ores, which resist the fire longer, are calcined with an addition of sulphur, or of sulphureous and antimonial matter, proportioned to the iron they contain; but sulphureous and antimonial ores require to be calcined with the scoria of iron. Arsenical ores, or those mixed with orpiment and sandarac, are calcined with lead glance; and those mixed with white or black bitumen, must be calcined with iron scoria or pounded limestone.

Amalgamation of Gold and Silver Ores.

The impurities of ores, and the additions proper to be made to them, are determined by pounding them coarsely, and throwing them upon a heated plate of iron. If the smoke be white or black, it shows a mixture of bitumen of these colours; if yellow, it shows orpiment; if red, sandarac; if greenish-yellow, sulphur.

Salt ought not to be used in the calcination of ores, as it would calcine the silver; and the duration of the calcining must be determined by the change of colour which the ores undergo by calcination by themselves, and the brightness they assume by trituration with quicksilver. It is also a mark of sufficient calcination when antimonial and sulphureous ores no longer send out a disagreeable smoke; if the thick and black smoke of bituminous ores become white; and if the silver in the stuff appears in white glittering sparks. Vitriolic ores may also be calcined in the same manner; but they require a longer time with the addition of alum and salt: they, however, require no farther addition in the subsequent operations; and in the course of four days all their silver will be taken up by the quicksilver. Less quicksilver will also be lost; for as there is no occasion for the frequent turning and working of the heap, a very small part of it only can be turned into useless dust. Vitriolic ores ought always to be well washed with water before they are calcined; and if there is still a suspicion of their being vitriolic, they must be tried by quicksilver: if it takes a lead-colour, the stuff must be washed till iron put into it no longer takes a copper colour. The lixivium is kept as an useful addition to some ores.

Amalgamation, according to Alonso Barba's method, is performed in three ways, viz. in heaps or caxons, in the boiler, and in mortars.

1. *In heaps.* Before the operation takes place in the large way, an essay is made of three or four pounds of the fine sifted powder taken from the general quantity; and according to the produce of this he calculates that of the whole. He tries it also with quicksilver, to know perfectly the method he is to follow, and the additions that are to be made. In this essay the following method is adopted: 1. The matter is elixated, to extract the vitriol if there be any. 2. One pound of the lixiviated matter is tried with quicksilver and salt, carefully observing the colour and its change. If the quicksilver assumes the appearance of silver filings, and these quicksilver flakes become thinner and thinner, it proves that the amalgamation goes on successfully, and that there is no occasion for any addition. The whole is stirred from time to time, till the quicksilver seems to diminish, and recover its natural form, but without dividing into small globules; after which the matter is to be washed, as all the silver is by that time completely taken up. The ores of *Verenguela de Pacages* are treated only with quicksilver and salt, and yet yield their full produce.

When the ore turns black, iron is added; when of a light lead-colour, tin; if a dark lead-colour, lead; and if of a yellowish or gold-colour, lime. The three last of these are styled by Baron Born, "very idle and useless additions."—The ore frequently divides into small and powdery globules, in consequence of the hardness of the minerals, or from too much stirring; but this may be prevented by calcination before it is reduced to powder, or by less stirring. In a great many operations, however, this quicksilver dust can scarcely be avoided. It serves the workmen as an index of the progress they have made, or sometimes as a direction how to operate; and has different names according to the cause by which it is produced; as quicksilver dust, the dust of addition, and silver dust. The first of these arises simply from too great division, and is white without any quickness, scarcely moving when the matter is stirred with water: it sticks somewhat to the bottom, and runs into globules when broken between the fingers. The second is produced by the amalgam of lead and tin; and, when pressed between the fingers, unites with the quicksilver which had begun to combine with the silver. The third comes from the amalgam of silver: it sinks towards the coarser stuff on the bottom, and floats about in flakes of different sizes; turning into an amalgam when rubbed or pressed between the fingers. All of these are produced chiefly when there are lead, marcasite, and irony ores in the mixture; or by vitriol of copper, which is particularly productive of this minute division of the quicksilver. They are produced also by too plentiful an addition of salt, which thickens the water, and prevents the descent of the particles of quicksilver.

According to the produce of the essay the large heap is regulated. It is first wetted with water, and mixed with the due proportion of salt; but at the beginning only one third of the quicksilver and one half of the lead and tin are added. It is turned over once every day during the two first days, because the quicksilver being then uncombined would be apt to be driven off in small globules, and a great waste occasioned. The heap is likewise too much cooled by the addition of too much quicksilver at once; so that it is better to put it gradually to the other matters. The lead and tin are always thrown into the heap along with the quicksilver; but too much of either is hurtful, by deadening the quicksilver, and preventing the amalgamation. All these additions, however, must vary according to circumstances; observing that the quantities added must always be less and less in proportion as the amalgam advances to perfection. The matter should be kept rather dry than otherwise, and two parts of amalgam be in the heap to one of fluid quicksilver. Too great an abundance of this fluid mass is very detrimental, on account of the quantity of quicksilver dust which it occasions; and if the other ingredients are accidentally wasted, the *dust of addition* will be changed into *quicksilver dust*; which having very little weight, will be poured off along with the water. But when lime is added, the whole must be mixed at once, and the entire heap turned over two or three days, till the quicksilver be added. Too much lime prevents the union of the two metals, and is an inconvenience which cannot be remedied.

The heaps are frequently turned and worked over after the first two days, which is attended with several advantages; as that the quicksilver is thus heated, more thoroughly mixed with the matter, and the silver is purified by the frequent rubbing. The heaps, however, are subject to various accidents, owing to the

the difference between the various kinds of ores, which cannot always be exactly known. When the quickfilver is deadened by too large an addition of lead, iron, tin, or lime, it loses its oval form, and assumes a vermicular one: if shaken in a glass, or other vessel, without water, it adheres to the sides in threads, and is unfit for taking up the silver. The best remedy is vitriol of copper, or the lixivium of vitriolic ores already mentioned; or powder of copper may be thrown into the heap. All additions of this kind, however, must be made very cautiously, and in consequence of experiments made by small essays, which determine the quantity of materials to be used. When the heaps have too much vitriol, without any correcting ingredient, the quickfilver has a leaden colour, and the smaller particles assume a spherical form. Iron might be added to absorb the too great quantity of vitriolic acid; but there is no certain rule for the proportion to be added, so that it must be determined by experiment.

When the quickfilver appears, on turning the heaps, like a bunch of grapes, this shows an excess of salt, which prevents the quickfilver from combining with the silver: it is to be remedied by the addition of some coarse stuff which cleanses the fluid. Some add ashes; but the best and most natural remedy is alum, which is found at Potosi in abundance, and whitens the silver. If the heap be not turned equally, or the quickfilver added at a proper time, or if the silver do not unite with it, some of the silver will appear in a dry form, and lie on the coarser stuff like a cobweb; and if not skimmed off in time, will be carried away by the washing water. To collect this dry silver, and the finest quickfilver dust, some silver amalgama is pressed upon it through a chamois skin; and the whole is once more turned and worked over. The frequent turning, the heat of the climate and season, as well as the fermentation produced in the heap by the vitriol and other additions, all promote the amalgamation; but cold, neglect of stirring, and the quickfilver assuming a lead-colour, are against it. It is, however, very difficult to determine the maturity of the heap, when all the silver is taken up, and the matter may go to the washing; though great inconveniences attend an ignorance in this respect. If washed too soon, some silver is left in the leavings; and if worked too long, there is a loss of quickfilver as well as time and labour. The difficulties attending the knowledge of this important point, are by our author enumerated as follow: "The heap may appear not to require any additional quickfilver; the silver dust may appear to be completely collected; that of quickfilver may begin to make its appearance; the amalgama may begin to appear pure, and to show a gold-colour; and yet silver may remain in the leavings. The most infallible test of the maturity of the heap, is the essay of the triturated stuff by fire. If no silver is produced thereby, then so much quickfilver is thrown into the heap, that it may contain three parts of amalgama to two of silver, or at least one part of quickfilver to two of amalgama. By this additional fresh quickfilver, all the dust of quickfilver, and the dry and uncombined quickfilver, are perfectly collected; the amalgam is the heavier for it, and sinks the more readily to the bottom when brought to the washing-tub.— Some clean quickfilver is also put into the bottom of this tub; the inside of which must be lined with iron plate well cleaned, and rubbed with quickfilver;" (though this last operation seems to be quite superfluous, as mercury will not in the least unite with iron by rubbing.) "The stuff brought into the tub must be diluted with a great quantity of water, and be stirred round with a pestle lined with iron-plate in such a manner that it may turn round six times one way and six times the other, always touching the bottom; the unconnected bodies of quickfilver and amalgam are thereby to meet, to combine, and to fall to the bottom. To recover the salt which had been mixed with the heap, the water must be evaporated:" but the Baron observes, that at Shemnitz no salt is recoverable from the lixivium; and if any be recovered by the Spaniards, it only shows that they add too much, and that part of the remainder is undecomposed by the vitriolic acid. The quickfilver is separated from the amalgama much in the same way as already described.

2. *Amalgamation by boiling*, was accidentally discovered by Barba, in an attempt to fix quickfilver.— On mixing silver ore finely powdered with quickfilver, and boiling it with water in a copper vessel, he found that the metals readily united; and thus having discovered a shorter method of amalgamation, he gradually improved and introduced it into practice in Peru. In this operation the boilers must be of copper, earthen or other vessels being found not to answer: the copper also must be pure, because the quickfilver would dissolve the metals with which it is alloyed. They must be in the shape of inverted cones, and flat-bottomed. The under part has a rim of six or eight inches high and half an inch broad, all beat of one piece. Other copper plates are fixed in the inside with copper nails; and care must be taken that it be water-tight, that no quickfilver may run off; and for the better security, the inside of the boiler may be lined with lime and ox-blood. The boilers may be of any magnitude; their upper parts being surrounded with iron rings with strong handles, into which a cross board is wedged. In the middle of this board is a hole for the spindle to move in. The spindle is of light wood, and moves on a brass pivot in the bottom. It has four wooden wings, with three or four perpendicular bars, also of wood; the farthest from the spindle being the shortest; the nighest so long as to sweep the bottom. It is turned by a moveable handle on the upper end.

These boilers are put into an oblong furnace, capable of holding 10 of them; the fire-place being in the middle, and the flame and smoke passing under the boilers, and going out on both ends of the furnace by two chimnies. The fire being lighted, first the water, then the fine stuff, and at last the quickfilver, is put in; observing always that the bottom be fully covered with quickfilver. The water must always be kept boiling, otherwise the operation may be interrupted or become tedious: on account of the evaporation, the boilers must be supplied with a quantity of water, in small quantities at a time, that the boiling be not checked. The stuff must be proportioned to the size of the boiler: if too little be put in, the amalgamation goes on too slowly; while too much would

Amalgamation of Gold and Silver Ores.

not allow the mafs to be thick enough, or to boil with fufficient freedom. Some of the amalgam is to be taken out from time to time with a long laddle, and the progrefs of the operation is judged of by the colour. The effay of the ftuff determines whether all the filver be taken out of it in this manner. Some quickfilver is then thrown upon the furface of a fample of the boiled ftuff, and worked round with it in a veffel two or three times. If the quickfilver rifes and takes up fome of the ftuff, fome filver remains; if not, the whole is taken up. Then the fire is ftopped, the fpindle is taken out, and the water and ftuff let off. The coarfer matter on the quickfilver may at all events be wafhed in cold water, and go once more to the mill. Almoft the whole of the filver amalgama lies upon the furface of the quickfilver, immediately under the ftuff, fometimes four or five fingers thick; the fire under the boilers preventing the filver from uniting with the quickfilver in the bottom. This metal, when poured off, muft be preffed and treated in the ufual manner.

The advantages attending this method are, that the heat promotes the union of the metals, while the boiling of the water and ftirring of the mixture with the fpindle bring them more frequently in contact with each other in a quarter of an hour, than they would be in feveral days in the common method; by which means the whole procefs is finifhed in about 24 hours. Lefs quickfilver is alfo loft by it; for being always covered with water, it cannot evaporate; and in well managed and fuccefsful operations, no quickfilver duft is produced: but the greateft recommendation is, that it is not attended with any lofs of filver, fo that even the pooreft ores will yield all that they contain. Barba looks upon the profit of this method above the other to amount to 25 dollars for every heap of 50 quintals; even making allowance for the coals. The only objections are, that both filver and copper are apt to be loft by the corrofion of the copper-boilers: but if the copper be pure, there is no great reafon to be apprehenfive of any thing of this kind; or, at all events, the bottom of the boiler, which is conftantly expofed to the action of the quickfilver, may be fecured by a copper ring three or four inches high; and the bottom itfelf may be fecured in the fame manner; fo that when corroded they may be changed for new ones: or the boilers may be paved or lined with varnifhes or mortars of different kinds; which will as effectually prevent any lofs. While the whole is boiling, the quickfilver violently feizes on the other metal; by which means the amalgam is filled with many heterogeneous particles. Thefe are feparated by wafhing in quickfilver, on the furface of which they fwim like fcoria, and may eafily be taken off, till the quickfilver fhows its ufual brightnefs; and as this cannot be done without taking off fome of the metals alfo, the fcum may be referved for the next operation. The advantage of amalgamation by boiling chiefly appears in this, that heaps, in which by too large additions, the quickfilver has been totally diffolved fo as to difappear, may be eafily cured by boiling them, in iron or copper veffels with bits of iron; for then the quickfilver appears again in its proper metallic form and brightnefs.

3. *Amalgamation in mortars.* It is difficult to procure the full produce from ores which contain native gold and filver either in the form of hair or wire, or in larger lumps and nodules. Thefe cannot be completely pounded, nor can they be amalgamated; for the mercury will not diffolve the large particles of gold and filver; and when they are treated by fire, the ftubborn nature of their matrices occafions a great lofs of metal. The following method of treating them in a mortar was difcovered by a Francifcan friar.

A round conical hole is cut in a hard ftone, half a foot in diameter at top, of an equal depth, and floping into a truncated, or rather obtufe and nearly flat bottom, of about four inches in diameter. Some quickfilver is poured into it, together with a proportional quantity of fmall bits of the native metal or ore; after which they are triturated with an iron peftle. By this violent trituration, the gold and filver combine with the quickfilver; and the finer, lighter ftuff of red filver ore and other filver calces, which are generally found with native filver, runs off by means of a fmall launder and current of water. It is not, however, fuffered to run away, but is left to fettle for common amalgamation.

Mortars of the dimenfions above defcribed being too fmall for any confiderable quantity of ore, Barba propofes to fubftitute in their place larger ftones of a concave figure, with vertical grinders, as in oil-mills; or common horizontal and parallel grinders of the griftmill. The ore and quickfilver are put between thefe ftones, with a fmall ftream of water; which, running off, will carry away the lighter ftuff, whilft the gold and filver will remain at the bottom, taken up by the quickfilver.

There are feveral other methods of amalgamation defcribed in Baron Born's work, as practifed by the Spaniards of South America: but as all of them agree in the moft material circumftances with thofe already mentioned, we fhall only farther take notice of that invented by the Baron himfelf, and by him lately introduced at Shemnitz in Lower Hungary.

This method is very pompoufly related, and at great length, in his work on the fubject. His theory contains the following particulars:

1. Quickfilver has a tendency to unite with other metals and femimetals, and to *quicken* or *animate* them according to certain laws of affinity which are determined by experience.

2. It unites with gold, filver, copper, tin, lead, bifmuth, and zinc, without heat; but with other metals and femimetals it will not unite but in a ftate of fufion. It unites with tin and bifmuth more eafily than with gold and filver; and with thefe more readily than with copper.

3. The union of quickfilver with other metals is promoted by heat.

4. This union is alfo greatly promoted by mechanical comminution.

5. No amalgamation, or only a very flow and partial one, will take place, if the furface of the quickfilver or metallic particles be covered with a coat of heterogeneous matter; which happens chiefly in the amalgamation of ores where the fine particles of the metal are involved in fulphur and arfenic.

6. Hence it is neceffary to free the noble metals

 from

Amalgamation of Gold and Silver Ores.

from the stony matter which surrounds them, and to reduce the baser ones from their calciform to a metallic state, before they can be amalgamated with success.

7. Particles of gold and silver may be freed from the stony matters which involve them by trituration; and from sulphur and arsenic, by calcination.

8. In calcination, some part of the sulphur is destroyed, and vitriolic acid disengaged; which, combining with the earthy matters contained in the ore, as well as the calces of the baser metals mixed with it, still leave the gold and silver involved: whence it is necessary to employ such chemical agents as will free the particles of these metals from their heterogeneous coat, and keep their surface as well as that of the quicksilver clean, without acting either upon the gold or silver. These agents are principally the mineral acids, which act variously according to their different natures. The marine acid is most efficacious for gold or silver ores; but it would be exceedingly expensive to use it in its proper form, so that it is necessary to take some method of expelling it extemporaneously from common salt by means of oil of vitriol.

9. The calcined ore, when pulverised, must be wetted with water, for the purpose of dissolving the disengaged vitriolic acid and the earthy and metallic neutral salts, which are produced by it in proportion to the sulphur contained in the ore. Vitriol is produced by calcination only in this proportion; and hence if the ore does not naturally contain a sufficiency of sulphur to produce vitriol for the purpose of decomposition, it will be necessary to add something of this kind. Vitriol of copper or of iron will answer, but the former is preferable. If, therefore, the pulverised ore, which has once gone through the process of amalgamation, should still appear to contain gold or silver, mix it with some additional vitriol and common salt; leave it for some time to macerate by itself; and, at a second trituration with quicksilver, a considerable quantity of silver will be found in the amalgama which had not been extracted in the first, though common salt had been used in it. Thus the common salt may be decomposed in the wet way.

10. To decompose the common salt in the dry way, the ore must be properly stamped and sifted, and the mixtures made up with a proportional quantity of pulverised common or rock salt, and then undergo an adequate calcination in an open fire. Thus the common salt will be decomposed according to the nature of the mixture; either by the vitriolic acid produced by the decomposition of the sulphur, or otherwise.—The muriatic acid, thus disengaged, dissolves the heterogeneous particles in which the metals are involved, and allows the quicksilver to act upon them much more effectually than it could have been enabled to do by any mechanical comminution; and this the more so as it takes up even those particles of dephlogisticated iron upon which the other acids are incapable of acting.

11. The calcination and corrosion of the baser metals is indispensably necessary, especially in a natural combination of gold and copper; for the affinity of these two is so strong, that unless the latter be perfectly calcined, or otherwise removed, very little of the gold can be extracted. The separation will also be promoted by the addition of sulphureous substances.

From these considerations, the Baron lays down the following rules concerning amalgamation.

" 1. The ores and mixtures previous to their amalgamation must be mechanically comminuted, and reduced to a fine powder, by stamping, grinding, and sifting, that the surfaces of the particles, and their points of contact, may be increased and multiplied.

" 2. This powder must be calcined, that, besides the pure particles of the nobler metals, those which are disguised in the ore may be disengaged and laid bare by desulphuration and calcination.

" 3. If before its calcination no common salt was added, it must be added afterwards; then it must be triturated with a proportionate quantity of quicksilver and water, long enough, and in such a manner, that the quicksilver, by an uninterrupted motion of the whole mass, may come into repeated contact with the disengaged gold and silver particles, and take them up.

" 4. As much depends on the just-mentioned proportions, the inspector, director, or master of the work, must be well acquainted with the elective attraction of bodies, that forming a just idea *of*, and judgment *on*, their different mechanical or chemical decomposition and combination, he may remedy and remove such untoward difficulties and impediments in the process as may, and will sometimes, prevent its full success."

The various steps by which the metals are extracted from their ores, according to the Baron's method, are, 1. Stamping, grinding, and sifting. 2. Calcination; after which the grinding and sifting must be repeated. 3. Trituration. 4. Washing of the residuum. 5. Eliquation of the amalgama. 6. Heating of the same. 7. Distillation of the quicksilver pressed from the amalgam. 7. Refining of the heated amalgam. 8. Extracting from the residua such parts of the noble metals as may still be contained in them.

1. *Stamping, grinding*, and *sifting*. The Baron recommends dry-stamps and mills for this purpose; as wet-stamps, he says, " would bring on great loss of silver, and expensive contrivances to prevent or recover it." On the other hand, E. Raspe, the translator of his work, says, that " late experiments have proved so much in favour of the wet stamps, that they have actually been adopted as great improvements."

The contents of the ores are accurately investigated by essays before any thing is done in the large way. The ores are delivered to the respective mills; the smaller ores are passed over a brass sieve, the meshes of which are about one-tenth of an inch wide, that the finer particles may be separated and not sent to the stamps, which would occasion some waste, especially in the dry way. The finer sand is sent directly to the mill, and the big lumps to the stamp. Each box, or set of stamps, has three stamp-heads, weighing 40 or 54 pounds, the sole being of cast-iron. The matter is every now and then wetted with water to prevent the finer parts from flying off. When the ore is sufficiently beat in the stamps, it is afterwards sifted, and the coarse part returned to the stamp. When the coarsest part is reduced in this manner to the size of coarse sand, it is sent to the mill; the running stone of which

which must be kept close in a box, and nothing left open but the admission-funnel. The millstones are a kind of porphyry, and the sieves of brass-wire.

2. *Calcination.* The ore being reduced to a sufficient degree of fineness, is next carried to the calcining furnace; previous to which it is again to be tried by essay, and to have the proper additions according to its nature. When the furnace is properly heated, the whole quantity of ore destined to one furnace, about 30 quintals, is brought up to the top by wheel-barrows; and being spread as even as may be, the proper quantity of salt and lime is sifted over it, and the whole turned with crooks and rakes till it be perfectly mixed. The calcination is then performed in the following manner: The back-door being carefully shut, eight hundred weight of the matter, prepared as already mentioned, is let down through a funnel upon the upper hearth. Here it is again to be spread and allowed to dry before it is put down on the lower hearth; and as soon as this is done, another quantity is put upon the upper hearth, that the two operations may regularly succeed each other.

Our author describes at great length all the minutiæ of this operation: but, as he justly observes, "Experience and practice are, and must be, the best teachers; for there are many things which must be attended to, and which words and descriptions will hardly make intelligible." We shall therefore only observe, that the calcining furnace must be kept heated day and night: but while the ore is shoved down from the upper to the lower hearth, the fire must be kept very moderate; and during the calcination it will be necessary to keep the matter constantly turning with iron rakes, the combs or teeth of which are from four to eight inches long.

The grinding and sifting after calcination is only necessary when the matter has run into hard indissoluble clots during the operation; and is performed in a grinding and sifting mill, which turns by water; but which it is unnecessary here to describe, as every possessor of mines would choose such mechanical contrivances as best suit his purpose.

3. *Trituration, boiling,* and *amalgamation.* After the ores have been properly calcined and pounded, the success of the amalgamation depends mostly on the proportions of quicksilver and water which are added to the stuff, and the construction of the stirring apparatus by which the whole is kept in constant motion and mutual contact. The lighter the stuff, the more voluminous and bulky it will prove, and consequently the gold and silver will be the more dispersed: in which case the quantity of quicksilver must be proportioned to the mass, that notwithstanding its constant gravitation towards the bottom it may the more frequently come into contact with the gold and silver. It acts in proportion to its bulk and surface. A larger quantity is therefore advisable, as it not only forms a larger surface on the bottom of the vessel, but comes likewise into contact with the gold and silver more frequently; nor is there any greater loss of quicksilver to be apprehended on that account. A larger proportion of fluid metal is in particular necessary when the matter is mixed with lead or antimony: for, by taking up the lead, it becomes proportionably less active and fit for the reception of gold and silver: and turning greasy by the antimony, it must in the former case leave rich residua, and in the latter bring on greater loss. It is also determined by experience, that the excess of quicksilver never does any hurt, while too small a quantity never fails to be disadvantageous.

With regard to the construction of the boilers, it is needless to be particular, as those recommended by Alonso Barba seem to be very adequate to the purpose. Heat is required: but it is not necessary that the matter should boil, a moderate fire being sufficient for making the metals unite. Nor is there occasion for more water than what will make the matter liquid. The stirring apparatus is put in motion by the crank of a water wheel, and a horizontal rack with cogs; which, being properly fixed in a groove by cross bars, slides forward and backward on brass rollers and casters. The cogs of this rack catch into those of the perpendicular trundle and spindle of the stirrers, which turns round twice by three and an half feet motion of the sliding rack. The whole moves quicker or slower in proportion to the box of water thrown upon the wheel; and the quicker motion of the rack produces of course a quicker turn and better trituration. The stirrers must be circular segments corresponding with the sides and bottom of the boiler, otherwise their motion is irregular and unsatisfactory. The time of trituration, as depending on the nature of the ore, must be determined by experience.

4. *The washing of the triturated leavings or residuum* is performed in large tubs, and requires no particular description, farther than that it be continued till all the soluble matter be got out; and for this purpose there must be a contrivance for stirring the matter all the time it is washing.

5. *Eliquation of the quicksilver and amalgama.* Formerly this was performed in bags made of deer-skins, strongly compressed with engines for the purpose; but this being found too expensive, it is now done by small quantities at a time, and pressed only by the hand till the ball of amalgam yields no more quicksilver. A small quantity always remains in the quicksilver which passes through; and this quantity is the greater in proportion to the warmth of the amalgam when pressed.

6. The *distillation of the amalgam* is performed *per descensum* in large iron pots. The undermost stands upright to its middle in a stream of cold running water which passes under the hearth; the upper part hardly appearing two inches above it. The amalgam, made up into balls, is placed in iron cullenders fixed upon a tripod set in the bottom of the lower pot, and covered in the inside with a coarse cloth. The upper pot is inverted on the lower one; and the juncture being luted, the fire is put all round the outer one, and the heat passing through to the amalgam quickly liquefies it, and raises the quicksilver in vapour, which condenses in the under pot continually kept cool by the stream of water. The upper pot is kept in a strong red heat for five or six hours; by which means the cloth is entirely converted into tinder, so that the cullenders must afterwards be cleaned with a brass brush.

The other operations contain nothing particular but what may be easily understood from what has been already delivered.

Copper Ores.

Sect. IV. *Ores of Copper.*

§ 1. Copper is found under ground in three different forms: 1. Native or virgin copper diversely ramified, which is much more rare than native silver. This native copper is not so ductile as copper purified by fusions from the ore (A). 2. Copper is found in form of calx, of verdigrise, of precipitates. Such are the minerals called *silky copper ores*, and several white and green earths. These matters are only copper almost pure and but little mineralised, but which has been corroded, dissolved, precipitated, calcined by saline matters, by the action of the air, of water, and of earths (B). 3. Copper is frequently in a truly mineral state, that is, combined with sulphur and with arsenic, with other metallic matters mixed with earths, and enveloped in different matrices (C). These are the true copper ores. They have no regular forms except they partake of the nature of pyrites. Their colours are very different, which depend chiefly on the proportion of the mineral substances composing them. Lastly, in almost all of them we may perceive green or blue colours, which always indicate an erosion or calcination of the copper. Most copper ores contain also some iron or ferruginous earth, to which the ochrey colour is to be attributed, which might make us believe them to be ores of iron. Ores which contain much iron are the most difficultly fusible.

Copper ores have almost all a yellow, golden, and shining colour, by which they are easily distinguished. Some of them are coloured with irises, and frequently have spots of verdigrise, by which also they are distinguishable from other ores.

Many copper ores are also rich in silver. Such is that called the *white copper ore*, the colour of which is rather occasioned by arsenic than by silver, although it contains so much silver as to be enumerated by several mineralogists amongst silver ores.

Lastly, the pyrites of a golden yellow colour which contains copper and sulphur, and the white pyrites which contains copper and arsenic, are considered as copper ores by several chemists and naturalists. Henckel and Cramer remark, that no proper ore of copper is known which does not contain a considerable quantity of arsenic.

Essaying of Ores of Copper.

§ 2. *Ores of copper* may be *essayed* in methods similar to those employed for smelting of large quantities of ores (Part III.), or they may in general be essayed by the following processes.

PROCESS I.

To reduce and precipitate copper from a pure and fusible ore in a close vessel.

"Mix one, or, if you have small weights, two docimastical centners of ore beat extremely fine, with six centners of the black flux; and having put them into a crucible or pot, cover them one inch high with common salt, and press them down with your finger: but let the capacity of the vessel be such that it may be only half full; shut the vessel close, put it into the furnace; heap coals upon it, so that it may be covered over with them a few inches high; govern the fire in such a manner that it may first grow slightly red-hot. Soon after you will hear your common salt crackle; and then there will be a gentle hissing noise. So long as this lasts, keep the same degree of fire till it is quite over. Then increase suddenly the fire, either with the funnel and cover put upon the furnace, or with a pair of bellows applied to the hole of the bottom part, that the vessel may grow very red-hot. Thus you will reduce and precipitate your copper in about a quarter of an hour: then take out the vessel, and strike with a few blows the pavement upon which you put it, that all the small grains of copper may be collected in one mass.

"Break the vessel, when grown cold, in two, from top to bottom, as nearly as you can: if the whole process has been well performed, you will find a solid, perfectly yellow and malleable regulus adhering to the bottom of the vessel, with scorias remaining at top of a brown colour, solid, hard, and shining, from which the regulus must be separated with several gentle blows of a hammer; this done, weigh it, after having wiped off all the filthiness.

A soft, dusty, and very black scoria, is a sign of a fire not sufficiently strong. Small neat grains of copper

(A) *Native copper* is solid; or consisting of friable masses, formed by precipitation of cupreous vitriolic waters, called *cement* or *ziment copper;* or forming crystallized cubes or grains, leaves, branches, or filaments.

(B) *Calciform ores* are either pure calces of copper, or are mixed with heterogeneous matters. 1. The *pure* are loose friable ochre, called *cæruleum montanum* "mountain-blue," and *viride montanum* "mountain-green;" and the *red indurated calx*, called improperly *glass copper ore*. 2. *Mixed* calciform ores are those in which the calx of copper is mixed; with *calcareous earth*, forming a mountain-blue; with *iron*, forming a black calx; with *gypsum*, an indurated green ore, called *malachites;* and with *quartz*, a red ore.

(C) Copper is *mineralised*, 1. By *sulphur*, forming the *grey copper ore*, improperly called *vitreous* (minera cupri vitrea Wallerii). 2. By *sulphurated iron*, forming the *hepatic copper ore* (minera cupri hepatica Wallerii) of a brown yellow colour. It is a kind of cupreous pyrites, and is called by Cronstedt *minera cupri pyritacea.* Sometimes it is of a blackish grey colour, and is then called *pyrites cupri griseus* (minera cupri grisea Wallerii); sometimes of a reddish yellow, and tarnished with blue irises on its surface, when it is called *minera cupri lazurea;* when of a yellowish green colour, it is the *pyrites cupri flavo-viridescens* (cuprum sulphure et ferro mineralisatum Wallerii); and when of a pale yellow colour, it is the *pyrites cupri pallidè flavus.* Most of the above pyritaceous ores contain also some arsenic, but their sulphur is predominant. 3. *Copper mineralised by sulphur, iron, and arsenic. White copper ore* (Minera cupri alba Wallerii). This ore contains also some silver. 4. *Copper dissolved by vitriolic acid. Native blue vitriol.* 5. *Copper united with bitumens. Copper-coal ore.* This is a pit-coal, from the ashes of which copper is obtainable. 6. Copper is also found in the mineral called *kupfer nickel.*

Essaying of Ores of Copper.

per reduced but not precipitated, and adhering still to scorias, especially not very far from the bottom, and an unequal and ramificated regulus, are signs of the same thing. A solid, hard, shining, red-coloured scoria, especially about the regulus, or even the regulus itself when covered with a like small crust, are signs of an excess in the degree and duration of the fire.

"*Remarks.* All the ores which are easily melted in the fire are not the objects of this process; for they must also be very pure. Such are the vitreous copper ores." (Mr Cramer means, it is presumed, the red calciform ore, called improperly *glass ore*, and not the *minera cupri vitrea* of Wallerius, which being composed of copper mineralised by sulphur, could not be treated properly by this process, in which no previous roasting is required. The sulphur of this ore would with the alkali of the black flux form a hepar, from which the metal would not precipitate). "But especially the green and azure-coloured ores, and the *cæruleum* and *viride montanum*, which are not very different from them. But if there is a great quantity of arsenic, sulphur, or of the ore of another metal and semimetal joined to the ore of copper, then you will never obtain a malleable regulus of pure copper, tho' ores are not always rendered refractory by the presence of these."

PROCESS II.

To reduce and precipitate copper out of ores rendered refractory by earth and stones that cannot be washed off.

"Beat your ore into a most subtile powder, of which weigh one or two centners, and mix as much sandiver to them. This done, add four times as much of the black flux with respect to the ore; for by this means, the sterile terrestrial parts are better disposed to a scorification, and the reducing and precipitating flux may act more freely upon the metallic particles freed from all their incumbrances.

"As for the rest, make the apparatus as in last process: but you must make the fire a little stronger for about half an hour together. When the vessel is grown cold and broken, examine the scorias, whether they are as they ought to be. The regulus will be as fine and ductile as the foregoing.

"*Remarks.* As these copper ores hardly conceal any sulphur and arsenic in them, the roasting would be of no effect, and much copper would be lost. For no metallic calx, except those of gold and silver, improperly so called, can be roasted, without you find a part of the metal lost after the reduction.

PROCESS III.

To precipitate copper out of an ore (D) *that contains iron.*

"Do all according to last process. But you will find, after the vessel is broken, a regulus upon no account so fine, but less ductile, wherein the genuine colour of the copper does not perfectly appear, and which must be further purified.

"*Remarks.* The fire used in this operation is not so strong that the iron should turn to a regulus. But as copper is the menstruum of iron, which is of itself very refractory in the fire; for this reason, while the ore and the flux are most intimately mixed and confounded by trituration, the greatest part of the iron being dissolved by the copper, turns into a regulus along with it."

PROCESS IV.

The roasting of a pyritose, sulphureous, arsenical, semimetallic, copper ore.

"Break two docimastical centners of the ore to a coarse powder, put them into a test covered with a tile, and place them under the muffle of a docimastical furnace. But the fire must be so gentle, that the muffle may be but faintly red-hot. When the ore has decrepitated, open the test and continue the fire for a few minutes; then increase it by degrees, that you may see the ore perpetually smoking a little: in the mean time, it is also proper now and then to stir it up with an iron hook. The shining particles will assume a dark red or blackish colour. This done, take out the test, that it may grow cold. If the small grains are not melted, nor strongly adherent to each other, hitherto all will be well; but if they run again into one single cake, the process must be made again with another portion of the ore, in a more gentle fire.

"When the ore is grown cold, beat it to a powder somewhat finer, and roast it by the same method as before; then take it out, and if the powder is not melted yet, beat it again to a most subtile powder; in this you are to take care that nothing be lost.

"Roast the powder in a fire somewhat stronger, but for a few minutes only. If you do not then find the ore any way inclined to melt, add a little tallow, and burn it away under the muffle, and do the same another time again, till, the fire being very bright, you no longer perceive any sulphureous, arsenical, unpleasant smell, or any smoke; and there remains nothing but a thin, soft powder, of a dark red, or blackish colour.

"*Remarks.* Every pyrites contains iron, with an unmetallic earth; to which sulphur or arsenic, and most commonly both, always join. Besides, there is copper in many pyrites; but sometimes more and sometimes less: some of them are altogether destitute of copper; therefore, so much as pyrites differ with regard to the proportion of their constituent particles, so much do they differ as to their disposition in the fire. For instance, the more copper there is in pyrites, the more it inclines to colliquation. The more sulphur and arsenic it has in it, the more quickly the melting of it will be procured, and the reverse: the more iron and unmetallic earth it contains, the more it proves refractory in the fire. Now if such pyrites melt in the roasting, as happens to some of them if they grow but red-hot, the sulphur and arsenic that lies hidden therein are so strictly united with the fixed part, that you would in vain attempt to dissipate them. Nay,

(D) Mr Cramer still means the calciform ores only, and not the mineralised ores of copper.

Essaying of Ores of Copper.

Nay, in this case, when it is reduced again into a powder, it requires a much greater time and accuracy in the regimen of the fire to perform the operation. For this reason, it is much better to repeat it with new pyrites. But you can roast no more than the double quantity at once of the ore you have a mind to employ in the foregoing experiment; to the end that, the precipitation by fusion not succeeding, there may remain still another portion entire; lest you should be obliged to repeat a tedious roasting. If you see the signs of a ferreous refractory pyrites, the operation must be performed with a greater fire, and much more quickly. However, take care not to do it with too violent a fire: for a great deal of copper is consumed not only by the arsenic, but also by the sulphur; and this happens even in vessels shut very close, when the sulphur is expelled by a fire not quite so strong; which a reiterated and milder sublimation of the sulphur in a vessel both very clean and well closed will clearly show.

"When the greatest part of the sulphur and the arsenic is dissipated by such causes as promote colliquation, you may make a stronger fire: but then it is proper to add a little of some fat body; for this dissolves mineral sulphur: it changes the mixture of it in some part, which, for instance, consists in a certain proportion of acid and phlogiston; and at the same time hinders the metallic earth from being reduced into copper, by being burnt to an excess. From these effects, the reason is plain, why assayers produce less metals in the trying of veins of copper, lead, and tin, than skilful smelters do in large operations. For the former perform the roasting under a muffle, with a clear fire, and without any oily reducing menstruum; whereas the latter perform it in the middle of charcoal or of wood, which perpetually emit a reductive phlogiston.

"The darker and blacker the powder of the roasted ore appears, the more copper you may expect from it. But the redder it looks, the less copper and the more iron it affords; for roasted copper dissolved by sulphur or the acid of it is very black, and iron, on the contrary, very red.

PROCESS V.

The precipitation of copper out of roasted ore of the last process.

"Divide the roasted ore into two parts: each of them shall go for a centner: add to it the same weight of sandiver, and four times as much of the black flux, and mix them well together. As for the rest, do all according to the process I.: the precipitated regulus will be half malleable, sometimes quite brittle, now and then pretty much like pure copper in its colour, but sometimes whitish, and even blackish. Whence it is most commonly called *black copper*, though it is not always of so dark a dye.

"It is easy to conceive, that there is as great a difference between the several kinds of that metal called *black copper*, as there is between the pyritose and other copper ores accidentally mixed with other metallic and semi-metallic bodies. For all the metals, the ores of which are intermixed with the copper ores, being reduced, are precipitated together with the copper, which is brought about by means of the black flux. Wherefore iron, lead, tin, the reguline part of antimony, bismuth, most commonly are mixed with black copper in a multitude of different proportions. Nay, it is self-evident, that gold and silver, which are dissolvable by all these matters, are collected in such a regulus when they have been first hidden in the ore. Besides, sulphur and arsenic are not always altogether absent. For they can hardly be expelled so perfectly by the many preceding roastings, but there remain some vestiges of them, which are not dissipated by a sudden melting, especially in a close vessel, wherein the flux swimming at top hinders the action of the air. Nay, arsenic is rather fixed by the black flux, and assumes a reguline semi-metallic form, while it is at the same time preserved from dissipating by the copper.

PROCESS VI.

To reduce black copper into pure copper by scorification.

"Separate a specimen of your black copper, of the weight of two small docimastical centners at least; and do it in the same manner, and with the same precautions, as if you would detect a quantity of silver in black copper.

"Then with lute and coal-dust make a bed in the cavity of a test moistened: when this bed is dry, put it under the muffle of the docimastical furnace, in the open orifice of which there must be bright burning coals, wherewith the test must likewise be surrounded on all parts. When the whole is perfectly red-hot, put your copper into the fire, alone, if it contains lead; but if it is altogether destitute of it, add a small quantity of glass of lead, and with a pair of hand-bellows increase the fire, that the whole may melt with all speed: this done, let the fire be made a little violent, and such as will suffice to keep the metallic mass well melted, and not much greater. The melted mass will boil, and scorias will be produced, that will gather at the circumference. All the heterogeneous matters being at last partly dissipated, and partly turned to scorias, the surface of the pure melted copper will appear. So soon as you see it, take the pot out of the fire, and extinguish it in water: then examine it in a balance; and if lead has been at first mixed with your black copper, add to the regulus remaining of the pure copper one 15th part of its weight which the copper has lost by means of the lead, then break it with a vice; and thus you will be able to judge by its colour and malleability, and by the surface of it after it is broken, whether the purifying of it has been well performed or no. But whatever caution you may use in the performing of this process, the product will neverthless be always less in proportion than what you can get by a greater operation, provided the copper be well purified in the small trial.

"*Remarks.* This is the last purifying of copper, whereby the separation of the heterogeneous bodies begun in the foregoing process is completed as perfectly as it possibly can be. For, except gold and silver, all the other metals and semimetals are partly dissipated and partly burnt, together with the sulphur and arsenic. For in the fusion they either turn of themselves to scoria or fumes, or this is perfomed by means of iron,

Essaying of Ores of Copper.

iron, which chiefly absorbs semimetals, sulphur, and arsenic, and the destruction of it is at the same time accelerated by them. Thus the copper is precipitated out of them pure; for it is self-evident, that the unmetallic earth is expelled, the copper being reduced from a vitrescent terrestrial to a metallic state, and the arsenic being dissipated by means of which the said earth has been joined to the coarser reguluses of the first fusion. But there is at the same time a good quantity of the copper that gets into the scorias: however, a great part of it may be reduced out of them by repeating the fusion.

"The fire in this process must be applied with all imaginable speed, to make it soon run: for if you neglect this, much of your copper is burnt; because copper that is only red-hot, cleaves much sooner, and in much greater quantity, into half-scorified scales, than it is diminished in the same time when melted. However, too impetuous a fire, and one much greater than is necessary for the fusion of it, destroys a much greater quantity of it than a fire sufficient only to put it in fusion would do. For this reason, when the purifying is finished, the body melted must be extinguished in water together with the vessel, lest, being already grown hard, it should still remain hot for a while; which must be done very carefully to prevent dangerous explosions.

"The scoria of the above process frequently contains copper. To extract which, let two or three docimastical centners of the scoria, if it be charged with sulphur, be beat to a subtile powder, and mix it, either alone, or, if its refractory nature requires it, with some very fusible common pounded glass without a reducing saline flux, and melt it in a close vessel, and in a fire having a draught of air; by which you will obtain a regulus.

"But when the scoria has little or no sulphur at all in it, take one centner of it, and with the black flux manage it as you do the fusible copper ore, (process I.) by which you will have a pure regulus."

PROCESS VII.

The following process is translated from Mr Gellert's *Elements of Essaying*, and describes a new method of essaying ores, concerning which, see the section *Of Essaying in general*, p. 338. col. 2.

To essay copper ores.

Roast a quintal of ore [in the manner described in process IV.]: add to it an equal quantity of borax, half a quintal of fusible glass, and a quarter of a quintal of pitch: put the mixture in a crucible the inner surface of which has been previously rubbed with a fluid paste of charcoal dust and water: cover the whole with pounded glass mixed with a little borax, or with decrepitated sea-salt: put a lid on the crucible, which you will place in an air-furnace, or in a blast-furnace: when the fire shall have extended to the bottom of the coals, let it be excited briskly during half an hour, that the crucible may be of a brisk red colour: then withdraw the crucible, and when it is cold break it: observe if the scoria be well made: separate the regulus, which ought to be semi-ductile; and weigh it. This regulus is black copper; which must be purified, as in process VI.

If the ore be very poor, and inveloped in much earthy and stony matters; to a quintal of it, a quintal and a half of borax, a quarter of a quintal of pitch, and ten pounds of calx of lead or minium, must be added. The calx of lead will be revived, and will unite with the scattered particles of the copper, and together with these will fall to the bottom of the crucible, forming a compound regulus. When the ores of copper are very rich, half a quintal of borax and a quarter of a quintal of glass will be sufficient for the reduction. If the ore is charged with much antimony, a half or three quarters of a quintal of clean iron-filings may be added; otherwise the large quantity of antimony might destroy the copper, especially if the ore contained no lead. If iron be contained in copper ore, as in pyrites, some pounds of antimony, or of its regulus, may be added in the essay; as these substances more readily unite with iron than with copper, and therefore disengage the latter metal from the former.

PROCESS VIII.

To essay ores of copper by humid solution.

Some pyrites and ores contain so small a quantity of copper, that it cannot be separated by the above processes, but is destroyed by the repeated roastings and fusions. These, and indeed any copper-ores, may be essayed by humid solution, or by menstruums.

1. By roasting a sulphureous ore, the sulphur is burnt or decomposed, its phlogiston with part of the acid evaporating, while the remaining part of the acid combines with the metals, especially with the copper and iron contained in the ore. Accordingly, from an ore thus roasted, a vitriolic solution may be obtained by lixiviation with warm water, especially if the ore has been exposed, during a few days after it has been roasted, to a moist air; as the water thus gradually applied unites better with the combination of the metallic calxes with the concentrated vitriolic acid of the sulphur: but all the copper is not thus reduced by one operation to a vitriol. More sulphur must therefore be combined with the residuous ore by fusion, and must be again burnt off, that the remaining part of the copper may be attacked by some of the acid of the sulphur. By repeating this operation, almost all the copper and iron will be reduced to a vitriolic lixivium, from which the copper may be separated and precipitated by adding clean pieces of iron.

2. Copper-ores may be more easily essayed by humid solution in the following manner:

Roast the mineralised ores in the manner directed in Process IV. and pulverise them. If the ores be calciform, they do not require a previous roasting. Put this powder into a matrass capable of containing ten times the quantity of the ore; pour upon the ore some water: set the matrass in a sand-bath, that the water may boil: pour off the lixivium: add to the residuous ore more water, with some vitriolic or marine acid: digest as before in the sand-bath, and add this lixivium to the former: repeat this operation, till you find that the acid liquor dissolves no more metal.

By adding clean plates of iron you may precipitate the copper, which ought then to be collected, fused with a little borax and charcoal dust, and weighed.

Essaying of Ores of Copper.

We may remark, that although copper is not soluble by a dilute vitriolic acid, yet the calx of it obtained by roasting the ore, and also the calciform ores, are readily soluble in that acid.

3 Stahl advises to essay copper-ores by boiling them, after they have been roasted and powdered, in water, together with tartar and common salt, or with alum and common salt: but we have not found this method so effectual as the preceding.

PROCESS IX.

Dr Fordyce's method of essaying copper ores, by means of aqua regia. [Phil. Transf. for 1781, vol. lxxx. art. 3.]

This method consists only in pouring a quantity of an aqua regia composed of equal parts of the nitrous and muriatic acids upon a small quantity of the ore in powder, till a fresh affusion of the menstruum shows no green or blue tinge; by which means all the metalline part of the ore will be dissolved. It is then to be precipitated by means of a solution of fixed alkali, or volatile alkali cautiously managed will answer the same purpose. The metal then appears in form of a green precipitate called *green verditer;* but is mixed with what calcareous earth might have been contained in the ore; which the acids would dissolve, and the fixed alkali, if that kind was used, would precipitate. The caustic volatile alkali would not throw down this earth, and is therefore to be preferred to any other; but care must be taken to hit the point of saturation very exactly with it, as it violently dissolves the metal if added in too great quantity. Dr Fordyce orders this green calx to be dissolved in vitriolic acid, and then, by adding a piece of clean iron to the solution, all the copper contained in the ore will be obtained in its metallic form.

This method can be subject to no fallacy, unless the ore contains a luminous matter; in which case some of the earth of alum will be mixed with the metal, as that earth will be precipitated by fixed alkali, by caustic volatile alkali, and by iron. This, however, may very effectually be prevented by dissolving the green calx first in volatile alkali, and then in vitriolic acid. It is even probable, that by reducing the ore to a very fine powder, and treating it with caustic alkali, all the metal might be separated from the ore, without the trouble of using aqua regia. For the principles on which this method is conducted, see the article CHEMISTRY *passim.*

Ores of Lead

SECT. V. *Ores of Lead.*

§ 1. LEAD is seldom found native (E) and malleable. Neither, says Mr Macquer (F), is it found in form of calx or precipitate, as copper is, because it is much less liable to lose its phlogiston by the action of air and water: therefore almost all lead is found naturally mineralised.

Lead is generally mineralised by sulphur (G). Its ores have a dark white, but a shining metallic colour. These ores, although they form irregular masses, are internally regularly disposed, and seem to be composed of cubes of different sizes applied to each other, but not adherent. These ores are generally distinguished by the name of *Galena.* They commonly contain about three quarters of lead and a quarter of sulphur. They are accordingly heavy and fusible, although much less so than pure lead.

Most lead-ores contain silver; none but those of Willach in Corinthia are known to be quite free from it: some of them contain so much of it, that they are considered as improper ores of silver. The smaller the cubes of galena are, the larger quantity of silver has been remarked to be generally contained.

§ 2. *Lead ores may be essayed,* 1. By means of the black flux, in the manner directed by Mr Cramer, as follows:

"Let one or more quintals of this ore be grossly powdered, and roasted in a test till no more sulphureous vapours be exhaled, and then reduced to a finer powder; it is then to be accurately mixed with twice its weight of black flux, a fourth part of its weight of clean filings of iron and of borax. The mixture is to be put into a good crucible, or rather into a test: it is then to be covered with a thickness of two or three fingers of decrepitated sea-salt; the crucible is to be closed, and placed in a melting furnace, which is to be filled with unlighted charcoal, so that the top of the crucible shall be covered with it. Lighted coals are then to be thrown upon the unkindled charcoal, and the whole is left to kindle slowly, till the crucible be red-hot; soon after which a hissing noise proceeds from the crucible, which is occasioned by the reduction of the lead: the same degree of fire is to be maintained while this noise continues, and is afterwards to be suddenly

(E) Cronstedt doubts whether any native lead has been found. Linnæus says, he has seen what externally appeared to be such.

(F) But he is mistaken. As lead unites strongly with vitriolic acid, we might expect to meet ochres of this metal as well as of copper. Accordingly, we find some calciform ores of lead. 1. A pure calx of lead, in form of a friable ochre, *cerussa nativa,* found on the surface of galena; or it is indurated with a radiated or fibrous texture, of a white or yellowish green colour, and resembling spar; it is called *spatum plumbi, sparry lead-ore,* and *lead-spar.* 2. A calx of lead is found mixed with calx of arsenic, forming the ore called *arsenicated lead spar.* Sometimes also that calx is mixed with calcareous earth.

(G.) Lead is mineralised, 1. With sulphur; such are the several kinds of steel-grained and tessellated galenas, which also contain generally some silver. 2. With sulphurated iron and silver. It is fine-grained or tessellated, and is distinguished from the former by yielding a black slag when scorified, whereas the former yields a yellow slag. 3. With sulphurated antimony and silver. *Plumbum stibiatum Linnæi.* Its colour is similar to that of galena, and its texture is striated. 4. With sulphur and arsenic. This ore is soft, almost malleable, like lead. From this ore lead may be melted by the flame of a candle.

Ores of Tin denly increafed, fo as to make a perfect fufion; in which ftate it is to be continued during a quarter of an hour; after which it is to be extinguifhed; and the operation is then finifhed." The filings of iron are added to the mixture to abforb the fulphur; a certain quantity of which generally remains united with the lead-ore, notwithftanding the roafting. We need not fear left this metal fhould unite with the lead and alter its purity; becaufe, although the fulphur fhould not hinder it, thefe two metals cannot be united. The refractory quality of the iron does not impede the fufion; for the union it forms with the fulphur renders it fo fufible, that it becomes itfelf a kind of flux. This addition of iron in the effay of lead-ores would be ufelefs, if the ores were fufficiently roafted, fo that no fulphur fhould remain.

Or, 2. By the following procefs of Mr Gellert.

"Mix a quintal of roafted lead-ore with a quintal of calcined borax, half a quintal of glafs finely pulverifed, a quarter of a quintal of pitch, and as much of clean iron-filings: put this mixture into a crucible wetted with charcoal-duft and water: place the crucible before the nozzle of the bellows of a forge, and when it is red raife the fire during 15 or 20 minutes; then withdraw the crucible, and break it when cold."

Some very fufible ores, fuch as the galena of Derbyfhire, may be effayed, as large quantities of it are fmelted, without previous roafting, and without addition, merely by fufion during a certain time. For this purpofe nothing more is requifite than to keep the ore melted in a crucible with a moderate heat, till all the fulphur is deftroyed, and the metal be collected. To prevent the deftruction of any part of the metal after it is feparated from the fulphur, fome charcoal duft may be thrown over the ore, when put into the crucible; but if the galena be mixed with pyrites, efpecially arfenical pyrites, it requires much roafting and faline fluxes.

Sect. VI. *Tin Ores.*

§ 1. Tin is very feldom found pure, but almoft always mineralifed, and chiefly by arfenic.

The richeft ore of tin is of an irregular form, of a black or tarnifhed colour, and almoft the heavieft of all ores. The caufe of this extraordinary weight is, that it contains much more arfenic than fulphur, whereas moft ores contain more fulphur than arfenic.

The moft common tin ore is of the colour of ruft, which proceeds from a quantity of iron or of iron-ore mixed with it. The tin-ores of Saxony and Bohemia appear to be all of this kind.

One kind of tin-ore is femi-tranfparent and like fpar. Laftly, feveral kinds of garnets are enumerated by mineralogifts among tin-ores, becaufe they actually contain tin.

The county of Cornwall, in England, is very rich in tin-ores; and the tin contained in them is very pure. From tin-mines in the Eaft Indies tin is brought, called *Malacca tin*. No mines of tin have been difcovered in France; only in Bretagne garnets are found which contain fome tin.

Native tin is faid to have been found in Saxony and Malacca. Its ores are all of the calciform kind, excepting black-lead, which appears to be tin mineralifed by fulphur and iron.

The calciform ores of tin are, 1. Tin-ftone, which is of a blackifh-brown colour, and of no determinate figure; and tin-grains, or cryftals of tin, which refemble garnets, and are of a fpherical or polygonal figure, which they have probably acquired by the attrition of their angles. The tin-ftone feems to confift of attrited tin-grains. This ore is calx of tin united with calx of arfenic, and frequently with calx of iron. 2. Garnets are faid to contain calx of tin united with calx of iron. 3. Manganefe is faid alfo to contain tin.

§ 2. *Ores of tin may be effayed* in the fame manner, according to Cramer, as he directed for the effay of lead-ores, *fupra*. He further makes upon this effay the following remarks.

1. Tin-ore, on account of its greater gravity, admits better of being feparated, by elutriation or wafhing, from earths, ftones, and lighter ores. 2. A moft exact feparation of earths and ftones ought to be made, becaufe the fcorification of thefe by fluxes require fuch a heat as would deftroy the reduced tin. 3. The iron ought to be feparated by a magnet. 4. By a previous roafting, the arfenic is diffipated, which would otherwife carry off a great deal of tin along with it in a melting heat, would change another part of it into afhes, and would vitiate the remaining tin. 5. The effay of tin is very precarious and uncertain; becaufe tin once reduced is eafily deftructible by the fire, and by the faline fluxes requifite for the reduction.

Mr Gellert directs, that ores of tin fhould be effayed in the following manner:

"Mix a quintal of tin-ore, wafhed, pulverifed, and twice roafted, with half a quintal of calcined borax, and half a quintal of pulverifed pitch: thefe are to be put into a crucible moiftened with charcoal-duft and water, and the crucible placed in an air-furnace: after the pitch is burnt, give a violent fire during a quarter of an hour; and then withdraw your crucible. If the ore be not very well wafhed from the earthy matters, as it ought to be, a larger quantity of borax is requifite, with fome powdered glafs, by which the too quick fufion of the borax is retarded, and the precipitation of the earthy matters is prevented. If the ore contains iron, to the above mixture may be added fome alkaline falt.

Sect VII. *Ores of Iron.*

Ores of Iron § 1. Iron is feldom found in its metallic ftate, and free from admixture; though Cramer gives an account of an ore which needs only to be put into a forge, and heated to a welding heat. Several fands and earths alfo have the appearance of iron, and are even attractable by a magnet. The ore mentioned by Cramer is found vitrefied: with moderate blows the fcorias are thrown out, and a mafs of iron obtained, which, by being put into the forge again, gives tough iron without any other procefs. But in general this metal is found in the ftate of a calx; or, though it is combined with a great quantity of the principle of inflammability, it has feldom enough of the metallic form; and it is very often intermixed with a certain proportion of fulphur. The minerals wrought for iron are three, *viz.* iron-ore, iron-ftone, and bog-ore.

 The

Ores of Iron

The iron ore is found in veins as the ores of other metals are, and the appearance is very various; sometimes it has a rusty iron colour resembling that of iron; sometimes it has a reddish cast; often it is formed into a sort of crystallizations which are protuberant knobs on the outside; and these consist of fibres tending to a common centre: and it is of a dark colour like coagulated blood. It is called *hæmatites* or *blood-stone;* and consists of a calx of iron with a small quantity of vitriolic acid.

Iron-stone in this country is clay found in strata with coal; but which contains a large quantity of iron, so as to make the working profitable. Sometimes it has little appearance of iron; but when burnt with a certain degree of heat, it becomes of a deep red.

The bog-ore is an ochre of iron, and is found generally in low situations, and in springs containing a small quantity of iron, which flowing over these grounds deposits it in the form of ochre; and after a number of ages it proves a rich mine of iron, and it is extracted from a calx of this kind in many parts of the world. There is also a particular kind of spar found in different countries of a pale blue colour, so that from its first appearance we would expect copper; but it contains a small quantity of iron, and is a combination of the metal with inflammable matter, as in Prussian blue.

The loadstone is a noted iron ore. It is always found in veins, and it is alleged that it is only possessed of its magnetic qualities when near the surface. In appearance, it does not differ from many of the ores of iron, and treated as an ore, it affords a considerable quantity of metal.

Neither is iron generally mineralised so distinctly as other metals are, unless in pyrites and ores of other metals.

Most of the minerals called *iron ores* have an earthy, rusty, yellowish, or brownish appearance, which proceeds from the facility with which the true iron ores are decomposed.

Iron is the most common and most abundant of all metals. In Europe, at least, we cannot find an earth, a sand, a chalk, a clay, a vitrifiable or calcinable stone, or even the ashes of any substance, which do not contain an earth convertible into iron. All earths and stones which are naturally yellow or red, and all those which acquire these colours by calcination, receive them from the ferruginous earth mixed with them. The yellow and red ochres consist almost solely of this earth: the black and heavy sands are generally very ferruginous.

The iron ore most commonly found is a stone of the colour of rust, of an intermediate weight betwixt those of ores in general and of unmetallic stones. This ore has no determinate form, and easily furnishes an iron of good quality.

Blood-stone or hematites, sanguine or red-chalk, and emery, are iron ores; some of which, for instance blood-stone, are almost all iron. Most of these substances require but a slight calcination to be rendered very attractable by a magnet, and soluble in aquafortis; but the iron obtained from them is of a bad quality, and they are therefore neglected. Iron from the hematites is very brittle; that obtained from ochres is red-short. All these iron ores are so refractory, that they can scarcely be fused.

Essaying Ores of Iron

Iron ores are very various in their form; or rather they have no determinate form. Sometimes they are earths, sometimes stones, sometimes grains. Accordingly, those naturalists who attend only to the external form of things in classing and subdividing minerals, have been obliged to multiply the names of iron ores: hence they are called *iron ores in form of pease, of beans, of coriander seeds, of pepper-corns, of cinnamon,* &c. which Mr Cramer treats as ridiculous trifles.

§ 2. *Ores of iron may be essayed* by the following process:

PROCESS I.

[*Cramer's Art of Assaying*, Proc. 54.]

To reduce a precipitate iron out of its ore in a close vessel.

"Roast for a few minutes in a test under a muffle, and with a pretty strong fire, two centners of the small weight of your iron ore grossly pulverised; that the volatiles may be dissipated in part, and the ore itself be softened in case it should be too hard. When it is grown cold, beat it extremely fine, and roast it a second time, as you do the copper-ore, but in a much stronger fire, till it no longer emits any smell; then let it grow cold again. Compose a flux of three parts of the white flux, with one part of fusible pulverised glass, or of the like sterile unsulphureous scorias, and add sandiver and coal-dust, of each one-half part; add of this flux three times the quantity of your roasted ore, and mix the whole very well together; then choose a very good crucible, well rubbed with lute within, to stop the pores that may be here and there unseen; put into it the ore mixed with the flux; cover it over with common salt; and shut it close with a tile, and with lute applied to the points.

"Put the wind-furnace upon its bottom-part, having a bed made of coal-dust. Introduce besides into the furnace a small grate supported on its iron bars, and a stone upon it, whereon the crucible may stand as on a support: surround the whole with hard coals, not very large, and light them at top. When the vessel begins to grow red, which is indicated by the common salt's ceasing to crackle, stop with gross lute the holes of the bottom part, except that in which the nozzle of the bellows is received: blow the fire, and excite it with great force, adding now and then fresh fuel, that the vessel may be never naked at top: having thus continued your fire in its full strength for three quarters of an hour, or for a whole hour, take next the vessel out of it, and strike several times the pavement upon which it is set, that the small grains of iron which happen to be dispersed may be collected into a regulus, which you will find after having broken the vessel.

"When the regulus is weighed, try its malleability: then make it red-hot; and when so, strike it with a hammer: if it bears the strokes of a hammer, both when red hot and when cold, and extends a little, you may pronounce your iron very good; but if, when either

Essaying of Ores of Iron

either hot or cold, it proves brittle, you may judge it to be not quite pure, but still in a semi mineral condition.

" *Remarks.* The arsenic, but especially the sulphur, must be dissipated by roasting: for the former renders the iron brittle; and the latter not only does the same, but, being managed in a close vessel, with a saline alkaline flux, turns to a liver of sulphur; to the action of which iron yielding in every respect, it can upon no account be precipitated; and if not the whole, a great part of it at least is retained by the sulphureous scoria; so that in this case you commonly in vain look for a regulus.

" The iron obtained from this first precipitation has hardly ever the requisite ductility, but is rather brittle: the reason of which is, that the sulphur and arsenic remain in it; for notwithstanding that the greatest part of these is dissipated by roasting, yet some part adheres so strictly, that it can never be separated but with absorbent, terrestrial, alkaline ingredients, that change the nature of the sulphur. For which reason, in larger operations, they add quicklime, or marble stones that turn into quicklime; which, while they absorb the said minerals, are, by it, and by help of the destroyed part of the iron, brought to a fusion, and turn to a vitrified scoria; although, at other times, they resist so much by their own nature a vitrification. Another cause of the brittleness of iron is the unmetallic earth, when it is not yet separated from it; for the iron ore contains a great quantity of it, and in the melting remains joined with the reguline part: whence the iron is rendered very coarse and brittle. Some iron ores are altogether untractable: nevertheless, the reguluses produced out of them, when broken, have sometimes a neat semimetallic look; which proceeds undoubtedly from a mixture of a small quantity of some other metal or semimetal."

PROCESS II.

[The following Process for essaying iron ores, and ferruginous stones and earths, is extracted from Mr Gellert's *Elements of Essaying.*]

" Roast two quintals of iron ore, or of ferruginous earth: divide the roasted matter into two equal parts: to each of which add half a quintal of pulverised glass, if the substance be fusible and contain much metal; but if otherwise, add also half a quintal of calcined borax. If the roasting has entirely disengaged the sulphur and arsenic, an eighth part, or even half a quintal, of quicklime may be added. With the above matters mix twelve pounds of charcoal-powder.

" Take a crucible, and cover the bottom and sides of its inner surface with a paste made of three parts of charcoal-dust and one part of clay beat together. In the hollow left in this paste put the above mixture; press it lightly down; cover it with pulverised glass; and put on the lid of the crucible.

" Place two such crucibles at the distance of about four fingers from the air-pipe, in such a manner that the air shall pass betwixt them at about the third part of the height from the bottom: fill the space betwixt the two crucibles with coals of a moderate size; throw lighted coals upon them, that the fire may descend and make them red-hot from top to bottom: at first let the bellows blow softly, and afterwards strongly during an hour, or an hour and a quarter: then take away the crucible, and break it when cold. A regulus will be found in the bottom, and sometimes some small grains of iron in the scoria, which must be separated and weighed along with the regulus: then try the regulus whether it can be extended under the hammer, when hot and when cold.

" *Remarks.* To disengage a metal from the earthy matters mixed with it by fire, we must change these matters into scoria or glass. This change may be effected by adding some substance capable of dissolving these matters; that is, of converting them into a scoria or glass, from which the metallic matters may, by their weight, separate and form a regulus at bottom. Fixed alkali, which is an ingredient of the black and of the white flux, is a powerful solvent of earths and stones: but the alkali does also dissolve iron, especially when this is in a calcined or earthy state; and this solution is so much more complete, as the fire is longer applied. Hence, in ordinary essays, where an alkaline salt is used, little or no regulus of iron is obtained. Now, glass acts upon and dissolves earths and stones; but not, or very little, iron: consequently glass is the best flux for such essays, and experience confirms this assertion. If the ore contains but little iron, we may also add to the glass some borax; but borax cannot be employed singly, because it very soon fuses, and separates from the ore before the metal is revived. Quicklime is added, not only to absorb the sulphur and arsenic remaining in the ore, but also because it dissolves and vitrifies the stony and earthy matters of iron ores, which are generally argillaceous. For which reason, in the large operations for smelting iron ore, quicklime, and even in certain cases gypsum, are commonly added to facilitate the fusion.

" The reduction of iron-ore, and even the fusion of iron, requires a violent and long-continued heat: therefore, in this operation, we must not employ an inflammable substance, as pitch, that is soon consumed, but charcoal pulverised, which in close vessels is not sensibly wasted. Too much charcoal must not be added, else it will prevent the action of the glass upon the earthy matter of the ore, and consequently the separation of the metallic part. Experiments have taught me, that one part of charcoal-dust to eight parts of oar was the best proportion.

" When iron is surrounded by charcoal, it is not decomposed or destroyed; hence the iron of the ore, which sinks into the hollow made of paste of charcoal-dust and clay, remains there unhurt. The clay is added in this paste to render it more compact, and to keep the fluid iron collected together.

" The air is directed betwixt the crucibles; because if it was thrown directly upon them, they would scarcely be able to resist the heat. The space betwixt the air-pipe and the crucibles ought to be constantly filled with charcoal, to prevent the cold air from touching the crucibles. Ductile and malleable iron is seldom obtained in this first operation. The sulphur and arsenic, and frequently also an earthy matter adhering to the iron, prevent these qualities."

Effaying of Ores of Mercury.

Sect. VIII. *Ores of Mercury.*

§ 1. Mercury is fometimes found pure, fluid, and in its proper metallic ftate, only mixed with earths and ftones. Such are the ores of mercury found near Montpelier, in Tufcany, and in other places.

But the largeft quantity of the mercury found in the earth is mineralifed by fulphur, and confequently is in the form of cinnabar.

Mercury is never mineralifed by arfenic. The richeft mine of mercury is that of Almaden, in Spain.

Linnæus and Cronftedt mention a fingular ore, in which the mercury is *mineralifed by fulphur and by copper*. It is faid to be of a blackifh-grey colour, of a glaffy texture, and brittle. When the mercury and fulphur are expelled by fire, the copper is difcovered by giving an opake red colour to glafs of borax, which, by continuance and increafe of heat, becomes green and tranfparent.

§ 2. Cramer directs, that *ores of mercury fhould be effayed* by the following proceffes:

PROCESS I.

To feparate mercury out of an unfulphureous ore by diftillation.

"Take a lump of the pulverifed ore, one common pound, which muft ftand for one centner: put it into a glafs retort perfectly clean, well loricated, or coated up to half the length of its neck: this muft be very long, and turned backwards with fuch a declivity, that a glafs recipient may be perpendicularly applied to it: but you muft choofe a retort fmall enough, that the belly of it may be filled hardly two-thirds with the ore: this retort muft be placed fo, that nothing of the fluid adherent to the neck of it may fall into the cavity of the belly, but that the whole may run forward into the recipient. Finally, have a fmall recipient full of cold water: let it be perpendicularly fituated, and receive the neck of the retort in fuch manner that the extremity of it be hardly one half-inch immerfed into the water.

"Let the retort be furrounded with hot burning coals placed at fome diftance in form of a circle, left the veffel fhould burft by too fudden a heat: then by degrees bring the burning coals nearer and nearer, and at laft furround the whole retort with them and with frefh charcoal, that it may grow flightly red-hot; this fire having been continued for an hour let the retort cool of itfelf; then ftrike the neck of it gently, that the large drops which are always adherent to it may fall into the recipient: let the recipient be taken away, and the water feparated from the mercury by filtration, and let the mercury be weighed. This operation may be more conveniently performed in a fand-bath; in which cafe the pot containing the fand muft be middling red-hot, and the retort be able to touch the bottom of it immediately; nor is it then neceffary that the retort be loricated."

PROCESS II.

To revive mercury from a fulphureous cinnabar-ore.

"Beat your ore extremely fine, and mix it exactly with an equal portion of iron-filings, not rufty; proceed to diftil it with the fame apparatus as in the former procefs, but urge it with the ftrongeft fire that can be made.

Ores of Antimony.

"Cinnabar may be feparated from ftones by fublimation thus: Beat it to a fine powder, and put it into a fmall narrow glafs or earthen cucurbit, the belly of which it muft not fill more than one-third part: ftop the orifice at top; this muft be very narrow, to hinder the free action of the air. Put this fmall cucurbit in an earthen pot above too inches wide in diameter, and gather fand around this pot about as high as the pulverifed ore rifes in the cucurbit. Then put it upon burning coals in fuch manner that the bottom of the pot may be middling red-hot. Thus will your cinnabar afcend and form a folid ponderous ring, which muft be got out by breaking the veffel."

Sect. IX. *Ore of the Regulus of Antimony.*

Native regulus of antimony was firft obferved by Mr Swab, in Sweden, in the mine of Salberg, and defcribed by him in the memoirs of the Swedifh Academy in 1749 Mr Wallerius mentions it in his Mineralogy.

Regulus of antimony is generally united with fulphur, with which it forms antimony, which ought to be confidered as a true ore of the regulus of antimony.

Another ore of regulus of antimony is alfo known, of a red colour, in which the regulus is mineralifed both by arfenic and by fulphur. This ore refembles fome iron ores, and fome kinds of blend. It is diftinguifhed by its great fufibility, which is fuch, that it may be eafily melted by the flame of a candle.

The *native regulus* of antimony, by Von Swab, is faid by that author to have differed from the regulus of antimony obtained from ores, in thefe two properties, that it was capable of being eafily amalgamated with mercury, and that its calx fhot into cryftals during the cooling

Befides the ores of regulus of antimony enumerated above, this femimetal is alfo found in ores of other metallic fubftances, as in the *plumofe filver-ore*, and in the *ftibiated lead-ore*.

§ 2. The *ores of antimony may be effayed* by the following proceffes defcribed by Mr Cramer.

PROCESS I

To obtain antimony from its ore.

"Choose a melting crucible, or an earthen pot not glazed, that may contain fome common pounds of the ore of antimony, broken into fmall bits. Bore at the bottom of the crucible fome fmall holes, two lines in diameter. Let the bottom of the veffel be received by the orifice of a fmaller one, upon which it muft be put; and when the ore is put into it, let it be covered with a tile, and all the joints be ftopped with lute.

"Put thefe veffels upon the pavement of a hearth, and put ftones all around them at the diftance of fix inches. Fill this intermediate fpace with afhes, fo high that the inferior pot be covered to the upper brim. Then put frefh and burning coals upon it, and with a pair of hand-bellows excite the fire, till the

Essaying the upper vessels grow red hot: take off the fire a quarter of an hour after; and when the vessels are grown cold, open them. You will find that the melted antimony has run through the holes made at the bottom of the upper vessel into the inferior one, where it is collected."

Ores of Antimony

PROCESS II.

To roast crude antimony, or its ore, with or without addition.

"CHOOSE an earthen, flat, low dish, not glazed; and if it cannot bear being made middling red-hot, cover it over with a coat of lute without. Spread it thinly over with crude antimony, or with its ore, beaten to a pretty coarse powder, not exceeding a few ounces at once. Put the dish upon a fire-pan, having a few burning coals in it: increase the fire till it begins to smoke a little. Meanwhile you must incessantly move the powder with a piece of new tobacco-pipe; for this causes the sulphur to evaporate the sooner. If you increase the fire a little too soon, the powder immediately gathers into large clots, or even begins to melt. When this happens, take it immediately off the fire before it melts entirely. Then pulverise it again, and finally make a gentle fire under it. Your black shining powder will assume an ash colour almost like that of earth, and become more refractory in the fire; wherefore you may then increase the fire till your powder grows middling red-hot, and let it last till it ceases to smoke. If you add to your crude antimony pulverised, half or an equal quantity of charcoal-dust, and perform the rest as above, the roasting will be done more conveniently: for it does not gather so easily into clots, and melts with much greater difficulty. When part of the sulphur is evaporated, add some fat to it at several times. Thus you will sooner finish the operation, and the remaining calx will not be burnt to excess. However, if it be thus exposed to too violent and long-lasting a fire, a great quantity of it evaporates; nor does it cease entirely to smoke in a great fire. And it will be enough, if, growing middling red-hot, it does no longer emit the unpleasant smell of the acid of sulphur."

PROCESS III.

To reduce a calx of antimony into a semimetallic regulus.

"MIX some calx of antimony with a quarter part of the black flux, and put it into the crucible. Cover the vessel with a tile; make the fire as quickly as the vessel can bear it, but not greater than is necessary to melt the flux. When the whole has been well in fusion for half a quarter of an hour (which may be tried with a tobacco-pipe, taking off the tile), pour it into the melting cone, which must be warm and done over with tallow. Then immediately strike the cone several times. You will find, when the cone is inverted, a regulus, above which is a saline scoria."

The methods of *calcining antimony by means of nitre*, are described under CHEMISTRY, n 1252—1265; and those of obtaining a *regulus of antimony* without a previous calcination or roasting, by throwing a mixture of powdered antimony, tartar, and nitre, into a red-hot crucible, and by fusing this mixture, and of obtaining a *martial regulus of antimony*, are described at the article REGULUS.

Ores of Bismuth.

SECT. X. *Ores of Bismuth.*

§ 1. BISMUTH is found *native*, resembling the regulus of bismuth.

An *ochre* of bismuth, of a whitish yellow colour, is mentioned by Cronstedt; and is different from the ore improperly called *flowers of bismuth*, which is a calx of cobalt.

Bismuth is mineralised, 1. By *sulphur*. This ore has the appearance of galena. 2. With *sulphurated iron*. Bismuth is found also in cobalts, and in some ores of silver.

§ 2. *Ores of bismuth* may be *essayed* by the following process.

"Bismuth ore may be melted with the same apparatus as was directed for the fusion of crude antimony out of its ore. Or you may beat your ore to a very fine powder, with the black flux, sandiver, and common salt, in a close vessel, like the ore of lead or of tin, and melt it in a middling fire, having a draught of air. But as this semimetal is destructible and volatile, you must as quick as possible apply it to that degree of fire which the flux requires to be melted; and so soon as it is well melted, the vessel must be taken out of the fire; and when it is grown quite cold and broken, you will find your regulus."

Mr Gellert directs that ores of bismuth should be essayed by fusing a quintal of pulverised ore with half a quintal of calcined borax and half a quintal of pulverised glass, in order to vitrify the adherent earths and stones which envelope the bismuth. But probably the heat requisite for this vitrification would volatilise part of the bismuth.

If the ore be of the kinds above described, mineralised by sulphur, or by sulphur and iron, a previous roasting would be expedient, which may be performed in the same manner as is directed for the roasting of antimony.

SECT. XI. *Ores of the Regulus of Cobalt.*

COBALT is a grey-coloured mineral, with more or less of a metallic appearance. Its grain is close; it is compact and heavy, and frequently covered with an efflorescence of peach-coloured flowers. Of this several kinds are known †. All the true cobalts contain the semimetal called *regulus* of cobalt, the calx of which becomes blue by vitrification. This regulus is mineralised in cobalt by sulphur, and especially by a large quantity of arsenic. Some cobalts also contain bismuth and silver.

† See *Cobalt*.

Authors have given the name of *cobalt* to many minerals, although they do not contain the semimetal above mentioned, but only because they externally resemble the ore of the regulus of cobalt. But these minerals can only be considered as false cobalts. They are distinguishable from true cobalt by trying whether they can yield the blue glass called *smalt*, and the sympathetic ink. The red efflorescence is also a mark by which true cobalt is distinguishable from the

5 false:

Ores of Cobalt.

false: but this efflorescence only happens when the ore has been exposed to a moist air.

The principal mines of cobalt are in Saxony, where they are dug for the sake of obtaining zaffre, azure-blue or smalt, and arsenic. Very fine cobalt is also found in the Pyrenean mountains. It has been likewise found in Cornwall and Scotland. And that it is in the eastern parts of Asia, appears from the blue colouring on old oriental porcelain: but probably the mines discovered in these countries are nearly exhausted, as considerable quantities of zaffre and smalt are exported from Europe to China.

Cobalt is heavier than most other ores, from the large quantity of arsenic it contains; and in this respect it resembles the ore of tin.

Besides the grey or ash-coloured cobalt above described, which is the most frequent, other cobalts are found of various colours and textures, mixed with various substances. Wallerius enumerates six species of cobalts. 1. The *ash-coloured ore*, which is regulus of cobalt mineralised by arsenic, consisting of shining leaden-coloured grains. Some ores of this kind are compact resembling steel, and others are of a loose texture and friable. 2. The *specular ore* is black, shining like a mirror, and laminated. This species is very rare; and is supposed by Wallerius to be a foliated spar, or selenites mixed with cobalt. 3. The *vitreous* or *slag-like ore*, is of a bluish, shining colour, compact, or spongy. 4. *Crystallized ore*, is a grey, deep-coloured cobalt, consisting of clusters of cubical, pyramidal, prismatic crystals. 5. *Flowers of cobalt*, red, yellow, or violet. These flowers seem to be formed from some of the above-described compact ores, decomposed by exposure to moist air. This decomposition is similar to that which happens to ferruginous and cupreous pyrites. 6. The *earthy cobalt* is of a greenish white, or of a yellow colour, and of a soft and friable texture. This species seems to be an ochre of cobalt; and is formed perhaps from the flowers of cobalt further decomposed, in the same manner as a martial ochre is formed from the saline efflorescence of decomposing pyrites, when this efflorescence is further decomposed by exposure to moist air; by which the vitriolic acid contained in it is expelled, and the efflorescence is changed from a saline state to that of an ochre or calx.

Besides these proper ores, cobalt is also found in a blue clay along with native silver, in ores of bismuth, and in the mineral called *kupfernickel*. See Nickel.

The *essay* of cobalt is described at the article Regulus *of Cobalt*.

Sect. XII. *Ores of Zinc.*

§ 1. The proper ore of zinc is a substance which has rather an earthy or stony than metallic appearance, and is called *calamy*, *calamine*, or *lapis calaminaris*. This stone, although metallic, is but moderately heavy, and has not the brilliancy of most other ores. Its colour is yellow, and like that of rust. It is also less dense than other metallic minerals. It seems to be an ore naturally decomposed. The calamine is not worked directly to obtain zinc from it, because this would only succeed in close vessels, and consequently with small quantities, according to Mr Margraaf's process. But it is successfully employed for the conversion of copper into brass by cementation, by which the existence of zinc in that stone is sufficiently proved.

Ores of Zinc.

Mr Wallerius enumerates also amongst the ores of zinc a very compounded mineral, consisting of zinc, sulphur, iron, and arsenic. This mineral, called *blend*, resembles externally the ore of lead, and hence has been called *false galena*. These blends have different forms and colours; but are chiefly red, like the red ore of antimony.

Zinc is obtained from certain minerals in the East Indies, of which we know little.

Calciform ores of zinc, according to Cronstedt, are pure or mixed. The pure are indurated, and sometimes crystallised, resembling lead-spar. The mixed ore contains also some calx of iron. This is *calamine*. It is whitish, yellowish, reddish, or brown.

Zinc is *mineralised*, 1. By *sulphurated iron*. *Ore of zinc.* Wallerius says, lead is sometimes contained in this ore. It is white, blue, or brown. 2. By *sulphur, arsenic, and iron*. *Blend*, or *pseudo-galena*, or *false-galena*, or *black-jack*. These are of various colours, white, yellowish, brown, reddish, greenish, black. They consist of scales, or are tessellated Mr Cronstedt thinks, that in blends the zinc is mineralised in the state of a calx, and in the ore of zinc in its metallic state

§ 2. Although the minerals above enumerated have been known, from their property of converting copper into brass, to be ores of zinc, yet the method of essaying them so as to obtain the contained zinc was not known, or at least not published, before Mr Margraaf's Memoir of the Berlin Academy for the year 1746, upon that subject. That very able chemist has shown, that zinc may be obtained from its ores, from the flowers, or from any other calx of zinc, by treating these with charcoal-dust, in close vessels, to prevent the combustion of the zinc, which happens immediately upon its reduction when exposed to air. For this purpose, he put a quantity of finely powdered calamine, or roasted blend, or other calx of zinc, well mixed with an eighth part of charcoal-dust, into a strong, luted earthen retort, to which he fitted a receiver. Having placed his retort in a furnace and raised the fire, he applied a violent heat during two hours. When the vessels were cold and broken, he found the zinc in its metallic form adhering to the neck of the retort.

The chief difficulty in this operation is to get an earthen retort sufficiently compact to retain the vapour of the zinc (for it easily pervades the Hessian crucibles, Stourbridge melting-pots, and similar vessels, as may be seen from the quantity of flowers which appear upon their outer surface, when zinc or its calxes and any inflammable matter have been exposed to heat within these vessels), and at the same time sufficiently strong to resist the violent fire which Mr Margraaf requires.

A pretty exact essay of an ore of zinc may be made in the following manner:

Mix a quantity of pulverised roasted ore or calx of zinc with

Ores of Arsenic. with an eighth part of charcoal-duſt. Put this mixture into a crucible capable of containing thrice the quantity. Diffuſe equally amongſt this mixture a quantity of ſmall grains or thin plates of copper equal to that of the calamine or ore employed, and upon the whole lay another equal quantity of grains or plates of copper; and laſtly, cover this latter portion of copper with charcoal-duſt. Lute a lid upon the crucible, and apply a red heat during an hour or two. The copper or part of it will unite with the vapour of the zinc, and be thereby converted into braſs. By comparing the weight of all the metal after the operation with the weight of the copper employed, the weight acquired, and conſequently the quantity of zinc united with the copper, will be known. The copper which has not been converted into braſs, or more copper with freſh charcoal-duſt, may be again added in the ſame manner to the remaining ore, and the operation repeated with a heat ſomewhat more intenſe, that any zinc remaining in the ore may be thus extracted. A curious circumſtance is, that a much greater heat is required to obtain zinc from its ore by diſtillation, than in the operation now deſcribed of making braſs; in which the ſeparation of the zinc from its ore ſeems to be facilitated by its diſpoſition to unite with copper.

Sect. XIII. *Ores of Arſenic.*

§ 1. The minerals which contain the largeſt quantity of arſenic are cobalts and white pyrites; although it is alſo contained in other ores, it being one of the mineraliſing ſubſtances. But as cobalt muſt be roaſted to obtain the ſulphur it contains, the arſenic alſo which riſes during this torrefaction is collected, as we ſhall ſee in Part III. (Smelting of Ores), and the particular articles of each of the metallic ſubſtances mentioned in this article.

I. Regulus of arſenic is found native. It is of a leaden colour; it burns with a ſmall flame; and is diſſipated, leaving generally a very ſmall quantity of calx of biſmuth, or of calx of cobalt, and a very little ſilver. When it is of a ſolid and teſtaceous texture, it has been improperly called *teſtaceous cobalt*, in German *ſcherbencobalt*. II. Calx of arſenic is found in form of powder; native flowers of arſenic, or of indurated ſemitranſparent cryſtals; native cryſtalline arſenic. III. Calx of arſenic is mixed, 1. With ſulphur; when yellow, it is called *orpiment*; when red, it is called *native realgar*: the difference of colour depends on the proportion of the two component parts. 2. With calx of tin; tin-grains. 3. With ſulphur and ſilver, in the red ſilver ore. 4. With calx of lead, in the lead-ſpar. 5. With calx of cobalt, in the efflorеſcence of cobalt. IV. Arſenic is mineraliſed, 1. With ſulphurated iron; arſenical pyrites. 2. With iron only; white pyrites, or miſpickle. 3. With cobalt, in almoſt all cobalt-ores. 4. With ſilver. 5. With copper. 6. With antimony.

§ 2. Arſenic may be ſeparated from its ore or earthy matter with which it happens to be mixed, by ſublimation, according to the following proceſs by Mr Cramer.

"Do every thing as was ſaid about mercury, or ſulphur; but let the veſſel which is put into the fire with the ore in it be of earth or ſtone, and the recipient be of glaſs, and of a middling capacity. Nor is it neceſſary that this ſhould be filled with water, ſo it be but well luted. The fire muſt likewiſe be ſtronger, and continued longer than for the extracting of ſulphur. Nevertheleſs, every kind of arſenic cannot be extracted in a confined fire: for it adheres to the matrix more ſtrongly than ſulphur and mercury. You will find in the part of the veſſel which is more remote from the fire, pulverulent and ſubtle flowers of arſenic; but there will adhere to the poſterior of the neck of the retort ſmall ſolid maſſes, ſhining like ſmall cryſtals, tranſparent, ſometimes gathered into a ſolid ſublimate, and perfectly white, if the ore of the arſenic was perfectly pure; which nevertheleſs happens very ſeldom. The flowers are moſt commonly thin, and of a grey colour: which proceeds from the phlogiſton mixed with the maſs. They are often of a citron or of a golden colour, which is a ſign that there is in the mixture ſome mineral ſulphur; and if the ſublimate be red or yellow, it is a ſign of much ſulphur.

"As all the arſenic contained in the ore is not expelled in cloſe veſſels, you muſt weigh the reſiduum; then roaſt it in a crucible till it ſmokes no longer, or rather in an earthen flat veſſel not glazed, and in a ſtrong fire to be ſtirred now and then with a poker, and then weigh it when grown cold: you will be able thus to know how much arſenic remained in the cloſe veſſel, unleſs the ore contain biſmuth."

If the arſenic be ſulphurated, it may be purified by triturating it with mercury or with fixed alkali, and by ſubliming the arſenic from the remaining ſulphurated mercury or alkali. The method of obtaining a regulus of arſenic is deſcribed at the article *Regulus of Arſenic*.

PART III.

SMELTING of ORES.

Having ſhown the nature of the principal metallic minerals, and the ſubſtances of which they are compoſed; and alſo explained the proceſſes by which an exact analyſis of theſe compound minerals may be made, and the nature and quantity of the contained metals may be known; in order to complete what relates to this important ſubject, we ſhall deſcribe in this Part the principal operations by which metals, &c. are obtained "in the great," as it is called, or for commercial purpoſes. What we ſhall ſay upon this ſubject will chiefly be extracted from a *Treatiſe on the Smelting of Ores, by Schlutter*, tranſlated from the German into French by M. Hellot; becauſe this, of all the modern works upon that ſubject, appears to be the moſt exact. We ſhall firſt deſcribe the operations upon pyritous matters for the extraction of ſul-

Sulphur Works.

phur, &c. and afterwards the operations by which metallic fubftances are extracted from *ores* properly fo called.

Sect. I. *Extraction of Sulphur from Pyrites and other Minerals.*

In order to obtain fulphur from pyrites, this mineral ought to be expofed to a heat fufficient to fublime the fulphur, or to make it diftil in veffels, which muft be clofe, to prevent its burning.

Sulphur is extracted from pyrites at a work at Schwartzember, in Saxony, in the high country of the mines; and in Bohemia at a place called *Alten-Sattel.*

The furnaces employed for this operation are oblong, like vaulted galleries; and in the vaulted roofs are made feveral openings. Thefe are called *furnaces for extracting fulphur.*

In thefe furnaces are placed earthen-ware tubes, filled with pyrites broken into pieces of the fize of fmall nuts. Each of thefe tubes contains about 50 pounds of pyrites. They are placed in the furnace almoft horizontally, and have fcarcely more than an inch of defcent. The ends, which come out of the furnace five or fix inches, become gradually narrower. Within each tube is fixed a piece of baked earth, in form of a ftar, at the place where it begins to become narrower, in order to prevent the pyrites from falling out, or choaking the mouth of the tube. To each tube is fitted a receiver, covered with a leaden pipe, pierced with a fmall hole to give air to the fulphur. The other end of the tube is exactly clofed. A moderate fire is made with wood, and in eight hours the fulphur of the pyrites is found to have paffed into the receivers.

The refiduum of the pyrites, after the diftillation, is drawn out at the large end, and frefh pyrites is put in its place. From this refiduum, which is called *burnings of fulphur*, vitriol is extracted.

The 11 tubes, into which were put, at three feveral diftillations, in all nine quintals, or 900 pounds of pyrites, yield from 100 to 150 pounds of crude fulphur, which is fo impure as to require to be purified by a fecond diftillation.

This purification of crude fulphur is alfo done in a furnace in form of a gallery, in which five iron cucurbits are arranged on each fide. Thefe cucurbits are placed in a floping direction, and contain about eight quintals and a half of crude fulphur. To them are luted earthen tubes, fo difpofed as to anfwer the purpofe of capitals. The nofe of each of thefe tubes is inferted into an earthen pot called the *fore-runner.* This pot has three openings; namely that which receives the nofe of the tube; a fecond fmaller hole, which is left open to give air; and a third in its lower part, which is ftopped with a wooden peg.

When the preparations are made, a fire is lighted about feven o'clock in the evening, and is a little abated as foon as the fulphur begins to diftil. At three o'clock in the morning, the wooden pegs which ftop the lower holes of the fore-runners are for the firft time drawn out, and the fulphur flows out of each of them into an earthen pot with two handles, placed below for its reception. In this diftillation the fire muft be moderately and prudently conducted; otherwife lefs fulphur would be obtained, and it alfo would be of a grey colour, and not of the fine yellow which it ought to have when pure. The ordinary lofs in the purification of eight quintals of crude fulphur is, at moft, one quintal.

When all the fulphur has flowed out, and has cooled a little in the earthen pots, it is caft into moulds made of beech-tree, which have been previoufly dipt in water and fet to drain. As foon as the fulphur is cooled in the moulds, they are opened, and the cylinders of fulphur are taken out and put up in cafks. Thefe are called *roll-brimftone.*

As fulphur is not only in pyrites, but alfo in moft metallic minerals, it is evident that it might be obtained by works in the great from the different ores which contain much of it, and from which it muft be feparated previoufly to their fufion: but as fulphur is of little value, the trouble of collecting it from ores is feldom taken. Smelters are generally fatisfied with freeing their ores from it, by expofing them to a fire fufficient to expel it. This operation is called *torrefaction*, or *roafting of ores.*

There are, however, ores which contain fo much fulphur, that part of it is actually collected in the ordinary operation of roafting, without much trouble for that purpofe. Such is the ore of Ramelfberg in the country of Hartz.

This ore, which is of lead, containing filver, is partly very pure, and partly mixed with cupreous pyrites and filver; hence it is neceffary to roaft it.

The roafting is performed by laying alternate ftrata of ore and wood upon each other in an open field, taking care to diminifh the fize of the ftrata as they rife higher; fo that the whole mafs fhall be a quadrangular pyramid truncated above, whofe bafe is about 31 feet fquare. Below, fome paffages are left open, to give free entrance to the air; and the fides and top of the pyramid are covered over with fmall ore, to concentrate the heat and make it laft longer. In the centre of this pyramid there is a channel which defcends vertically from the top to the bafe. When all is properly arranged, ladlefuls of red-hot fcoria from the fmelting furnace are thrown down the channel, by which means the fhrubs and wood placed below for that purpofe are kindled, and the fire is from them communicated to all the wood of the pile, which continues burning till the third day. At that time the fulphur of the mineral becomes capable of burning fpontaneoufly, and of continuing the fire after the wood is confumed.

When this roafting has been continued 15 days, the mineral becomes greafy; that is, it is covered over with a kind of varnifh: 20 or 25 holes or hollows are then made in the upper-part of the pile in which the fulphur is collected. From thefe cavities the fulphur is taken out thrice every day, and thrown into water. This fulphur is not pure, but crude; and is therefore fent to the manufacturers of fulphur, to be purified in the manner above related.

As this ore of Ramelfberg is very fulphureous, the firft roafting, which we are now defcribing, lafts three months; and during this time, if much rain has not fallen, or if the operation has not failed by the pile falling

falling down or cracking, by which the air has so much free access, that the sulphur is burnt and consumed, from 10 to 20 quintals of crude sulphur are by this method collected.

The sulphur of this ore, like that of most others, was formerly neglected, till, in the year 1570, a person employed in the mines called *Christopher Sauder*, discovered the method of collecting it, nearly as it is done at present.

Metallic minerals are not the only substances from which sulphur is extracted. This matter is diffused in the earth in such quantities, that the metals cannot absorb it all. Some sulphur is found quite pure, and in different forms, principally in the neighbourhood of volcanoes, in caverns, and in mineral waters. Such are the opaque kind called *virgin-sulphur*; the transparent kind called *sulphur of Quito*; and the native flowers of sulphur, as those of the waters of Aix-la-Chapelle. It is also found mixed with different earths. Here we may observe, that all those kinds of sulphur which are not mineralised by metallic substances, are found near volcanoes, or hot mineral waters, and consequently in places where nature seems to have formed great subterranean laboratories, in which sulphureous minerals may be analysed and decomposed, and the sulphur separated, in the manner in which it is done in small in our works and laboratories. However that be, certainly one of the best and most famous sulphur-mines in the world is that called *Solfatara*. The Abbé Nollet has published, in the Memoirs of the Academy, some interesting observations upon this subject, which we shall here abridge.

Near Puzzoli, in Italy, is that great and famous mine of sulphur and alum called at present *Solfatara*. It is a small oval plain, the greatest diameter of which is about 400 yards, raised about 300 yards above the level of the sea. It is surrounded by high hills and great rocks, which fall to pieces, and whose fragments form very steep banks. Almost all the ground is bare and white, like marle; and is every-where sensibly warmer than the atmosphere in the greatest heat of summer, so that the feet of persons walking there are burnt through their shoes. It is impossible not to observe the sulphur there; for every-where may be perceived by the smell a sulphureous vapour, which rises to a considerable height, and gives reason to believe that there is a subterraneous fire below, from which that vapour proceeds.

Near the middle of this field there is a kind of bason three or four feet lower than the rest of the plain, in which a sound may be perceived when a person walks on it, as if there were under his feet some great cavity, the roof of which was very thin. After that, the lake Agnano is perceived, whose waters seem to boil. These waters are indeed hot, but not so hot as boiling water. This kind of ebullition proceeds from vapours which rise from the bottom of the lake, which being set in motion by the action of subterranean fires, have force enough to raise all that mass of water. Near this lake there are pits, not very deep, from which sulphureous vapours are exhaled. Persons who have the itch come to these pits, and receive the vapours in order to be cured. Finally, there are some deeper excavations, whence a soft stone is procured which yields sulphur. From these cavities vapours exhale, and issue out with noise, and which are nothing else than sulphur subliming through the crevices. This sulphur adheres to the sides of the rocks, where it forms enormous masses: in calm weather, the vapours may be evidently seen to rise 25 or 30 feet from the surface of the earth.

These vapours, attaching themselves to the sides of rocks, form enormous groups of sulphur, which sometimes fall down by their own weight, and render these places of dangerous access.

In entering the Solfatara, there are warehouses and buildings erected for the refining of sulphur.

Under a great shed, or hangar, supported by a wall behind, and open on the other three sides, the sulphur is procured by distillation from the soft stones we mentioned above. These stones are dug from under ground; and those which lie on the surface of the earth are neglected. These last are, however, covered with a sulphur ready formed, and of a yellow colour: but the workmen say they have lost their strength, and that the sulphur obtained from them is not of so good a quality as the sulphur obtained from the stones which are dug out of the ground.

These last mentioned are broken into lumps, and put into pots of earthen ware, containing each about 20 pints Paris measure. The mouths of these pots are as wide as their bottoms; but their bellies, or middle parts, are wider. They are covered with a lid of the same earth, well luted, and are arranged in two parallel lines along two brick walls, which form the two sides of a furnace. The pots are placed within these walls; so that the centre of each pot is in the centre of the thickness of the wall, and that one end of the pots overhangs the wall within, while the other end overhangs the wall without. In each furnace ten of these pots are placed; that is, five in each of the two walls which form the two sides of the furnace." Betwixt these walls there is a space of 15 or 18 inches; which space is covered by a vault resting on the two walls. The whole forms a furnace seven feet long, two feet and a half high, open at one end, and shut at the other, excepting a small chimney through which the smoke passes.

Each of these pots has a mouth in its upper part without the furnace, in order to admit a tube of 18 lines in diameter and a foot in length, which communicates with another pot of the same size placed without the building, and pierced with a round hole in its base of 15 or 18 lines diameter. Lastly, to each of these last-mentioned pots there is a wooden tub placed below, in a bench made for that purpose.

Four or five of these furnaces are built under one hangar, or shed. Fires are kindled in each of them at the same time; and they are thrown down after each distillation, either that the pots may be renewed, or that the residuums may be more easily taken out.

The fire being kindled in the furnace, heats the first pots containing the sulphureous stones. The sulphur rises in fumes into the upper part of the pot, whence it passes through the pipe of communication into the external vessel. There the vapours are condensed, become liquid, and flow through the hole below into the tub, from which the sulphur is easily turned out, because the form of the vessel is that of a truncated cone

Smelting of Ores in general.

whose narrower end is placed below, and because the hoops of the tub are so fastened that they may be occasionally loosened. The mass of sulphur is then carried to the buildings mentioned before, where it is remelted for its purification, and cast into rolls, such as we receive it.

Extraction of VITRIOL *from pyrites.* See CHEMISTRY.

Extraction of ALUM *from pyritous substances and from aluminous earths.* See CHEMISTRY.

SECT II. *Smelting of Ores in general.*

§ 1 As ores consist of metallic matters combined with sulphur and arsenic, and are besides intermixed with earthy and stony substances of all kinds, the intention of all the operations upon these compound bodies is to separate these different substances from each other. This is effected by several operations founded on the known properties of those substances. We now proceed to give a general idea of these several operations.

First of all, the ore is to be separated from the earths and stones accidentally adherent to it; and when these foreign substances are in large masses, and are not very intimately mixed in small particles with the ore, this separation may be accomplished by mechanical means. This ought always to be the first operation, unless the adherent substance be capable of serving as a flux to the ore. If the unmetallic earths be intimately mixed with the ore, this must necessarily be broken and divided into small particles. This operation is performed by a machine which moves pestles, called *bocards* or *stampers*. After this operation, when the parts of the mineral are specifically heavier than those of the unmetallic earth or stone, these latter may be separated from the ore by washing in canals through which water flows. With regard to this washing of ores, it is necessary to observe, that it cannot succeed but when the ore is sensibly heavier than the foreign matters. But the contrary happens frequently, as well because quartz and spar are naturally very ponderous, as because the metallic matter is proportionally so much lighter as it is combined with more sulphur

When an ore happens to be of this kind, it is necessary to begin by roasting it, in order to deprive it of the greatest part of its sulphur.

It happens frequently that the pyritous matters accompanying the ore are so hard that they can scarcely be pounded. In this case it is necessary to roast it entirely, or partly, and to throw it red-hot into cold-water; by which the stones are split, and rendered much more capable of being pulverised

Thus it happens very frequently, that roasting is the first operation to which an ore is exposed.

When the substance of the ore is very fusible, this first operation may be dispensed with, and the matter may be immediately fused without any previous roasting, or at least with a very slight one. For, to effect this fusion, it is necessary that it retain a great quantity of its sulphur, which, with the other fluxes added, serves to destroy or convert into scoria a considerable part of the stony matter of the mineral, and to reduce the rest into a brittle substance, which is called the *matt of lead* or of *copper*, or other metal contained in the ore. This matt is therefore an intermediate matter betwixt the mineral and the metal; for the metal is there concentrated, and mixed with less useless matter than it was in the ore. But as this matt is always sulphureous, the metal which it contains cannot have its metallic properties. Therefore it must be roasted several times to evaporate the sulphur, before it is remelted, when the pure metal is required. This fusion of an ore not roasted, or but slightly roasted, is called *crude fusion*.

We may here observe upon the subject of washing and roasting of ores, that as arsenic is heavier than sulphur, and has nearly the weight of metals, the ores in which it prevails are generally very heavy, and consequently are susceptible of being washed, which is a great advantage. But on the other side, as arsenic is capable of volatilising, scorifying, and destroying many metals, these ores have disadvantages in the roasting and fusion, in both which considerable loss is caused by the arsenic. Some ores contain, besides arsenic, other volatile semimetals, such as antimony and zinc. These are almost untractable, and are therefore neglected. They are called *mineræ rapaces*, "rapacious ores."

When the metal has been freed as much as is possible from foreign matters by these preliminary operations, it is to be completely purified by fusions more or less frequently repeated; in which proper additions are made, either to absorb the rest of the sulphur and arsenic, or to complete the vitrification or scorification of the unmetallic stones and earth.

Lastly, as ores frequently contain several different metals, these are to be separated from each other by processes suited to the properties of these metals, of which we shall speak more particularly as we proceed in our examination of the ores of each metal.

§ 2. To facilitate the extraction of metallic substances from the ores and minerals containing them, some operations previous to the fusion or smelting of these ores and minerals are generally necessary. These operations consist of, 1. The *separation* of the ores and metallic matters from the adhering unmetallic earths and stones, by hammers and other mechanical instruments, and by washing with water. 2. Their *division* or reduction into smaller parts by contusion and trituration, that by another washing with water they may be more perfectly cleansed from extraneous matters, and rendered fitter for the subsequent operations, calcination or roasting, and fusion. 3. *Roasting* or *calcination*; the uses of which operation are, to expel the volatile, useless, or noxious substances, as water, vitriolic acid, sulphur, and arsenic; to render the ore more friable, and fitter for the subsequent contusion and fusion; and, lastly, to calcine and destroy the viler metals, for instance the iron of copper-ores, by means of the fire, and of the sulphur and arsenic. Stones, as quartz and flints, containing metallic veins or particles, are frequently made red-hot, and then extinguished in cold water, that they may be rendered sufficiently friable and pulverable, to allow the separation of the metallic particles.

Roasting is unnecessary for native metals; for some of the richer gold and silver ores; for some lead-ores, the

Roasting of Ores.

the sulphur of which may be separated during the fusion; and for many calciform ores, as these do not generally contain any sulphur and arsenic.

In the roasting of ores, the following attentions must be given, 1. To reduce the mineral previously into small lumps, that the surface may be increased; but they must not be so small, nor placed so compactly, as to prevent the passage of the air and flame. 2. The larger pieces must be placed at the bottom of the pile, where the greatest heat is. 3. The heat must be gradually applied, that the sulphur may not be melted, which would greatly retard its expulsion; and that the spars, fluors, and stones, intermixed with the ore, may not crack, fly, and be dispersed. 4. The ores not thoroughly roasted by one operation must be exposed to a second. 5. The fire may be increased towards the end, that the noxious matters more strongly adhering may be expelled. 6. Fuel which yields much flame, as wood and fossil coals free from sulphur, is said to be preferable to charcoal or coaks. Sometimes cold water is thrown on the calcined ore at the end of the operation, while the ore is yet hot, to render it more friable.

No general rule can be given concerning the duration or degree of the fire, these being very various according to the difference of the ores. A roasting during a few hours or days is sufficient for many ores; while some, such as the ore of Rammelsberg, require that it should be continued during several months.

Schlutter enumerates five methods of roasting ores. 1. By constructing a pile of ores and fuel placed in alternate strata, in the open air, without any furnace. 2. By confining such a pile within walls, but without a roof. 3. By placing the pile under a roof, without lateral walls. 4. By placing the pile in a furnace consisting of walls and a roof. 5. By roasting the ore in a reverberatory furnace, in which it must be continually stirred with an iron rod.

Several kinds of fusions of ores may be distinguished. 1. When a sulphureous ore is mixed with much earthy matter, from which it cannot be easily separated by mechanical operations, it is frequently melted, in order to disengage it from these earthy matters, and to concentrate its metallic contents. By this fusion, some of the sulphur is dissipated, and the ore is reduced to a state intermediate betwixt that of ore and of metal. It is then called a *matt (lapis sulphureo-metallicus)*; and is to be afterwards treated like a pure ore by the second kind of fusion, which is properly the smelting, or extraction of the metal by fusion. 2. By this fusion or smelting, the metal is extracted from the ore previously prepared by the above operations, if these be necessary. The ores of some very fusible metals, as of bismuth, may be smelted by applying a heat sufficient only to melt the metals, which are thereby separated from the adhering extraneous matters. This separation of metals by fusion, without the vitrification of extraneous matters, may be called *eliquation*. Generally, a complete fusion of the ore and vitrification of the earthy matters are necessary for the perfect separation of the contained metals. By this method, metals are obtained from their ores, sometimes pure, and sometimes mixed with other metallic substances, from which they must be afterwards separated; as we shall see when we treat of the extraction of particular metals. To procure this separation of metals from ores, these must be so thinly liquefied, that the small metallic particles may disengage themselves from the scoria; but it must not be so thin as to allow the metal to precipitate before it be perfectly disengaged from any adhering extraneous matter, or to pervade and destroy the containing vessels and furnace. Some ores are sufficiently fusible; but others require certain additions called *fluxes*, to promote their fusion and the vitrification of their unmetallic parts; and also to render the scoria sufficiently thin to allow the separation of the metallic particles.

Fusion of Ores.

Different fluxes are suitable to different ores, according to the quality of the ore, and of the matrix, or stone adherent to it.

The matrixes of two different ores of the same metal frequently serve as fluxes to each other; as, for instance, an argillaceous matrix with one that is calcareous; these two earths being disposed to vitrification when mixed, though each of them is singly unfusible. For this reason, two or more different ores to be smelted are frequently mixed together.

The ores also of different metals require different fluxes. Thus calcareous earth is found to be best suited to iron-ores, and spars and scoria to fusible ores of copper.

The fluxes most frequently employed in the smelting of ores are, calcareous earths, fluors or vitreous spars, quartz, and sand, fusible stones, as slates, basaltes, the several kinds of scoria, and pyrites.

Calcareous earth is used to facilitate the fusion of ores of iron, and of some of the poorer ores of copper, and, in general, of ores mixed with argillaceous earths, or with feltspar. This earth has been sometimes added with a view of separating the sulphur, to which it very readily unites: but by this union the sulphur is detained, and a hepar is formed, which readily dissolves iron and other metals, and so firmly adheres to them, that they cannot be separated without more difficulty than they could from the original ore. This addition is therefore not to be made till the sulphur be previously well expelled.

Fluors or *fusible spars* facilitate the fusion of most metallic minerals, and also of calcareous and argillaceous earths, of steatites, asbestus, and some other unfusible stones, but not of silicious earths without a mixture of calcareous earth.

Quartz is sometimes added in the fusion of ferruginous copper ores, the use of which is said chiefly to be, to enable the ore to receive a greater heat, and to give a more perfect vitrification to the ferruginous scoria.

The *fusible stones*, as *slates*, *basaltes*, are so tenacious and thick when fused, that they cannot be considered properly as fluxes, but as matters added to lessen the too great liquidity of some very fusible minerals.

The *scoria* obtained in the fusion of an ore is frequently useful to facilitate the fusion of an ore of the same metal, and sometimes even ores of other metals.

Sulphurated pyrites greatly promote the fusibility of the scoria of metals, from the sulphur it contains. It is chiefly added to difficultly-fusible copper-ores, to form the sulphureous compounds called *matts*, that the ores, Smelting of Ores of Silver.

ores thus brought into fusion may be separated from the adhering earthy matters, and that the ferruginous matter contained in them may be destroyed, during the subsequent calcination and fusion, by means of the sulphur.

As in the ores called *calciform*, the metallic matter exists in a calcined state; and as calcination reduces the metals of mineralised ores (excepting the perfect metals) to that state also; therefore all calciform and calcined ores require the addition of some inflammable substance, to reduce them to a metallic state. In great works, the charcoal or other fuel used to maintain the fire produces also this effect

Metals are sometimes added in the fusion of ores of other more valuable metals, to absorb from these sulphur or arsenic. Thus iron is added to sulphurated, cupreous, and silver ores. Metals are also added in the fusion of ores of other more valuable metals, to unite with and collect the small particles of these dispersed through much earthy matter, and thus to assist their precipitation. With these intentions lead is frequently added to ores and minerals containing gold, silver, or copper.

Ores of metals are also sometimes added to assist the precipitation of more valuable metals. Thus antimony is frequently added to assist the precipitation of gold intermixed with other metallic matters. Thus far of smelting of ores in general.

Sect. III. *Smelting of Ores of Silver.*

§ 1. As silver, even in its proper ores, is always allayed with some other metals from which it is intended to be separated after the silver-ore has been well roasted, it must be mixed with a greater or less quantity of lead previous to its fusion.

Lead has the same effect in fusion of gold and silver as mercury has upon these metals by its natural fluidity; that is to say, it unites with them, and separates them from unmetallic matters, which, being lighter, rise always to the surface. But lead has the further advantage of procuring, by its own vitrification, that of all metallic substances, excepting gold and silver. Hence it follows, that when gold and silver are obtained by means of mercury, they still remain allayed with other metallic substances; whereas when they are obtained by fusion and scorification with lead, they are then pure, and not allayed with any metals but with each other.

In proportion as the lead, which has been united to the gold and silver of the ore, is scorified by the action of the fire, and promotes the scorification of the other metallic matters, it separates the perfect metals, and carries with it all the others to the surface. There it meets the unmetallic substances, which it likewise vitrifies, and which it changes into a perfect scoria, fluid, and such as a scoria ought to be to admit all the perfect metal contained in it to precipitate.

When all heterogeneous matters have been thus disengaged by scorification with lead, the perfect metals, to which some lead still remains united, are to be further purified by the ordinary operation of the cupel.

The common rule for the fusion and scorification of silver-ore with lead, is to add to the ore a quantity of lead so much greater as there is more matter to be scorified, and as these matters are more refractory and of more difficult fusion. Silver ores, or those treated as such, are often rendered refractory by ferruginous earths, pyritous matters, or cobalts, containing always a considerable quantity of an earth which is unmetallic, very subtile, and very refractory, and which renders a considerable augmentation of the quantity of lead necessary.

Smelting Ores of Silver.

The quantity of lead which is commonly added to fusible silver ores, that do not contain lead, is eight times the quantity of the ore. But when the ore is refractory, it is necessary to add twelve times the quantity of lead, and even more; also glass of lead, and fluxes, such as the white and black fluxes; to which however borax and powder of charcoal are preferable, on account of the liver of sulphur formed by these alkaline fluxes.

It is necessary to observe, that saline fluxes are only used in small operations, on account of their dearness. To these are substituted, in the great operations, of which we now treat, sandiver, fusible scoria, and other matters of little value.

The greatest part of silver now employed in commerce is not obtained from the proper ores of silver, which are very scarce; but from lead, and even copper ores, which are more or less rich in silver. To give an idea of the manner of treating these kinds of ores, from which silver is extracted in the great works, we shall briefly describe here, after Schlutter, the smelting of the ore of Ramelsberg, which contains, as we have already said, several different kinds of metals, but particularly lead and silver.

When this mineral has been disengaged from its sulphur as much as possible by three very long roastings, it is melted, in the Lower Hartz in Saxony, in a particular kind of furnace, called a *furnace for smelting upon a hollow or casse*. The masonry of this furnace is composed of large thick slates, capable of sustaining great heat, and cemented together by clay. The interior part of the furnace is three feet and a half long, and two feet broad at the back part, and one foot only in the front. Its height is nine feet eight inches. It has a foundation of masonry in the ground; and in this foundation channels are made for the evaporation of the moisture. These channels are covered over with stones called *covering stones*. The hollow or casse, which is made above these, is formed of bricks, upon which are placed, first, a bed of clay; then a bed of small ore and sifted vitriols; and, lastly, a bed of charcoal powder beat down, called *light brasque*. The anterior wall of the furnace is thinner than the others, and is called the *chemise*. The back wall, which is pierced to give passage to the pipes of two large wooden bellows, is called the *middle wall*. When the furnace is thus prepared, charcoal is thrown into the hollow, or casse; which being kindled, the fire is to be continued during three hours, before the matters to be fused are added. Then these matters are thrown in, which are not the pure ore, but a mixture of several substances, all of which are somewhat profitable. The quantity of these matters is sufficient for one day's work; that is, for a fusion of eighteen hours; and it consists of, 1. Twelve schorbens or measures of well roasted Rammelsberg ore (the schorben is a measure whose contents are two

two feet five inches long, one foot seven inches broad, and a little more than a foot deep: it is equal to 32 quintals of that country, Cologn weight, at 123 pounds each quintal). 2. Six meafures of fcoria produced by the fmelting of the ore of Upper Hartz, which is refractory, and what workmen call *cold.* 3. Two meafures of knobben, which is an impure fcoria containing fome lead and filver, which has been formerly thrown away as ufelefs, and is now collected by women and children. Befides thefe, other matters are added, containing lead and filver, as the tefts employed in refining, the drofs of lead, impure litharge, and any rubbifh containing metal, which was left in the furnace after the foregoing fufion. All thefe matters being mixed together, are thrown into the furnace: and to each meafure of this mixture a meafure of charcoal is added. The fufion is then begun by help of bellows; and as it proceeds, the lead falls through the light brafque or charcoal-bed into the hollow, or caffe, where it is preferved from burning under the powder of charcoal. The fcoria, on the other hand, being lighter and lefs fluid, is fkimmed off from time to time by means of ladles, that it may not prevent the reft of the lead from falling down into the hollow. Thus, while the fufion lafts, frefh matters and frefh charcoal are alternately added, till the whole quantity intended for one fufion, or, as they call it, one *day*, be thrown in.

There are feveral effential things to be remarked in this operation, which is very well contrived. Firft, The mixture of matters from which a little lead and filver is procured, which would otherwife be loft; and which have alfo this advantage, that they retard the fufion of the Ramelfberg ore, which, however well roafted it has been, retains always enough of the fulphur and iron of the pyrites mixed with it, to render it too fufible or too fluid; fo that without the addition of thofe matters nothing would be obtained but a matt. It is even neceffary, notwithftanding thefe additions, not to haften the fufion too much, but to give time for the ore to mix with other matters, elfe it would melt and flow of itfelf before the reft. Secondly, The fufion of the ore through charcoal, which is practifed in moft fmelting-houfes, and for almoft all ores, is an excellent method, the principal advantage of which is the faving of fuel. The action of the burning charcoal directed immediately upon the mineral, at the fame time that it melts it more readily and efficacioufly, alfo fupplies it with the phlogifton neceffary to bring it to a perfect ftate.

From the Ramelfberg ore after its firft roafting a *white vitriol* is obtained and prepared at Goflar, whofe bafis was *zinc:* which proves that this ore contains alfo a certain quantity of this femimetal. As this ore is fmelted in a country where the art is well underftood of extracting every thing which a mineral contains, fo in this fufion *zinc* and *cadmia* are obtained in the following manner: When the furnace is prepared for the fufion, it is neceffary to clofe it up in the fore part before the fufion is begun.

"Firft of all, a gritt-ftone is to be placed, fupported at the height of three inches. This ftone is as long as the furnace is broad, and the height of it is level with the hole where the bellows-pipe enters. It is faftened on each fide of the furnace, externally and internally, with clay. Upon this ftone a kind of receptacle, or, as it is called, the *feat of the zinc*, is made in the following manner: A flat flaty ftone is chofen, as long as the furnace is broad, and eight inches in breadth. This is placed on the gritt-ftone above mentioned, in fuch a manner that it inclines confiderably towards the front of the furnace, and that its bottom touches clofely the gritt-ftone. It is faftened with clay, which is alfo laid upon the feat of the zinc. Upon this feat, which is to receive the zinc, two round pieces of charcoal are placed, and alfo a ftone called the *zinc-ftone*, which is about a foot and an half in length, and clofes one part of the front of the furnace. This ftone alfo is faftened on each of its fides with clay. Clay is likewife put under the ftone betwixt the two pieces of charcoal, which hinder it from touching the feat of the zinc. The under-part of this ftone is but flightly luted, that the workmen may make an opening for the zinc to flow out. Thus is made the feat or receptacle of the zinc to detain this metallic fubftance, which would otherwife fall into the hotteft part of the fire, called by the workmen the *melting-place*, and would be there burnt: whereas it is collected upon this receptacle during the fufion, where it is fheltered from the action of the bellows, and confequently from too great heat.

"When all the matter to be fufed in one day is put into the furnace, the blaft of air is continued till that matter has funk down. When it is half way down the furnace, they draw out the fcoria, that more of the ore and other matters may be expofed to the greateft heat. As foon as the fcoria is coolled and fixed a little, two fhovel-fulls of fmall wet fcoria or fand is thrown clofe to the furnace, and beat down with the fhovel; then the workmen open the feat or receptacle of zinc, and ftrike upon the zinc-ftone to make the femimetal flow out. As foon as the pureft part of it has flowed out, it is fprinkled with water and carried away. Then the workmen feparate entirely the zinc-ftone from the wall of the furnace, and they continue to give it little ftrokes, that the fmall particles of zinc difperfed among the charcoal may fall down. This being done, the ftone is removed; and the zinc is feparated from the charcoal by an iron inftrument, is cleaned, and remelted along with the zinc that flowed out at firft, and is caft into round cakes. The reafon why the zinc is withdrawn before the bellows ceafe to blow, is, that if it was left till the charcoal on the feat or receptacle was confumed, it would be moftly burnt, and little would be obtained. Thus after the zinc is withdrawn, the fufion is finifhed by blowing the bellows till the end."

Thus the zinc is feparated from the ore of Ramelfberg, and is not confounded in the hollow or caffe with the lead and filver, becaufe, being a volatile femimetal, it cannot fupport the activity of the fire without rifing into vapours, which are condenfed in the place leaft hot, that is to fay, upon the ftones exprefsly prepared for that purpofe; and which, being much thinner than the other walls of the furnace, are continually coolled by the external air.

It is alfo in this furnace, and after the fufion of the Ramelfberg ore, that the *cadmia of zinc*, or the *cadmia of furnaces*, is obtained. This ore is compofed of fulphureous and ferruginous pyrites, of true lead-

Smelting of Ores of Silver.

lead-ore containing silver, and a very hard and compact matter of a dark brownish-grey colour, which is probably a *lapis calaminaris*, or an ore of zinc. These several matters of the Ramelsberg ore are not separated from each other, either for the roasting or for the fusion. Thus there is zinc in all the parts of the roasted ore; and much more of it would be obtained, if it was not so easily inflammable. All the zinc which is obtained is preserved from burning by falling, while in fusion, behind the chemise or fore-part of the furnace, which is, as has been said, a kind of schistus or slate, called by the workmen *steel-stone*. But the part of this semimetal which falls in the middle of the furnace, near the middle-wall, or towards the sides, being exposed to the greatest heat of the fire, is there burnt; and its smoke or flowers attaching itself on all sides to the walls of the furnace, undergo there a semifusion, which renders this matter so hard and so thick, that it must be taken away after every fourth fusion, or, at most, after every sixth fusion. That which is found attached to the highest part of the furnace is the best and purest. The rest is altered by a mixture of a portion of lead which it has carried up with it; and which, from its great weight and fixity, has hindered the zinc from rising so high as it would have done alone. Therefore, with this kind of impure cadmia, ductile brass cannot be made.

Almost all the zinc we have, as well as the cadmia of the furnaces, is obtained from the Ramelsberg ore by the process described, and consequently is not the produce of a pure ore of zinc or *lapis calaminaris*, which is never fused for that purpose. Before Mr Margraaf, although it was well known that this ore contained zinc, and that it was employed for the making of brass, a convenient process for extracting zinc from it was not known; because, when treated by fusion with fluxes, like other ores, it does not yield any zinc: which proceeds partly from the refractory quality of the earth contained in the calamine, that cannot be fused without a very violent fire; and also from the volatility and combustibility of the zinc, which for this reason cannot be collected at the bottom of a crucible, as a regulus under a scoria, like most metals.

M. Margraaf has remedied these inconveniences by distilling *lapis calaminaris*, mixed with charcoal, in a retort, to which is joined a receiver containing some water, and consequently in close vessels, where the zinc, by the help of a very strong fire indeed, is sublimed in its metallic form without burning. He also by the same method reduced into zinc the *flowers of zinc*, or *pompholix*, *cadmia of the furnaces*, *tutty*, which is also a kind of cadmia; in a word, all matters capable of producing zinc by combination with phlogiston.—But it is evident that such operations as these are rather fit to supply proofs for chemical theory, than to be put in practice for works in great. M. Margraaf has observed, that the zinc which he obtained by this process was less brittle than what is obtained from the fusion of ores; which may proceed from its greater purity, or from its better combination with phlogiston.

Zinc is obtained, not only in the method used at Goslar above described; but is also extracted in great works, from *lapis caluminaris* and calcined blend, by a distillation similar to that by which M. Margraaf has essayed ores of zinc. The first work of that kind was erected in Sweden by Mr Von Swab, in the year 1738. The ore employed was a kind of blend; this ore, when calcined, powdered, and mixed with charcoal, was put into iron or stone retorts, and the zinc was obtained by distillation. In Bristol a work is established in which zinc is obtained by distillation *by descent*.

Fining of Silver.

After this digression which we have now made concerning the operation in the great by which zinc and cadmia are obtained, and which we could not insert elsewhere, because of the necessary relation it has with the smelting of the Ramelsberg ore, we proceed to the other operations of the same ore; that is to say, to the *finery*, by which the silver is separated from the lead, which are mixed together, forming what is called the *work*.

This operation differs from the *fining of essay*, or *in small*, principally in this circumstance, that in the latter method of fining all the litharge is absorbed into the cupel, whereas in the former method the greatest part of this litharge is withdrawn.

The fining in great of the work of Ramelsberg is performed in a furnace called a *reverberatory furnace*. This furnace is so constructed that the flame of wood burning in a cavity called the *fire-place*, is determined by a current of air (which is introduced through the ash-hole, and which goes out at an opening on one side of that part of the furnace where the work is, that is, where the lead and silver are) to circulate above, and to give the convenient degree of heat, when the fire is properly managed. In this furnace a great cupel, called a *test*, is disposed. This test is made of the ashes of beech-wood, well lixiviated in the usual manner. In some founderies different matters are added, as sand, spar, calcined gypsum, quicklime, clay. When the test is well prepared and dried, all the work is put at once upon the cold test, to the quantity of 64 quintals for one operation. Then the fire is lighted in the fire-place with faggots; but the fusion is not urged too fast, 1. That the test may have time to dry; 2. Because the work of the Ramelsberg ore is allayed by the mixture of several metallic matters, which it is proper to separate from it, otherwise they would spoil the litharge and the lead procured from it. These metallic matters are, copper, iron, zinc, and matt. As these heterogeneous substances are hard and refractory, they do not melt so soon as the work, that is, as the lead and silver; and when the work is melted, they swim upon its surface like a skin, which is to be taken off. These impurities are called the *scum* or the *first-waste*. What remains forms a second scum, which appears when the work is at its greatest degree of heat, but before the litharge begins to form itself. It is a scoria which is to be carefully taken off. It is called the *second waste*.

When the operation is at this point, it is continued by the help of bellows, the wind of which is directed, not upon the wood or fuel, but upon the very surface of the metal, by means of iron-plates put for that purpose before the blast-hole, which are called *papilions*. This blast does not so much increase the intensity of the fire, as it facilitates the combustion of the lead, and throws the litharge that is not imbibed by the test towards a channel, called the *litharge-way*, through which

Various processes for extracting Silver.

which it flows. The litharge becomes fixed out of the furnace: the matter which is found in the middle of the largest pieces, and which amounts to about a half or a third of the whole, is friable, and falls into powder like sand. This is put into barrels containing each five quintals of it; and is called *saleable litharge*, because it is sold in that state. The other part, which remains solid, is called *cold litharge*, and is again melted and reduced into lead. The fusion is called *cold fusion*, and the lead obtained from it *cold lead*, which is good and saleable when the work has been well cleared from the heterogeneous matters mentioned above. The tests and cupels impregnated with litharge are added in the fusion of the ore, as we have already related.

When two-thirds, or nearly that quantity, of the lead are converted into litharge, no more of it is formed. The silver then appears covered with a white skin, which the finers call *lightening*, and the metal *lightened* or *fined silver*.

The silver obtained by this process of fining is not yet altogether pure. It still contains some lead, frequently to the quantity of four drams in each marc, or eight ounces. It is delivered to the workmen, who complete its purification by the ordinary method. This last operation is the refining, and the workmen employed to do it are called *refiners*. A fining of 64 quintals of work, yields from 8 to 10 merks of fined silver, and from 35 to 40 quintals of litharge; that is, from 12 to 18 of saleable litharge, from 22 to 23 of cold litharge, from 20 to 22 quintals of impregnated test, and from 6 to 7 quintals of lead-dross. The operation lasts from 16 to 18 hours.

§ 2. Ores containing silver may be divided into four kinds, 1. Pure, or those which are not much compounded with other metals. 2. Galenical, in which the silver is mixed with much galena, or ore of lead mineralised by sulphur. 3. Pyritous, in which the silver is mixed with the martial pyrites. 4. Cupreous; in which the silver is contained in copper ores. To extract the silver from these several kinds of ores, different operations are necessary.

Native silver is separated from its adhering earths and stones by amalgamation with mercury in the manner directed for the separation of gold; or by fusion with lead, from which it may be afterwards separated by cupellation.

Pure ores seldom require a previous calcination; but when bruised and cleansed from extraneous matters, may be fused directly, and incorporated with a quantity of lead; unless they contain a large proportion of sulphur and arsenic, in which case a calcination may be useful. The lead employed must be in a calcined or vitrified state, which, being mixed with the ore, and gradually reduced by the phlogiston of the charcoal added to it, may be more effectually united with the silver of the ore, than if lead itself had been added, which would too quickly precipitate to the bottom of the containing vessel or furnace. The silver is to be afterwards separated from the lead by cupellation.

Galenical ores, especially those in which pyrites is intermixed, require a calcination, which ought to be performed in an oven, or reverberatory furnace. They are then to be fused together with some inflammable matter, as charcoal, by which the lead is revived, and together with the silver is precipitated.

Pyritous ores must be first melted, so as to form a matt. If the sulphur is not sufficient for this kind of fusion, more sulphurated pyrites may be added. This matt contains, besides silver and sulphur, also various metals, as lead, iron, and sometimes cobalt. The matt must be exposed to repeated calcinations till the sulphur is dissipated. By these calcinations most of the iron is destroyed. The calcined matt is to be fused with litharge, and the silver incorporated with the revived lead; from which, and from the other imperfect metals with which it may be mixed, it must afterwards be separated by cupellation.

The silver contained in cupreous ores may be obtained, either, 1. By separating it from the copper itself, after this has been extracted along with the silver, in the usual manner, from the ore; or, 2. By precipitating it immediately from the other matters of the ore.

1. It may be separated from the copper by two methods. One of these is by adding lead, and scorifying the imperfect metals. By this method much of the copper would be destroyed, and it is therefore not to be used unless the quantity of silver relatively to the copper be considerable. Another method by which silver may be separated from copper is by eliquation; that is, by mixing the mass of copper and silver with a quantity of lead, and applying such a heat as shall be just sufficient to make the lead eliquate from the copper, together with the silver, which being more strongly disposed to unite with the lead than with the copper, is thus incorporated with the former metal, and separated from the latter.

2. Silver may also be extracted from these cupreous ores by precipitation. For this purpose, let the ore, previously bruised and cleansed, be formed into a matt, that the earthy matters may be well separated. Let the matt be then fused with a strong heat; and when the scoria has been removed, and the heat is diminished, add to it some clean galena, litharge, and granulated lead. When the fire has been raised, and the additions well incorporated with the matt, let some cast or filed iron be thrown into the liquid mass, which, being more disposed than lead is to unite with sulphur, will separate and precipitate the latter metal, and along with it the silver or gold contained in the matt. This method was introduced by Scheffer, and is practised at Adelfors in Smoland. In this work the proportion of the several materials is, four quintals of matt, two quintals of black copper containing some lead with the perfect metal, one quintal of galena, one quintal of litharge, a fifth part of a quintal of granulated lead, and an equal quantity of cast iron.

The silver in this, and in all other instances where it is united with lead, is to be afterwards separated from the lead by cupellation; which process is described at the articles *Essay of the Value of Silver*, and Refining.

Sect. IV. *Smelting of Ores of Copper.*

§ 1. The smelting in great of copper ores, and even of several ores of silver and lead, excepting that of Rammelsberg, is performed in furnaces not essentially different

Smelting of Ores of Copper.

ferent from that already defcribed; but in this refpect only, that the fcoria and metal are not drawn out of the furnace, but flow fpontaneoufly, as foon as they are melted, into receiving bafons, where the metal is freed from the fcoria. Thefe furnaces are generally called *pierced furnaces*.

Inftead of a light brafque, or bed of charcoal powder, under which the metal lies hid, the bottom of thefe furnaces is covered with a bafon compofed of heavy brafque, which is a mixture of charcoal-powder and clay. In the front of the furnace, and at the bottom of the chemife, there is a hole, called the *eye*, through which the melted matter flows, and runs along a trench or furrow, called the *trace*, into one or more receiving bafons made of earth, fcoria, fand, &c. There the metal is feparated from the fcoria, by making it flow from thefe bafons into another lateral one. Thefe furnaces are alfo called *crooked furnaces*.

Different names are given to them according to fome difference in their conftruction. For inftance, thofe which have two eyes, and two traces, through which the melted matter flows alternately into two bafons, are called *fpectacle-furnaces*. Their greater or lefs height gives occafion alfo to the diftinction of *high furnaces* and *middle furnaces*.

The high furnaces are of modern invention. They were firft introduced at Mansfeldt in the year 1727; and they are now ufed in almoft all countries where ores are fmelted, as in Saxony, Bohemia, Hungary, &c. Their chief advantage confifts in fimplifying and diminifhing the labour. This advantage is effected by the great height of the furnace, which allows the ore to remain there a long time before it falls down into the hotteft part of the fire and is melted. Confequently, it fuffers fucceffively different degrees of heat; and, before it is melted, it undergoes a roafting which cofts nothing: therefore the high furnaces are chiefly employed for crude fufions; and particularly for the flate-copper ore. Thefe furnaces are above 18 feet high. A too great height is attended with an inconvenience, befides the trouble of fupplying it with ore and fuel, which is, that the charcoal is moftly confumed before it gets down where the greateft heat is required, and is then rendered incapable of maintaining a fire fufficiently intenfe.

All the furnaces which we have mentioned are fupplied with large bellows, moved by the arbor of a wheel, which is turned round by a current of water.

The only kind of furnace for fmelting ores where bellows are not employed, is what is called a *reverberatory furnace*. The Germans call it a *wind furnace*. It is alfo diftinguifhed by the name of *Englifh furnace*, becaufe the invention of it is attributed to an Englifh phyfician of the name of *Wright*, who was well verfed in chemiftry; and becaufe the ufe of it was firft introduced in England about the end of the laft century, where it is much employed, as well as in feveral other countries, as at Konigfberg, in Norway.

The length of thefe furnaces is about 18 feet, comprehending the mafonry: their breadth is 12 feet, and their height nine feet and a half. The hearth is raifed three feet above the level of the foundery: on one fide is the fire-place, under which is an afh-hole hollowed in the earth; on the other fide is a bafon made, which is kept covered with fire when there is occafion: on the anterior fide of this furnace there is a chimney, which receives the flame after it has paffed over the mineral that is laid upon the hearth. This hearth, which is in the interior part of the furnace, is made of a clay capable of fuftaining the fire. The advantage of this furnace is, that bellows are not neceffary; and confequently it may be conftructed where there is no current of water, and wherever the mine happens to be. This furnace has a hole in its front, through which the fcoria is drawn out; and a bafon, as we have faid, on one fide, made with fand, in which are oblong traces for the reception of the matt, and of the black copper, when they flow out of the furnace.

Copper is generally mineralifed, not only by fulphur and arfenic, but alfo by femimetals and pyritous matters, and is frequently mixed with other metals. As this metal has great affinity with fulphur and arfenic, it is almoft impoffible to difengage it from them entirely by roafting: hence, in the fmelting in great, nothing is obtained by the firft operation but a copper matt, which contains all the principles of the ore, excepting the earthy and ftony parts, particularly when the ore is fmelted crude and unroafted. Afterwards this matt muft be again roafted and fufed. The produce of this fecond fufion begins ftill more to refemble copper, but is not malleable. It continues mixed with almoft all the minerals, particularly with the metals. As it is frequently of a black colour, it is always called *black copper*, when it is unmalleable, whatever its colour happens really to be.

As, of all the imperfect metals, copper is moft difficultly burnt and fcorified, it is again remelted feveral times, in order to burn and fcorify the metallic fubftances mixed with it; and this is done till the copper is perfectly pure, which is then called *red* or *refined copper*, and thefe laft fufions are called the *fining* and *refining* of it: red copper contains no metals but gold and filver, if any of thefe happened to be in the ore.

In order to avoid all thefe fufions, it has been propofed to treat in the humid way certain copper ores, particularly thofe which are very pyritous. This method confifts in making blue vitriol from the ore, by roafting and lixiviating it, and in precipitating pure copper from this lixivium, which is called *cement-water*, by means of iron: but it is not much practifed, becaufe it has been obferved, that all the copper contained in the ore was not procured by this means.

As expence is not much regarded in fmall effays and experiments, thefe fufions are much abridged and facilitated by adding at firft faline and glaffy fluxes; and then by refining the black copper with lead in the cupel, as gold and filver are done. In this method of refining, it is to be moft carefully obferved, that the metal be fufed as quickly as poffible, and expofed to no more heat than is neceffary, left it be calcined.

When the black copper contains fome iron, but not a great

Smelting of Ores of Copper.

a great deal, the lead presently separates the iron from it, and makes it rise to the surface of the copper: but if the iron be in too large a proportion, it prevents the lead from uniting with the copper. These two phenomena depend on the same cause, which is, that lead and iron cannot unite.

Frequently copper ores contain also a quantity of silver sufficient to make its extraction by particular processes profitable. It was long before any process could be thought of for this purpose which was not too expensive and troublesome: but at length it is accomplished by the excellent operation called *eliquation*.

The copper from which silver has been separated by eliquation must be refined after this operation, as it is generally black copper from which silver is extracted: but even if it had not been black copper which was employed for this operation, it would require to be refined on account of a little lead it always retains. It is therefore carried to the refiner's furnace, when this operation is performed by help of bellows, the blast of which is thrown upon the surface of the melted metal. As in this refining of copper the precise time when it becomes pure cannot be known, because scoria is always formed on its surface, it is necessary to use an essay-iron, the polished end of which being dipt in melted copper, shows that this metal is pure when the copper adhering to the iron falls off as soon as it is dipt in cold water.

When this mark of the purity of the copper has been observed, its surface ought to be well cleaned; and as soon as it begins to fix, it must be sprinkled with a broom or besom dipped in cold water. The surface of the copper which is then fixing, being suddenly cooled by the water, detaches itself from the rest of the metal, is taken hold of by tongs, and is thrown red-hot into cold water. By again sprinkling water on the mass of copper, it is all of it reduced into plates, which are called *rosettes*, and these plates are what is called *rosette-copper*

§ 2. The copper of pyritous cupreous ores cannot be obtained without several operations, which vary according to the nature of the ores. These operations are chiefly roastings and fusions. By the first fusion a matt is produced, which is afterwards to be roasted; and thus the fusions and roastings are to be alternately applied, till by the last fusion copper is obtained. These methods of treating pyritous copper ores depend on the two following facts: 1. Sulphur is more disposed to unite with iron than with copper. 2. The iron of these ores is destructible by the burning sulphur during the roasting or the fusion of the ores, while the copper is not injured. This fact appears from experiments mentioned by Scheffer and by Wallerius, and from the daily practice of smelting cupreous ores.

From these facts we learn, 1. That sulphur may be employed to separate and destroy iron mixed with copper. 2. That iron may be employed to separate the sulphur from copper, as is sometimes done in the essay of sulphurated copper-ores. 3. That by adjusting the proportion of the iron and sulphur to each other in the smelting of copper-ores, these two substances may be made to destroy each other, and to procure a separation of the copper: and this adjustment may be effected, by adding sulphur or sulphureous pyrites to the copper-ore, when the quantity of sulphur contained in this ore relatively to the iron is too small; or by adding iron when the sulphur predominates; or by roasting, by which the superfluous sulphur may be expelled, and no more left than is sufficient for the destruction of the iron contained in the ore. We shall apply these principles to the following cases.

1. When the quantity of sulphur and of iron in a copper-ore is small, and especially when the iron does not too much abound, a previous roasting will at once calcine the iron, and expel most of the sulphur; so that by one fusion the calcined iron may be scorified, and black copper may be obtained. If the sulphur has not been sufficiently expelled, a second roasting and fusion are requisite; for the whole quantity of sulphur ought not to be expelled during the first roasting: but as much ought to be left as is sufficient for the scorification of the calcined iron; otherwise this might, during the fusion, be again revived and united with the copper.

2. If, in a copper ore, the quantity of iron be too great, relatively to the sulphur, some sulphurated pyrites, especially that kind which contains copper, ought to be added, that a matt may be obtained, and that the iron may be calcined and scorified.

3. When the quantity of sulphur and iron is very great, that is, when the ore is very pyritous and poor, it ought to be first formed into a matt; by which it is separated from the adherent earths and stones, and the bulk is diminished: then by repeated and alternate roastings and fusions, the copper may be obtained.

4. When the quantity of sulphur in an ore is greater than is sufficient for the forming a matt, the superfluous quantity ought to be previously expelled by roasting.

The copper thus at first obtained is never pure, but is generally mixed with sulphur or with iron. It is called *black copper*. This may be refined in furnaces, or on hearths.

In the former method, to the copper when melted a small quantity of lead is added, which unites with the sulphur, and is scorified together with the iron, and floats upon the surface of the melted copper. This purification of copper by means of lead is similar to the refining of silver by cupellation; and is founded on the property of lead, by which it is more disposed to unite with sulphur than copper is; and on a property of copper, by which it is less liable than any other imperfect metal to be scorified by lead. But as copper is also capable of being scorified by lead, this operation must be no longer continued, and no more lead must be employed, than is sufficient for the separation of the sulphur, and for the scorification of the iron.

The copper might also be purified from any remaining sulphur by adding a sufficient quantity of iron to engage the sulphur. Thus Mr Scheffer found, that by adding to sulphurated copper from $\frac{1}{20}$th to $\frac{1}{18}$th of old cast iron, he rendered the copper pure and ductile. See his Dissertation on the Parting of Metals amongst the *Swedish Memoirs* for the year 1752. In this purification, the quantity of iron added ought not to be too little, else all the sulphur will not be separated; and it ought not to be too great, else the superfluous quantity will unite with and injure the purity of the copper. The fusion and scorification, with addition of lead, seems to be the best method for the last purification of copper.

Sect. V. *Smelting*, &c. *of Ores of Iron.*

Notwithstanding the great importance of this subject, and the labours of Reaumur, Swedenborgius, and of some other authors, we have still a very imperfect knowledge of the causes of the differences of the several kinds of ores, of the methods of smelting best adapted to these differences, of the causes of the good and bad qualities of different kinds of iron, and of the means of so meliorating this metal, that we may obtain tough and ductile iron from any of its ores.

Swedenborgius has very industriously and exactly described the different processes now used in most parts of Europe for the smelting of ores of iron, for the forging of that metal, and for the conversion of it into steel: but we do not find that he or any other author have, by experiments and discoveries, contributed much to the illustration or to the improvement of this part of metallurgy, unless, perhaps, we except those of Mr Reaumur, concerning the softening of cast iron by cementation with earthy substances.

The ores of iron are known to vary much in their appearance, in their contents, in their degrees of fusibility, in the methods necessary for the extraction of their contained metal, and in the qualities of the metal when extracted.

Most ores require to be roasted previously to their fusion; some more slightly, and others with a more violent and longer-continued fire. Those which contain much sulphur, arsenic, or vitriolic-acid, require a long-continued and repeated roasting, that the volatile matters may be expelled. Of this kind is the black-iron ore, from which the Swedish iron is said to be obtained.

Some ores require a very slight roasting only, that they may be dried and rendered friable.—Such are the ores called *bog ores*, and others, which being in a calcined state, and containing little sulphureous matter, would, by a farther calcination, be rendered less capable of being reduced to a metallic state.

The roasting of ores of iron is performed by kindling piles, consisting of strata of fuel and of ore placed alternately upon one another, or in furnaces similar to those commonly employed for the calcination of limestone.

Some authors advise the addition of a calcareous earth to sulphureous ores during the roasting, that the sulphur may be absorbed by this earth when converted into quicklime. But we may observe, that the quicklime cannot absorb the sulphur or sulphureous acid, till these be first extricated from the ore, and does therefore only prevent the dissipation of these volatile matters; and, secondly, that the sulphur thus united with the quicklime forms a hepar of sulphur, which will unite with and dissolve the ore during its fusion, and prevent the precipitation of the metal.

The next operation is the *fusion* or *smelting* of the ore. This is generally performed in furnaces or towers, from 20 to 30 feet high, in the bottom of which is a bason for the reception of the fluid metal. When the furnace is sufficiently heated, which must be done at first very gradually, to prevent the cracking of the walls; a quantity of the ore is to be thrown in, from time to time, at the top of the furnace, along with a certain quantity of fuel and of lime-stone, or whatever other flux is employed. When the fuel below is consumed by the fire excited by the wind of the bellows, the ore, together with its proportionable quantity of fuel and of flux, sink gradually down, till they are exposed to the greatest heat in the furnace. There the ore and the flux are fused, the metallic particles are revived by the fuel, are precipitated by means of their weight through the scoria formed of the lighter earthy parts of the flux and of the ore, and unite in the bason at the bottom of the furnace, forming a mass of fluid metal covered by a glassy scoria. When a sufficient quantity of this fluid metal is collected, which is generally twice or thrice in 24 hours, an aperture is made, through which the metal flows into a channel or groove made in a bed of sand; and from thence into smaller lateral or connected channels, or other moulds. There it is cooled, becomes solid, and retains the forms of the channels or moulds into which it flows. The piece of iron formed in the large channel is called a *sow*, and those formed in the smaller channels are called *pigs*. Sometimes the fluid iron is taken out of the furnace by means of ladles, and poured into moulds ready prepared, of sand or of clay, and is thus formed into the various utensils and instruments for which cast iron is a proper material.

The *scoria* must be, from time to time, allowed to flow out, when a considerable quantity of it is formed, through an aperture made in the front of the furnace for that purpose. A sufficient quantity of it must, however, be always left to cover the surface of the melted iron, else the ore which would fall upon it, before the separation of its metallic from its unmetallic parts, would lessen the fluidity and injure the purity of the melted metal. This scoria ought to have a certain degree of fluidity; for if it be too thick, the revived metallic particles will not be able to overcome its tenacity, and collect together into drops, nor be precipitated. Accordingly, a scoria not sufficiently fluid, is always found to contain much metal. If the scoria be too thin, the metallic particles of the ore will be precipitated before they are sufficiently metallised, and separated from the earthy and unmetallic parts. A due degree of fluidity is given to the scoria by applying a proper heat, and by adding fluxes suited to the ore.

Some ores are fusible without addition, and others cannot be smelted without the addition of substances capable of facilitating their fusion.

The *fusible ores* are those which contain sulphur, arsenic, or are mixed with some fusible earth.

The *ores difficultly fusible* are those which contain no mixture of other substance. Such are most of the ores

Manufacturing of Iron.

ores which contain iron in a ftate nearly metallic. As iron itfelf, when purified from all heterogeneous matters, is fcarcely fufible without addition, fo the metal contained in thefe purer kinds of ores cannot be eafily extracted without the addition of fome fufible fubftance. 2. Thofe which are mixed with fome very refractory fubftance. Some of thefe refractory ores contain arfenic; but as this fubftance facilitates the fufion of ores, we may prefume that their refractory quality depends upon a mixture of fome unmetallic earth or other unfufible fubftance. The earth which is mixed with the common calciform ores is in confiderable quantity; and is fometimes calcareous, fometimes filiceous, and fometimes argillaceous.

Perhaps the fufibility of different ores depends greatly on the degree of calcination to which the metal contained in them has been reduced; fince we have reafon to believe, that by a very perfect calcination, fome metals at leaft may be reduced to the ftate of an earth almoft unfufible, and incapable of metallifation; and fince we know, that in every calcination and fubfequent reduction of a given quantity of any imperfect metal, a fenfible part of that quantity is always loft or deftroyed, however carefully thefe operations may have been performed. That fome of thefe ores are already too much calcined, appears from the inftance above-mentioned of the *bog ores*, which are injured by roafting; and even the great height of the common fmelting furnaces, although advantageous to many ores that require much roafting, is faid to be injurious to thofe which are already too much calcined, by expofing them to a further calcination, during their very gradual defcent, before they arrive at the hotteft part of the furnace, where they are fufed.

But as too violent calcination renders fome ores difficultly fufible, fo too flight calcination of other ores injures the purity of the metal, by leaving much of the fulphureous or other volatile matter, which ought to have been expelled.

Various *fubftances are added to affift the fufion of ores difficultly fufible.* Thefe are, 1. *Ores* of a fufible quality, or which, being mixed with others of a different quality, become fufible: accordingly, in the great works for fmelting ores of iron, two or more different kinds of ore are commonly mixed, to facilitate the fufion, and alfo to meliorate the quality of the iron. Thus an ore yielding an iron which is brittle when hot, which quality is called *red-fhort*, and another ore which produces iron brittle when cold, or *cold-fhort*, are often mixed together; not, as fometimes fuppofed, that thefe qualities are mutually deftructive of each other, but that of each of them is diminifhed in the mixed mafs of iron, as much as this mafs is larger than the part of the mafs originally poffeffed of that quality. Thus, if from two fuch ores the mafs of iron obtained confifts of equal parts of cold-fhort and of red-fhort iron, it will have both thefe qualities, but will be only half as *cold-fhort* as iron obtained folely from one of the ores, and half as *red-fhort* as iron obtained only from the other ore. 2. *Earths* and *ftones* are alfo generally added to facilitate the fufion of iron ores. Thefe are fuch as are fufible, or become fufible when mixed with the ore, or with the earth adhering to it. Authors direct that, if this earth be of an argillaceous nature, limeftone or fome calcareous earth fhould be added; and that, if the adherent earth be calcareous, an argillaceous or filiceous earth fhould be added; becaufe thefe two earths, though fingly unfufible, yet, when mixed, mutually promote the fufion of each other: but as limeftone is almoft always added in the fmelting of iron ores, and as in fome of thefe, at leaft, no argillaceous earth appears to be contained, we are inclined to believe, that it generally facilitates the fufion, not merely by uniting with thofe earths, but by uniting with that part of the ore which is moft perfectly calcined, and leaft difpofed to metallifation; fince we know, that by mixing a calciform or roafted ore of iron with calcareous earth, without any inflammable matter, thefe two fubftances may be totally vitrified. See *Experiments made upon quicklime and upon iron, by Mr Brandt, in the Swedifh Memoirs for the years* 1749 *and* 1751. Calcareous earth does indeed fo powerfully facilitate the fufion of iron ores, that it deferves to be confidered whether workmen do not generally ufe too great a quantity of it, in order to haften the operation. For when the fcoria is rendered too thin, much earthy or unmetallifed matter is precipitated, and the caft iron produced is of too vitreous a quality, and not fufficiently approximated to its true metallic ftate.

Some authors pretend, that a principal ufe of the addition of limeftone in the fmelting of iron ores is to abforb the fulphur, or vitriolic acid, of thefe ores: but, as we have already obferved, a hepar of fulphur is formed by that mixture of calcareous earth and fulphur, which is capable of diffolving iron in a metallic ftate; and thus the quantity of metal obtained from an ore not fufficiently diverted of its fulphur, or vitriolic acid, (which, by uniting with the fuel, is formed into a fulphur during the fmelting), muft be confiderably diminifhed, though rendered purer, by addition of calcareous earth: hence the utility appears of previoufly expelling the fulphur and vitriolic acid from the ore by a fufficient roafting. 3. The *fcoria* of former fmeltings is frequently added to affift the fufion of the ore; and, when the fcoria contains much iron, as fometimes happens in ill-conducted operations, it alfo increafes the quantity of metal obtained.

The quantity of thefe fufible matters to be added varies according to the nature of the ore; but ought in general to be fuch, that the fcoria fhall have its requifite degree of thinnefs, as is mentioned above.

The *fuel* ufed in moft parts of Europe for the fmelting of ores of iron is charcoal. Lately, in feveral works in England and Scotland, iron ore has been fmelted by means of pit-coal, previoufly reduced to cinders or *coaks*, by a kind of calcination fimilar to the operation for converting wood into charcoal, by which the aqueous and fulphureous parts of the coal are expelled, while only the more fixed bituminous parts are left behind. In France, pit coal not calcined has been tried for this purpofe, but unfuccefsfully. The ufe of *peat* has alfo been introduced in fome parts of England.

The quality of the iron depends confiderably upon the quality and alfo upon the quantity of the fuel employed. Charcoal is fitter than coaks for producing

Manufacturing of Iron.

ducing an iron capable of being rendered malleable by forging.

The quantity of fuel, or the intensity of the heat, must be suited to the greater or less fusibility of the ore. Sulphureous, and other ores easily fusible, require less fuel than ores difficultly fusible. In general, if the *quantity of fuel be too small*, and the heat not sufficiently intense, all the iron will not be reduced, and much of it will remain in the scoria, which will not be sufficiently thin. This defect of fuel may be known by the blackness and compactness of the scoria; by the qualities of the iron obtained, which in this case is hard, white, light, intermixed with scoria, smooth in its texture, without scales or grains, rough and convex in its surface, and liable to great loss of weight by being forged; and, lastly, it may be known by observing the colour and appearance of the drops of metal falling down from the smelted ore, and of the scoria upon the surface of the fluid metal, both which are darker-coloured than when more fuel is used. When the *quantity of fuel is sufficiently large*, and the heat is intense enough, the iron is darker-coloured, denser, more tenacious, contains less scoria, and is therefore less fusible, and loses less of its weight by being forged. Its surface is also smoother and somewhat concave; and its texture is generally granulated. The scoria, in this case, is of a lighter colour, and less dense. The drops falling down from the smelted ore and the liquid scoria in the furnace appear hotter and of a brighter colour. When the quantity of fuel is too great, and the heat too intense, the iron will appear to have a still darker colour, and more conspicuous grains or plates, and the scoria will be lighter, whiter, and more spongy. The drops falling from this smelted ore, and the fluid scoria, will appear to a person looking into the furnace through the blast-hole to be very white and shining hot. The quantity of charcoal necessary to produce five hundred weight of iron, when the ore is rich, the furnace well contrived, and the operation skilfully conducted, is computed to be about 40 cubic feet; but is much more in contrary circumstances.

The *time, during which the fluid metal ought to be kept in fusion* before it is allowed to flow out of the furnace, must also be attended to. How long that time is, and whether it ought not to vary according to the qualities of ores and other circumstances, we cannot determine. In some works the metal is allowed to flow out of the furnace every six or eight, and in others only every 10 or 12, hours. Some workmen imagine, that a considerable time is necessary for the concoction of the metal. This is certain, that the iron undergoes some change by being kept in a fluid state; and that if its fusion be prolonged much beyond the usual time, it is rendered less fluid, and also its cohesion, when it becomes cold, is thereby greatly diminished. The marquis de Courtivron says, that the cohesion may be restored to iron in this state, by adding to it some vitrescible earth, which he considers as one of the constituent parts of iron, and which he thinks is destroyed by the fusion too long continued. That the fusibility of cast-iron does depend on an admixture of some vitrescible earth, appears probable from the great quantity of scoria forced out of iron during its conversion into malleable or forged iron, and from the loss of fusibility which it suffers nearly in proportion to its loss of scoria. The quantity of iron daily obtained from such a furnace as is above described, is from two to five tons in 24 hours, according to the richness and fusibility of the ore, to the construction of the furnace, to the adjustment of the due quantity of flux and of fuel, and to the skill employed in conducting the operation.

The *quality of the iron* is judged of by observing the appearances during its flowing from the furnace, and when it is fixed and cold. If the fluid iron, while it flows, emits many and large sparkles; if many brown spots appear on it while it is yet red-hot; if, when it is fixed and cold, its corners and edges are thick and rough, and its surface is spotted; it is known to have a red-short quality. If, in flowing, the iron seems covered with a thin glassy crust, and if, when cold, its texture be whitish, it is believed to be cold-short. Mr Reaumur says, that dark-coloured cast iron is more impure than that which is white. The marquis de Courtivron is of a contrary opinion. But no certain rules for judging of the quality of iron before it be forged can be given. From brittle cast-iron, sometimes ductile forged iron is produced. Cast-iron with brilliant plates and points, when forged, becomes sometimes red-short and sometimes cold-short. Large shining plates, large cavities called *eyes*, want of sufficient density, are almost certain marks of bad iron; but whether it will be cold or red short cannot be affirmed till it be forged. Whiteness of colour, brittleness, closeness of texture, and hardness, are given to almost any cast iron by sudden cooling; and we may observe, that in general the whiter the metal is, the harder it is also, whether these properties proceed from the quality of the iron, or from sudden cooling; and that, therefore, the darker-coloured iron is fitter for being cast into moulds, because it is capable in some measure of being filed and polished, especially after it has been exposed during several hours to a red-heat in a reverberatory furnace, and very gradually cooled. This operation, called by the workmen *annealing*, changes the texture of the metal, renders it softer, and more capable of being filed than before, and also considerably less brittle.

Mr Reaumur found, that by cementing cast iron with absorbent earths in a red-heat, the metal may be rendered softer, tougher, and consequently a fit material for many utensils formerly made of forged iron. Whether cementation with absorbent earths gives to cast iron a greater degree of these properties than the annealing commonly practised, has not been yet determined.

In Navarre, and in some of the southern parts of France, iron-ore is smelted in furnaces much smaller, and of a very different construction from those above described. A furnace of this kind consists of a wide-mouthed copper-caldron, the inner surface of which is lined with masonry a foot thick. The mouth of this caldron is nearly of an oval or elliptic form. The space or cavity contained by the masonry is the furnace in which the ore is smelted. The depth of this cavity is equal to two feet and a half: the larger diameter of the oval mouth of the cavity is about eight feet, and its smaller diameter is about six feet: the space of the furnace is gradually contracted towards the bottom,

Manufacturing of Iron.

bottom, the greateſt diameter of which does not exceed ſix feet: eighteen inches above the bottom is a cylindrical channel in one of the longer ſides of the caldron and maſonry, through which the nozzle of the bellows paſſes. This channel, and alſo the bellows pipe, are ſo inclined, that the wind is directed towards the loweſt point of the oppoſite ſide of the furnace. Another cylindrical channel is in one of the ſhorter ſides of the furnace, at the height of a few inches from the bottom, which is generally kept cloſed, and is opened occaſionally to give paſſage to the ſcoria: and above this is a third channel in the ſame ſide of the furnace, through which an iron inſtrument is occaſionally introduced to ſtir the fluid metal, and to aſſiſt, as is ſaid, the ſeparation of the ſcoria from it. The greateſt height of this channel is at its external aperture on the outſide of the furnace, and its ſmaller height is at its internal aperture; ſo that the inſtrument may be directed towards the bottom of the furnace; but the ſecond channel below it has a contrary inclination, that, when an opening is made, the ſcoria may flow out of the furnace into a baſon placed for its reception. When the furnace is heated ſufficiently, the workmen begin to throw into it alternate changes of charcoal and of ore previouſly roaſted. They take care to throw the charcoal chiefly on that ſide at which the wind enters, and the ore at the oppoſite ſide. At the end of about four hours, a maſs of iron is collected at the bottom of the furnace, which is generally about 600 weight; the bellows are then ſtopt; and when the maſs of iron is become ſolid, the workmen raiſe it from the bottom of the furnace, and place it, while yet ſoft, under a large hammer, where it is forged. The iron produced in theſe furnaces is of the beſt quality; the quantity is alſo very conſiderable, in proportion to the quantity of ore, and to the quantity of fuel employed. In theſe furnaces no limeſtone or other ſubſtance is uſed to facilitate the fuſion of the ore. We ſhould receive much inſtruction concerning the ſmelting of iron-ore, if we knew upon what part of the proceſs, or circumſtance, the excellence of the iron obtained in theſe furnaces depends; whether on the quality of the ore; on the diſuſe of any kind of flux, by which the proportion of vitreous or earthy matter, intermixed with the metallic particles, is diminiſhed; on the forging while the iron is yet ſoft and hot, as the Marquis de Courtivron thinks; or on ſome other cauſe, not obſerved.

The iron thus produced by ſmelting ores is very far from being a pure metal; and though its fuſibility renders it very uſeful for the formation of cannon, pots, and a great variety of utenſils, yet it wants the ſtrength, toughneſs, and malleability, which it is capable of receiving by further operations.

Caſt-iron ſeems to contain a large quantity of vitreous or earthy matter mixed with the pure iron; which matter is probably the chief cauſe of its fuſibility, brittleneſs, hardneſs, and other properties by which it differs from forged iron. The ſulphur, arſenic, and other impurities of the ore, which are ſometimes contained in caſt-iron, are probably only accidental, and may be the cauſes of the red-ſhort quality, and of other properties of certain kinds of iron: but the earthy matter above-mentioned ſeems principally to diſtinguiſh caſt-iron from forged or malleable iron; for, firſt, by depriving the former of this earthy matter, it is rendered malleable, as in the common proceſs hereafter to be deſcribed; and, ſecondly, by fuſing malleable iron with earthy and vitreſcible matters, it loſes its malleability, and is reſtored to the ſtate and properties of caſt-iron.

The earthy vitreous matter contained in caſt-iron conſiſts probably of ſome of the ferruginous earth or calx of the ore not ſufficiently metalliſed, and alſo of ſome unmetallic earth. Perhaps it is only a part of the ſcoria which adheres to, and is precipitated with, the metallic particles, from which it is more and more ſeparated, as the heat applied is more intenſe, and as the fuſion is longer continued.

To ſeparate theſe impurities from caſt-iron, and to unite the metallic parts more cloſely and compactly, and thus to give it the ductility and tenacity which render this metal more uſeful than any other, are the effects produced by the following operations.

The firſt of theſe operations is a fuſion of the iron, by which much of its impurities is ſeparated in form of ſcoria; and by the ſecond operation, a further and more complete ſeparation of theſe impurities, and alſo a cloſer compaction of the metallic particles, are effected by the application of mechanical force or preſſure, by means of large hammers.

Some differences in the conſtruction of the forge or furnace, in which the *fuſion* or *refining of caſt-iron* is performed, in the method of conducting the operation, and in other circumſtances, are obſerved to occur in different places. We ſhall deſcribe from Swedenborgius the *German method*.

The fuſion of the caſt-iron, which is to be rendered malleable, is performed upon the hearth of a forge ſimilar to that uſed by blackſmiths: at one ſide of this hearth is formed a cavity or fire-place, which is intended to contain the fuel and the iron to be melted: this fire-place is 20 inches long, 18 inches broad, and 12 or 14 inches deep: it is bounded on three ſides by three plates of caſt-iron placed upright; and on the fourth ſide, which is the front, or that part neareſt to which the workmen ſtand, by a large forge-hammer, through the eye of which the ſcoria is at certain times allowed to flow. The floor alſo of the fire-place is another caſt-iron plate. The thickneſs of theſe plates is from two to four inches. One of the upright ſide-plates reſts againſt a wall, in an aperture through which a copper-tube, called the *tuyere*, is luted with clay. This tube is a kind of caſe or covering for the pipe of a pair of bellows placed behind the wall, and its direction is therefore parallel to that of the bellows-pipe; but it advances about half a foot further than this pipe into the fire-place; and thus gives greater force to the air, which it keeps concentrated, or prevents the divergency of the air till it is required to act. The tube reſts upon the edge of the ſide-plate which leans againſt the wall, nearer to the back-part than to the front of the fire-place; and in ſuch an oblique direction, that the wind ſhall be impelled towards the furtheſt part of the floor of the fire-place, or where this floor is interſected by the oppoſite ſide-plate. The obliquity of the tuyere ought to vary according to the quality of the iron; and therefore, in every operation, it may be ſhifted till its proper poſition is found. The more nearly its direction approaches

Manufacturing of Iron.

proaches to a horizontal plane, the more intenfe is the heat; but a larger quantity of fuel is confumed than is even proportional to the increafe of heat, becaufe the flame is not then fo well confined. When the iron is eafily fufible, great heat is not required: the tuyere may then decline confiderably from the horizontal plane, and thus fuel may be faved. This tuyere, tho' made of copper, a metal more eafily fufible than iron, is preferved from fufion by the conftant paffage of cold air through it. It muft be carefully kept open, and cleanfed from the fcoria, which would be apt to block up its cavity, by which not only the heat would be too much diminifhed for the fuccefs of the operation, but the tube itfelf would be melted.

To prepare for the fufion, a quantity of fcoria of a former operation is thrown into the fire-place, till one third-part of this be full; and the remaining two thirds of the fire-place are to be filled with fmaller fcoria, coal-duft, and fparks ejected from hot iron.—These matters, being fufible, form a bath for the reception of the iron when melted. Upon this bed of fcoria, the mafs of caft iron to be melted is placed; fo that one end of it fhall be within the fire-place, oppofite to the tuyere, and at the diftance of about four or five inches from its aperture; and the other end fhall ftand without the fire-place, to be pufhed in, as the former is melted. The upper fide of the mafs of iron ought to be in the fame horizontal plane as the upper part of the orifice of the tuyere, that the wind may, by means of the obliquity of its courfe, ftrike upon and pafs along the under-fide of the mafs; but if the iron be difficultly fufible, the tuyere is to be difpofed more horizontally, fo that the wind fhall ftrike directly upon the mafs of iron; and that one part of the blaft fhall graze along the upper furface, and the other part along the under furface of the iron. The mafs of iron weighs generally from 200 to 400 pounds. Sometimes two or three fmaller maffes are put one above another, fo as not to touch. When thefe are of different qualities, the cold-fhort piece is placed undermoft, that being more unfufible than the red-fhort. The iron being placed, charcoal-powder is thrown on both fides, and coals are accumulated above, fo as to cover entirely the iron.

The coals are then to be kindled, and the bellows are made to blow, at firft flowly, and afterwards with more and more force. The iron is gradually liquefied, and flows down in drops through the melted fcoria to the bottom of the fire-place; during which the workmen frequently turn the iron, fo that the end oppofed to the blaft of wind may be equally expofed to heat, and uniformly fufed. While the coals are confumed, more are thrown on, fo that the whole may be kept quite covered. During the operation, a workman frequently founds the bottom and corners of the fire-place by means of a bar or poker, raifes up any mafs of metal which he finds adhering to thefe, and expofes them to the greateft heat, that they may be more perfectly fufed.

When all the iron is fufed, no more coals are to be added; but the melted mafs is to remain half uncovered for fome time; during which the iron boils and bubbles, and its furface fwells and rifes higher and higher. When the iron has rifen as high as the upper edge of the fire-place, the coals upon its furface muft be removed; and by thus expofing it to cold air, its ebullition and fwelling fubfide. In this ftate, or coction, the iron is kept during half an hour or more, by adding occafionally pieces of good coal, which maintain a fufficient heat, without covering entirely the furface of the mafs. During this coction, the workmen allow the orifice of the tuyere to be half ftopped up by the fcoria, that the air may not blow upon the iron with all its force, by which it would be too much cooled. Accordingly, when they think that the coction has continued fufficiently long, they clear the paffage of the tuyere, and the mafs is foon cooled by the cold air. At the fame time alfo they open a paffage in the eye of the hammer placed in the front of the fire-place, through which fome of the fcoria is allowed to flow out. When the iron has become folid, the bellows are ftopt, the coals are removed, and the mafs is left during an hour; and then the workmen raife it from the fire-place, turn it upfide down, and proceed to the fecond coction or fufion of the iron.

From this fecond operation, the mafs is to be fo placed, that one part of it fhall reft upon the tuyere, and the other upon the fcoria remaining in the fire-place. This fcoria is to be difpofed in an oblique direction parallel to the tuyere, by which means the wind of the bellows is obliged to pafs along the under fide of the mafs of iron. About the fides of the mafs, charcoal-powder and burnt afhes are thrown; but towards the tuyere, dry and entire pieces of coals are placed, to maintain the fire. When thefe are kindled, more coals are added, and the fire is gradually excited. The workman attends to the direction of the flame, that it pafs equally along the under furface of the iron, quite to the further extremity, and that it do not efcape at the fides, nor be reverberated back towards the tuyere, by which this copper tube might be melted. During this fufion, pieces of iron are apt to be feparated from the mafs, and to fall down unfufed to the bottom and corners of the fire-place. Thefe are carefully to be fearched for, and expofed to the greateft heat till they are melted. When the whole mafs is thus brought into perfect fufion, the coals are removed; and the wind blowing on its fuface, whirls and diffipates the fmall remaining pieces of fcoria and fparks thrown out from the fluid iron. This jet of fire continues about feven or eight minutes, and the whole operation about two hours. In this fecond fufion the fcoria is to be thrice removed, by opening a paffage through the eye of the hammer. The firft time of removing the fcoria is about 20 minutes from the kindling of the fire, the fecond time is about 40 minutes after the firft, and the third time is near the end of the operation.

The mafs is then removed from the hearth, and put upon the ground of the forge, where it is cleanfed from fcoria, and beat into a more uniform fhape. It is then placed on an anvil, where, by being forged, it receives a form nearly cubical. This mafs is to be divided into five, fix, or more pieces, by means of a wedge; and thefe are to be heated and forged till they are reduced to the form of the bars commonly fold.

In fome forges, the iron is fufed only once, and in others it fuffers three fufions, by which it is faid to be rendered

Manufacturing of Iron.

rendered very pure. Where only one fusion is practised, it is called the *French method*. In this, no greater quantity of iron is fused at once than is sufficient to make one bar. The fire-place is of considerably less dimensions, and especially is less deep, than in the German method above described. The fire is also more intense, and the proportion of fuel consumed to the iron is greater. The iron, when melted, is not kept in a state of ebullition as is above described; but this ebullition is prevented by stirring the fluid mass with an iron bar, till it is coagulated, and becomes solid

By these operations, fusion and forging, the iron loses about $\frac{3}{11}$ parts of its former weight, sometimes more and sometimes less, according to the quality of the cast-iron employed; it is purified from the vitreous and earthy parts which were intermixed with it, its metallic particles are more closely compacted, its texture is changed, and it is rendered more dense, soft, and malleable, tough, and difficultly fusible.

The degrees, however, of these qualities vary much in different kinds of iron. Thus some iron is tough and malleable, both when it is hot and when it is cold. This is the best and most useful iron. It may be known generally by the equable surface of the forged bar, which is free from transverse fissures or cracks in the edges, and by a clear, white, small-grained, or rather fibrous texture. Another kind is tough when it is heated, but brittle when it is cold. This is called *cold-short* iron; and is generally known by a texture consisting of large, shining plates, without any fibres. It is less liable to rust than other iron. A third kind of iron, called *red-short*, is brittle when hot, and malleable when cold. On the surface and edges of the bars of this kind of iron, transverse cracks or fissures may be seen; and its internal colour is dull and dark. It is very liable to rust. Lastly, some iron is brittle both when hot and when cold.

Most authors agree, that the red-short quality of iron proceeds from some sulphur or vitriolic acid being contained in it, because sulphur is known to produce this effect when added to iron, and because the iron obtained from pyritous and other sulphurated ores has generally this quality.

The cause of the cold-short quality of iron is not so well ascertained. Some imagine, that it proceeds from a mixture of arsenic or of antimony. But this opinion seems to be improbable, when we consider that these metallic substances may in a great measure be dissipated by roasting, whereas the ores which yield a cold-short iron are injured by much roasting; that no arsenic or antimony are observable in most, if in any, of these ores; and lastly, that these semimetals would render the iron brittle both when hot and when cold. Cramer and other authors impute this vicious quality to a mixture of unmetallic earth or vitreous matter; and affirm, that it may be destroyed by cementation with phlogiston, and by forging. And lastly, others ascribe the cold-short quality of iron to a defect of phlogiston, or, as Swedenborgius says, of sulphur. To ascertain the causes of the bad qualities of iron, and to discover practical remedies, are still desiderata in metallurgy.

In one bar frequently two or more different kinds of iron may be observed, which run all along its whole length, and scarcely a bar is ever found of entirely pure and homogeneous iron. This difference probably proceeds from the practice we have mentioned of mixing different kinds of ores together, in the smelting; and also from the practice of mixing two or more pigs of cast iron of different qualities in the finery of these; by which means, the red-short and cold-short qualities of the different kinds are not, as we have already remarked, mutually counteracted or destroyed by each other, but each of these qualities is diminished in the mixed mass of iron, as much as this mass is larger than the part of the mass originally possessed of that quality: that is, if equal parts of red-short and of cold-short iron be mixed together, the mixed mass will be only half as red short as the former part, and half as cold-short as the latter. For these different kinds of iron seem as if they were only capable of being interwoven and diffused through each other, but not of being intimately united or combined.

The quality of forged iron may be known by the texture which appears on breaking a bar. The best and toughest iron is that which has the most fibrous texture, and is of a clear greyish colour. This fibrous appearance is given by the resistance which the particles of the iron make to their rupture. The next best iron is that whose texture consists of clear, whitish, small grains, intermixed with fibres. These two kinds are malleable, both when hot and when cold, and have great tenacity. *Cold-short iron* is known by a texture consisting of large, shining plates, without fibres: and *red-short iron* is distinguished by its dark dull colour, and by the transverse cracks and fissures on the surface and edges of the bars. The quality of iron may be much improved by violent compression, as by forging and rolling; especially when it is not long exposed to too violent heat, which is known to injure, and at length to destroy, its metallic properties.

For the conversion of iron into *steel*, see the article Steel.

Smelting of Tin Ores.

Sect. VI. *Of the Smelting of Tin Ores.*

The tin-ores commonly smelted are those which consist of calx of tin combined with calx of arsenic and sometimes with calx of iron. These are either pure, as the tin-grains, or intermixed with spars, stones, pyrites, ores of copper, iron, or of other metals.

The impure ores must be cleansed as much as is possible from all heterogeneous matters. This cleansing is more necessary in ores of tin than of any other metal; because in the smelting of tin-ores a less intense heat must be given than is sufficient for the scorification of earthy matters; lest the tin be calcined. Tin-ores previously bruised may be cleansed by washing, for which operation their great weight and hardness render them well adapted. If they be intermixed with very hard stones or ferruginous ores, a slight roasting will render these impure matters more friable, and consequently fitter to be separated from the tin-ores. Sometimes these operations, the roasting, contusion, and lotion, must be repeated. By roasting, the ferruginous particles are so far revived, that they may be separated by magnets.

Smelting of Ores of Lead.

The ore, thus cleanfed from adhering heterogeneous matters, is to be roafted in an oven or reverberatory furnace, with a fire rather intenfe than long continued; during which it muft be frequently ftirred to prevent its fufion. By this operation, the arfenic is expelled, and in fome works is collected in chambers built purpofely above the calcining furnace.

Laftly, the ore cleanfed and roafted is to be fufed, and reduced to a metallic ftate. In this fufion, attention muft be given to the following particulars. 1. No more heat is to be applied than is fufficient for the reduction of the ore; becaufe this metal is fufible with very little heat, and is very eafily calcinable. 2. To prevent this calcination of the reduced metal, a larger quantity of charcoal is ufed in this than in moft other fufions. 3. The fcoria muft be frequently removed, left fome of the tin fhould be involved in it; and the melted metal muft be covered with charcoal powder, to prevent the calcination of its furface. 4. No flux or other fubftance, excepting the fcoria of former fmeltings which contains fome tin, are to be added, to facilitate the fufion.

Sect. VII. *Smelting of Ores of Lead.*

Ores of lead are either pure, that is, containing no mixture of other metal; or they are mixed with filver, copper, or pyrites. The methods of treating ores of lead containing filver and copper, are defcribed in the fections of *Smelting of Ores of Silver* and *of Copper*; and in the former of thefe an inftance is given of the method of fmelting the ore of Ramelfberg, which contains all thefe three metals.

Pure ores of lead, and thofe which contain fo fmall a quantity only of filver as not to compenfate for the expence of extracting the nobler metal, may be fmelted in furnaces, and by operations fimilar to thofe ufed at Ramelfberg, or in the following methods. 1. From the lead-ore of Willach in Carinthia, a great part of the lead is obtained by a kind of eliquation, during the roafting of the ore. For this purpofe, the ore is thrown upon feveral ftrata or layers of wood, placed in a calcining or reverberatory furnace. By kindling this wood, a great part of the lead flows out of the ore, through the layers of fuel, into a bafon placed for its reception. The ore which is thus roafted is beat into fmaller pieces, and expofed to a fecond operation fimilar to the former, by which more metal is eliquated; and the remaining ore is afterwards ground, wafhed, and fmelted, in the ordinary method.

The lead of Willach is the pureft of any known. Schlutter afcribes its great purity to the method ufed in extracting it, by which the moft fufible, and confequently the pureft part of the contained lead, is feparated from any lefs fufible metal which happens to be mixed with it, and which remains in the roafted ore. This method requires a very large quantity of wood.

2. In England, lead ores are fmelted either upon a hearth, or in a reverberatory furnace called *a cupel*.

In the firft of thefe methods, charcoal is employed as fuel, and the fire is excited by bellows. Small quantities of fuel and of ore are thrown alternately and frequently upon the hearth. The fufion is very quickly effected; and the lead flows from the hearth as faft as it is feparated from the ore.

Smelting of Ores of Semi-metal.

3. In the fecond method practifed in England, pit-coal is ufed as fuel. The ore is melted by means of the flame paffing over its furface; its fulphur is burnt and diffipated, while the metal is feparated from the fcoria, and collected at the bottom of the furnace. When the ore is well cleanfed and pure, no addition is requifite; but when it is mixed with calcareous or earthy matrix, a kind of flour or fufible fpar found in the mines is generally added to render the fcoria more fluid, and thereby to affift the precipitation of the metal. When the fufion has been continued about eight hours, a paffage in the fide of the furnace is opened, through which the liquid lead flows into an iron ciftern. But immediately before the lead is allowed to flow out of the furnace, the workmen throw upon the liquid mafs a quantity of flacked quicklime, which renders the fcoria fo thick and tenacious, that it may be drawn out of the furnace by rakes. Schlutter mentions this addition of quicklime in the fmelting of lead ores in England, but thinks that it is intended to facilitate the fufion of the ores; whereas it really has a contrary effect, and is never added till near the end of the operation, when the fcoria is to be raked from the furface of the metal.

Sect. VIII. *Of the Smelting of Ores of Semi-metals.*

Antimony is obtained by a kind of eliquation from the minerals containing it, as is defcribed in the article Antimony; and the regulus of antimony is procured from antimony, by the proceffes defcribed in the fame article, and in the article *Regulus of Antimony*.

Arfenic, *faffre*, and *bifmuth*, are obtained generally from one ore, namely, that called *cobalt*. The arfenic of the ore is feparated by roafting, and adheres to the internal furface of a chimney, which is extended horizontally about 200 or 300 feet in length, and in the fides of which are feveral doors, by means of which the arfenic, when the operation is finifhed, may be fwept out and collected. Thefe chimneys are generally bent in a zig zag direction, that they may better retard and ftop the arfenical flowers. Thefe flowers are of various colours, white, grey, red, yellow, according to the quantity of fulphur or other impurity with which they happen to be mixed. They are afterwards purified by repeated fublimations; while fome alkaline or other fubftances are added to detain the fulphur, and to affift the purification.

In the fame roafting of the ore by which the arfenic is expelled, the bifmuth, or at leaft the greateft part of this femimetal which is contained in the ore, being very fufible, and having no difpofition to unite with the regulus of cobalt, which remains in the ore, is feparated by eliquation.

The remaining part of the roafted ore confifts chiefly of calx of regulus of cobalt, which not being volatile, as the arfenic is, nor fo eafily fufible as bifmuth is, has been neither volatilized nor melted. It contains alfo fome bifmuth, and a fmall quantity of arfenic, together

Smelting of Ores of Semi-metals.

gether with any silver or other fixed metal which happened to be contained in the ore. This roasted ore being reduced to a fine powder, and mixed with three or four times its weight of fine sand, is the powder called *saffre* or *zaffre*. Or the roasted ore is sometimes fused with about thrice its quantity of pure sand and as much pure pot-ash, by which a blue glass, called *smalt*, is produced; and a metallic mass, called *speiss*, is collected at the bottom of the vessel in which the matters are fused. The metallic mass or speiss is composed of very different substances, according to the contents of the ore and the methods of treating it. The matters which it contains at different times are, nickel, regulus of cobalt, bismuth, arsenic, sulphur, copper, and silver.

The Zaffre.

The Smalt.

Bismuth is seldom procured from any other ores but that of cobalt. It might, however, be extracted from its proper ores, if a sufficient quantity of these were found, by the same method by which it is obtained from cobalt, namely, by eliquation.

Mercury, when native, and inveloped in much earthy or other matter, from which it cannot be separated merely by washing, is distilled either by ascent or by descent. When it is mineralised by sulphur, that is, when it is contained in cinnabar, some intermediate substance, as quicklime or iron, must be added in the distillation, to disengage it from the sulphur.

The rich ore of Almaden in Spain is a cinnabar, with which a calcareous stone happens to be so blended, that no addition is required to disengage the mercury from the sulphur. The distillation is there performed in a furnace consisting of two cavities, one of which is placed above another. The lower cavity is the fire-place, and contains the fuel, resting upon a grate, through the bars of which the air enters, maintains the fire, and passes into a chimney, placed at one side of the fire-place immediately above the door thro' which fuel is to be introduced. The roof of this fire-place, which is vaulted and pierced with several holes, is also the floor of the upper cavity. Into this upper cavity, the mineral from which mercury is to be distilled is introduced, through a door in one of the sides of the furnace. In the opposite wall of this cavity are eight openings, all at the same height. To each of these openings is adapted a file of aludels connected and luted together, extending 60 feet in length. These aludels, which are earthen vessels open at each end, and wider in the middle than at either extremity, are supported upon an inclined terras; and the aludel of each file, that is most distant from the furnace, terminates in a chamber built of bricks, which has two doors and two chimneys.

When the upper cavity is filled sufficiently with the mineral, a fire is made below, which is continued during 12 or 14 hours. The heat is communicated thro' the holes of the vaulted roof of the fire-place to the mineral in the upper cavity, by which means the mercury is volatilised, and its vapour passes into the aludels, where much of it is condensed, and the rest is discharged into the brick-chamber, in which it circulates till it also is condensed. If any air or smoke passes through the aludels along with the vapour of the mercury, they escape through the two chimneys of the chamber. Three days after the operation, when the apparatus is sufficiently cooled, the aludels are unluted, the doors of the chamber are opened, and the mercury is collected.

Metamorphosis, Metaphor.

METAMORPHOSIS, in general, denotes the changing of something into a different form; in which sense it includes the transformation of insects, as well as the mythological changes related by the ancient poets.

Mythological metamorphoses were held to be of two kinds, apparent and real: thus, that of Jupiter into a bull, was only apparent; whereas that of Lycaon into a wolf, was supposed to be real

Most of the ancient metamorphoses include some allegorical meaning, relating either to physics or morality: some authors are even of opinion that a great part of the ancient philosophy is couched under them; and Lord Bacon and Dr Hook have attempted to unriddle several of them.

METAPHOR, in rhetoric. See ORATORY, n° 50.

METAPHOR *and Allegory*, in poetry.—A metaphor differs from a simile, in form only, not in substance: in a simile the two subjects are kept distinct in the expression, as well as in the thought; in a metaphor, the two subjects are kept distinct in the thought only, not in the expression. A hero resembles a lion, and upon that resemblance many similies have been raised by Homer and other poets. But instead of resembling a lion, let us take the aid of the imagination, and feign or figure the hero to be a lion, by that variation the simile is converted into a metaphor; which is carried on by describing all the qualities of a lion that resemble those of the hero. The fundamental pleasure here, that of resemblance, belongs to the thought. An additional pleasure arises from the expression: the poet, by figuring his hero to be a lion, goes on to describe the lion in appearance, but in reality the hero; and his description is peculiarly beautiful, by expressing the virtues and qualities of the hero in new terms, which, properly speaking, belong not to him, but to the lion. This will better be understood by examples. A family connected with a common parent, resembles a tree, the trunk and branches of which are connected with a common root: but let us suppose, that a family is figured, not barely to be like a tree, but to be a tree; and then the simile will be converted into a metaphor, in the following manner:

Metaphor.

> Edward's sev'n sons, whereof thyself art one,
> Were sev'n fair branches, springing from one root;
> Some of these branches by the dest'nies cut:
> But Thomas, my dear lord, my life, my Glo'ster,
> One flourishing branch of his most royal root,
> Is hack'd down, and his summer-leaves all faded,
> By Envy's hand and Murder's bloody axe.
>
> *Richard* II. *act.* i. *sc.* 3.

Figuring human life to be a voyage at sea:

> There is a tide in the affairs of men,
> Which, taken at the flood, leads on to Fortune:

Omitted, all the voyage of their life
Is bound in ſhallows and in miſeries.
On ſuch a full ſea are we now afloat;
And we muſt take the current when it ſerves,
Or loſe our ventures. *Julius Cæſar, act* iv. *ſc.* 5.

Figuring glory and honour to be a garland of flowers:
Hotſpur. ———— ——— -Wou'd to heav'n,
Thy name in arms were now as great as mine!
Pr.Henry. I'll make it greater ere I part from thee;
And all the budding honours on thy creſt
I'll crop, to make a garland for my head.
Firſt part of Henry IV. *act* v. *ſc.* 9.

Figuring a man who hath acquired great reputation and honour to be a tree full of fruit:
—————— Oh, boys, this ſtory
The world may read in me; my body's mark'd
With Roman ſwords; and my report was once
Firſt with the beſt of note. Cymbeline lov'd me;
And when a ſoldier was the theme, my name
Was not far off; then was I as a tree,
Whoſe boughs did bend with fruit. But in one night,
A ſtorm or robbery, call it what you will,
Shook down my mellow hangings, nay my leaves;
And left me bare to wither.
Cymbeline, act iii. *ſc.* 3.

"Bleſt be thy ſoul, thou king of ſhells, ſaid Swaran of the dark-brown ſhield. In peace, thou art the gale of ſpring; in war, the mountain-ſtorm. Take now my hand in friendſhip, thou noble king of Morven."
Fingal.

"Thou dwelleſt in the ſoul of Malvina, ſon of mighty Oſſian. My ſighs ariſe with the beam of the eaſt: my tears deſcend with the drops of night. I was a lovely tree in thy preſence, Oſcar, with all my branches round me: but thy death came like a blaſt from the deſart, and laid my green head low; the ſpring returned with its ſhowers, but no leaf of mine aroſe."
Fingal.

An *allegory* differs from a metaphor; and a *figure of ſpeech* differs from both. A metaphor is defined above to be an act of the imagination, figuring one thing to be another. An allegory requires no ſuch operation, nor is one thing figured to be another: it conſiſts in chooſing a ſubject having properties or circumſtances reſembling thoſe of the principal ſubject: and the former is deſcribed in ſuch a manner as to repreſent the latter: the ſubject thus repreſented is kept out of view: we are left to diſcover it by reflection; and we are pleaſed with the diſcovery, becauſe it is our own work. (See the word ALLEGORY.) Quintilian gives the following inſtance of an allegory,

O navis, réferent in mare te novi
Fluctus. O quid agis? fortiter occupa portum.
Horat. lib. i. *ode* 14.

and explains it elegantly in the following words: "Totuſque ille Horatii locus, quo navim pro republica, fluctuum tempeſtates pro bellis civilibus, portum pro pace atque concordia, dicit."

In a *figure of ſpeech*, there is no fiction of the imagination employed, as in a metaphor; nor a repreſentative ſubject introduced, as in an allegory. This figure, as its name implies, regards the expreſſion only, not the thought; and it may be defined, the uſing a word in a ſenſe different from what is proper to it.— Thus youth, or the beginning of life, is expreſſed figuratively by *morning of life:* morning is the beginning of the day; and in that view it is employed to ſignify the beginning of any other ſeries, life eſpecially, the progreſs of which is reckoned by days. See FIGURE *of Speech.*

Metaphor and *allegory* are ſo much connected, that it ſeemed proper to handle them together: the rules particularly for diſtinguiſhing the good from the bad, are common to both. We ſhall therefore proceed to theſe rules, after adding ſome examples to illuſtrate the nature of an *allegory*, which, with a view to this article, was but ſlightly illuſtrated under its proper name.

Horace, ſpeaking of his love to Pyrrha, which was now extinguiſhed, expreſſeth himſelf thus:
————— Me tabulâ ſacer
Votivâ paries indicat uvida
Suſpendiſſe potenti
Veſtimenta maris Deo. *Carm. lib.* i. *ode* 5.
Again:
Phœbus volentem prælia me loqui,
Victas et urbes, increpuit, lyrâ
Ne parva Tyrrhenum per æquor
Vela darem. *Carm. lib.* iv. *ode* 15.

Queen. Great Lords, wiſe men ne'er ſit and wail their loſs,
But cheerly ſeek how to redreſs their harms.
What though the maſt be now blown overboard,
The cable broke, the holding-anchor loſt,
And half our ſailors ſwallowed in the flood!
Yet lives our pilot ſtill. Is't meet that he
Should leave the helm, and, like a fearful lad,
With tearful eyes add water to the ſea,
And give more ſtrength to that which hath too much;
While in his moan the ſhip ſplits on the rock,
Which induſtry and courage might have ſav'd?
Ah, what a ſhame! ah, what a fault were this!
Third part of Henry VI. *act.* v. *ſc.* 5.

Oroonoko. Ha! thou haſt rous'd
The lion in his den; he ſtalks abroad,
And the wide foreſt trembles at his roar.
I find the danger now. *Oroonoko, act* iii. *ſc.* 2.

"My well-beloved hath a vineyard in a very fruitful hill. He fenced it, gathered out the ſtones thereof, planted it with the choiceſt vine, built a tower in the midſt of it, and alſo made a wine-preſs therein; he looked that it ſhould bring forth grapes, and it brought forth wild grapes. And now, O inhabitants of Jeruſalem, and men of Judah, judge, I pray you, betwixt me and my vineyard. What could have been done more to my vineyard, that I have not done? Wherefore, when I looked that it ſhould bring forth grapes, brought it forth wild grapes. And now go to, I will tell you what I will do to my vineyard: I will take away the hedge thereof, and it ſhall be eaten up; and break down the wall thereof, and it ſhall be trodden down. And I will lay it waſte: it ſhall not be pruned, nor digged, but there ſhall come up briars and thorns: I will alſo command the clouds that they rain no rain upon it. For the vineyard of the Lord of hoſts is the houſe of Iſrael, and the men of Judah his pleaſant plant." *Iſaiah*, v. 1.

 The

The rules that govern metaphors and allegories are of two kinds. The construction of these figures comes under the first kind: the propriety or impropriety of introduction comes under the other.— To begin with rules of the first kind; some of which coincide with those already given for similies; some are peculiar to metaphors and allegories.

In the first place, it has been observed, that a simile cannot be agreeable where the resemblance is either too strong or too faint. This holds equally in metaphor and allegory; and the reason is the same in all. In the following instances, the resemblance is too faint to be agreeable.

Malcolm. ——— But there's no bottom, none,
In my voluptuousness: your wives, your daughters,
Your matrons, and your maids, could not fill up
The cistern of my lust. *Macbeth, Act* iv. *sc.* 4.

The best way to judge of this metaphor, is to convert it into a simile: which would be bad, because there is scarce any resemblance between lust and a cistern, or betwixt enormous lust and a large cistern.

Again:

He cannot buckle his distemper'd cause
Within the belt of rule. *Macbeth, Act* v. *sc.* 2.

There is no resemblance between a distempered cause and any body that can be confined within a belt.

Again:

Steep me in poverty to the very lips.
Othello, Act iv. *sc.* 9.

Poverty here must be conceived a fluid, which it resembles not in any manner.

Speaking to Bolingbroke banish'd for six years:

The sullen passage of thy weary steps
Esteem a soil, wherein thou art to set
The precious jewel of thy home-return.
Richard II. *Act* ii. *sc.* 6.

Again:

Here is a letter, lady,
And every word in it a gaping wound
Issuing life-blood.
Merchant of Venice, Act iii. *sc.* 3.

Tantæ *molis* erat Romanam condere gentem.
Æneid. i. 37.

The following metaphor is strained beyond all endurance: Timur-bec, known to us by the name of *Tamerlane the Great*, writes to Bajazet emperor of the Ottomans in the following terms:

"Where is the monarch who dares resist us? where is the potentate who doth not glory in being numbered among our attendants? As for thee, descended from a Turcoman sailor, since the vessel of thy unbounded ambition hath been wreck'd in the gulf of thy self-love, it would be proper, that thou shouldst take in the sails of thy temerity, and cast the anchor of repentance in the port of sincerity and justice, which is the port of safety; lest the tempest of our vengeance make thee perish in the sea of the punishment thou deservest."

Such strained figures, as observed above, are not unfrequent in the first dawn of refinement; the mind in a new enjoyment knows no bounds, and is generally carried to excess, till taste and experience discover the proper limits.

Secondly, whatever resemblance subjects may have, it is wrong to put one for another, where they bear no mutual proportion. Upon comparing a very high to a very low subject, the simile takes on an air of burlesque: and the same will be the effect where the one is imagined to be the other, as in a metaphor; or made to represent the other, as in an allegory.

Thirdly, These figures, a metaphor especially, ought not to be crowded with many minute circumstances; for in that case it is scarcely possible to avoid obscurity. A metaphor above all ought to be short: it is difficult, for any time, to support a lively image of a thing being what we know it is not; and for that reason, a metaphor drawn out to any length, instead of illustrating or enlivening the principal subject, becomes disagreeable by overstraining the mind. Here Cowley is extremely licentious: take the following instance.

Great and wise conqu'ror, who, where-e'er
Thou com'st, dost fortify, and settle there!
Who canst defend as well as get;
And never hadst one quarter beat up yet;
Now thou art in, thou ne'er wilt part
With one inch of my vanquish'd heart;
For since thou tookst it by assault from me,
'Tis garrison'd so strong with thoughts of thee,
It fears no beauteous enemy.

For the same reason, however agreeable long allegories may at first be by their novelty, they never afford any lasting pleasure: witness the *Fairy Queen*, which with great power of expression, variety of images, and melody of versification, is scarce ever read a second time.

In the fourth place, the comparison carried on in a simile, being in a metaphor sunk by imagining the principal subject to be that very thing which it only resembles; an opportunity is furnished to describe it in terms taken strictly or literally with respect to its imagined nature. This suggests another rule, That in constructing a metaphor, the writer ought to make use of such words only as are applicable literally to the imagined nature of his subject: figurative words ought carefully to be avoided; for such complicated figures, instead of setting the principal subject in a strong light, involve it in a cloud, and it is well if the reader, without rejecting by the lump, endeavour patiently to gather the plain meaning, regardless of the figures:

A stubborn and unconquerable flame
Creeps in his veins, and drinks the streams of life.
Lady Jane Gray, Act i. *sc.* 1.

Copied from Ovid,

Sorbent avidæ præcordia flammæ.
Metamorph. lib. ix. 172.

Let us analyse this expression. That a fever may be imagined a flame, we admit: though more than one step is necessary to come at the resemblance: a fever, by heating the body, resembles fire; and it is no stretch to imagine a fever to be a fire: again, by a figure of speech, Metaphor. speech, flame may be put for fire, because they are commonly conjoined; and therefore a fever may be termed a *flame*. But now admitting a fever to be a flame, its effects ought to be explained in words that agree literally to a flame. This rule is not observed here; for a flame drinks figuratively only, not properly.

King Henry to his son prince Henry:
Thou hid'st a thousand daggers in thy thoughts,
Which thou hast whetted on thy stony heart
To stab at half an hour of my frail life.
Second part Henry IV. *Act* iv. *sc.* 11.

Such faulty metaphors are pleasantly ridiculed in the *Rehearsal:*

" *Physician.* Sir, to conclude, the place you fill has more than amply exacted the talents of a wary pilot; and all these threatening storms, which, like impregnate clouds, hover o'er our heads, will, when they once are grasp'd but by the eye of reason, melt into fruitful showers of blessings on the people.

" *Bayes.* Pray mark that allegory. Is not that good?

" *Johnson.* Yes, that grasping of a storm with the eye is admirable." *Act* ii. *sc.* 1.

Fifthly, the jumbling different metaphors in the same sentence, beginning with one metaphor and ending with another, commonly called a *mixt metaphor*, ought never to be indulged.

K. Henry ——Will you again unknit
This churlish knot of all abhorred war,
And move in that obedient orb again,
Where you did give a fair and natural light?
First part Henry VI. *Act* v. *sc.* 1.

Whether 'tis nobler in the mind, to suffer
The stings and arrows of outrageous fortune;
Or to take arms against a sea of troubles,
And by opposing end them.
Hamlet, Act iii. *sc.* 2.

In the sixth place, It is unpleasant to join different metaphors in the same period, even where they are preserved distinct: for when the subject is imagined to be first one thing and then another in the same period without interval, the mind is distracted by the rapid transition; and when the imagination is put on such hard duty, its images are too faint to produce any good effect:

At regina gravi jamdudum saucia cura,
Vulnus alit venis, et cæco carpitur igni.
Æneid. iv. 1.

————Est mollis flamma medullas
Interea, et tacitum vivit sub pectore vulnus.
Æneid. iv. 66.

Motum ex Metello consule civicum,
Bellique causas, et vitia, et modos,
Ludumque fortunæ, gravesque
Principum amicitias, et arma
Nondum expiatis uncta cruoribus,
Periculosæ plenum opus aleæ,
Tractas, et incedis per ignes
Subpositos cineri doloso.
Horat. Carm. lib. ii. *ode* 1.

In the last place, It is still worse to jumble together metaphorical and natural expression, so as that the period must be understood in part metaphorically, in part literally; for the imagination cannot follow with sufficient ease changes so sudden and unprepared: a metaphor begun and not carried on, hath no beauty; and instead of light, there is nothing but obscurity and confusion. Instances of such incorrect composition are without number: we shall, for a specimen, select a few from different authors. Speaking of Britain.

This precious stone set in the sea,
Which serves it in the office of a wall,
Or as a moat defensive to a house
Against the envy of less happier lands.
Richard II. *act* ii. *sc.* 1.

In the first line Britain is figured to be a precious stone: in the following line, Britain, divested of her metaphorical dress, is presented to the reader in her natural appearance.

These growing feathers pluck'd from Cæsar's wing,
Will make him fly an ordinary pitch
Who else would soar above the view of men,
And keep us all in servile fearfulness.
Julius Cæsar, act i. *sc.* 1.

Rebus angustis animosus atque
Fortis adpare: sapienter idem
Contrahes vento nimium secu
Turgida vela. *Hor.*

The following is a miserable jumble of expressions, arising from an unsteady view of the subject, between its figurative and natural appearance:

But now from gath'ring clouds destruction pours,
Which ruins with mad rage our halcyon hours:
Mists from black jealousies the tempest form,
Whilst late divisions reinforce the storm.
Dispensary, canto iii.

To thee the world its present homage pays,
The harvest early, but mature the praise.
Pope's imitation of Horace, B. ii.

Oui, sa pudeur ne'st que franche grimace,
Qu'une ombre de vertu qui garde mal la place,
Et qui s'evanouit, comme l'on peut savoir,
Aux rayons du soleil qu'une bourse vait voir.
Moliere, L'Etourdi, act iii. *sc.* 2.

Et son feu, de pourvû de sense et de lecture,
S'éteint à chaque pas, saut de nourriture.
Boileau, L'art poetique, chant. iii. l. 319.

Dryden, in his dedication of the translation of *Juvenal,* says, " When thus, as I may say, before the use of the loadstone, or knowledge of the compass, I was sailing in a vast ocean, without other help than the pole-star of the ancients, and the rules of the French stage among the moderns, &c."

" There is a time when factions, by the vehemence of their own fermentation, stun and disable one another." *Bolingbroke.*

This fault of jumbling the figure and plain expression into one confused mass, is not less common in allegory than in metaphor.

Take

Take the following examples:

——————Heu! quoties fidem,
Mutatosque Deos flebit, et aspera
Nigris æquora ventis
Emirabitur insolens.
Qui nunc te fruitur credulus aureâ:
Qui semper vacuam, semper amabilem
Sperat, nescius auræ
Fallacis. *Horat. Carm. lib.* i. *ode* 5.

Pour moi sur cette mer, qu'ici bas nous courons,
Je songe à me pourvoir d'esquif et d'avirons,
A regler mes desires, à prévenir l'orage,
Et sauver, s'il se peut, ma Raison du naufrage.
Boileau, epitre 5.

Lord Halifax, speaking of the ancient fabulists: "They (says he) wrote in signs, and spoke in parables: all their fables carry a double meaning: the story is one, and entire; the characters the same throughout; not broken or changed, and always conformable to the nature of the creature they introduce. They never tell you, that the dog which snapped at a shadow, lost his troop of horse; that would be unintelligble. This is his (Dryden's) new way of telling a story, and confounding the moral and the fable together." After instancing from the hind and panther, he goes on thus: "What relation has the hind to our Saviour? or what notion have we of a panther's Bible? If you say he means the church, how does the church feed on lawns, or range in the forest? Let it be always a church, or always a cloven-footed beast; for we cannot bear his shifting the scene every line."

A few words more upon allegory. Nothing gives greater pleasure than this figure, when the representative subject bears a strong analogy, in all its circumstances, to that which is represented: but the choice is seldom so lucky; the analogy being generally so faint and obscure, as to puzzle and not please. An allegory is still more difficult in painting than in poetry: the former can show no resemblance but what appears to the eye; the latter hath many other resources for showing the resemblance. And therefore, with respect to what the Abbé du Bos terms *mixt allegorical compositions*, these may do in poetry; because, in writing, the allegory can easily be distinguished from the historical part: no person, for example, mistakes Virgil's Fame for a real being. But such a mixture in a picture is intolerable; because in a picture the objects must appear all of the same kind, wholly real or wholly emblematical. For this reason, the history of Mary de Medicis, in the palace of Luxembourg, painted by Rubens, is unpleasant by a perpetual jumble of real and allegorical personages, which produce a discordance of parts, and an obscurity upon the whole: witness, in particular, the tablature representing the arrival of Mary de Medicis at Marseilles; where, together with the real personages, the Nereids and Tritons appear sounding their shells: such a mixture of fiction and reality in the same group, is strangely absurd. The picture of Alexander and Roxana, described by Lucian, is gay and fanciful; but it suffers by the allegorical figures. It is not in the wit of man to invent an allegorical representation deviating farther from any shadow of resemblance, than one exhibited by Louis XIV. anno 1664; in which an enormous chariot, intended to represent that of the sun, is dragged along, surrounded with men and women, representing the four ages of the world, the celestial signs, the seasons, the hours, &c. a monstrous composition, and yet scarce more absurd than Guido's tablature of Aurora.

In an allegory, as well as in a metaphor, terms ought to be chosen that properly and literally are applicable to the representative subject: nor ought any circumstance to be added that is not proper to the representative subject, however justly it may be applicable properly or figuratively to the principal. The following allegory is therefore faulty:

Ferus et Cupido,
Semper ardentes acuens sagittas
Cote *cruentâ*. *Horat. lib.* ii. *ode* 8.

For though blood may suggest the cruelty of love, it is an improper or immaterial circumstance in the representative subject: water, not blood, is proper for a whetstone.

We proceed to the next head, which is, to examine in what circumstances these figures are proper, in what improper. This inquiry is not altogether superseded by what is said upon the same subject in the article Comparison; because, upon trial, it will be found, that a short metaphor or allegory may be proper, where a simile, drawn out to a greater length, and in its nature more solemn, would scarce be relished.

And, in the first place, a metaphor, like a simile, is excluded from common conversation, and from the description of ordinary incidents. Second, in expressing any severe passion that totally occupies the mind, metaphor is unnatural.

The following example, of deep despair, beside the highly figurative style, has more the air of raving than of sense:

Calista. Is it the voice of thunder, or my father?
Madness! confusion! let the storm come on,
Let the tumultuous roar drive all upon me,
Dash my devoted bark; ye surges, break it;
'Tis for my ruin that the tempest rises.
When I am lost, sunk to the bottom low,
Peace shall return, and all be calm again.
Fair Penitent, act 5.

The following metaphor is sweet and lively; but it suits not the fiery temper of Chamont, inflamed with passion: parables are not the language of wrath venting itself without restraint:

Chamont. You took her up a little tender flow'r,
Just sprouted on a bank, which the next frost
Had nipp'd; and with a careful loving hand,
Transplanted her into your own fair garden,
Where the sun always shines: there long she flourish'd,
Grew sweet to sense, and lovely to the eye;
Till at the last a cruel spoiler came,
Cropt this fair rose, and rifled all its sweetness,
Then cast it like a loathsome weed away. *Orph. act* 4.

The following speech, full of imagery, is not natural in grief and dejection of mind.

Gonsalez. O my son! from the blind dotage
Of a father's fondness these ills arose.
For thee I've been ambitious, base, and bloody:

For-

Metaphor.

For thee I've plung'd into this ſea of ſin;
Stemming the tide with only one weak hand,
While t'other bore the crown (to wreathe thy brow),
Whoſe weight has ſunk me ere I reach'd the ſhore.
Mourning Bride, act 5. ſc. 6.

There is an enchanting picture of deep diſtreſs in Macbeth, where Macduff is repreſented lamenting his wife and children, inhumanly murdered by the tyrant. Stung to the heart with the news, he queſtions the meſſenger over and over: not that he doubted the fact, but that his heart revolted againſt ſo cruel a misfortune. After ſtruggling ſome time with his grief, he turns from his wife and children to their ſavage butcher; and then gives vent to his reſentment, but ſtill with manlineſs and dignity:

O, I could play the woman with mine eyes,
And braggart with my tongue. But, gentle Heav'n!
Cut ſhort all intermiſſion, front to front
Bring thou this fiend of Scotland and myſelf;
Within my ſword's length ſet him. If he 'ſcape,
Then Heav'n forgive him too.

Metaphorical expreſſion, indeed, may ſometimes be uſed with grace where a regular ſimile would be intolerable: but there are ſituations ſo ſevere and diſpiriting, as not to admit even the ſlighteſt metaphor. It requires great delicacy of taſte to determine with firmneſs, whether the preſent caſe be of that nature: perhaps it is; yet who could wiſh a ſingle word of this admirable ſcene altered?

But metaphorical language is proper when a man ſtruggles to bear with dignity or decency a misfortune however great; the ſtruggle agitates and animates the mind:

Wolſey. Farewell, a long farewell, to all my greatneſs!
This is the ſtate of man: to day he puts forth
The tender leaves of hope; to-morrow bloſſoms,
And bears his bluſhing honours thick upon him;
The third day comes a froſt, a killing froſt,
And when he thinks, good eaſy man, full ſurely
His greatneſs is a ripening, nips his root,
And then he falls as I do. *Henry VIII. act 3. ſc. 6.*

METAPHRAST, a tranſlator, or perſon who renders an author into another form or another language, word for word.

METAPHYSICS.

1 Definition.

METAPHYSICS has been defined, by a writer deeply read in the ancient philoſophy, "The ſcience of the principles and cauſes of all things exiſting." This definition, we think, extremely proper: and hence it is, that *mind* or intelligence, and eſpecially the *ſupreme intelligence*, which is the cauſe of the univerſe and of every thing which it contains, is the principal ſubject of this ſcience; and hence, too, the ſcience itſelf received its name. Ariſtotle, indeed, who, of all the ancient metaphyſicians whoſe works have come down to us, was unqueſtionably the greateſt, calls this ſcience THE FIRST PHILOSOPHY, as being not only ſuperior, but alſo prior in the order of nature, to the whole circle of the other arts and ſciences But, "what is firſt to nature, is not firſt to man." Nature begins with *cauſes* which produce *effects*. Man begins with *effects*, and by them aſcends to *cauſes*. Thus all human ſtudy and inveſtigation proceed of neceſſity in the reverſe of the natural order of things, from *ſenſible* to *intelligible*, from *body* the effect, to *mind*, which is both the firſt and the final cauſe. Now, PHYSICS being the name given by the Stagyrite to the philoſophy of body, ſome of his interpreters, from this neceſſary courſe of human ſtudies, called that of mind METAPHYSICS, implying by that term, not only that its ſubject is more ſublime and difficult, but alſo that the ſtudy of it would be moſt properly and ſucceſsfully entered upon AFTER THAT OF PHYSICS. To this name, which, though it has ſometimes been treated with ridicule, is abundantly ſignificant, the followers of Ariſtotle were led by their maſter, who, to the books in which he pretends to elevate the mind above things corporeal to the contemplation of God and things ſpiritual, prefixed the Greek words [illegible] (A).

2 Diviſion of the Science into

The ſcience of Metaphyſics has been divided, according to the objects which it conſiders, into ſix principal parts, which are called, 1. *Ontology*; 2. *Coſmology*; 3. *Anthropoſophy*; 4. *Pſychology*; 5. *Pneumatology*; and, 6. *Metaphyſical theology*.

3 Ontology.

1. That part of the ſcience which is named *ontology*, inveſtigates and explains the nature and eſſence of all beings, as well as the qualities and attributes that eſſentially appertain to them. Hence it has been ſaid that ontology ſhould proceed in its operations from the moſt ſimple ideas; ſuch as do not admit of any other qualities of which they may be compounded. Theſe ſimple ideas are of *being*, of *eſſence*, of *ſubſtance*, of *mode*, of *exiſtence* as well with regard to time as place, of a *neceſſary cauſe* of *unity*; the idea of *negation*; the difference between a *being* that is *ſimple* or *compound*, *neceſſary* or *accidental*, *finite* or *infinite*; the ideas of *eſſential* and *abſtract properties*, ſuch as of the *greatneſs*, *perfection*, and *goodneſs* of *beings*, &c. The buſineſs therefore of ontology, is to make us acquainted with every kind of being in its nature and eſſential qualities, which diſtinguiſh it from all other beings. This knowledge being once eſtabliſhed on ſimple principles, juſt conſequences may thence be drawn, and thoſe things proved after which the metaphyſician enquires,

(A) ΤΩΝ ΜΕΤΑ ΤΑ ΦΥΣΙΚΑ. Cujus inſcriptionis hæc ratio eſt, quod in hoc opere ea tractantur quorum theoria poſterior eſt doctrina naturali ſaltem quoad nos, qui a corporum cognitione rerumque caducarum in ſubſtantiarum immaterialium atque immortalium contemplationem provehimur.
Du Val. Synopſ. Doctr. Peripat.

Divisions of the Science

quires, and which is the business of his science to prove.

It is easy to conceive, that even a clear knowledge of beings, and their essential properties, would be still defective and useless to man, if he did not know how to determine and fix his ideas by proper denominations, and consequently to communicate his perceptions to those whom he would instruct, or against whom he is obliged to dispute. To render our ideas therefore intelligible to others, we must have determinate words or denominations for each being, and the qualities of each being; and ontology teaches us those terms which are so necessary to fix our ideas, and to give them the requisite perspicuity and precision, that when we endeavour to extend the sphere of our knowledge, we may not waste our time in disputes about words.

4 Cosmology;

2. Metaphysics, having, in as solid a manner as possible, explained and established the principles above mentioned, continues its enquiries to the second part, which is called *cosmology*, and examines into the essence of the world and all that it contains, its eternal laws; of the nature of matter; of motion; of the nature of tangible bodies, their attributes and adjuncts; and of all that can be known by reasoning and experience. It is also in cosmology that the metaphysicians of this school examine the Leibnitzian system; that is, whether God, in creating the world, must necessarily have created the best world; and if this world be so in fact. In this manner they pursue the argument, from consequence to consequence, to its last resort, frequently with very little advantage to truth and science.

5 Anthroposophy;

3. *Anthroposophy*, or the knowledge of man, forms the third branch of metaphysics. It is subdivided into two parts. The first, which consists in the knowledge of the exterior parts of the human frame, belongs not to this science, but to Anatomy and Physiology. The business of the metaphysician is here to ascertain the nature of those powers by which all the motions essential to life are produced; and to discover, if possible, whether they be corporeal or spiritual. This inquiry leads at the same time to

6 Psychology;

4. *Psychology*; which consists in the knowledge of the intellectual soul in particular: concerning which, the most profound, the most subtile, and most abstract researches, have been made that human reason is capable of; and concerning the substance of which, in spite of all these efforts, it is yet extremely difficult to support any positive opinion with conclusive or probable arguments.

7 Pneumatology;

5. The fifth part of metaphysics is called *pneumatology*. By this term, which has not been long in use, metaphysicians mean the knowledge of all spirits, *angels*, &c. It is easy to conceive what infinite art is necessary to give an account of that, of which nothing positive can ever be known in the present state of human existence. But the metaphysician of this school readily offers to show us, "what is the idea of a spirit; the effective existence of a spirit; what are its general qualities and properties; that there are rational spirits, and that these rational spirits have qualities that are founded in the moral attributes of God:" for this is in so many words what is attempted to be taught in pneumatology.

8 Metaphysical theology.

6. *Metaphysical theology*, which Leibnitz and some others call *theodicy*, is the sixth and last branch of the science of metaphysics. It teaches us the knowledge of the existence of God; to make the most rational suppositions concerning his divine essence, and to form a just idea of his attributes and perfections, and to demonstrate them by abstract reasoning. Theodicy differs from natural theology, in as much as this last borrows, in fact, from theodicy proofs and demonstrations to confirm the existence of a supreme Being: but after having solidly established that great truth, by extending its consequences natural theology teaches us what are the relations and connections that subsist between the supreme Being and men, and what are the duties which result from those relations.

9 This division useless and improper.

We have briefly mentioned these divisions of the science, because they were once prevalent in the schools. The greater part of them, however, appears to us to be not only superfluous, but such as can serve no other purpose than to perplex the mind. The only beings of which we know any thing are mind and body; and we have no reason to think that there are any other beings in the universe. Of bodies indeed there are various kinds, endowed with different properties: and it is extremely probable, that of minds endowed with different powers, the variety may be equally great. Our own minds we know to be united in one system with bodies by which they perform all their operations; and we can demonstrate that there is another Mind, which is independent of all body, and is the cause of all things. Between these there may be numberless orders of minds; but their energies are wholly unknown to us, and therefore they can never become the objects of science.

Mind and body therefore, *i.e.* the minds and bodies which we know to exist, together with their powers and properties, essential and accidental, can alone be the subjects of rational inquiry. We may inquire into the essence of mind and the essence of body, and endeavour to ascertain in what respects they differ. We may examine the nature of different bodies, in order to discover whether all bodies, however modified, have not something in common; and we may consider the properties, relations, and adjuncts of bodies, and endeavour to distinguish those which are accidental from such as appear to be so necessary that without them body itself could not exist. Of minds we cannot make the same comparison. In this part of the science we have not sufficient data for an accurate and complete induction: we can only examine the powers of our own mind; and by probable analogy make some estimate of the powers of superior minds, as observation will help us to guess at the powers of those which are placed beneath us in the scale of existence.

If this be so, Cosmology, as distinguished from Ontology, cannot properly be a branch of Metaphysics. For if mind and body, with their several powers, properties, and adjuncts, compose the universe, it is obvious, that when we have ascertained, as well as we are able to ascertain, the essence of mind and the essence of body, together with the powers and properties of each, and have traced them all to the first cause, we have done every thing in the science of the universe, if we may use the expression, which belongs to

Divisions of the Science. to the province of the metaphysician. The particular laws of motion on the earth and in the planetary system belong to the natural philosopher and astronomer.

In like manner, Anthroposophy, Psychology, and Pneumatology, if they be not words expressive of distinctions where there is no difference, seem to be at least very needlessly disjoined from each other. Of the nature of spirits we can know nothing but from contemplating the powers of our own minds; and the body of man is in the province, not of the metaphysician, but of the anatomist and physiologist. Anthroposophy, psychology, and pneumatology, if they be used to denote our knowledge of all minds except the Supreme, are words of the same import; for of no created minds except our own can we acquire such knowledge as deserves the name of science.

Ontology has sometimes been defined the science of *being in the abstract;* but in the course of our inquiries it will be seen, that *being in the abstract* is a phrase without meaning. Considered as the science of *real beings* and their *properties*, Ontology is a very significant word, of the same import with Metaphysics, comprehending in itself the knowledge of the nature of all things existing. Or if it be thought proper to make a distinction between ontology and theology, the former branch of the science will teach the knowledge of body and created minds, whilst it is the province of the latter to demonstrate the existence and attributes of that mind which is uncreated.

10 Another proposed. Body and mind therefore, with their properties, adjuncts, and powers, comprehend the whole subject of the science of metaphysics: and as we are earlier acquainted with body than with mind, the natural order of conducting our inquiries seems to be, to begin with the former, and thence proceed to the latter. It is however obvious, that if we would pursue these inquiries with any hopes of success, we must first trace human knowledge from its source, ascertain the nature of truth, and show what kind of evidence on each topic to be treated ought to enforce conviction. In this view of the science, metaphysics appears to be divided into three parts; the first treating *of human understanding;* the second, *of body with its adjuncts;* and the third, *of mind with its powers.*

11 Idea and notion explained. Previous to the entering upon such inquiries, some philosophers of great merit have lately thought it expedient to explain the terms which they should have occasion to use. Their conduct is judicious and worthy of imitation; for the objects of metaphysics being, for the most part, such as fall not under the cognisance of the senses, are liable to be differently apprehended by different men, if the meanings of the words by which they are expressed be not ascertained with the utmost precision. We intend, however, to use very few words but in the common acceptation; and we therefore hope, that as terms of science are explained under different words in the Dictionary, to which references are made, we have little or no occasion for swelling the article by previous definitions. There are indeed two words which have given rise to much useless disputation, which yet cannot be banished from speculative philosophy, and which it will therefore be proper here to define. The words to which we allude are *idea* and *notion.* These are very generally considered as synonymous; but we think that much loquacity might have been avoided by assigning to each a determinate signification. We know not any philosopher who made much use of the word *idea* before Plato; but with his mysterious doctrine concerning ideas we have here nothing to do: our present business is to ascertain the precise meaning of the word, which is evidently derived from ειδω to *see*, as the word *notion* is from "nosco, novi, *notum*," and that from γινωσκω, to *know* or *understand.* In the original sense of the two words, therefore, *notion* is more comprehensive than *idea*, because we *know* many things which cannot be *seen.* We have not a doubt, but that at first the word *idea* was employed to denote only those forms of external objects which men contemplate in their imaginations, and which are originally received through the sense of *sight.* Its signification was afterwards extended to the relicts of every sensation, of touch, taste, sound, and smell, as well as of sight; and at last it was confounded with *notion*, which denotes the mental apprehension of whatever may be known. In our use of the word *idea*, except when we quote from others, we shall employ it only to denote that appearance which absent objects of sense make in the memory or imagination (A); and by the word *notion* we shall denote our apprehension or knowledge of spirits, and all such things as, though they be the objects of science, cannot be perceived by the external senses. Having said this, we proceed to our inquiries, beginning with that into human understanding.

(A) In thus restricting the meaning of the word *idea*, we have the honour to agree with the great English Lexicographer.—"He was particularly indignant against the almost universal use of the word *idea* in the sense of *notion* or *opinion*, when it is clear that *idea* can only signify something of which an image may be formed in the mind. We may have an *idea* or *image* of a mountain, a tree, or a building; but we cannot surely have an *idea* or *image* of an *argument* or *proposition.* Yet we hear the sages of the law delivering their *ideas* upon the question under consideration; and the first speakers in parliament entirely coinciding in the *idea*, which has been so ably stated by an honourable member; or representing an *idea* as unconstitutional, and fraught with the most dangerous consequences to a great and free country. This Johnson called *modern cant.*" *Boswell's Life of Johnson.*

PART

Part I. Of HUMAN UNDERSTANDING.

Preliminary Obſervations on the Origin *of our* Ideas *and* Notions.

11 …innate …as or no… …in the …man …nd.

THAT the mind of man has no innate ideas or notions, but comes into the world ignorant of every thing, is a truth which ſince the days of Locke has been very little diſputed. In the firſt book of his Eſſay on the Human Underſtanding, that acute philoſopher has demonſtrated, that the rudiments or firſt principles of all our knowledge are communicated to us by ſenſation; and he has compared the mind, previous to the operation of external objects upon the ſenſes, to a *tabula raſa* or ſheet of white paper. To repeat his arguments would ſwell the article to no purpoſe. There is not a man capable of attending to his own ideas, who can entertain a doubt in what manner he received them. Without the ſenſe of ſight, we could never have known colours; nor ſound, without hearing; nor hardneſs, ſoftneſs, ſmoothneſs, pain, or bodily pleaſure, without touch; nor odours, without ſmell, &c.

Self-evident as theſe facts are, objections have been ſtarted to the inferences drawn from them; and Locke has been accuſed of advancing principles ſubverſive of all diſtinction between truth and falſehood, and favourable of courſe to univerſal ſcepticiſm.—" The firſt book of his Eſſay, which with ſubmiſſion (ſays Dr Beattie*) I think the worſt, tends to eſtabliſh this dangerous doctrine, that the human mind, previous to education and habit, is as ſuſceptible of one impreſſion as of another: a doctrine which, if true, would go near to prove that truth and virtue are no better than human contrivances; or at leaſt that they have nothing permanent in their nature, but may be as changeable as the inclinations and capacities of men; and that there is no ſuch thing as common ſenſe in the world. Surely this is not the doctrine which Mr Locke meant to eſtabliſh." We are ſo thoroughly ſatisfied that it is not, that we cannot help wondering how ſuch inferences could, by a man of learning, genius, and candour, be drawn from any thing which is to be found in the Eſſay on the Human Underſtanding.

* …ſſay on …Nature …Immutability of …uth.

But the Doctor thinks Mr Locke's "ſimile of the mind to white paper one of the moſt unlucky alluſions that could have been choſen; becauſe the human ſoul, when it begins to think, is not extended, nor of a white colour, nor incapable of energy, nor wholly unfurniſhed with ideas, nor as ſuſceptible of one impreſſion or character as of any other:" and it has been obſerved by another objector†, that "on a ſheet of white paper you may write that ſugar is bitter; wormwood ſweet; fire and froſt in every degree pleaſing and ſufferable; that compaſſion and gratitude are baſe; treachery, falſehood, and envy, noble; and that contempt is indifferent to us."

† …Uſher, …ſor of … See a …of Fugitive Pieces …ted for …Davies, …ndon, …4.

All this is true; but we apprehend it is not to the purpoſe. Mr Locke has no where expreſſed himſelf in ſuch a manner as to lead us to ſuppoſe that he believed the ſoul to be extended or coloured; or, when it begins to think, incapable of energy, and wholly unfurniſhed with ideas: but he certainly did believe, that it begins not to think the firſt inſtant of its exiſtence, and that it *acquires* all the ideas of which it is ever poſſeſſed. We may undoubtedly write upon a piece of white paper that ſugar is bitter, and that wormwood is ſweet; but how the capacity of paper to receive the ſymbols of falſe propoſitions ſhould make Mr Locke's compariſon improper or dangerous, we cannot comprehend. Mr Uſher indeed ſays, that it is improper on this account, "that no human art or induſtry is able to make thoſe impreſſions upon the mind: in reſpect of them, the mind diſcovers not a paſſive capacity, but reſiſts them with the force of fate." Does it indeed? does the mind reject the idea of ſugar or of bitterneſs, of contempt or of indifference? May not any man have the *idea* of ſugar and at the ſame time the *idea* of bitterneſs, and compare the one with the other in his mind, as well as the word *ſugar* may be written beſide the word *bitter*, and connected with it on the ſame piece of paper? In all this we perceive nothing that is impoſſible or even difficult. The mind cannot indeed be made to feel that ſugar has the ſame taſte with wormwood; but who ever thought that it could? Not Mr Locke, we ſhall be bold to ſay; nor does his ſimile give the ſmalleſt countenance to ſuch an abſurdity. The author of the Eſſay on the Human Underſtanding underſtood his ſubject too well to imagine that either truth or falſehood could be communicated to paper, or that paper is capable of comparing ideas. Paper is capable of receiving nothing but lines or figures; and it paſſively receives whatever lines or figures we may chooſe to inſcribe on it: yet if a pen be carried over it in a circular direction, the figure impreſſed will not be a ſquare; juſt as, to the mind of one eating ſugar, the taſte communicated is not that of wormwood.

13 …ections …wered.

On a piece of paper a circle may be deſcribed, and cloſe beſide it a ſquare: in like manner an agreeable ſenſation may be communicated to the mind, and immediately afterwards a ſenſation that is diſagreeable. Theſe two ſenſations, or the ideas which they leave behind them, may be compared together; and it is certainly true that no art or induſtry can make them appear ſimilar in the mind: but is it not equally true, that no art or induſtry can make the circle and the ſquare ſimilar on the paper? The paper is ſuſceptible of any ſort of plain figures, and the mind is equally ſuſceptible of any ſort of ideas or ſenſations; but figures diſſimilar cannot be made to coincide, neither can diſcordant ideas be made to agree. Again, one may write upon paper, that "a circle *is* a ſquare," and likewiſe that "a circle *is not* a ſquare:" and both theſe propoſitions may be communicated to the mind by the organs of ſight or of hearing. The paper receives the *words* expreſſive of the falſe as well as thoſe expreſſive of the true propoſition; and the mind receives the *ideas* and *relations* ſignified by the one cluſter of words as well as thoſe ſignified by the other: but in the mind the *idea* of a ſquare is *different* from that of a circle, and on the paper the *figure* of a ſquare is *different* from the *figure* of a circle. The great difference between the mind and the paper is, that *the former* is *conſcious* of its ideas, and *perceives* their agreement or diſagreement; whereas the paper is *not* conſcious of

Origin of Ideas and Notions.

the figures drawn upon it, nor perceives any thing about them. But still those figures are what they are; they either agree or disagree on the paper, as well as the ideas either agree or disagree in the mind. It is not in the power of the mind to alter the *ideas* of the square and the circle, nor in the power of the paper to alter the *forms* of these figures.

It appears then, that the principles of Mr Locke, and the comparison by which he illustrates them, have no more tendency to subvert the difference between truth and falsehood, right and wrong, than the passiveness of paper has to subvert the difference between a straight line and a crooked, a circle and a square: and with a view to establish the doctrine of innate ideas and instinctive principles of knowledge, we might with as much propriety ask, Whether it be possible to imagine that any mode of manufacture could make paper of such a nature, as that a pen drawn over it in a circular direction would leave the figure of a square? as that, "Whether it be possible to imagine, that any course of education could ever bring a rational creature to believe that two and two are equal to three?"

14 But all derived from sensation and reflection.

The mind being thus, as we may say, originally white paper, void of all characters, without ideas or notions of any kind, the first question which we have to consider is, Whence and in what manner it derives the materials of all its knowledge? To this question the only answer which can be given is, That it derives them from observation and experience; from observation, either employed upon external objects of sense, or turned inwardly upon its own operations. Our senses, conversant about particular external objects, convey into the mind several distinct perceptions; such as those of *colour*, *figure*, *heat*, *cold*, *bitterness*, *sweetness*, and all those things which are usually called *sensible qualities*. The notions, ideas, or whatever else they may be called, which are acquired in this manner, may be called *sensible knowledge*; and the source of that knowledge is termed *sensation*.

The other fountain from which experience furnishes the understanding with knowledge, is that attention which we are capable of giving to the operations of our own minds when employed about those ideas which were originally suggested by objects of sense. These operations, when the soul comes to reflect on them, furnish us with a set of notions entirely different from the ideas of sense; such as the notions of *perception*, *thinking*, *doubting*, *believing*, *reasoning*, *knowing*, *willing*, and all the different energies and passions of our own minds. Of these operations we are always conscious when we are awake; but it requires, as shall be shown afterwards, no inconsiderable effort to set them, as it were, at a distance, to reflect on them and consider what they are; but when we have made this effort, we acquire notions as distinct, and perhaps more important, than those ideas which we receive by the medium of the senses.

Sensation and reflection then furnish mankind with the first materials of all their knowledge. The mind seems not to have ideas or notions of any kind which it did not receive by one of these ways. By means of the senses it perceives external objects; and by that power which it has of turning its attention upon itself, it discovers the nature and manner of its own operations.

Although the knowledge which we acquire from *reflection* be of equal importance, and perhaps of greater certainty than that which we receive through the medium of the senses, it comes into the mind at a much later period; both because it is impossible that the faculties of the mind should operate without materials, and because it is much more difficult to attend to these operations even while they are going on, than to the objects of sense which solicit our attention. It is for this reason pretty late before children have any notions whatever of the operations of their own minds; and of the greater part of these operations the bulk of mankind have no clear or accurate notions during their whole lives. On the other hand, every human being is so surrounded with bodies, which perpetually and variously affect his senses, that a variety of sensible ideas force an entrance even into the minds of children. In order therefore to trace the procedure of the understanding, and to ascertain the extent and limits of human knowledge, it should seem that we must begin with considering the external senses, that we may discover the manner in which we receive knowledge by means of them, the objects of that knowledge, and its certainty. It is to be observed, however, that though we consider the mind as possessed of many powers or faculties, and inquire first into the nature of that faculty which we conceive to be first exerted, this is done merely for the sake of proceeding in our subject with method and perspicuity. The mind is one simple and undivided being; and in every mental energy it is the whole mind, and not any part or portion of it, that is energetic. On this account, it is impossible to explain even the nature of sensation and perception to him who knows not what is meant by *will* and *understanding*; but to every one who is acquainted with the common import of these words, and who has read the short system of Logic inserted in this Work, we hope that our theory of perception will be intelligible and convincing.

Chap. I. *Of* Sensation *and* Perception.

Sect. I. *Of Sensation.*

15 Sensation by five organs.

The Supreme Being, who made us and placed us in this world, has given us such powers of mind as he saw to be suited to our state and rank in his creation. He has given us the power of perceiving many objects around us: but that power is limited in various ways; and particularly in this, that without the organs of the several senses we perceive no external object. The senses, as every one knows, are five in number, and each communicates its proper sensation. It is by the eyes alone that we see, by the ears that we hear, by the nose that we smell, and by the tongue and palate that we taste; the sense of feeling or touch is spread over the whole body, for we feel equally by our hands and by our feet, &c. To the powers of perception by the senses it is necessary not only that we have all the organs enumerated, but that we have them also in a sound and natural state. There are many disorders of the eye which cause total blindness, as well as others which impair without destroying the power of vision. The same thing is true of the organs of all the other senses.

All this is so well known from experience, that it needs no proof; but it may be worth while to observe, that

Of Senſation.

that it is known from experience only†. For any thing that we know to the contrary, our Creator might have endowed us with the power of perception by a thouſand organs of ſenſe, all different from thoſe which we poſſeſs; and it is certain that he himſelf perceives every thing more perfectly than we do without bodily organs. For it is to be obſerved, that the organs of ſenſe are different from the being which is ſentient.—

† Reid's Eſſays on the Intellectual Powers of Man.

16
Theſe organs themſelves not ſentient.

It is not the eye which ſees, nor the ear which hears; theſe are only the organs by which we ſee and hear. A man cannot ſee the ſatellites of Jupiter but by means of a teleſcope, nor hear a low voice but by means of an ear-trumpet. Does he from this conclude, that it is the teleſcope which ſees thoſe ſatellites, or the trumpet which hears that voice? Such a concluſion would be evidently abſurd. It is no leſs abſurd to conclude that it is the eye which ſees, or the ear which hears. The teleſcope and the trumpet are artificial organs of ſight and of hearing, of which the eye and the ear are natural organs; but the natural organs ſee and hear as little as the artificial.

17
Arguments for ſenſation.

That this is the caſe with reſpect to the eye and the ear, is ſo obvious, that, as far as we know, it has never been denied. But with reſpect to the ſenſes of touch, taſte, and ſmell, the truth at firſt view appears not ſo evident. A celebrated writer has obſerved *, that "after the utmoſt efforts, we find it beyond our power to conceive the flavour of a roſe to exiſt in the mind: we are neceſſarily led to conceive that pleaſure as exiſting in the noſtrils, along with the impreſſion made by the roſe upon that organ (c); and the ſame will be the reſult of experiments with reſpect to every feeling of taſte, touch, and ſmell. Touch (he ſays), affords the moſt ſatisfactory evidence, and philoſophy detects the deluſion." To detect this deluſion requires, indeed, no great depth in philoſophy; for it is ſo far from being true that we are neceſſarily led otherwiſe than by aſſociation, of which the laws ſhall be explained afterwards, to conceive the pleaſure or pain of touch as exiſting at that part of our body upon which the impreſſion is made, that, as every man muſt have obſerved, children previous to experience cannot diſtinguiſh the preciſe place of their bodies which is affected by the touch of any external object. Nay, we believe it will be found upon trial, that if a full grown man, with all the experience of age to guide him, be pricked with a pin on any part of his body which he has ſeldom handled, and never ſeen, he will not readily nor at firſt put his finger upon the wound, nor even come very *near* to the wound. This, however, he would certainly and infallibly do were the ſenſe of touch neceſſarily conceived as exiſting at the organ. To theſe obſervations objections may perhaps be made, which we cannot ſtay to obviate; but the following, we think, will admit of none. We appeal to every man who has experienced that particular ſenſation of touch which Scaliger dignified with the name of a ſixth ſenſe, whether, whilſt thoſe ſenſations were new to him, he was neceſſarily led to conceive them as exiſting at any particular organ. If he was not, it follows undeniably that the organs of ſenſation are different from the being which is ſentient; that it is not the eye which ſees, the ear which hears, the noſtrils which ſmell, the tongue which taſtes, nor any part of the body which feels; and that it is by experience that we learn to aſſociate our ſeveral ſenſations with thoſe organs upon which the impreſſions are made.

* Elements of Criticiſm.

It is, however, certain that we receive no ſenſation from external objects, unleſs when ſome impreſſion is made upon the organ of ſenſe, either by the immediate application of the object itſelf, or by ſome medium which paſſes between the object and the organ †. In two of our ſenſes, viz. *touch* and *taſte*, there muſt be an immediate application of the object to the organ. In the other three the ſenſation is occaſioned by the impreſſion of ſome medium paſſing from the object to the organ. The effluvia of bodies drawn into the noſtrils with the breath are the medium of ſmell; the undulations of the air are the medium of hearing; and the rays of light paſſing from viſible objects to the eye are the medium of ſight. Theſe are facts known from experience to hold univerſally both in men and in brutes. It is likewiſe a law of our nature perfectly known to all who know any thing of anatomy, that in order to actual ſenſation the impreſſions made upon the external organs muſt be communicated to the nerves, and from them to the brain. Firſt, the object, either immediately, or by ſome medium, makes an impreſſion upon the organ; the organ ſerves only as a medium, by which the impreſſion is communicated to the nerves; and the nerves ſerve as a medium to carry it on to the brain. Here the corporeal part ends; at leaſt we can trace it no farther. The reſt is all intellectual.

† Reid's Eſſays on the Intellectual Powers of Man, and Hartley's Obſervations on Man.

18
The brain and nerves neceſſary to ſenſation.

The proof of theſe impreſſions upon the nerves and brain in ſenſation is this, that from many obſervations and experiments it is found, that when the organ of any ſenſe is perfectly ſound, and has the impreſſion made upon it by the object ever ſo ſtrongly, yet if the nerve which ſerves that organ be cut or tied hard, there is no ſenſation; and it is well known that diſorders in the brain deprive us of ſenſation, while both the organ and its nerve are ſound.

19
Proceſs of nature in ſenſation.

There is ſufficient reaſon, therefore, to conclude, that in ſenſation the object produces ſome change in the organ; that from the organ the change proceeds to the nerve, and from the nerve to the brain. Hence it is that we have poſitive ſenſations from negative objects, or mere non-entities, ſuch as *darkneſs*, *blackneſs*, and *vacuity*. For, ſenſation reſulting from changes in the brain, whatever produces any change muſt of courſe

6

(c) Another eminent writer thinks on this ſubject very differently, and in our opinion much more juſtly.—"Suppoſe (ſays Dr Reid) a perſon who never had this ſenſe (viz. *ſmell*) before, to receive it all at once, and to ſmell a roſe; can he perceive any ſimilitude or agreement between the ſmell and the roſe? or indeed between it and any other object whatever? Certainly he cannot. He finds himſelf affected in a new way, he knows not why, or from what cauſe. He is conſcious that he is not the cauſe of it himſelf; but he cannot from the nature of the thing determine whether it be cauſed by body or ſpirit; by ſomething near, or by ſomething at a diſtance. He cannot give it a *place* any more than he can give a place to melancholy or joy; nor can he conceive it to have any exiſtence but when it is ſmelled." *Inquiry into the Human Mind*, ch. 2. ſect. 2.

Of Senſation.

courſe occaſion a new ſenſation: but it is obvious, that the mere abſence of any impreſſion, by the removal of the object which produced it, muſt as neceſſarily cauſe a change in the organ, nerves, and brain, as the preſence of a new impreſſion from a new object. To theſe changes, or that which *immediately* produces them, we give the name of *impreſſions;* becauſe we know not how, in a general manner, to expreſs more properly any change produced by an external cauſe, without ſpecifying the nature of that cauſe. Whether it be preſſure, or attraction, or repulſion, or vibration, or ſomething unknown, for which we have no name, ſtill it may be called an impreſſion.

Sir Iſaac Newton was perhaps the firſt who ſuppoſed that the rays of light falling upon the bottom of the eye excite vibrations in the *tunica retina;* and that thoſe vibrations being propagated along the ſolid fibres of the optic nerves into the brain, cauſe the actual ſenſation of ſeeing. This hypotheſis was adopted by Dr Hartley, applied to the other ſenſes, and ſhown to be at leaſt as probable as any which has yet been invented to account for the perception of external objects by means of the organs of ſenſe. Be this as it may, experience informs us, that whatever be the nature of thoſe impreſſions and changes which are made by external objects upon the ſenſes, nerves, and brain, we have without them no actual ſenſation, and of courſe perceive nothing *ab extra.* Hence it has been

20 In ſenſation the mind is partly active.

ſuppoſed, that the mind is wholly paſſive in ſenſation, and that ſenſation is *neceſſarily* produced by thoſe impreſſions. But this we believe to be a miſtake. Every man who has been attentive to his own thoughts and actions, muſt know inſtances of impreſſions having been certainly made upon his organs of ſenſe without producing any ſenſation, or ſuggeſting to his mind the perception of the particular objects by which the impreſſions were cauſed. He whoſe mind is intenſely employed in any particular purſuit, may have his eyes open upon an object which he does not ſee; or he may not hear the ſound of a clock ſtriking within two yards of him: Nay, we will venture to affirm, that there is hardly one reader of this article to whom ſuch abſences of ſenſation have not often occurred. Now, as there is no reaſon to ſuppoſe, that in the one caſe the undulations of the air, cauſed by the ſtriking of the clock, did not reach his ears, or that in the other the rays of light, reflected from the object, did not fall upon his eyes, which were open to receive them; the only reaſon which can be aſſigned for his not having, in theſe inſtances, had audible and viſible ſenſations, is, that his mind was ſo engaged in ſomething elſe as not to pay to the vibrations in his brain that attention, if we may ſo ſay, without which impreſſions *ab extra* can produce no ſenſation. There are, indeed, ſome impreſſions on the organs of ſenſe ſo violent and ſo ſudden, as to force themſelves upon the mind however employed. Such are thoſe made on the ear by thunder, and on the eye by ſtrong light. In theſe caſes, ſenſation is involuntary and unavoidable; whence we conclude, not that in ſuch inſtances the mind is paſſive or deſtitute of energy, but that by the violent agitation given to the brain, it is rouſed from its reverie, and compelled to give attention. It appears, therefore, that in ſenſation the mind exerts ſome kind of energy; for in nothing but in the ſentient being itſelf can we ſeek for the cauſe why, when all external circumſtances are the ſame, organical impreſſions ſometimes produce ſenſations and ſometimes not; and that cauſe can only be the energy of the mind: what kind of energy, we pretend not to ſay.

Of Per tion

Sect. II. *Of Perception by the Senſes.*

21 Difficu accoun the per tion of object

How the correſpondence is carried on between the thinking principle within us and the material world without us, has always, as Dr Reid obſerves, been found a very difficult problem to thoſe philoſophers who conſider themſelves as obliged to account for every phenomenon in nature. It is, indeed, a problem of which we expect not to ſee a complete ſolution. A few ſteps beyond the vulgar we may certainly go; but the nature of that connection by which the mind and body are united, will probably remain for ever unknown. One queſtion, however, which has employed much of the attention of philoſophers, both ancient and modern, appears to be not wholly unanſwerable. It is, Whether by means of our ſenſes we perceive external objects mediately or immediately; or in other words, Whether ſenſation and perception be one and the ſame thing, or two things ſucceeding each other? On this ſubject, till of late, there appears to have been in the main a great uniformity in the ſentiments of philoſophers, notwithſtanding their variations reſpecting particular points. Of ſome of the moſt eminent of them, we ſhall give the opinions as we find them collected by one * who is well acquainted with their writings, who is thoroughly qualified to eſtimate their reſpective merits, and who cannot be ſuſpected of partiality to that theory, which we feel ourſelves compelled to adopt.

* Dr R his *E the In tual P of M.*

22 The h theſi Plato

" Plato illuſtrates our manner of perceiving external objects thus: He ſuppoſes a dark ſubterraneous cave, in which men lie bound in ſuch a manner as that they can direct their eyes only to one part of the cave. Far behind there is a light, of which ſome rays come over a wall to that part of the cave which is before the eyes of our priſoners. A number of men variouſly employed paſs between them and the light, whoſe ſhadows are ſeen by the priſoners, but not their perſons themſelves. In this manner did that philoſopher conceive, that by our ſenſes we perceive not things themſelves, but only the ſhadows of things; and he ſeems to have borrowed his notions on this ſubject from the diſciples of Pythagoras.

Of A ſtotle

" If we make due allowance for Plato's allegorical genius, his ſentiments with reſpect to ſenſation and perception correſpond very well with thoſe of the Peripatetics. Ariſtotle, the founder of that ſchool, ſeems to have thought, that the ſoul conſiſts of two or three parts, or rather that we have three ſouls—the vegetable, the animal, and the rational. The animal ſoul he held to be a certain *form* of the body, which is inſeparable from it, and periſhes at death. To this ſoul the ſenſes belong: and he defines a ſenſe to be that which is capable of receiving the ſenſible forms, or ſpecies of objects, without any of the matter of them; as wax receives the form of the ſeal without any of its matter. Of this doctrine it ſeems to be a neceſſary conſequence, that bodies are conſtantly ſending forth, in all directions, as many different kinds of forms without matter as they have different ſenſible qualities. This was according-

Of Perception. ly maintained by the followers of Aristotle, though not, as far as we know, taught by himself. They disputed concerning the nature of these forms or species, whether they were real beings or nonentities: but of matter and form we shall have occasion to speak afterwards.

24 Of Des Cartes; "After Aristotle had kept possession of the schools for more than a thousand years, his authority, which had often supplied the place of argument, was called in question by Lord Bacon and others. Des Cartes, however, was the first philosopher who, convinced of the defects of the prevailing system, attempted to form another entirely new: but on the nature of perception by means of the senses he differs little or nothing from those who had preceded him in that department of science. He denies, indeed, and refutes by solid reasoning, the doctrine which maintains that *images*, *species*, or *forms* of external objects, come from the objects themselves, and enter into the mind by the avenues of the senses. But he takes it for granted, as all the old philosophers had done, that what we immediately perceive must be either in the mind itself, or in the brain, to which the mind is immediately present. The impressions made upon our organs, nerves, and brain, can be nothing, according to his philosophy, but various modifications of extension, figure, and motion. There can be nothing in the brain like *sound* or *colour*, *taste* or *smell*, *heat* or *cold*. These are sensations in the mind, which, by the laws of the union of the soul and body, are raised on occasion of certain traces in the brain; and although he sometimes gives the name of ideas to these traces, he does not think it necessary that they should be perfectly like the things which they represent, any more than that words and signs should resemble the things which they signify.

"According to this system it would appear, that we perceive not external objects *directly* by means of our senses; but that these objects, operating either mediately or immediately upon the organs of sense, and they again upon our nerves and brain, excite in the mind certain sensations; whence we *infer* the existence of external objects from our sensations of which they are the cause. Perception of external objects, therefore, according to Des Cartes, is not one simple original act of the mind, but may be resolved into a process of reasoning from effects to causes."

25 Of Malebranche; The doctrines of Malebranche, Locke, and Hartley, respecting perception, differ not essentially from that of Des Cartes. Malebranche, indeed, supposes, that external objects are not themselves the causes of perception; but that the Deity, being always present to our minds more intimately than any other being, does, upon occasion of the impressions made upon our organs of sense, discover to us, as far as he thinks proper, and according to fixed laws, his own ideas of the object: and thus, according to him, we see all things in God, or in the divine ideas. He agrees, however, with Des Cartes and the ancient philosophers, in considering it as a truth which it is impossible to question, that we perceive not the objects without us, the sun, moon, and stars, &c. because it is not likely that the soul sallies out of the body, and takes a walk, as it were, through the heavens to contemplate these objects. She sees them not therefore by themselves; and the immediate object of the mind, when it sees the sun, is not the sun itself, but something which is intimately united to the mind, and is that which he calls an *idea*.

26 Of Locke. Locke speaking of the reality of our knowledge, says: "It is evident the mind knows not things immediately, but only by the intervention of the *ideas* it has of them. Our knowledge, therefore, according to him, is real only so far as there is a conformity between our ideas and the things which they represent." The manner of our perceiving external objects he illustrates by the following similitude: "Methinks the understanding is not much unlike a closet wholly shut from light, with only some little opening left, to let in external visible resemblances or ideas of things without. Would the pictures coming into such a dark room but stay there, and lie so orderly as to be found upon occasion, it would very much resemble the understanding of a man in reference to all objects of sight, and the ideas of them *." He has elsewhere † defined an *idea* thus: "Whatsoever the mind perceives in itself, or is the immediate object of perception, thought, or understanding, that I call an *idea*; and the power to produce any idea in our mind, I call *quality* of the subject wherein the power is." He likewise thinks it "easy to draw this observation, that the ideas of what he calls primary qualities of bodies, viz. *extension*, *solidity*, *figure*, and *mobility*, &c. are resemblances of these qualities as they really exist in the body themselves."

* *Essay on the Understanding*, book ii. chap. 11.

† Book ii. chap. 8.

This unguarded expression, which affirms that ideas in the mind are the resemblances of external things, has brought upon Mr Locke much undeserved ridicule. That on this and other occasions he uses the word *idea* with too great latitude, and that he often confounds ideas with sensations, and even with the causes of sensation, must be admitted by his warmest admirers: but we believe, that by an attentive reader, who peruses his whole work, and compares such passages as are obscure with those which are clearer, his meaning may always be discovered, and with respect to sensation and perception will generally be found just. That by calling the ideas of primary qualities resemblances of the qualities themselves, he meant nothing more than that bodies in all possible states impress the senses, nerves, and brain, in such a manner as to produce in the mind certain sensations: between which and those impressions there is an inseparable, though unknown, connection, is evident from the account which he gives of the manner of perception. "Our senses (says he), conversant about particular sensible objects, do convey into the mind several distinct perceptions of things, according to those various ways in which these objects affect them: and thus we come by those ideas we have of *yellow*, *white*, *heat*, *cold*, *soft*, *hard*, *bitter*, *sweet*, and all those which we call sensible qualities; which when I say the senses convey into the mind, I mean, they from external objects convey into the mind what produces those perceptions." And as bodies can act only by impulse, he adds, that "those perceptions can be produced only by an impression made upon the senses, and some motion thence continued by our nerves to the brain or seat of perception."

27 Of Hartley. Dr Hartley was the pupil of Locke and Newton; and has, in a more satisfactory manner than all who

had

Of Perception.

had preceded or have fince followed him, explained the material part of the procefs of perception. His principles we fhall have occafion, during the courfe of the article, to develope pretty fully. For our prefent purpofe it is fufficient to fay, that all his obfervations and arguments evidently fuppofe, that nothing diftant from the mind can be perceived in the immediate act of fenfation; but that the apparently immediate perception of external objects is an inftance of early and deep-rooted affociation.

28
Of Hume.

In this fentiment Mr Hume agrees with his predeceffors; but he obfcures his philofophy, and mifleads his reader, by confounding fenfations with the impreffions from which they proceed. "Every one (fays he *) will allow, that there is a confiderable difference between the perceptions of the mind, when a man feels the pain of exceffive heat, or the pleafure of moderate warmth, and when he afterwards recals to his memory this fenfation or anticipates it by his imagination." The lefs forcible and lively of thefe perceptions he with great propriety calls *ideas;* but it is either through wilful perverfenefs, or confufion of intellect, that he chooses to call the others *impreffions.* Senfation and perception are caufed by *impreffions;* but they are no more impreffions themfelves, than the pain occafioned by the ftroke of a bludgeon is the ftroke itfelf, or the bludgeon with which it was ftruck. But more of this afterwards.

* *Inquiry concerning Human Underftanding*, fect. ii.

29
Agreement of philofophers, and the reafon of it.

Thus far, then, that we perceive not external objects *directly*, but infer their exiftence from certain fenfations excited in our minds by the operation of thefe objects upon our *fenfes*, *nerves*, and *brain*, feems to have been the opinion of every philofopher from Pythagoras † to Mr Hume. For an opinion fo univerfal, and at the fame time fo contrary to the perfuafion of the multitude, fome cogent reafon muft have been affigned. That reafon has been given by many philofophers, but by none with greater perfpicuity than the late Dr Porterfield in his effay concerning the motion of the eyes. "How body acts upon mind, or mind upon body (fays he), I know not; but this I am very certain of, that nothing can act, or be acted upon, where it is not: and therefore, our mind can never perceive any thing but its own proper modifications, and the various ftates of the fenforium to which it is prefent. So that it is not the external fun and moon, which are in the heavens, that our mind perceives, but only their image or reprefentation impreffed on the fenforium. How the foul of a feeing man fees thofe images, or how it receives thofe ideas from fuch agitations in the fenforium, I know not; but I am fure it can never perceive the external bodies themfelves to which it is not prefent."

† See *Mofheim's edition of Cudworth's Intellectual Syftem*, where the opinions of the philofophers of antiquity are more faithfully collected than in any other work with which we are acquainted.

30
Dr Reid differs from his predeceffors.

This reafoning appears to have force; and, perhaps, the unanimous agreement of thinking men in all ages has ftill greater force: yet the doctrine which prevailed fo long, and which to Locke appeared fo evident as to need no proof, has been lately called in queftion by fome eminent philofophers of our own country; who, though they allow that we cannot perceive external objects but by means of the fenfes, yet affirm that they are the objects themfelves which we perceive directly; and that in perception there is no affociation which can be refolved into a procefs of reafoning from fenfations the effects, to external objects the caufes. Dr Reid, who was perhaps the firft, and is unqueftionably the ableft of this clafs of philofophers, has expreffed himfelf on the fubject as follows.

31
Combats their arguments.

"If we attend to the ACT of our mind which we call the perception of an external object of fenfe, we fhall find in it thefe three things: *firft*, Some conception or notion of the object perceived. *Secondly*, A ftrong and irrefiftible conviction and belief of its prefent exiftence. And, *thirdly*, That this conviction and belief are immediate, and not the effect of reafoning ‡." To the firft and fecond of thefe propofitions, we are perfuaded that Des Cartes and Locke would readily have affented; nor do we imagine that they would have denied the third, had the author allowed that this ftrong and irrefiftible conviction is the confequence of an early and deep-rooted affociation refolvable into a procefs of reafoning. This, however, the learned profeffor does not allow; for he repeatedly affirms, that it is inftinctive and original, and that "the conftitution of our power of perception determines us to hold the exiftence of what we diftinctly perceive as a firft principle, from which other truths may be deduced, but it is deduced from none." With this view of the matter, he could with no propriety attempt to fupport his own opinion by argument; but to the reafonings of Dr Porterfield and others in defence of the Cartefian theory, he replies in the following words: "That nothing can act immediately where it is not, I think muft be admitted (D); for I agree with Sir Ifaac Newton, that power without fubftance is inconceivable. It is a confe-

‡ *Effays on the Intellectual Powers of Man*, Eff. II. c. 5

(D) One of the moft celebrated of Dr Reid's followers thinks otherwife. "That no diftant fubject can act upon the mind, is a propofition (fays Lord Kames) which undoubtedly requires evidence; for it is not inftinctively certain: And, therefore, till the propofition be demonftrated, every man may without fcruple rely upon the conviction of his fenfes, that he hears and fees things at a diftance." But his Lordfhip ought to have known, that Locke and Berkeley, the two philofophers whom he was combating, have no where called in queftion the conviction of their fenfes. They do not, indeed, admit, that the external organs are themfelves percipient, or that by means of them the mind can *immediately* perceive diftant objects; but they have no where denied, that through the *medium* of them the mind comes to the knowledge of external exiftence. And the reafons which they affign for this twofold opinion are, that in perception they experience action or the effects of action, which is not their own; and that it is an intuitive truth, that nothing can act where it is not prefent. "But admitting (fays his Lordfhip) that no being can act but where it is, is there any thing more fimple or more common, than the acting upon fubjects at a diftance by intermediate means? This holds in fact with refpect both to feeing and hearing." It certainly does, and with refpect to the other fenfes likewife; but it is the very thing for which Locke and Berkeley would have contended, had any man in their days prefumed to call it in queftion. It is the very foundation of their fyftem; and if it be granted, nothing can be more evident than that external exiftence is not the *immediate* object of perception. See *Appendix to Elements of Criticifm.*

Of Perception.

consequence of this, that nothing can be acted upon immediately where the agent is not present: let this, therefore, be granted. To make the reasoning conclusive, it is farther necessary, that when we perceive objects, either they act upon us, or we act upon them. This does not appear self-evident, nor have I ever met with any proof of it ‡."

‡ Essays on Intellectual Powers of Man, Essay ii. chap. 14.

Of the profundity of Dr Reid's understanding, we have the most firm conviction; nor is there any metaphysician, ancient or modern, from whom we differ with greater reluctance: but we cannot help thinking this a very rash assertion, as his own works appear to us to afford complete proof, that, in perception, the mind both acts and is acted upon. Let us attend however to the reasons which, on this occasion, induce him to think that in perception there is no action either of the object on the mind or of the mind on the object.

"When we say, that one being acts upon another, we mean, that some power or force is exerted by the agent, which produces, or has a tendency to produce, a change in the thing acted upon. If this be the meaning of the phrase, as I conceive it is, there appears no reason for asserting, that in perception, either the object acts upon the mind or the mind upon the object. An object, in being perceived, does not act at all. I perceive the walls of the room where I sit; but they are perfectly inactive, and therefore act not upon the mind. To be perceived, is what logicians call an external denomination, which implies neither action nor quality in the object perceived."

32
We think successfully, and

This last sentence we pretend not to understand. Substance without qualities is to us inconceivable, and certainly is no object of perception; for Dr Reid himself has told us, and told us truly, that "the objects of perception are the various qualities of bodies." That an object in being perceived does not act at all, is directly contrary to what the ingenious author has taught us, both in his *Inquiry* and in his *Essays*, viz. that "it is a law of our nature that we perceive not external objects, unless certain impressions be made by the object upon the organ, and by means of the organ upon the nerves and brain;" for if the external object in being perceived make impressions, it is certainly not true that it acts not at all. It is indeed readily acknowledged, that when one perceives the walls of the room where he sits, these walls do not act immediately upon the organs of sight; but it does not, therefore, follow, that they are perfectly inactive: for it is known to all mankind, that from every point of the wall which is seen, rays of light are reflected to the eye; that those rays make upon the *retina tunica* an impression, which is conveyed by the optic nerve to the brain; and that this impression on the brain is one of the immediate causes of vision In what *particular manner* it causes vision, we shall never be able to discover, till we know more of the laws which unite mind and body, and by which one of these is qualified to act upon the other; but because we know not the *manner* of this operation, to affirm that there is no operation at all, seems to be as absurd as it would be to affirm, because we perceive no necessary connection between a stroke and the sensation of sound, that the sound of a musical string is not caused by the stroke of a plectrum. That God might have given us powers of perception of a different kind from those which we possess, there can be no doubt; but with what we might have been, we have no concern. As we are, we know perfectly that the eye is an instrument of vision, because without it nothing can be seen: we know also, that the retina and optic nerves are equally necessary; because if they be disordered, vision is still wanting: we know likewise, that the brain is necessary to all perception; because, when it is disordered, thinking either entirely ceases or is proportionably disturbed. And, lastly, we are not more certain of our own existence, than that *actual perception* takes not place but when the object makes an impression upon some organ of sense: for when no rays of light fall upon the eye, we see nothing; when no sapid body is applied to the tongue and palate, we taste nothing; and if we could be removed from every thing solid, we would feel nothing. These are conclusions which cannot be controverted. They are admitted equally by the philosopher and by the plain unlettered man of common sense; nor are they rendered one whit less certain by our not being able to go a step farther, so as to discover in what *manner* the brain or the affections of it can be the immediate instrument of sensation and perception. For (as Dr Reid, in the spirit of true philosophy, observes ‡), "in the operations of mind, as well as in those of bodies, we must often be satisfied with knowing that certain things are connected and invariably follow one another, without being able to discover the chain that goes between them. It is to such connections that we give the name of *laws of nature*: and when we say that one thing produces another by a law of nature, this signifies no more, but that one thing which we call in popular language *the cause*, is constantly and invariably followed by another which we call *the effect*; and that we know not *how* they are connected."

‡ Inquiry into the Human Mind, 4th edit. p. 258.

In the preceding section we have observed, that in sensation the mind exerts some energy; and therefore, as on every hypothesis perception is a consequence of sensation, it follows, that in perception the mind cannot be wholly inactive. Dr Reid, in his Essays on the Intellectual Powers of Man, seems to affirm that it is. "I see no reason (says he) to believe, that in perception the mind acts upon the object. To perceive an object is one thing, to act upon it is another: Nor is the last at all included in the first. To say that I act upon the wall, by looking at it, is an abuse of language, and has no meaning." This is indeed true: it would be a great abuse of language to say, that by looking at the wall a man acts upon it; but we do not believe that any man ever said or supposed such a thing. The philosophers whose opinion he is combating, might argue in this manner. We are conscious that in perception the mind is active; nothing can act immediately where it is not; the mind cannot act immediately upon external existence: external existence, therefore, is not the immediate object of that energy which is exerted in perception. As Dr Reid affirms that external existence is the immediate object of perception, he must deny the first proposition in this argument; for *if it* be granted, as we have just seen that in his reply to Dr Porterfield he admits the second,

Of Perception.

second, the laws of reasoning will compel him to admit the third. To say that in perception the mind acts not upon *external* objects, is a truth in which all mankind are agreed; and it is the very principle from which his antagonists infer, that the conviction of the present existence of external objects is not an original and instinctive consequence of sensation, but an early and deep-rooted association which may be resolved into a process of reasoning. His meaning, therefore, must be, that in perception the mind *acts not at all*: but this is directly contrary to his definition of perception, which he calls an ACT of the mind: it is likewise contrary to his theory of perception, as it is detailed in *the Inquiry into the Human Mind on the principles of Common Sense*. We are there taught, with equal elegance and perspicuity, "that an impression made by an external object upon the organ, nerves, and brain, is followed by a *sensation*, and that this sensation is followed by the perception of the object." We are likewise taught, that "although the Peripatetics had no good reason to suppose an active and passive intellect, they yet came nearer the truth, in holding the mind to be, in sensation, partly passive and partly active, than the moderns in affirming it to be purely passive. Sensation, imagination, memory, and judgment, have by the vulgar, in all ages, been considered as acts of the mind. The manner in which they are expressed in all languages shows this: for when the mind is much employed in them, we say, it is very active; whereas, if they were impressions only, we ought to say that the mind is very passive." All this is undeniable; but if sensation necessarily precede perception, and if in sensation the mind be active, what becomes of the assertion, that in perception it acts not at all? Indeed we may appeal to the common sense of mankind, whether any thing can be perceived without some mental energy of the percipient. For when the impressions made on the external senses are faint, in order to be conscious of them an evident exertion is requisite, not of the organ only, but also of the mind, as in perceiving very remote objects and sounds; but when the impressions are stronger, the perception is involuntary and unavoidable, as has been already explained in the preceding section.

33
Therefore the old theory of perception to be preferred to his.

It being thus certain that in perception the mind both acts and is acted upon, and it being universally acknowledged that nothing can act where it is not, we feel ourselves compelled to admit with the Cartesians, that in perception the conviction of the present existence of external objects is not original and instinctive, but the consequence of an early and unavoidable association of certain sensations with the causes which produce them. In this opinion we are still more confirmed by the well-known fact, that particular pressures upon the organ, nerves, and brain, excite not only sensations, but even perceptions of objects apparently external, when no such objects are within the reach of our senses. Thus §, if a man in the dark press either corner of his eye with his finger, he will see a circle of colours like those in the feather of a peacock's tail, though no such external object be before him, and though the room be so dark that nothing external could possibly be seen. Again, if a burning coal be nimbly moved round in a circle, with gyrations continually repeated, the whole circumference of the circle will at once appear on fire, though it is certain that there can be really on fire but one portion of that circumference, equal in length to the diameter of the coal. These are facts known to all mankind; and they are perfectly irreconcileable with the supposition, that the perception of external objects by the sense of sight is original and instinctive; but they are at once accounted for, if it be true that rays of light falling from external objects upon the *retina* tunica agitate the optic nerves and brain, and that such agitations excite sensations in the mind which experience has taught us to refer to external objects, as, under God, their ultimate cause.

§ Hartley's Observations on Man.

But though we have declared ourselves to be in this instance Cartesians, we do not admit all the absurdities which have sometimes been imputed to that system of perception. We do not believe that external objects are perceived by means of images of them in the mind or the brain; nor do we think that Des Cartes or Locke has any where affirmed that they are, otherwise than by an expression obviously figurative, denoting, not that the actual shapes of things are delineated in the brain or upon the mind, but only that impressions of some kind or other are conveyed to the brain by means of the organs of sense and their corresponding nerves; and that between those impressions and the sensations excited in the mind, there is a real, and in our present state a necessary, though unknown, connection.

34
That theory fairly stated, &c.

Upon the whole, we think that there is good evidence for believing, that in perception the process of nature is as follows: *First*, If the object be not in contact with the organ of sense, there must be some medium which passes between them; as, in vision, the rays of light; in hearing, the vibrations of elastic air; and in smelling, the effluvia of the body smelled; otherwise we have neither sensation nor perception. *Secondly*, There must be some action or impression upon the organ of sense, either by the immediate application of the object, as in the two senses of touch and taste; or by the medium that goes between them, as in the other three senses. *Thirdly*, The nerves which go from the brain to the organ, must receive some impression by means of that which was made upon the organ; and by means of these nerves that impression must be carried to the brain. *Fourthly*, The impression made upon the organ, nerves, and brain, rouses the dormant energy of the mind; and this double action of the mind and the object produces a sensation. And, *lastly*, As we know by experience that the mind alone cannot by any exertion of its own produce one sensation, and are intuitively certain that nothing can begin to exist without a cause, we infer from the existence of any new sensation the existence of some other cause than the internal energy of the mind, from which that sensation proceeds; and this cause experience teaches us to be the external object. This process is carried on so rapidly, and the several parts of it, by being continually repeated, are so closely associated, that except by a reflex act of the mind we distinguish them not from one another, and therefore we denominate the whole *perception*.

35
Shows the difference between this and Dr Reid's.

It is with extreme diffidence that we advance a doctrine which Dr Reid has controverted; but he differs from us only in the last stage § of the process, where he supposes sensation and perception to be two simple and independent acts of the mind. Yet he sometimes expresses

§ See *Inquiry into the Human Mind*, 4 edit. p. 3..

Of Perception.

expresses himself, as if he thought as we do, that in perception the belief of the present existence of external objects is rather the result of experience than an instinctive persuasion. Thus, speaking of the perception which we have in smelling a rose, he says §, "Perception has always an external object, and the object of my perception in this case is that quality in the rose which I discern by the sense of smell. Observing that the agreeable sensation is raised when the rose is near, and ceases when it is removed, I am led by my nature [we think *by experience* would have been more proper] to conclude some quality to be in the rose, which is the cause of this sensation. This quality in the rose is the object perceived; and that act of my mind, by which I have the conviction and belief of this quality, is what in this case I call perception." Again (he says) that "three of our senses, viz. smell, taste, and hearing, originally give us only certain sensations, and a conviction that these sensations are occasioned by some external object. We give a name to that quality of the object by which it is fitted to produce such a sensation, and connect that quality with the object and with its other qualities. Thus we learn, that a certain sensation of smell is produced by a rose; and that quality in the rose by which it is fitted to produce this sensation we call the *smell of the rose*. Here it is evident that the sensation is original. The perception that the rose has that quality which we call its *smell*, is acquired."

§ Essays on Intellectual Powers of Man, Essay ii. chap. 15. p. 241.

To this doctrine no Cartesian could possibly object; for it is the very account which Des Cartes himself would have given of perception by the organ of smell, as it resolves such a perception into an early association between a certain sensation and that external quality from which we know by experience that the sensation proceeds. Indeed the excellent author repeatedly affirms, that every different perception is conjoined with a sensation which is proper to it; and that the one is the sign, and the other the thing signified. He likewise doubts *, whether children, from the time that they begin to use their senses, make a distinction between things which are only conceived or imagined, and things which really exist. But if the conviction of the present existence of external objects were in perception *instinctive*, we cannot see how there could be room for such a doubt: for the mere senses of children are as perfect as those of full grown men; and they know well the difference between actually sucking their nurses and only thinking of that operation, though they be not capable of expressing that difference in language.

* Essays on Intellectual Powers of Man.

36 The theory offered to prove the existence of something external.

But if in perception our conviction of the present existence of external objects be not instinctive, what, it may be asked, is the evidence that such objects really exist? This question we shall partly answer in the following section, and more completely when we come to examine Berkeley's theory of the non-existence of matter: but from what has been said already, it is sufficiently evident, that every sensation compels us to believe in the present existence of something different from ourselves, as well as from our sensations.

Sect. III. *Of the Objects of each Sense respectively.*

37 Touch, the sense by which we perceive heat and cold, &c.

Hitherto we have considered sensation and perception in general, and shown that it is not by instinct that we perceive the existence of external objects. This will appear more clearly, if we can ascertain the precise nature of that information which each sense affords us: and in order to this, we shall begin with the sense of *touch*, not only because it is that which is certainly first exercised, but also because there is a meaning in which all the others may be resolved into it.

38 The nature of heat and cold, which are perceived immediately.

By means of touch we perceive many things; of which the chief are, heat and cold, hardness and softness, roughness and smoothness, extension, figure, solidity, and motion. Of these perceptions, some are immediate; and others, as we are persuaded, early associations, which may be resolved into a process of reasoning. The perceptions of heat and cold are immediate. When a person for the first time in his life approaches the fire, he feels heat; and when he is first exposed to the frost, he feels cold. What are heat and cold, and where do they reside? They are obviously the reverse of each other; but are they external objects, or mere sensations in the mind? They are undoubtedly sensations which have no existence but when they are felt. To every man not altogether a stranger to these speculations, this proposition is self-evident; but to the bulk of the people it appears an extravagant paradox. To make it plain, however, to the meanest capacity, it is sufficient to observe, that at a certain distance the fire has no perceptible influence upon any person; if that distance be lessened, we feel an agreeable warmth; approach a little nearer, and the warmth becomes disagreeable; and still nearer, it will rise to pain. No man supposes the pain inflicted by a sword to exist in the sword, or any where else but in a sentient being: It is equally absurd to suppose pain to exist in fire, or any where else but in a sentient being. But that which at one distance is pain, at another is only agreeable warmth; and since warmth and pain are only different degrees of the same feeling, it is equally absurd to suppose the one as the other in the fire. What then is the object of sense when we feel heat? There is obviously no object beyond the present sensation.

39 Their external causes.

But has the sensation of heat no cause independent of us? Undoubtedly it has, and experience teaches us that the cause is in the fire. We know that we cannot produce the sensation of heat in ourselves by any mental energy of our own; and we are intuitively certain, that nothing can begin to exist without some cause. A man on the top of a mountain covered with snow, may imagine or remember what he felt when in the neighbourhood of fire, and thus have in his mind what is called an *idea* of heat; but that idea will not warm him (E) like the actual sensation, which no exertion of his own can in such circumstances produce.

3 Q 2 When

(E) ——Who can hold a fire in his hand,
By thinking on the frosty Caucasus?
Or cloy the hungry edge of appetite,
By bare imagination of a feast?
Or wallow naked in December's snow,
By thinking on fantastic summer's heat?
Oh no! the apprehension of the good
Gives but the greater feeling to the worse.
K. Richard II.

Objects of the reſpective Senſes.

When he leaves the mountain, however, and approaches the fire, he feels the ſenſation actually produced, and produced as often as he makes the experiment. He is, therefore, under the neceſſity of inferring, that in the fire there is ſome power or quality which, acting either mediately or immediately upon his ſenſe of touch, excites the feeling which is called *heat*. What that power is, we ſhall perhaps never be able to diſcover; but it is ſelf-evident, that it is neither heat nor the reſemblance of heat, though in vulgar language it is known by that name.

The ſame reaſoning holds good with reſpect to cold. There is at certain times, and in certain countries, ſome power in the air which congeals water and cauſes cold; but that power is as different from the ſenſation of cold, as the power of fire is different from the ſenſation of heat, or the point of a ſword from a fleſh wound.

40 The perceptions of extenſion and figure, &c. not immediate.

By the ſenſe of touch we perceive extenſion, figure, and ſolidity, &c. but we do not perceive them *immediately* as we perceive heat and cold; for extenſion, figure, and ſolidity, are not ſenſations. Thoſe perceptions then muſt be acquired; and more clearly to aſcertain the manner in which we acquire them, let us ſuppoſe a man from his birth deſtitute of the ſenſe of ſight and the power of local motion, but poſſeſſed of intellect and every other faculty which we enjoy.—Such a perſon, it is obvious, would be capable of every ſenſation and perception which is *original* to us, except the perception of colours; but we doubt whether it would be poſſible to give him perceptions of extenſion, figure, and ſolidity. Let us try: and as he cannot move a ſingle limb or member of himſelf, let us ſuppoſe a ſolid ſubſtance of ſmall dimenſions to be gently preſſed againſt any part of his body; what would ſuch preſſure communicate to him? We think it could communicate nothing but a new ſenſation, to which, as it is neither pleaſing nor painful, no name has hitherto been given, except the general one of *feeling*. This ſenſation he would not know whether to refer to an external or internal cauſe; or rather he could have no notion whatever of an external cauſe, though he would at the ſame time be conſcious that the new ſenſation was not excited by any energy of his own will. Were the preſſure to be gradually increaſed till it roſe to pain, our blind man would ſtill be conſcious of nothing but a ſenſation, which could not lead him to the notion of extenſion, figure, or ſolidity, becauſe mere ſenſations cannot be conceived as either ſolid or extended. Let us next ſuppoſe the preſſure to be applied ſucceſſively to different parts of his body; he would now indeed be conſcious of ſucceſſive ſenſations, but he could not aſſign to them either extenſion or *place*: for it has been already ſhown that the external parts of the body are not themſelves ſentient; and it ſhall be ſhown afterwards, that to a man who has never perceived motion, place is abſolutely inconceivable. Laſtly, let us ſuppoſe the dimenſions of the preſſing ſubſtance to be greatly enlarged: what would then follow? nothing, we apprehend, but an increaſe of pain: for though his whole body were preſſed *ab extra*, the preſſure could affect the individual being which is ſentient, not more extenſively, but only more violently. It appears, therefore, that a man blind from his birth, and deſtitute of the power of local motion, could never be made to perceive extenſion, figure, or ſolidity.

Objects of the reſpective Senſes.

41 How they are acquired.

Let us now ſuppoſe this man to receive by a miracle the uſe of his limbs, and to be ſuddenly prompted, by ſome inſtinctive impulſe, to ariſe and walk. So long as he met with no obſtacle in his way, he would not, we apprehend, acquire by this exerciſe any correct notions of extenſion or figure; but were a ſtone or log of wood of conſiderable dimenſions to be laid acroſs his uſual walk, the caſe would ſoon be altered. He would feel himſelf interrupted in his courſe, and he would at the ſame inſtant recognize his wonted ſenſations of touch. After being twice or thrice thus interrupted, he would learn from experience that the interruption or reſiſtance proceeded from the ſame cauſe which in this inſtance communicated to him the ſenſation of feeling; and were he to run his hand along the ſurface of the log or ſtone, he would perceive the reſiſtance and the ſenſation continued. As every effect muſt have an adequate cauſe, this continued reſiſtance would compel him to believe the continuity of ſomething external in every direction in which he felt his hand reſiſted; but ſuch continuity of being is all that is meant by the word extenſion. At the very ſame time, and by the very ſame means, he would gradually acquire the perception of figure; for by running his hand in every direction over the ſurface of the obſtacle which oppoſed him, he would ſoon perceive it on all ſides limited; but the limits of extenſion is a phraſe of preciſely the ſame import with figure. It appears, therefore, that without the power of local motion, men could never by the ſenſe of touch acquire the notions of extenſion and figure; and the ſame will be found to be the caſe with reſpect to hardneſs and ſoftneſs.

42 Hardneſs and ſoftneſs, how perceived.

When we preſs our hand gently againſt a ſtock or a ſtone, we feel a ſenſation which is neither painful nor pleaſing. When we preſs it more violently, the ſenſation becomes painful, and we experience in the object a reſiſtance which we have not power to overcome. When we preſs butter or pomatum very gently, we have a ſenſation in all reſpects ſimilar to that which we felt when we gently touched the ſtock or the ſtone. But when we preſs the butter with violence, we feel no pain, and experience little reſiſtance; for the parts of which it is compoſed give way before the hand, though the parts of the ſtock or the ſtone remained fixed and immoveable. That the parts of one body ſhould thus reſiſt a preſſure to which the parts of another ſo readily yield, muſt proceed from ſome difference in the texture of the two bodies: for by the ſenſe of touch we perceive the effects to be different; and are therefore certain that they muſt proceed either from different cauſes, or from the ſame cauſe operating with different degrees of force. That particular texture which makes the parts of a ſtone reſiſt the preſſure of touch, we call hardneſs; and the texture which makes the parts of butter or pomatum give way to touch, we call ſoftneſs. But what hardneſs and ſoftneſs are in themſelves, touch cannot inform us; for they are neither ſenſations, nor ſimilar to ſenſations. We acquire, however, by experience, ſo complete notions of hardneſs and ſoftneſs, that every one who underſtands the Engliſh language perfectly knows the meaning of theſe words as ſoon as he hears them; and when he is told that

Objects of the respective Senses. that one body is hard and another soft, he knows with absolute certainty that the meaning of the assertion is, that the parts of the body which is said to be hard are held together by some unknown cause operating forcibly, and that the parts of the other are held together by the same or a similar cause operating with less force.

43 Roughness and smoothness. We acquire the notions of roughness and smoothness in the very same way and by the very same means that we acquire ideas of extension and figure. To describe the process at large would certainly be superfluous; for if what we have said concerning our perceptions of extension and figure be just and intelligible, every one will, without farther assistance, discover for himself how he perceives roughness and smoothness. *Motion* shall be considered among the adjuncts of body; but in order to understand what body itself is, it will be necessary, before we dismiss the sense of touch, to inquire how we come by the notion of solidity.

44 Solidity, and how perceived. Solidity is one of those notions, or, in the language of Locke, one of those ideas, which are commonly said to be acquired by the sense of touch. That touch gives the first hint towards our notion of solidity, is certainly true; but that hint must be afterwards improved by the intellect, or we never could have an adequate knowledge of what is meant when any thing is said to be absolutely solid. We know by experience, that we can at pleasure open and shut our empty hand without meeting with any resistance. We know likewise, that when we grasp an ivory ball of three or four inches diameter, no force which we can exert will bring together the several parts of the hand, which were easily brought together when we grasped nothing. In this way do we acquire our first notion of solidity; for that word denotes nothing more in this instance than the power or property of the ball, by which our fingers are excluded from the place which it occupies. Solidity differs from hardness in this respect, that hardness results from the strong cohesion of the parts of a hard body, which renders it difficult to change the places of those parts, as they respect one another; whereas solidity respects the whole mass, and is as essential a quality of water as of adamant. A drop of water, indeed, placed between two plane surfaces of marble, will not like adamant preclude their contact; because the parts of a drop of water, cohering but loosely to one another, give way to the pressure, and escape in every lateral direction. But if a drop of water be confined on all sides, as in a globe of gold, we know from experiment that no force will bring the sides of the globe together without forcing the water through the pores of the metal; and hence we infer solidity to be essential to every corporeal substance.

Thus then it appears, that of the objects perceived by touch not one is *immediately* perceived except heat, cold, and other sensations. The sensations, as they are not excited by any internal energy of our own, lead us indeed to something external as their cause; and by comparing the different sensations with each other, and observing what effects their external causes have upon our own motions, we are naturally led to conceive these causes as extended, figured, solid, hard or soft, rough or smooth, &c.; but it is obvious that this conception is the result of experience, and a process of mental reasoning

On the senses of taste, smell, and hearing, it is needless to say much. The immediate objects of these are confessedly sensations which have no existence but when they are perceived; though experience teaches us to refer them all to external objects as their respective causes. With respect to smell, this has been made sufficiently evident in the preceding section, and it is not less evident with respect to taste and hearing. Objects of the respective Senses. 45 Nothing but mere sensations the objects of smell,

46 Taste, and Certain bodies applied to the tongue and palate, and moistened with the saliva, excite certain sensations which we call tastes. These sensations, however, are not in the bodies; nor can they have any existence but in a sentient being. They are produced in consequence of impulses on the nerves of the tongue and palate, exciting certain agitations in the brain; but the sensation itself is neither impulse nor agitation. Some substances excite tastes which are agreeable, and others such as are disagreeable; and there are not a few which excite no taste at all. Bodies, which applied to the tongue and palate of one man produce tastes that are agreeable, applied to the same organs of another man give him tastes which are disagreeable; and we have all experienced, that the same substance, which, when the organs are sound, excites a sweet or pleasant taste, has, when the organs were disordered, excited a taste which was bitter or unpleasant. These facts, which cannot be controverted, afford the fullest evidence, if evidence were wanted, that taste, as we feel it, is no quality of bodies, nor has any existence out of the mind.

The organ of hearing is the *ear*, and its object is sound. It is well known, that sound is produced by certain vibrations of the air striking the tympanum of the ear, and that those vibrations are caused by the sonorous body. Sound, however, is not vibration, nor the idea of sound the idea of vibration. Sound considered by itself is a mere sensation, which can have no existence but in a sentient being. We know by experience, that it is caused by something external; but we know likewise that the effect has no resemblance to the cause. Previous to experience we could not refer sound to any external cause; far less could we discern whether it proceeded from an object above us or below us, on our right hand or on our left. It appears to us self-evident, that if a man born deaf were suddenly made to hear, he would consider his first sensation of sound as originating wholly within himself. Between that sensation and the sensations of touch, taste, smell, and sight, there is no resemblance; nor are there any relations among them, which, previous to experience, could induce him to trace them all to external objects as their several causes. Our deaf man might have learned to refer all his other sensations to their true causes, in some such way as we have described under the sense of touch; but sound would be something so new to him, and so totally different from touch, taste, and smell, that he could attribute it to nothing external. 47 Hearing.

48 It is by experience that we distinguish different sonorous bodies by their respective sounds. Experience, however, would soon teach him, that the ear is its organ, and the sonorous body its cause; and he would in time learn to distinguish one sound, that of a trumpet for instance, from another, suppose the sound of a bell; and to attribute each to its proper cause, even when neither the trumpet nor the bell was perceived by his other senses. With respect to sounds

Objects of the respective Senses.

sounds which we have been accustomed to hear, this is done so instantaneously, that some philosophers have imagined it to be the effect of an instinctive principle in our nature, totally different from experience, and independent of reason. But the fact is not so. Long before we are capable of making sensation and perception objects of reflection, we have heard the sound produced by the ringing of a bell, and seen the object which produced the sound so often, that, when we hear a similar sound again, we instantly refer it to a *bell*, though we see not the bell from which it proceeds: but this is the effect of habit, and not of instinct. Had we never perceived a bell while ringing by either of our senses of sight or touch, we could not by the sense of hearing acquire any notion of the figure or texture of the body from which the cause of the sound proceeds, tho' we had heard that sound every day of our lives. It is, indeed, by experience only that we learn to distinguish by the ear whether a sonorous body be before or behind us, on our right hand or on our left; for we find it always difficult to say from what precise quarter a strange sound proceeds; and this difficulty would be heightened to impossibility, had not all sounds something in common. Dr Sparman relates, that when he first heard the roaring of a lion, he did not know on what side of him to appprehend danger, as the sound seemed to proceed from the ground, and to inclose a circle of which he and his companions stood in the centre. The same thing has happened to every man, when the sound was such as he had never heard before; even though it was neither so loud nor so terrific as the roaring of a lion in a desert wilderness: but with respect to sounds which we are daily hearing on each side of us, we soon learn to distinguish with tolerable accuracy whether they be before or behind us, above or below, on our right hand or on our left. All this, however, is the effect, not of instinct, but of experience improved into habit.

49
Sight originally perceives nothing but colours, which are mere sensations.

Sight is justly considered as the noblest and most comprehensive of all our senses. The reason is obvious: for when a full-grown man opens his eyes, he perceives houses, trees, rivers, the earth, sun, and moon, &c. and to each of these objects belong figure, extension, colour, &c. which are all perceived instantly by means of this sense. Yet it is certain, that the sense of sight does not originally communicate to us so many perceptions; and there is abundant evidence, that an infant cannot at first, or for some weeks after its birth, distinguish by vision one object from another. *Colour* is the proper object of sight, and for some time its only object; but colour as perceived by us is a mere sensation, which can have no existence but in a sentient being. If this proposition stood in need of proof, we might observe that there are men, and even whole families, who possess the sense of sight in a degree of perfection sufficient for all the purposes of life, and yet cannot distinguish certain colours from each other; blue, for instance, from green, or perhaps from red: and there is no man who can distinguish between some particular shades of blue and green by the feeble light of a candle. Were colours the real qualities of body, this mistake of one for another could never be experienced. No man who possesses the sense of touch ever confounded hardness with softness, a sphere with a cube, or an ell with an inch. The reason is, that hardness and softness, figure and extension, are the qualities of things external; whereas colour being a mere sensation, is nothing but an affection or modification of the sentient being. But it is obvious, that sentient beings, according as they differ from one another, may be differently affected by the same external cause; so that one man may perceive that to be green which all other men perceive to be blue. The immediate external cause of the sensation of colour, is the rays of light reflected from the body, which in common language is said to be coloured. These rays falling upon the pupil of the eye, are refracted differently, according as their incidence is more or less oblique into points on the retina, where they form a picture of the external object; and from the picture, by means of the optic nerve, is communicated to the brain some impulse or agitation, which produces vision or the perception of colour. As rays of light are corporeal substances, it is obvious that they can act upon body only by impulse; but between impulse and the various sensations of *red*, *green*, *blue*, &c. there is no resemblance. For the laws of reflection and refraction, and for the structure of the eye, see OPTICS and ANATOMY. That which we have to inquire into at present is, how we learn, by means of the sense of sight, to perceive the figure, magnitude, motion, and distance of external objects, or indeed to distinguish one object from another.

A ray of light proceding, as all rays do, in a straight line, must, however great its length, affect the eye, retina, and optic nerve, as if it were a single point. From this obvious and undeniable fact, Bishop Berkeley predicted *, that a man born blind, who should be suddenly made to see, would at first perceive nothing without him, would distinguish neither the distance, size, figure, nor situation, of external objects; that he would only see in his eyes themselves, or, to speak more properly, would only experience new modifications in his mind, until joining *touch* to *sight*, he formed thus a communication with the external world, and learned, by the simultaneous exercise of the two senses, that natural language in which the *visible* is the sign of the *tangible*. This truth, which was discovered by the Bishop merely by contemplating in his own mind the nature of sensation, and the known laws of optics, after having been laughed at for more than 20 years as one of the many dreams of a visionary genius, was completely confirmed by the case of the famous patient whom Cheselden cured of a cataract; and that too, though the cataract does not produce total blindness: which makes it evident, that the first visual perceptions of the patient after his recovery could not be wholly new and unmixed. It may indeed be confirmed at any time by a simple experiment made upon an infant. For several weeks after birth, a child shuts not its eyes upon the sudden approach of an object to them, nor shows the least symptom of distinguishing one distance from another; and it is easy by a little attention to observe, how it gradually learns to distinguish objects at greater and greater distances. Indeed colour, or the immediate object of sight, being a mere sensation or affection of the mind, can have no natural relation whatever to any thing external.

* *Essay towards a new Theory of Vision.*

It is plain, therefore, that distance is in its own nature

ture imperceptible to the eye, and yet it is often perceived by ſight. How is this done? We think, in the following manner. Diſtance is one mode of extenſion, which, we have already ſeen, is perceived by means of touch. Of ſhort diſtances, our firſt ideas are doubtleſs acquired by the ſtretching out and drawing back of our arms; and thoſe ideas are ſoon ſo connected with certain ſenſations which we have in actual viſion, that the latter inſtantly ſuggeſts the former. Thus, it is a fact known by experience, that when we look at a near object with both eyes, according as it approaches or recedes from us, we alter the diſpoſition of our eyes, by leſſening or widening the interval between the pupils This diſpoſition, or turn of the eyes, is attended with a ſenſation of which every man is conſcious at the time of viſion; and this ſenſation ſeems to us to be that which in this caſe ſuggeſts the idea of greater or leſs diſtance to the mind. Not that there is any natural or *neceſſary* connection between the ſenſation of which we are conſcious, and greater or leſs diſtance; for the ſenſation is wholly internal, and the diſtance is external: But becauſe the mind has, by conſtant *experience*, found the different ſenſations occaſioned by different diſpoſitions of the eyes to correſpond to different degrees of diſtance in the object, there has grown an habitual or cuſtomary connection between thoſe ſenſations and the notions of greater or leſs diſtance. So that the mind no ſooner perceives the ſenſation ariſing from the different turn it gives the eyes in order to bring the *pupils* nearer or farther aſunder, than it is inſtantly impreſſed with a certain notion of the diſtance which was wont to be connected with that ſenſation. Again, an object placed at a certain diſtance from the eye, to which the breadth of the pupil bears a ſenſible proportion, being made to approach nearer, is ſeen more confuſedly; and the nearer it is brought, the confuſion is always the greater. The reaſon of all this is known to every optician: but it being conſtantly experienced by thoſe who never dipt into optics, there ariſes in the mind of every man an habitual connection between the ſeveral degrees of confuſion and diſtance; the greater confuſion ſtill implying the leſs diſtance, and the leſs confuſion the greater diſtance. It is of no avail to ſay, that between confuſed viſion and diſtance, great or ſmall, there is no neceſſary connection: for there is as little connection between a bluſh in the face and the mental feeling of ſhame; and yet no ſooner does a man of obſervation perceive that particular colour in the face of another, than it ſuggeſts to him the notion of that feeling or paſſion with which he has conſtantly obſerved it accompanied.

In theſe ways, however, we perceive only ſmall diſtances. Of diſtances more remote our judgment is formed from other data; and happily theſe data are not far to ſeek. It is a fact known to every man who is not totally ignorant of the ſcience of optics, that a greater number of rays fall upon the eye when reflected from a body near at hand, than can fall from the ſame body at a diſtance; and as thoſe rays operate by impulſe, it is ſelf-evident that the impreſſion muſt be ſtronger, and of courſe the ſenſation or colour more vivid, when the body is near than when it is diſtant. Now having acquired the notion of the true diſtance of objects by motion and the ſenſe of touch, and finding by uniform experience, that as they are near or far off, the ſenſation or colour which they excite in the mind through the organ of viſion is more or leſs vivid, thoſe degrees of ſenſation come to be ſo cloſely aſſociated with the reſpective diſtances of the object, that the one inſtantly ſuggeſts the other.

51 It is juſt ſo that we perceive figure by ſight. Having experienced by the ſenſe of touch that one ſurface is a ſquare and another a circle, that one body is a cube and another a ſphere; and finding our ſenſe of ſight differently affected by the ſquare and the circle, by the cube and the ſphere; theſe different affections come to be ſo cloſely connected in our minds with the figures of the reſpective bodies, that long before we are capable of reaſoning on the ſubject the one is never preſent to us without ſuggeſting the other. Nay, ſo complete in this caſe is the connection or aſſociation, that we cannot even in idea abſtract the colour from the figure; though it is certain that colour is a mere ſenſation, and figure an external quality; that colour alone is immediately perceivable by the eye, and the notion of figure ſuggeſted by the colour. We are aware that it has been affirmed, and affirmed with great vehemence, that figures of two dimenſions are immediately perceived by the eye, and perceived with greater accuracy than by the ſenſe of touch. But they who inſiſt upon this doctrine affirm likewiſe, contrary to experience and the cleareſt reaſoning, that the immediate objects of ſight are external, and that colour is a quality of bodies. In the arguments too by which they ſupport their hypotheſis, they ſeem to confound ſight as an affection of the mind, with the picture on the bottom of the eye, as if the retina were the ſentient being; whereas the retina and picture are no more than inſtruments of ſenſation. It is indeed a fact, that the picture has the ſame figure nearly with the plane of the object which is preſented to the eye; as when the object is a ſphere, the picture is a circle variouſly ſhaded in colour. It is likewiſe a fact, that the picture is enlarged in proportion as the object is brought near, and diminiſhed as it is carried to a diſtance. But theſe facts are known only to perſons ſkilled in optics; and therefore it is evident, that though calculations may be raiſed from them by mathematicians to determine the diſtance and figure of external objects, they cannot poſſibly be the data from which diſtance and figure are inferred by the vulgar, who know not that ſuch pictures on the retina exiſt. Beſides all this, it is univerſally known, that a painter, by laying on his colours properly, can make a plain ſquare ſurface appear to the eye in certain poſitions as an oblong or as a cube, and a plain circular ſurface as a concave or a convex hemiſphere. But not one of theſe things could poſſibly be done, were figure, or indeed any thing elſe than colour, the immediate object of viſion.

52 As we ſee diſtance and figure, ſo we ſee magnitude; and we ſee both in the ſame way that we ſee ſhame or anger in the looks of a man. The impreſſion made upon the bottom of the eye by rays reflected from a large magnitude, muſt neceſſarily be different from the impreſſion made by rays reflected from a magnitude that is leſs. This is ſelf-evident: and ſince the impreſſion *ab extra* is in ſome way or other the cauſe of that ſenſation, which is all of which we are originally conſcious in viſion, it is obvious that the ſenſation,

Objects of the ſeveral external Senſes.

50 Perception of diſtance by ſight, how acquired.

Objects of the reſpective ſenſes.

How figure is perceived by ſight.

Magnitude.

Objects of the reſpective Senſes.

like every other effect, muſt correſpond to the cauſe from which it proceeds. Being therefore conſcious of different ſenſations; and having, at an earlier period than we diſtinctly remember, learned by experience to refer them to different magnitudes; no ſooner is each ſenſation excited than it ſuggeſts the notion, or if you pleaſe the perception, of that magnitude with which it is connected. So completely is this aſſociation fixed in the mind, that when we look at a known object, its real magnitude appears to be as inſtantly obſerved as its colour, whilſt we hardly attend at all to the particularity of the ſenſation by which the magnitude is ſuggeſted. It is indeed cuſtomary with writers on optics to diſtinguiſh between tangible and viſible magnitude, as if any kind of magnitude were the immediate object of viſion: but this is not ſo; for magnitude is ſomething external, whereas the immediate object of viſion is a mere ſenſation. What has introduced into ſcience this mode of ſpeaking is the following fact, that as we approach a diſtant object it appears to the eye larger and larger every ſtep, and leſs and leſs as we recede from it; whereas the tangible magnitude of an object is always the ſame. The reaſon of this apparent change of magnitude to the eye, according to the diſtance at which any particular object is viewed, is, that from a near object rays of light fall in greater numbers and more diverging than from the ſame object viewed at a diſtance. This of courſe alters the nature of the viſible ſenſation: each common ſenſation is in the mind cloſely linked with a particular notion of magnitude; and by the exerciſe of ſight and touch we have learned from experience, that the particular ſenſation cauſed by diverging rays muſt be referred to a larger magnitude than that which is cauſed by parallel rays proceeding from the ſame diſtance.

53
Viſible ſenſations a kind of natural language.

Upon the whole, then, we think ourſelves intitled to conclude, that the proper and original objects of viſion conſtitute an univerſal language of the Author of Nature, by which we are inſtructed how to regulate our actions, in order to attain thoſe things that are neceſſary to the preſervation and well-being of our bodies, as alſo to avoid whatever may be hurtful or deſtructive to them. It is principally by the information of this language that we are guided in all the tranſactions and concerns of life: And the manner in which it ſignifies and marks to us the objects which are at a diſtance, is ſimilar to that of languages and ſigns of human appointment, which do not ſuggeſt the things ſignified by any likeneſs or identity of nature, but only by an habitual connection, which experience has made us to obſerve, between them. This language of the eye, like the language of the tongue, ſuggeſts by one ſenſation what may be reſolved into a variety of perceptions. A tree is compoſed of a trunk, branches, leaves; it has colour, figure, ſize; and all theſe things are at once ſuggeſted to the mind by the two words *ſpreading oak*. Juſt ſo it is with reſpect to viſion: the ſenſation received by the eye ſuggeſts at once the *trunk*, *branches*, *leaves*, *colour*, *figure*, and *ſize* of the oak, and ſuggeſts them all as the qualities of one object.

Chap. II *Of* Retention *and* Ideas.

Retention and Ideas.

From the experiment with the burning coal mentioned in n° 33, it is apparent, that ſenſations excited through the eye, together with their correſponding perceptions, remain in the mind for a ſhort time after the external exciting cauſe is removed. The ſame thing appears from another experiment which was firſt made by Sir Iſaac Newton, and which every man may repeat for his own ſatisfaction. It is univerſally known, that a proper mixture of the ſeven original colours, *red*, *yellow*, *green*, *blue*, &c. conſtitutes that uniform appearance which we call *white*. But when theſe colours are made to paſs in a rapid conſecution before the eye, they excite the very ſame perception as when they are properly mixed: which is a ſatisfactory proof that the impreſſion made by each ſeparate colour remains in the brain until a revolution of all the colours be completed; for nothing but the impreſſion of all the colours at *once* can produce the ſenſation and perception of *white*. Indeed no perſon capable of paying the proper attention to theſe things, can keep his eye fixed upon a luminous object, and afterwards ſhut it, without experiencing that the ſenſation and perception remain for ſome time after the external object is ſhut out, and that they go off gradually till they leave behind them the mental appearance, which is properly called an *idea* of the object.

54
Senſation and perception remain for very little time after the removal of the object. *Hartley on Man*

The ſame continuance of the ſenſation after the removal of its cauſe is equally obſervable in the ſenſe of hearing: for every ſound which we hear is reflected by the neighbouring bodies; and therefore conſiſts in reality of a variety of ſounds ſucceeding each other at different diſtances of time, according to the diſtances of the ſeveral reflecting bodies. Yet this cauſes no confuſion or apparent complexity of ſound, unleſs when the diſtance of the reflecting bodies is very conſiderable, as in ſpacious buildings.

With reſpect to the continuance of the ſenſation of touch, doubts have been ſtarted; but for theſe there is as little room as for doubting the continuance of the ſenſations of ſeeing and hearing. The continuance of heat after the heating body is removed, and of the ſmart of a wound after the inſtant of infliction, are proofs that every ſenſation of touch does not vaniſh with its cauſe. A man unuſed to the motion of a ſhip or a coach, after having been a day at ſea or on the road, feels or imagines he feels the rolling of the ſhip or the jolting of the coach after he is in bed and actually at reſt. Of theſe facts we know not what other account can be given, than that the agitation in the brain, which is the immediate cauſe of the ſenſation of touch, remains for ſome time after the external cauſe of the agitation is removed.

As to the ſenſes of taſte and ſmell, Dr Hartley ſeems to think that there is no clear and direct evidence for the continuance of their ſenſations after their proper objects are removed: but in this inſtance the ingenious author does not juſtice to his own theory. Let any man eat onions, garlic, or any other thing of a very pungent taſte, and immediately waſh his mouth with freſh water, ſo as that he may be ſure no part of the ſapid body remains on his tongue or palate. According to this doctrine, the taſte of the onion or garlic ſhould inſtantly vaniſh with its object; but the fact is otherwiſe. Whoever ſhall make the experiment, will find the ſenſation to remain a conſiderable time; not indeed in its original force, but weakened no more than what it muſt neceſſarily be by the introduction of

Retention and Ideas.

of a new sensation excited by the water. It is more difficult to ascertain the permanency of smell: but analogy inclines us to believe, that in this particular it resembles the other senses, though we know not how to direct the reader to an experiment which will give him absolute conviction.

55 Hence we have that power or faculty called *memory*.

Whether the cause of these continued sensations, after the removal of their objects, be in the brain alone, in the mind alone considered as an immaterial being, or in both together, is of very little importance; because, taking the mind and its internal organs as one *metaphysical whole**, it matters not to our present inquiry, where this retentive power resides, as long as it can be proved to exist within us: for it seems evident, that what has the faculty of retaining a sensation when no longer acted upon by the object which excited it, must also have a power to preserve the vestiges of that sensation even after the sensation itself shall be entirely obliterated. This is in fact the case with the mind. When an object which we have once perceived is most remote from our thoughts, we are certain that there is within us a capacity, disposition, tendency, or power, by which a representation of that object may be at any time revived and presented to the intellect. Thus the same inherent power of the mind and its internal organs, which retains a sensation and perception in the absence of the object by which they were excited, can also reproduce that perception, or bring into the view of the intellect something exactly similar to it. The reproduction will not indeed be so lively as the original perception when accompanied with its corresponding sensation, because sensation and actual perception are effected by a double cause, the action of the external object upon the organ, nerves, and brain, and the corresponding energy of the mind or sentient principle: whereas, in the reproduction, the mind seems to act solely by its own power, and certainly without the assistance of external objects. This reproductive power is commonly called *memory*. By many of the ancient philosophers, and by *M. Schwab*, with one or two others among the moderns, it is called *imagination*. We do not choose either to revive antiquated modes of expression, or to introduce innovations of our own; but as we cannot disapprove of the ancient phraseology, after the definitions which the reader will by and by find of *imagination*, *memory*, and *recollection*, as given by Mr Harris, we have prefixed to this chapter the general title of *retention* which comprehends them all.

* See *An Essay on the Reduction of the Faculties of the Mind, by M. Schwab.*

56 The opinion of philosophers respecting memory.

When one recals an object of sight by the power of memory, it appears to him precisely the same as in the original survey, only less distinct, and with a conviction (which is perhaps the result of experience) that the real object is not immediately before him. How is an object recalled by the power of memory? Does the man endeavour to form in his mind a picture or representative image of the object? Let us listen to the answers given by different philosophers to this question.

57 The Peripatetics and Platonists.

The sentiments of the Peripatetics, as expressed by *Alexander Aphrodisiensis*, one of the earliest commentators on *Aristotle*, are thus translated by Mr Harris in his Hermes.—"Now, what fancy or imagination is, we may explain as follows: We may conceive to be formed within us, from the operation of the senses about sensible subjects, some impression (as it were), or picture in our original sensorium, being a relict of that motion caused within us by the external object; a relict which, when the external object is no longer present, remains, and is still preserved, being as it were its image; and which, by being thus preserved, becomes the cause of our having memory. Now such a sort of relict, and (as it were) impression, they call *fancy* or *imagination* (E)." A passage from ALCINOUS *of the doctrines of Plato*, as rendered into English by Dr Reid †, shows, that in this theory, as in that of perception, the Platonists agreed with the Peripatetics. "When the form or type of things is imprinted on the mind by the organs of the senses, and so imprinted as not to be deleted by time, but preserved firm and lasting, its preservation is called *memory*."

† *Essays on the Intellectual Powers of Man.*

Mr Harris, who was deeply read in the ancient philosophy, and who considered the authority of Aristotle and Plato as superseding all reasoning and all inquiry, after justly observing, that if the soul had no other faculties than the senses it could never acquire the least idea of *time*, thus expresses himself on the subject before us:—"But happily for us we are not deserted here. We have, in the first place, a faculty called *imagination* or *fancy*; which, however as to its *energies* it may be subsequent to sense, yet is truly prior to it both in *dignity* and *use*. This it is which *retains the fleeting forms of things*, when things themselves are gone, and *all sensation* is at an end. That this faculty, however connected with sense, is still perfectly different, may be seen from hence. We have an *imagination* of things that are gone and extinct; but no such things can be made objects of *sensation*. We have an easy command over the objects of our *imagination*, and can call them forth in almost what manner we please; but our *sensations* are necessary when their objects are present, nor can we control them but by removing either the objects or ourselves. As wax would not be adequate to its business of signature, had it not a power to retain as well as receive; the same holds of the SOUL, with respect to *sense* and *imagination*. SENSE is its *receptive* power; IMAGINATION its *retentive*. Had it sense without imagination, it would not be as wax but as water; where, though all impressions may be instantly made, yet as soon as made they are entirely lost. Thus then, from a view of the two powers taken together, we may call SENSE (if we please), *a kind of transient imagination*; and IMAGINATION, on the contrary, *a kind of permanent sense*."

58 distinguish properly between imagination and memory, &c.

Great part of the office which is here given to imagination, is in common English attributed to memory; but between these two faculties, as well as between them and recollection, the author accurately di-

(E) The original is as follows: Τι τοινυν εστιν ἡ φαντασια ωδε αν γνωρισαιμεν· δει νοειν εν ημιν απο των ενεργειων των περι τα αισθητα, οιον τυπον τινα αναζωγραφημα εν τω πρωτω αισθητηριω, εγκαταλειμμα τι της υπο του αισθητου γινομενης κινησεως, ὁ και μηκετι του αισθητου παροντος, υπομενει τε και σωζεται, ον ωσπερ εικον τις αυτου, ὁ και της μνημης ημιν σωζομενον αιτιον γινεται· το τοιουτον εγκαταλειμμα, και τον τοιουτον ωσπερ τυπον, φαντασιαν καλουσιν. *Alex Aphrod. de Anima*, p. 135. *Edit. Ald.*

Retention and Ideas.

distinguishes thus:—"When we view some *relict* of sensation reposed within us, *without thinking of its rise, or referring it to any sensible object*, this is FANCY or IMAGINATION. When we view some such *relict*, and *refer it withal to that sensible object which in time past was its cause and original*, this is MEMORY. Lastly, the *road which leads to memory through a series of ideas however connected, whether rationally or casually*, this is recollection."

59 Objections to their theory.

Of this theory we shall only remark, that if we could understand the words *picture* and *form* in a metaphorical sense, as candor obliges us to understand Locke's *images* in the mind, the doctrine of *Alexander Aphrodisiensis* would be very little wide of the truth. Experience teaches us that memory as well as perception depends upon the state of the brain; and as it is undeniable, that when a man to-day contemplates an object which he perceived yesterday, or at any former period, he has a view of it in all respects similar to the original perception, only fainter and less distinct, it is extremely probable, that an impression *ab extra*, which produces a sensation and perception, leaves behind it some *tendency* in the brain, to vibrate as in the actual sensation, and that this *tendency* is carried into *effect* by the internal energy of the mind itself. But in the Peripatetic philosophy, *pictures* and *forms* in the *sensorium* were considered as real things, and by no means as metaphorical expressions. This is evident from their being constantly compared to the impression of a seal upon wax, and from their converting the *materia prima* from something, which can neither be seen nor felt, into visible and tangible body, of which we shall treat afterwards. Now it being certain that on a being immaterial, no corporeal *form* can be impressed, and repeated dissections having shown that no such forms are in fact impressed on the brain, this whole theory is at once overturned.

[59] Locke's doctrine concerning memory

Modern philosophers having denied that there are real *images* or *forms* in the mind during the immediate act of perception, cannot consistently with themselves admit such images in the act of retention, or when those things which were formerly objects of perception are recalled to the mind by the power of memory. Mr Locke's doctrine is, that "the mind retains these simple ideas which it first received from sensation or reflection, two ways: first, by keeping the idea, which is brought into it, for some time actually in view, which is called CONTEMPLATION: and secondly, by the power which we have to revive again in our minds those ideas, which, after imprinting, have disappeared, or have been, as it were, laid out of sight; as when we conceive heat or light, yellow or sweet, the object being removed. This (he says) is MEMORY; which is, as it were, the store-house of our ideas †.

To explain this more fully, he immediately adds the following observation:—"But our ideas being nothing but actual perceptions in the mind, which cease to be any thing when there is no perception of them, this laying up of our ideas in the repository of the memory, signifies no more but this, that the mind has a power, in many cases, to revive perceptions which it has once had, with this additional perception annexed to them, that it has had them before. And in this sense it is, that our ideas are said to be in our memories, when indeed they are actually nowhere; but only there is an ability in the mind, when it will, to revive them again, and, as it were, paint them anew on itself, though some with more some with less difficulty, some more lively and others more obscurely. And thus it is, by the assistance of this faculty, that we are said to have all those ideas in our understandings, which, though we do not actually contemplate them, yet we can bring in sight, and make appear again, and be the objects of our thoughts, without the help of those sensible qualities which first imprinted them there."

† Essay, Book ii. chap. 10.

To attempt a defence of the accuracy of this language would be vain; but as the author's meaning is sufficiently obvious, his expressions may be easily and certainly corrected. Had Locke said—"But our ideas being nothing but scenes or appearances in the mind, which cease to be any thing when there is no perception of them, this laying up of our ideas in the repository of the memory signifies no more but this, that the mind has a power, in many cases, to revive scenes which it has once viewed, with this additional perception annexed to them, that it has viewed them before;" there would have been no room for the many petulant remarks which have been made upon the passage.

60 Objected t

But against this account of memory, a much heavier charge has been brought than that which regards the propriety of the language. It has been said, that the additional perception, which, according to Locke, attends the revival of our ideas by the power of memory, "would be a fallacious perception, if it led us to believe that we had them before, since they cannot have two beginnings of existence: nor can we believe them to have two beginnings of existence; we can only believe that we had formerly ideas or perceptions very like to them, though not identically the same." Let us examine this question somewhat narrowly: for if it be really true, that in the sense in which the word *same* is here used, we cannot twice contemplate the same idea, all confidence in memory would seem to be at an end.

61 The objection obviated.

Suppose a man to stand on some of the rising grounds about Edinburgh, the Calton-hill for instance, and from that eminence to view the glorious prospect of the coast of Fife, the ocean, the frith of Forth, and the little islands scattered in the frith. Let him go away, and return next day to the same place, and look the same way: we would ask whether he has the same *view* or *perception* which he had the day before? The man must surely be very captious who would say that he has not: and yet it is certain that the energy of mind by which he perceives on one day cannot be identically the same with that by which he perceived on another; nor are the rays of light which fall upon his eyes on the second day, identically the same with those which fell upon his eyes and occasioned vision on the first day. Let the same man now shut his eyes, and contemplate the various objects at which he had been just looking. They will appear to him in all respects the same as when viewed by means of his organs of sight, only fainter and less distinct, with this additional conviction, that the immediate objects of his present contemplation are not real external things, but *ideas* or *mental representations* of those things which had so lately been the objects of his sight. Let him think no more about the matter for some

ſome days, and then exert his power of memory. We have no heſitation to ſay, that in the ſenſe of the word *ſame*, as uſed by Mr Locke, the very ſame ideas will recur and be preſent to his intellect which were preſent to it at the former contemplation. The ſecond energy of memory or imagination, or whatever it may be called, is not indeed identically the ſame with the firſt; nor is that agitation or motion, or whatever other affection of the brain is neceſſary to memory, identically the ſame at the ſecond time as at the firſt: but the mind exerting itſelf in the very ſame manner at the one time as at the other, produces the ſame kind of agitation in the brain, and is itſelf affected in the very ſame way at the ſecond as at the firſt exertion. Whence it follows, that the ſecond *ideal ſcene* will be as much the ſame with the firſt, as the ſecond *actual perception* is the ſame with the firſt; and the two ideal ſcenes, and the two actual perceptions, are reſpectively ſaid to be the ſame with each other, only becauſe they impreſs the mind with a conviction that they were occaſioned by the ſame external objects.

But though we think Locke's doctrine, with reſpect to memory, may be thus eaſily vindicated from the charge of fallaciousneſs, we muſt acknowledge that to us it appears not to be of much value. It teaches nothing, but that the mind has a power to retain ideas of thoſe objects which it formerly perceived, and in many inſtances to recal them as occaſion may require. But theſe are truths known to all mankind, to the clown as well as to the philoſopher.

62 he opinion of ume.

Philoſophers in general have paid leſs regard to the retentive faculties of the mind than to its original powers of perception. Perhaps they imagined, that as memory depends upon perception, and in ſome reſpects appears to reſemble it, a competent knowledge of the nature of the former faculty would lead to that of the ſecond. Be this as it may, Mr Hume, who was at ſome pains to detail his notions of perception, has in his Philoſophical Eſſays only dropt concerning memory and imagination a few hints, ſo looſely thrown together, that, if he had not elſewhere expreſſed himſelf with more preciſion, it would have been difficult to diſcover his real meaning. According to him, that which is commonly called the *perception of an external object*, is nothing but a ſtrong impreſſion upon the mind; and that which is called the *remembrance of a paſt object*, is nothing but a preſent impreſſion or idea weaker than the former. Imagination is an idea weaker than the idea or impreſſion which he calls *memory*. This ſeems to be a wonderful abuſe of language. Impreſſions are not perceptions; and, if poſſible, they can ſtill leſs be called *ideas*, which are but ſecondary perceptions. It is likewiſe far from being true, that an idea of imagination has neceſſarily leſs vivacity than an idea of memory. We have ſeen Mr Hume, and have at the preſent moment an idea of his form and dreſs: we can likewiſe imagine to ourſelves a centaur; and though a centaur was never ſeen, and therefore cannot be *an impreſſion repeated by memory*, our idea of the monſter is much more lively and diſtinct than that of the philoſopher.

63 Of Dr Reid.

Dr Reid having obſerved of memory *, that it is by it we have an immediate knowledge of things paſt; that it muſt have an object; that in this reſpect it agrees with perception, but differs from ſenſation, which has no object but the feeling itſelf; and that every man can diſtinguiſh the thing remembered from the remembrance of it—proceeds to inquire what memory is? And, " Firſt (ſays he), I think it appears that memory is an original faculty given us by the Author of our being, of which we can give no account but that we are ſo made. The knowledge (continues he) which I have of things paſt by my memory, ſeems to me as unaccountable as an immediate knowledge would be of things to come (F); and I can give no reaſon why I ſhould have the one and not the other, but that ſuch is the will of my Maker. I find in my mind a diſtinct conception and a firm belief of a ſeries of paſt events; but how this is produced I know not. I call it *memory*; but this is only giving a name to it; it is not an account of its cauſe. I believe moſt firmly what I diſtinctly remember; but I can give no reaſon of this belief. It is the inſpiration of the Almighty which gives me this underſtanding. When I believe the truth of a mathematical axiom or of a mathematical propoſition, I ſee that it muſt be ſo: every man who has the ſame conception of it ſees the ſame. There is a neceſſary and an evident connection between the ſubject and the predicate of the propoſition; and I have all the evidence to ſupport my belief which I can poſſibly conceive. When I believe that I waſhed my hands and face this morning, there appears no neceſſity in the truth of the propoſition. It might be or it might not be. A man may diſtinctly conceive it without believing it at all. How then do I come to believe it? I remember it diſtinctly. This is all I can ſay. This remembrance is an act of my mind. Is it impoſſible that this act ſhould be, if the event had not happened? I confeſs I do not ſee any neceſſary connection between the one and the other. If any man can ſhow ſuch a neceſſary connection, then I think that belief which we have of what we remember will be fairly accounted for: but if this cannot be done, that belief is unaccountable; and we can ſay no more but that it is the reſult of our conſtitution. Our original faculties are all unaccountable: Of theſe memory is one. He only who made them comprehends fully how they are made, and how they produce in us not only a conception, but a firm belief and aſſurance, of things which it concerns us to know."

On this account of memory we ſhall make no remarks. There is a certain ſenſe of the words, in which every thing which the author has ſaid on the ſubject is undoubtedly juſt; and it would be very uncandid to take

* *Eſſays on the Intellectual Powers of Man.*

(F) If memory depends upon the ſtate of the brain as it has been affected in paſt perceptions, this appears to us a ſtrange poſition. Perhaps the excellent author means nothing more, than that it is as unaccountable to us, that impreſſions on the brain ſhould cauſe perception, and the veſtiges of thoſe impreſſions ſhould cauſe remembrance, as how the mind might not perceive things to come without the intervention of impreſſions on the brain. If this be his meaning, no man will controvert it: for it is impoſſible to diſcover the nature of that relation which ſubſiſts between an impreſſion and perception; but that there is ſuch a relation, we know from experience.

Retention and Ideas.

take his words in any other ſenſe. But though memory, as it is the reſult of that conſtitution which was given us by God, and not the offspring of habit or human contrivance, is unqueſtionably an original faculty; and though it is therefore impoſſible to account for it ſo fully as to ſilence every inquiry which may be made; yet we could wiſh that Dr Reid had beſtowed a little more pains upon it, in order to diſcover if poſſible in what reſpects it reſembles or differs from perception. He has well obſerved, that there are laws of nature by which the operations of the mind are regulated, as well as laws of nature which govern the material ſyſtem. As the latter are the ultimate concluſions which the human faculties can reach in the philoſophy of bodies, ſo the former are the ultimate concluſions which we can reach in the philoſophy of minds. The more general that theſe laws are in both caſes, the more uſeful they are and the more ſatiſfactory: for as they are themſelves inexplicable, the fewer they are in number, and the more comprehenſive each, the fewer will thoſe phenomena be for which we can give no account. Thus, as we know not what makes the planets tend to the centre of the ſun, or heavy bodies tend to the centre of the earth, we can give no other account of theſe phenomena, but that, as they appear to be of the ſame kind, it is reaſonable to conlude that they proceed from ſimilar cauſes. What the cauſe is of this tendency of bodies towards each other, we know not We call it *gravitation*, and employ it to account for all phenomena of the ſame kind. In like manner it is univerſally allowed, that as we know not how mind and matter operate upon each other, there is ſomething in perception wholly unaccountable. That perception follows ſenſation; and that there is no ſenſation which is not occaſioned by ſome affection of the brain, proceeding from ſome impreſſion *ab extra;* we have the evidence of experience: but how a particular affection of the brain ſhould excite a ſenſation in the mind, we know not; though we may here, as in the corporeal ſyſtem, attribute ſimilar effects to the ſame or ſimilar cauſes Thus, if when we exert an act of memory we have the ſame appearance of things as in the original act of perception, the rules of philoſophiſing authoriſe us to refer both phenomena to the ſame general law; juſt as they authoriſe us to refer the motion of the planets and of projectiles to the ſame general law. On the other hand, if we perceive no ſimilarity between memory and perception, we have made no progreſs in the philoſophy of mind; for in that caſe we have diſcovered two phenomena proceeding from two cauſes totally different from each other, and both inexplicable. Although we ſcarcely hope to throw any light upon a ſubject which Dr Reid has not attempted to illuſtrate, we ſhall ſtate a few facts reſpecting the memory, and ſubmit to the reader the concluſions to which we think theſe facts lead.

64 The appearance of ſenſible objects when recalled by the power of memory.

1. Objects once perceived by the ſenſes, when recalled to the mind by the power of memory, appear preciſely the ſame as in the original perception, only leſs diſtinct*. For example, having ſeen yeſterday a ſpreading oak growing on the bank of a river, and having heard a ſhepherd play, and handled a ſquare ſtone, we endeavour to recal to our minds theſe objects which are now abſent. How is this operation performed? Do we endeavour to form in our minds pictures of them or repreſentative images? or, does our intellect ſurvey the types or forms which, according to Ariſtotle, thoſe objects left in the imagination when originally perceived? Neither of theſe things is done. We conceive ourſelves as ſtanding in the ſame place where we ſtood yeſterday; upon which we have perceptions of the objects ſimilar in all reſpects to the perceptions which we had when we employed our eyes, our ears, and our hands. The tree appears, as it were, before us; faint indeed, but attended with all the objects which we obſerved around it yeſterday: we ſeem to hear the ſound of the pipe confuſedly, and at a diſtance; to move our hands over the ſtone, and to feel the ſame ſurfaces and the ſame angles which we felt in the original perception. In this recollection we are not conſcious of pictures or images more than in the original ſurvey. The perceptions ſeem to be of the tree and river themſelves, of the ſound itſelf, and of the ſtone itſelf, exactly as at the firſt; and yet we are ſatisfied that in the act of remembrance we perceive no ſuch object as a *real* tree, pipe, or ſtone. That theſe are facts, every man muſt be convinced who attends to the energies of his own mind when exerting the powers of retention: and therefore it is, in our opinion, with no impropriety that Mr Harris ſays, we may call SENSE, if we pleaſe, *a kind of tranſient imagination;* and IMAGINATION, on the contrary, *a kind of permanent ſenſe:* for if theſe two faculties, as far as the mind or intellect is concerned, be not the ſame, they ſeem to reſemble each other much.

* *Appendix to Elements of Criticiſm.*

65 What ideas remain longeſt in the memory.

2. The *primary* perception of a *viſible* object is more complete, lively, and diſtinct, and remains longer in the *ſenſorium*, than that of any other object. We know likewiſe by experience, that an *idea* or *ſecondary* perception of a viſible object is as much more complete, lively, and diſtinct, than the idea of any other object, as was the *primary* perception; and that we remember things which we have ſeen for a longer time than ſounds which we have heard, or than tangible objects which we have only handled. Yet there ſeems to be a conſtant decay of all our ideas, even of thoſe which are ſtruck (G) deepeſt and in minds the moſt retentive; ſo that if they be not frequently renewed by repeated exerciſe of the ſenſes, or by reflection on thoſe objects which at firſt occaſioned them, the print (G) wears out, and at laſt there remains nothing to be ſeen. Concerning ideas, it is eaſy to remark, that thoſe remain longeſt and cleareſt in the memory which are derived from two or more ſenſes, eſpecially if the ſenſe of ſight be one of the number, or which are ofteneſt refreſhed by a return of the objects which produced them. Hence a man has a longer and more diſtinct remem-

(G) Theſe expreſſions, which mention ideas as things which are *deep ſtruck*, and as *prints which wear out*, are the expreſſions of Locke. We hope it is needleſs to warn our readers, that they are uſed by us as they were by him in a metaphorical ſenſe. On theſe ſubjects it is impoſſible to write without metaphor; which, while the meaning is obvious, no man will condemn, who reflects that the words of language were not invented by metaphyſicians, and are for the moſt part *literally* ſignificant only of ſenſible objects.

Retention and Ideas.

remembrance of what he has ſeen than of what he has only heard, of what he has both ſeen and felt than of what he has only ſeen; and the ideas which we have of heat and cold, of hunger and thirſt, and of all thoſe things which moſt frequently affect our ſenſes, are extremely clear, and are never quite loſt whilſt the mind retains any ideas at all.

66 Memory a kind of habit.

3. Memory appears to be a kind of habit, which is not always in exerciſe with regard to things we remember, but is ready to ſuggeſt them when there is occaſion. The moſt perfect degree of this habit is, when the thing preſents itſelf to our remembrance ſpontaneouſly, and without labour, as often as there is occaſion. A ſecond degree is, when the thing is forgotten for a longer or ſhorter time, even when there is occaſion to remember it, and yet at laſt ſome incident, ſuch as a violent paſſion *, which agitates the whole mind and ſenſorium, tumbles the idea, as it were, out of its dark corner, and brings it into view without any ſearch. A third degree is, when we call about and ſearch for what we would remember, and after ſome labour find it out. This ſearching faculty of the ſoul is by Ariſtotle called ἀνάμνησις, by Dr Reid and others *reminiſcence*, and by Mr Harris *recollection*. Should it be ſaid, that what we *will* to remember we muſt already conceive, as we can will nothing of which we have not a conception; and that, therefore, a *will* to remember a thing, ſeems to imply that we remember it already—we anſwer, with Dr Reid, that when we will to remember a thing, we muſt indeed remember ſomething relating to it; but we may have no poſitive idea or conception of the thing itſelf, but only of the relation which it bears to that other thing which we do remember. Thus, one remembers that a friend charged him with a commiſſion to be executed at ſuch a place, but he has forgotten what the commiſſion was. He applies himſelf to diſcover it; and *recollects* that it was given by *ſuch a perſon*, upon *ſuch an occaſion*, in conſequence of ſuch a *converſation*: and thus by a train of thought he is led to the very thing which he had forgotten and wiſhed to remember. To this operation it is not always neceſſary that the relations between the various ideas which the mind turns over be very cloſe, or have their foundation in nature; for a caſual connection is often ſufficient. Thus, from ſeeing a garment, we think of its owner; thence of his habitation; thence of woods; thence of timber; thence of ſhips; thence of admirals; thence of cannons, iron, furnaces, and forges, &c."

* *Reid's Eſſays on the Intellectual Powers of Man, Locke's Eſſay, &c. and Harris's Hermes.*

67 Recollection, one idea ſuggeſts another, and why.

That, in the proceſs of recollection, one idea ſhould ſuggeſt another, may be eaſily accounted for. When, in perception, our minds are expoſed to the influence of external objects, all the parts and properties, and even the accidental variable adjuncts of theſe objects, are perceived by full-grown men at the ſame time; ſo that the whole group makes but one impreſſion upon our organs of ſenſe, and conſequently upon the mind. By theſe means all the parts of the ſimultaneous impreſſion †, and conſequently of the perception occaſioned by that impreſſion, are ſo intimately aſſociated or linked together, that the idea of any one of them recurring at any future period, generally introduces the ideas of all the reſt. But as the neceſſary parts and properties of any thing are more cloſely linked together, and occur more frequently than any particular variable adjuncts, it is obvious, that by the idea of any one of theſe properties, the idea of the reſt, and of the object itſelf, will be more readily introduced than by the idea of any variable adjunct. It ſeems, however, to be certain, that we have no power of calling up any idea at pleaſure, but only ſuch as have a connection, either in nature or by means of former aſſociations, with thoſe that are at any time preſent to the mind. Thus the ſight, or the idea, of any particular perſon, generally enables us to recollect his name, becauſe his name and his perſon have been conſtantly aſſociated together. If that fail to introduce the name, we are at a loſs and cannot recollect it at all till ſome other aſſociated circumſtance help us. In naming a number of words in a ſentence, or lines in a poem, the end of each preceding word or line being connected with the beginning of the word or line which ſucceeds it, we can eaſily repeat them in that order; but we are not able to repeat them backwards with any eaſe, nor at all till after many fruitleſs efforts. By frequent trials, however, we acquire at laſt a facility in doing it, as may be found by making the experiment on the names of number from one to twenty. It is, indeed, probable, that in the wildeſt flights of *fancy*, no ſingle idea occurs to us but ſuch as had a connection with ſome other idea, perception, or notion, previouſly exiſting in the mind, as ſhall be ſhown more fully in a ſubſequent chapter.

† *Hartley on Man.*

68 Memory depends on the ſtate of the brain.

4. "Memory appears to depend entirely or chiefly upon the ſtate of the brain *. For diſeaſes, concuſſions of the brain, ſpirituous liquors, and ſome poiſons, impair or deſtroy it; and it generally returns again with the return of health, from the uſe of proper medicines and methods. It is obſervable, too, that in recovering from concuſſions and other diſorders of the brain, it is uſual for the perſon to recover the power of remembering the then preſent common incidents for minutes, hours, and days, by degrees; alſo the power of recalling the events of his life preceding his illneſs. At length he recovers this laſt power perfectly; and at the ſame time forgets almoſt all that paſt in his illneſs, even thoſe things which at firſt he remembered for a day or two. Now the reaſon of this ſeems to be, that upon a perfect recovery the brain recovers its natural ſtate, and all its former affections and tendencies; but that ſuch affections or tendencies as took place during the preternatural ſtate, *i. e.* during the patient's illneſs, are obliterated by the return of the natural ſtate." All this we are induced to believe; becauſe, though it is a fact incontrovertible, that in certain diſeaſes the memory is impaired, and recovers its vigour with the return of health, it is not conceivable that the mind itſelf ſhould ſuffer any change by diſeaſes, concuſſions, or ſpirituous liquors, &c.

* *Hartley on Man.*

From theſe facts we are ſtrongly inclined to conclude, that the power of the *mind*, or *immaterial* (H) *principle*

(H) Though the whole of this and the preceding chapters, we have taken it for granted that the ſentient principle in man is not material. This is the *common*, and, as ſhall be ſhown afterwards, the moſt *probable* opinion; but whether it be abſolutely certain or not, makes no difference on the theories of ſenſation and perception. Theſe are obviouſly neither figure nor motion, and therefore not ſubject to the laws which govern the material world.

ciple, by which it remembers paſt events, differs not from that by which it perceives preſent objects. In perception, impreſſions are made upon the organs of

69
External objects operating on the ſenſes leave ſome permanent effect in the brain.

ſenſe, which are communicated to the brain; and, by ſome unknown means, occaſion ſenſations which are followed by the perception of the external object. When by the power of memory we recal paſt objects of ſenſe, the mind has the ſame view of them as in the original perception, except that they appear fainter, leſs diſtinct, and generally more diſtant. We have, therefore, reaſon to conclude, that in the act of remembrance the brain is affected in the ſame way, though not ſo forcibly, as in perception. That memory depends as much as perception upon the ſtate of the brain, is confirmed by daily experience; and therefore there cannot be a doubt but that external objects, operating upon the ſenſes, nerves, and brain, leave ſome permanent effect behind them. What that effect preciſely is we cannot know, and we need not deſire to know; but that they leave *ſome* effect we have as good evidence as that the planets are moved round the ſun by forces of the ſame kind with thoſe by which projectiles are moved on the earth. Could we ſuppoſe that they leave real *prints* or *impreſſions* behind them, which we confeſs to be very little probable, memory would ſeem to be nothing but the perceptive power of the mind turned to thoſe impreſſions. If the permanent effect of impreſſions by external objects be, as Dr Hartley ſuppoſes, only a tendency in the brain to vibrate as in the original perception, remembrance will reſult from the mind's operating upon the brain as in actual perception; and the reaſon that ideas of memory are fainter than perceptions of ſenſe, is, that the former are produced by a ſingle, and the latter by a double, operation.

70
Why the memory advances to perfection, and then gradually decays.

This theory appears to be greatly confirmed by the following well-known facts, that children ſoon commit to their memory any thing which they underſtand, and as ſoon forget it; that the powers of memory gradually advance to perfection, and then gradually decay; and that old men remember more diſtinctly what they perceived in their youth, than what they perceived a year ago. For if the memory belonged wholly to the pure intellect, and had no dependence upon the brain, it is not eaſy to conceive how it ſhould advance towards a ſtate of perfection and afterwards decay. A being which is unextended and indiviſible, can ſuffer no change either in its eſſence or in its faculties: the ideas which it had once retained, it would retain forever. But if memory be occaſioned by ſome relict of ſenſe left in the brain, it is eaſy to ſee how all thoſe changes ſhould take place: and therefore, though we have the weight of Dr Reid's authority againſt us, we cannot help thinking that Ariſtotle was in the right, when he imputed the ſhortneſs of memory in children to this cauſe, that their brain is too moiſt and ſoft to retain impreſſions made upon it; and that he was likewiſe in the right, when he imputed the defect of memory in old men to the hardneſs and rigidity of the brain, which hinders it from receiving any durable impreſſion.

Another argument to prove, that in remembrance the mind acts upon ſomething left in the brain by the impreſſions of ſenſe, is this, that nothing can act but where it is preſent. The truth of this axiom is acknowledged by Dr Reid, and we believe by all mankind except Dr Prieſtley and one or two others, whoſe paradoxes we ſhall conſider afterwards. Now it is confeſſed, that in recollection at leaſt the mind is active; and therefore it muſt act, *not* upon an object which has now perhaps no exiſtence, and certainly no immediate exiſtence, *but* upon ſomething left by that object in the brain or ſenſorium, to which the mind is intimately preſent.

71
By what means we never confound memory with perception.

But if this be ſo, we may be aſked how it comes to paſs that men never confound memory with perception, nor fancy that they perceive things which they only remember? If perception be an inference drawn from certain ſenſations excited by an impreſſion on the brain, and if remembrance reſult from the mind's operating upon relicts of thoſe impreſſions, one would think it natural to ſuppoſe, that in both caſes we have actual perceptions, though in the one caſe the perception muſt be more vivid and diſtinct than in the other. To this we anſwer, That previous to all experience, perception and memory are very probably confounded; and that we believe a man brought into the world with all his faculties in their full *natural* perfection, would not inſtantly be able to diſtinguiſh what he remembered from what he perceived. This we know to be the caſe with reſpect to imagination, a faculty which ſtrongly reſembles memory; for in dreams, and ſometimes even in waking reveries, we fancy that we actually perceive things which it is certain we can only imagine. A very ſhort experience, however, would enable this newly created man to make the proper diſtinction between remembrance and perception. For let us ſuppoſe him to be brought into a dark room, and ſoon afterwards a candle to be introduced. The candle would give him a viſible ſenſation, though not at firſt the perception of an external object. Let the candle after ſome time be carried out: the man would retain a viſible *idea*, which he might confound with the actual ſenſation. But if, whilſt this idea remained in his mind, the candle were brought back, he would inſtantly feel a difference between the real ſenſation and the idea, when both were together preſent to his mind. And having, in ſome ſuch manner as we have already deſcribed, acquired the power of perceiving external objects by means of his ſenſes, he would ſoon diſcover, without any effort of his own, the difference between actual perceptions and the ideas treaſured up in his memory.

72
The order of ſucceſſion in which objects recur to the memory.

The only remaining difficulty which ſeems to encumber this theory of remembrance, is, to account for the order of ſucceſſion in which objects recur to the memory, and to which we give the name of *time*.—But this difficulty will vaniſh when we have aſcertained what *time* is. At preſent it is ſufficient to obſerve, that our perceptions of external objects remain a certain ſpace of time in the mind; that this time is different, according to the ſtrength and other circumſtances of the impreſſion which occaſioned the perception; and that traces of thoſe perceptions, *i. e. ideas*, may be recalled after the intervention of other trains of ideas, and at very different intervals. If one look upon a houſe, and then ſhut his eyes, the impreſſion which it made upon his mind will not inſtantly vaniſh:

nish: he can contemplate the house almost as long as he pleases; and, by the help of various associated circumstances, he may recal the idea several years afterwards, and refer it to the original perception.

73 Brutes have memory, and Before we dismiss the subject of retention, it may not be improper to take notice of the retentive powers of inferior animals. Aristotle, Locke, Dr Reid, and almost every philosopher of eminence both among the ancients and moderns, have maintained, that inferior animals have memory as well as men; and indeed we do not perceive how the fact can be denied of the more perfect animals, and those with whose operations we are best acquainted. A dog knows his master again after a long absence; a horse will trace back a road which he has but once travelled, often with more accuracy than his rider; and it is well known that many species of singing birds have a capacity to learn tunes from the human voice, and that they repeat the notes again and again, approaching nearer and nearer to perfection, till at last they sing the tune correctly. These phenomena can be accounted for only by supposing, that in the brains of the several animals traces are left by perception, of the same kind with those which perception leaves in the brain of man, and which are the cause or occasion of his remembrance. With respect to this point, the learned author of *Ancient Metaphysics* differs from his master Aristotle. He allows that brutes have imagination, but denies that they have memory: for (says he) "memory necessarily implies a sense of *time*, and what is *first* and *last*; but brutes have no idea of time, or of first and last; and it is certain that they have not consciousness or reflection, by which only they could review their own operations. At the same time he admits, that imagination in the brute serves the purpose of memory in us; for whenever he sees the object that is painted on his *phantasia*, he knows it again, but without any perception of the time when he first saw it." But that a brute, when he sees the object which is painted on his phantasia, should know it *again* without referring it to a former perception, is plainly impossible. The recognisance of any thing consists in a consciousness of its having been perceived before; and nothing more than such recognisance is essential to memory. The author's mistake seems to lie in supposing that memory necessarily implies a sense of some determinate portion of past time; but we surely remember many things of which we can only say that we have formerly perceived them, without being able to ascertain the precise period at which we had such perceptions. A child has the use of memory sooner than he acquires the faculty of speech; but he must have spoken and even reasoned before he can have an accurate notion of time, which, as shall be shown afterwards, arises from comparing the fleeting succession of our own ideas with the permanence of ourselves and other objects. The author's distinction between memory and imagination seems to be on all accounts improper. Aristotle has said, and said truly, that there is memory of *ideas* as well as of sensible objects; meaning by ideas general conceptions or propositions: but this reviver of his philosophy is inclined to say, "that *memory* is only of *ideas*, consequently belongs only to man; and that *imagination* is only of sensible objects, and consequently belongs both to man and brute."— But surely man *remembers* what he has *seen* and *felt* as well as what he has *conceived* or *thought*; and if imagination and memory be properly distinguished by Mr Harris, the reverse of this writer's doctrine must be true, viz. that imagination belongs only to *man*, and memory of sensible objects both to *man* and *brute*.— We can contemplate in imagination the idea of a *centaur* or a *golden mountain*; but we cannot be said to remember them, for they were never perceived. That a dog can contemplate in his imagination the idea of a *centaur* or of a *golden mountain*, we have not the least reason to suppose; but were he not capable of viewing relicts of sense reposed within him, and referring them to their original causes, he could not possibly recognise his master after a day's absence.

74 the power of recollection. Dr Reid and the same author agree with Aristotle, in thinking it probable that brutes have not reminiscence, or the power of recollection; but there are many well attested facts which seem to prove the contrary. We shall mention one which fell under our own observation. One of the persons concerned in this work was, when a young man, absent for five months from the house of his father. Upon his return, a dog of that species which is commonly called the *shepherd's cur*, and which had been in the possession of his father only a few months before his departure, gazed at him for a few minutes as at any other stranger. The animal then began to walk round him with looks which soon attracted his notice. This made him call the dog by the name which he bore in the family, and stretch out his hand to caress him, when the creature instantly leaped upon him with all that appearance of attachment which those animals so commonly exhibit upon the return of their master after a few days absence. If this was not recollection, we should be glad to know what it was, for we cannot distinguish it from recollection in men. Indeed, if dogs and some other animals possess, as Aristotle, Locke, and others, allow them to possess, the power of memory, and something of ratiocination; and if, as Dr Reid expressly says §, "they expect events in the same order and succession in which they happened before;" it is not conceivable that they can be wholly destitute of reminiscence, or the power of recollection.

§ *Essays on the Intellectual Powers of Man.*

75 Memory capable of improvement. That memory is a faculty of the first importance, cannot be denied; since it is obvious, that, without the power of retaining the ideas and notions which we receive by the senses and other faculties, we never could make any progress in the acquisition of knowledge, but should begin every day, nay every hour, in the same state of ignorance in which we are born. That it is a faculty capable of improvement by exercise, and that there are some methods of exercise better adapted for this purpose than others, has been shown elsewhere. See MEMORY.

CHAP. III. *Of* SIMPLE APPREHENSION *and* CONCEPTION.

76 Ideas of sensation the first materials of human knowledge. The ideas received into the mind by the senses, and treasured up in the memory and imagination, are the original materials of human knowledge. It is by comparing those ideas with one another, or by analysing them into their first principles, that we acquire all our knowledge in mathematics and philosophy,

and

and indeed all the knowledge which regulates our conduct through life. It must, therefore, be of importance to trace the progress of the mind in her various operations upon these materials; beginning, as she certainly begins, with that which is most simple, and proceeding regularly to those which are more complex and difficult.

77
Simple apprehension of ideas

Now the first operation of the mind about her ideas appears plainly to be that which logicians term *simple apprehension*. Having yesterday observed a *tree* or any other object, if we contemplate the idea of that tree to day as it remains in the imagination, without comparing it with any other idea, or referring it to any external object, we perform the operation which is called *simple apprehension*. We consider simple apprehension as an *operation*, because the mind in the apprehension of her own ideas is certainly active; she turns them, as it were, round and round, and views them on every side.

78
Different from conception.

Simple apprehension is a phrase which is commonly taken to be of the same import with the word *conception*; and in the ordinary affairs of life no confusion can arise from an indiscriminate use of the two words: but in this article we think it expedient to employ the phrase *simple apprehension*, to denote the view or contemplation of those ideas only which the mind by sensation has actually received from external objects; and the word *conception* to denote the view, not only of those ideas, but also of such as the mind fabricates to herself. Thus, a man may *conceive* a centaur, but we would not choose to say that he may *apprehend* a centaur: not that there is any impropriety, perhaps, in this last expression; but as there is certainly a difference between *apprehending* the idea of what has been seen or felt, and *conceiving* that which never existed, perspicuity requires that these different operations be expressed by different names.

79
In what sense it is true that we can conceive objects which never existed.

We have said that the mind may conceive what never existed; and every man may easily satisfy himself that what we have said is true: but though this has been frequently called the creative power of the mind, it has in fact no resemblance to *creation*. The materials of all our most complex and fantastic conceptions are furnished to our hands by sensation and reflection; nor can we form one simple idea which was not originally received by some of our senses from external objects, or, as shall be shown afterwards, one intellectual notion which was not acquired by reflecting on the operations of our own minds. To explain the process of fantastic conception, it is to be observed, that in every sensible object we perceive at once several things, such as *colour*, *figure*, *extension*, and *motion* or *rest*, &c. These are the objects of different senses: but they are not, at least by full grown men, perceived in succession, but all at once; whence it comes to pass that the memory, or the imagination, retains not several distinct and disjointed ideas, but the idea of *one coloured*, *figured*, and *extended object*. But when we compare various objects, or the ideas of various objects, together, we find that in some respects they agree and in others disagree; *i. e.* that several objects affect some of our senses in the same way, and other senses differently. Thus one globe is black, and another white; one black substance is circular and hard, and another square and soft. In the first instance, the two globes affect our sense of touch in the same way, and our sense of seeing differently; in the second, the two black substances affect our sense of sight in the same way, and our sense of touch differently.

From observing this difference among objects by means of the different sensations received from them, the mind learns to analyse its original ideas, which are copies of those sensations, into their first principles, and to combine those principles in such a manner as to form complex ideas of objects which were never actually perceived by the senses. Of the simple and unmixed principles which compose those complex ideas, there is not indeed one which was not originally received by some sense; so that the whole difference between complex ideas fabricated by the mind, and those which are the relicts of sensation, consists in the order in which the constituent simple ideas of each are put together. Thus, no man ever saw a mountain of pure gold; and therefore the idea of such a mountain can be in no human mind as a relict of sensation: but we have all seen pieces of gold of different sizes, and we have all seen mountains; and nothing is more easy than to *conceive* a piece of gold extended on all sides to the size of a mountain, and rising out of the earth. Again, though no person ever saw a centaur, yet it is easy to *conceive* the upper parts of a man joined to the breast and shoulders of a horse. In these instances, the complex conceptions are of things which it is in the highest degree probable never had a real existence, and which it is certain we never *perceived* as existing: but the simple ideas of which they are composed are the relicts of actual sensations; for every one has perceived as really existing the body of a horse and the upper parts of a man, and when conceiving a centaur he only perceives them to exist united. That we have not in the imagination one simple and unmixed idea which was not left there as a relict of sense, every man will be convinced who shall try to conceive a simple colour or taste which is totally different from all the colours and tastes, and all the shades and varieties of them, which he has received by sensation; but his simple ideas, though all received from without, he may put together in numberless manners, differing from any order in which he has ever actually perceived the qualities of external objects existing.

80
This p[…] of exe[…]tion li[…]ed to p[…]sible e[…]ence.

Yet even this power of the mind is limited. It is impossible to put together a number of *contrary* and *inconsistent* ideas, in such a manner as to form of them one complex conception. No man, for instance, can conceive a thing to be at once white and black, round and square, hard and soft, in motion and at rest.—Hence it is a maxim among philosophers almost universally received, that though we can conceive many things which never *actually* existed, yet we can form no ideas but of such things as *might possibly exist*. A centaur never existed, but it may be conceived; for it is by no means impossible that the head of a man might be joined to the body of a horse: but black snow cannot be *conceived*; for in the complex idea denoted by the word *snow* whiteness is an essential part, and nothing can be conceived to be both black and white at the same time. From this undoubted fact, that we cannot conceive impossible existence, the power of conception has by some writers in certain instances been made a test of truth. "In every idea is implied (says

Of Simple Apprehension and Conception.

(says Dr Price*) the possibility of the existence of its object; nothing being clearer, than that there can be no idea of an impossibility, or conception of what cannot exist." "It is an established maxim in metaphysics (says Hume), that whatever the mind conceives, includes the idea of possible existence; or, in other words, that nothing we imagine is absolutely impossible ‡." In a word, it has been admitted by all philosophers, from Pythagoras to Dr Reid, to be an axiom as evident and undeniable as any in Euclid, that whatever we can distinctly conceive is possible, though many things may be possible, nay, may really exist, of which we can form no conception.

This axiom has been denied by the author of the Essays on the Intellectual Powers of Man; who affirms, that "any two sides of a triangle may be conceived to be equal to the third," as distinctly as "any two sides of a triangle may be conceived to be greater than the third." This assertion from such a man surprised us as much as any paradox which we ever read: for nothing is more certain, than that *we* ourselves can form no conception of a triangle of which two of the sides are only equal to the third. We can, indeed, resolve the proposition into its different parts, and form the distinct and independent ideas of a *triangle*, *two sides*, and *one side*; and we can likewise form the general notion of *equality*: but to combine these ideas and this notion into one individual complex conception, we find to be absolutely impossible. A man who knows nothing of triangles, if such a man there be, might *believe* Dr Reid that it is a figure of which one of its sides is equal to the other two; but such a person would have no *conception* of the *figure itself*, but only a confidence in the Doctor's veracity.

What is it to *conceive* a corporeal thing to exist? Is it not to fancy that we view it on all sides, as what may be seen, or felt, or smelt, or tasted? The Doctor, indeed, repeatedly reprobates as the source of much error the notion of ideas as images in the mind; and if ideas be taken as real material figures, he is certainly in the right: But we appeal to the common sense of mankind, whether every person who distinctly *conceives a triangle*, is not at the time conscious that his mind is affected in a manner similar, though not so forcibly, as when he actually views a triangle with his eyes? What other men may feel, they know best; but we are as certain that this is the case with respect to ourselves, as we are certain of our own existence. That this affection of the mind is occasioned by some agitation in the brain, of the same kind with that which occasions actual perception, is highly probable; but whatever be the cause, the fact is undeniable.

The Doctor's words indeed, taken by themselves, would lead one to think, that by *conception* he means in this case nothing more than the understanding of the terms of a proposition: but if that be his meaning, there was no room for controversy; as the great philosophers *Cudworth*, *Clarke*, *Price*, and *Hume*, whose opinion he is combating, would have been as ready as himself to allow, that when a man is thoroughly master of any language, he will find no difficulty in understanding the meaning of any particular words in that language, however absurdly these words may be put together. When Dr Price says, that "in every idea is implied the possibility of the existence of its object, nothing being clearer than that there can be no idea of impossibility or conception of what cannot exist," his meaning evidently is, that we cannot mentally contemplate or fancy ourselves viewing any thing corporeal, which we might not actually view with our eyes, or perceive by some other sense (1). This is the true meaning of *conception*, which is something very different from understanding the separate meaning of each word in a proposition.

The learned professor, however, appeals to the practice of mathematicians for the truth of his opinion: and if they be on his side we must give up the cause; for in no science have we such clear ideas, or such absolute certainty, as in mathematical reasonings. But it is to be observed, that the word *conception* is with no propriety applied to *abstract truth*, but to *real* or *possible* existence; nor can we be said to conceive distinctly a *real* or *possible* object, unless we be able to turn it round and round, and view it on all sides.— The faculties which are conversant about *abstract truth* are the judgment and the reason; and truth itself consists in the agreement, as falsehood does in the disagreement, of two or more ideas or terms compared together. If those ideas about which the judgment is to be made can be immediately brought together, without the intervention of a third idea, it is impossible that we should *judge*, or, if Dr Reid will have it so, *conceive* that to be *true* which is *really false*. If the two ideas cannot be immediately brought together, it is impossible that we should form any *judgment* or *conception* at all about their *agreement* or *disagreement*: but we may *suppose* or *admit*, for the sake of argument, that they agree or disagree; and if that supposition conduct to a manifest absurdity, we then *know* that the supposition was false. It is, therefore, perfectly agreeable to the

(1) Dr Price may be thought by some to have contradicted in this passage what he had asserted in a former. He is a strenuous advocate for abstract and general ideas even of material objects: but those among the moderns who contend the most zealously for these, contend for them only as conceptions of the mind which can have no possible existence out of it. Were this likewise the opinion of Dr Price, he would certainly have fallen into a direct contradiction; but this is not his opinion. His notion of abstract ideas seems to be the same with that of Plato, who considers ideas, not only as the possibilities of existence, but as things actually existing from eternity, uncreated and independent even of the Supreme Mind. That Dr Price carries the matter thus far, we are unwilling to believe; but he certainly considers general ideas as real existences independent of *our* minds, though the immediate objects of our understanding. That in this notion he is mistaken, we shall endeavour to prove in the next chapter. It is enough for our present purpose to have shown that he does not contradict himself; and that he might with great propriety affirm on his own principles, as well as upon the principles of those who admit not of universal ideas, that in every idea is implied the possibility of its object.

Of Simple Apprehension and Conception

the max'm of Price and Hume, that mathematicians should in many cases prove some things to be possible and others impossible, which without demonstration would not have been believed; because if the ideas compared cannot be immediately brought together, no *judgment* previous to the demonstration can be formed of the truth or falsehood of the proposition; and if it concern not real or possible existence, it is a proposition with which *conception* has nothing to do.

"But (says Dr Reid) it is easy to *conceive*, that, in the infinite series of numbers and intermediate fractions, some one number integral or fractional may bear the same ratio to another as the side of a square bears to its diagonal." We are so far from thinking this an easy matter, that if the word *conceive* be taken in the sense in which it is used by the philosophers whose opinion he is combating, we must confess that we can form no adequate conception at all of an infinite series. When we make the trial, we can only bring ourselves to *conceive* the real numerical figures 1, 2, 3, &c. or the fractional parts $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, &c.; and even here our *conception* reaches but a small way.—We have reason to believe, that minds of a larger grasp can conceive at once more of the series than we can; and that the Supreme Mind conceives the whole of it, if the whole of a mathematical infinity be not a contradiction in terms: but surely no man will say that he can conceive an infinite series as he conceives a centaur, and have an adequate and distinct view of it at once. If, by conceiving that in an infinite series some one number may bear the same ratio to another that the side of a square bears to its diagonal, the Doctor only means that such a *supposition* may be made, his observation is not to the purpose for which it is brought; for the question is not about our power to make suppositions of this kind, but about our power to raise in our imaginations an adequate and distinct mental view of possible or impossible existence. "To suppose (says Johnson), is to advance by way of argument or illustration, without maintaining the truth of the position." In this sense a man may *suppose* that in an infinite series there may be some one number which bears the same ratio to another that the side of a square bears to its diagonal: but such a supposition contains in it nothing that is *positive*, which conception always does; it is only admitting, for the sake of argument, a position, of the truth or falsehood of which the person who makes the supposition knows nothing.—He is only talking of ratios as a blind man may talk of colours. A man born blind may be made to comprehend many of the laws of optics, and may make suppositions about colours, and reason from such suppositions to a certain extent, as clearly and justly as one who sees; but will any person say that a man blind from his birth can conceive *red* or *green?* It is much the same with respect to an infinite series. We can follow such a series so far, and may know the ratio by which it increases or decreases, and reason from what we know with the utmost certainty: but no man ever *conceived the whole of an infinite series* as he conceives an individual object; nor can any reasonings upon the nature of it be applied to the question of conceiving impossible existence.

But "mathematicians often require us (says Dr Reid) to conceive things that are impossible, in order to prove them to be so. This is the case in all their demonstrations *ad absurdum*. Conceive (says Euclid) a right line drawn from one point of the circumference of a circle to another, to fall without the circle. I conceive this, I reason from it, until I come to a consequence that is manifestly absurd, and from thence conclude that the thing which I conceived is impossible." If it be indeed true, that Euclid desires his readers to conceive a mathematical circle with a line drawn from one point of its circumference to another, and that line lying without the circle—if he really desires them to form such a complex conception as this, we have no hesitation to affirm, that he requires them to do what is manifestly impossible. The writer of this article has not in his custody any copy of the elements in the original Greek, and therefore cannot say with certainty what are Euclid's words, nor is it of much importance what they be; for on a question which every man may decide for himself, by looking into his own mind, the authority of Euclid is nothing.—The proposition to which the Doctor refers, is the second of the third book; and, in the edition of Simpson, is expressed thus: "If any two points be taken in the circumference of a circle, the straight line which joins them shall fall within the circle." Every mathematician who can form an adequate conception of a circle and a straight line, perceives the truth of this proposition instantly, for it results necessarily from his conception; but he who has not an adequate conception of a circle, *may* stand in need of a demonstration to show him the truth: for it is to be observed, that demonstration does not *make truth;* it only points it out to those who cannot perceive it intuitively, just as a microscope does not make the hairs on a mite's back, but only brings them within the field of vision.

Were a man who never examined a mite through a microscope, and who has no adequate ideas of the insect kingdom, to be asked whether there be hairs on a mite's back? he would probably answer that he did not know, but he could *conceive* no such hairs. In like manner, were a man who has no adequate conception of a mathematical circle, to be asked whether a straight line, which joins any two contiguous points in the circumference, could lie *without* the circle? he would probably answer that he did not know. Now it is to be remembered, that the reader of the Elements can have no very adequate conception of a circle when he comes to the second proposition of the third book. The definition of a circle was indeed given him in the introduction to the first book; but of that definition he has hitherto had occasion to make very little use, so that his idea of a circle will be little more accurate than that of an illiterate clown, who has no other idea of the figure than what he takes from a half-penny or a shilling. Dr Reid himself has elsewhere † well observed, that "when a youth of moderate parts begins to study Euclid, every thing at first is new to him. His apprehension is unsteady; his judgment is feeble; and rests partly upon the evidence of the thing, and partly upon the authority of his teacher: but every time he goes over the definitions, the axioms, the elementary propositions, more light breaks in upon him; the language becomes familiar, and conveys clear and steady conceptions." In this state he certainly

† See Kames Sketches of the History of Man; Appendix to the first Sketch on the sciences.

Simple apprehension and conception.

tainly is when he reads for the firſt time the ſecond propoſition of the third book: his conception of a circle can then be neither clear nor ſteady. Our young geometrician, however, muſt allow, that the propoſition is either true or falſe; and if he has read the preceding books with any advantage, he muſt have clear and ſteady conceptions of angles and triangles, and be able to demonſtrate many of their properties. "Well (ſays Euclid), though you have no adequate conception of a circle, you are well acquainted with plane angles and triangles, and many of their properties: let us ſuppoſe, if that be poſſible, that my propoſition is falſe, and I will ſhow you that the ſuppoſition is abſolutely inconſiſtent with what you know to be demonſtrable or ſelf-evident truth." This is all which Euclid can be ſuppoſed to require, when, in the words of his excellent tranſlator, he ſays, "If it (viz. the ſtraight line) do not fall within (the circle), let it fall, if poſſible, without." He could not poſſibly deſire a man who has an adequate idea of a circle, to form the poſitive and complex conception of that figure, with a ſtraight line touching two points of the circumference, and yet lying on the outſide of the circumference; becauſe all his figures and lines are mere conceptions, and not real material things; and ſuch a requeſt would have been the ſame thing as if he had ſaid, Conceive what cannot be conceived (K).

We have inſiſted the longer on this point, because we think it of the higheſt importance: for were it indeed true, that we could conceive impoſſible exiſtence, the conſequences would be very melancholy. Theſe conſequences it is needleſs to enumerate. Our readers will perceive, that if we could put together inconſiſtent ideas of ſenſible objects, and view them ſo united as one conſiſtent whole, nothing is clearer than that our faculties would be contrived to deceive us, and we would be doomed to cheerleſs and univerſal ſcepticiſm.

Chap. IV. *Of* Abstraction *and* general Ideas.

83 Every ſenſible object is an individual, and every ideas are individual.

Every ſenſible object is an individual, and differs in many reſpects from every other object. As ſuch it is perceived by the ſenſes; and ideas being nothing more than relicts of ſenſation preſerved in the imagination or memory, every idea muſt of courſe be an individual, as much as the object to which it refers. But all ſcience, whether mathematical, moral, or metaphyſical, is converſant about general truths; and if truth conſiſt, as we have already obſerved, and ſhall more fully evince afterwards, in the agreement or coincidence of ideas, how, it may be aſked, can general truth reſult from the compariſon of particular ideas? To get rid of this difficulty, many philoſophers, both ancient and modern, pretend that the mind is furniſhed with *general ideas*, from a compariſon of which reſult general propoſitions applicable to many individuals. Philoſophers, indeed, have differed in opinion reſpecting the ſource of thoſe ideas; ſome of the ancients deriving them immediately from the ſupreme mind to the human, whilſt almoſt all the moderns ſay that they are framed by abſtraction, and therefore call them *abſtract ideas*.

Of Abstraction and general Ideas.

84 The doctrine of abſtract ideas ſtated, and

The doctrine of *abſtract* ideas has been ſo fairly ſtated, and, in our opinion, ſo completely overturned, by Biſhop Berkeley, that we ſhall content ourſelves with abridging what he has ſaid on the ſubject, and obviating ſome cavils which have lately been urged againſt his reaſoning. "It is agreed on all hands (ſays that learned and ingenious prelate †), that the qualities or modes of things do never really exiſt each of them apart by itſelf and ſeparated from all others; but are mixed, as it were, and blended together, ſeveral in the ſame object. But, we are told, the mind being able to conſider each quality ſingly, or abſtracted from thoſe other qualities with which it is united, does by that means frame to itſelf abſtract ideas. For example: There is perceived by ſight an object extended, coloured, and moved: this mixed or compound idea, the mind reſolving into its ſimple conſtituent parts, and viewing each by itſelf excluſive of the reſt, does frame the abſtract ideas of extenſion, colour, and motion. Not that it is poſſible for colour or motion to exiſt without extenſion; but only that the mind can frame to itſelf by *abſtraction* the idea of colour excluſive of extenſion, and of motion excluſive of both colour and extenſion. Again, the mind having obſerved, that in the particular extenſions perceived by ſenſe, there is ſomething common and alike in all, and ſome other things peculiar, as this or that figure or magnitude, which diſtinguiſh them from one another; it conſiders apart, or ſingles out by itſelf, that which

† *Introduction to the Principles of Human Knowledge.*

(K) Principal Campbell, treating of the commonly received doctrine of abſtraction, and having ſhown, that though Locke has in one paſſage of his immortal work expreſſed himſelf on the ſubject in terms unintelligible, his ſentiments on the whole differed little from thoſe of Berkeley and Hume, adds—"Some of the greateſt admirers of that eminent philoſopher ſeem to have overlooked entirely the preceding account of his ſentiments on this ſubject; and, through I know not what paſſion for the paradoxical (I ſhould rather ſay the impoſſible and unintelligible), have ſhown an amazing zeal for defending the propriety of the haſty expreſſions which appear in the paſſages formerly referred to. Has not the mind of man (ſay they) an unlimited power in moulding and combining its ideas? The mind, it muſt be owned, hath an unlimited power in moulding and combining its ideas. It often produces wonderful forms of its own out of the materials originally ſupplied by ſenſe; forms indeed of which there is no exemplar to be found in nature:—centaurs and griffins,

Gorgons and hydras, and chimeras dire.

But ſtill it muſt not attempt abſolute impoſſibilities, by giving to its creature contradictory qualities. It muſt not attempt to conceive the ſame thing to be black and white at the ſame time; to be no more than three inches long, and yet not leſs than three thouſand; to conceive two or more lines to be both equal and unequal; the ſame angle to be at once acute, obtuſe, and right;" or, we may add, the two ſides of a triangle to be not greater than the third. See *Philoſophy of Rhetoric*, vol. ii. p. 108, &c.

which is common, making thereof a moſt abſtract idea of extenſion, which is neither line, ſurface, nor ſolid, nor has any figure or magnitude, but is an idea entirely preſcinded from all theſe. So likewiſe the mind, by leaving out of the particular colours perceived by ſenſe that which diſtinguiſhes them one from another, and retaining that only which is common to all, makes an idea of colour in abſtract, which is neither red, nor blue, nor white, nor any other determinate colour. And as the mind frames to itſelf abſtract ideas of qualities or modes, ſo does it by the ſame preciſion or mental ſeparation attain abſtract ideas of the more compounded beings, which include ſeveral coexiſtent qualities. For example: The mind having obſerved that *Peter*, *James*, and *John*, reſemble each other in certain common agreements of ſhape and other qualities, leaves out of the complex or compounded idea it has of *Peter*, *James*, and any other particular man, that which is peculiar to each, retaining only what is common to all, and ſo makes an abſtract idea wherein all the particulars equally partake, abſtracting entirely from and cutting off all thoſe circumſtances and differences which might determine it to any particular exiſtence. After this manner, it is ſaid, we come by the abſtract idea of *man*, or, if you pleaſe, humanity or human nature: in which, it is true, there is included colour, becauſe there is no man but has ſome colour; but then it can be neither *black* nor *white*, nor any *particular* colour, becauſe there is no one particular colour wherein all men partake. So likewiſe there is included ſtature; but then it is neither tall ſtature, nor low ſtature, nor middle ſtature, but ſomething abſtracted from all theſe; and ſo of the reſt. Moreover, there being a great variety of other creatures that partake in ſome parts, but not all, of the complex idea of *man;* the mind, leaving out thoſe parts which are peculiar to man, and retaining thoſe only which are common to all the living creatures, frameth the idea of *animal*; which abſtracts not only from all particular men, but alſo from all birds, beaſts, fiſhes, and inſects. The conſtituent parts of the abſtract idea of animal, are body, life, ſenſe, and ſpontaneous motion. By *body*, is meant body without any particular ſhape or figure, there being no one ſhape or figure common to all animals, without covering either of hair or feathers or ſcales, &c. and yet not naked; hair, feathers, ſcales, and nakedneſs, being the diſtinguiſhing properties of particular animals, and for that reaſon left out of the *abſtract idea.* Upon the ſame account, the ſpontaneous motion muſt be neither walking, nor flying, nor creeping: it is nevertheleſs motion; but what that motion is, it is not eaſy to conceive.

85 controverted; and

"Whether others have this wonderful faculty of *abſtracting their ideas* (continues the Biſhop), they beſt can tell; for myſelf, I find indeed that I have a faculty of imagining or repreſenting to myſelf the ideas of thoſe particular things which I have perceived, and of variouſly compounding and dividing them. I can imagine a man with two heads, or the upper parts of a man joined to the body of a horſe. I can conſider the hand, the eye, the noſe, each by itſelf abſtracted or ſeparated from the reſt of the body. But then, whatever hand or eye I imagine, it muſt have ſome particular ſhape, and ſome particular colour.—Likewiſe the idea of man that I frame to myſelf, muſt be either of a white, or a black, or a tawney, a ſtraight or a crooked, a tall or a low, or a middle-ſized man. I cannot by any effort of thought conceive the abſtract idea above deſcribed. To be plain, I own myſelf able to abſtract in one ſenſe, as when I conſider ſome particular parts or qualities ſeparated from others, with which, though they are united in ſome objects, yet it is poſſible they may really exiſt without them. But I deny that I can abſtract one from another, or conceive ſeparately thoſe qualities which it is impoſſible ſhould exiſt ſo ſeparated; or that I can frame a general notion by abſtracting from particulars in the manner aforeſaid; and there are grounds to think moſt men will acknowledge themſelves to be in my caſe."

86 ſhown to be abſurd.

To think this, there are indeed ſuch good grounds, that it is probable ſome of our readers, little converſant with the writings of modern metaphyſicians, are by this time diſpoſed to ſuſpect, that the Biſhop in his zeal may have miſrepreſented the doctrine of *abſtraction;* as no man in his ſenſes, who is not perverted by ſome darling hypotheſis, can ſuppoſe himſelf capable of tagging together ſuch monſtrous inconſiſtencies, as magnitude which is neither large nor ſmall, and colour which is neither white, red, green, nor black, &c. But that the ingenious prelate, in his account of this proceſs of *lopping* and *pruning*, as Mr Harris contemptuouſly, but moſt properly, terms it, has not exaggerated in the ſmalleſt degree, is apparent from the following account of *abſtraction* given by Mr Locke. "*Abſtract ideas* (ſays that writer) are not ſo obvious or eaſy to children, or the yet unexerciſed mind, as particular ones. If they ſeem ſo to grown men, it is only becauſe by conſtant and familiar uſe they are made ſo: for when we nicely reflect upon them, we ſhall find that general ideas are fictions and contrivances of the mind that carry difficulty with them, and do not ſo eaſily offer themſelves as we are apt to imagine. For example, Does it not require ſome pains and ſkill to form the general idea of a triangle (which is yet none of the moſt abſtract, comprehenſive, and difficult)? for it muſt be neither oblique nor rectangle, neither equilateral, equicrural, nor ſcalenon, but *all and none of theſe at once.* In effect, it is ſomething imperfect that cannot exiſt, an idea wherein ſome parts of ſeveral different and *inconſiſtent* ideas are put together." "Surely (to uſe the words of principal Campbell *) the bare *mention* of this hypotheſis is equivalent to a confutation of it, ſince it really confutes itſelf." But if any man has the faculty of framing in his mind ſuch an idea of a triangle as is here deſcribed, it would be vain in us to diſpute with him; for we are poſſeſſed of no ſuch faculty, and therefore would fight on unequal terms. All we have to deſire is, that the reader would fully and certainly inform himſelf whether he has ſuch an idea or not; and this can be no hard taſk to perform. What is more eaſy for any one than to look a little into his own thoughts, and there try whether he has, or can attain to have, an idea of *colour* ſeparated from all *extenſion;* of *extenſion*, which is neither *great* nor *ſmall;* of *taſte*, which is neither *ſweet* nor *bitter*, nor *acid*,

* Philoſ. of Rhet.

Of Abstraction and general Ideas.

acid, nor *agreeable*, nor *disagreeable*; or the general idea of a triangle, which is neither *oblique* nor *rectangle*, *equicrural*, *equilateral*, nor *scalenon*, *but all and none of these at once* (L)?

7 Abstract conceptions the same as abstract ideas.

Dr Reid having denied that there are or can be in the mind any *ideas* of sensible objects, rejects of course the doctrine of *abstract general ideas*, whilst he maintains in fact the same thing, only substituting the word *conception* for the word *idea*. "What hinders me (says he) from attending to the whiteness of the paper before me, without applying that colour to any other object?" We know nothing indeed which can hinder any man from performing this operation, which is daily and hourly performed by infants; but will the Doctor say, that he can attend to colour, or conceive it, abstracted from the paper and every other surface? We are persuaded he will not, though he immediately adds, "the whiteness of this individual object is an *abstract conception*." Now we should rather have thought, that, consistent with his own notions of colour, he would have called the whiteness of the paper a *concrete quality*, and his own conception of it a *particular* and *concrete conception*. If he conceives the whiteness as separated from the paper, it is no longer the whiteness of that individual object: and he must either conceive it as abstracted from *all* objects, which is plainly impossible: or he must conceive it as inhering in some other object; and then neither the quality of whiteness, nor his conception of it, is abstract and general, but concrete and particular. He affirms, however, "that in abstraction, strictly so called, he can perceive nothing that is difficult either to be understood or practised." This is going much farther into the doctrine than Mr Locke went; for he owned that there was much difficulty in it. Let us see how it becomes so easy to Dr Reid. "What can be more easy (says he) than to distinguish the different attributes which we know to belong to a subject? In a man, for instance, to distinguish his size, his complexion, his age, his fortune, his birth, his profession, and twenty other things that belong to him." All this indeed, and much more, we can do with the utmost ease; but this is not abstraction, strictly so called, nor any thing like abstraction. We distinguish the size, the complexion, the age, &c. of the man, from *one another*: but still we conceive them all as *his* qualities; nor is it possible, at least for us, *to abstract them from him*, without conceiving them as the qualities of some *other* man; so that *our* conceptions are all concrete and particular. "It ought likewise to be observed (says the Professor), that attributes may with perfect ease be distinguished and *disjoined* in our conception, which cannot be *actually separated* in the subject." They may be so in his conception, but certainly not in ours; for *we* can conceive nothing which may not actually exist. "Thus (continues he) I can in a body distinguish its solidity from its extension, and its weight from both. In extension, I can distinguish length, breadth, and thickness; yet none of these can be separated from the body, or from one another. It is therefore *certain*, that attributes, which in their nature are absolutely inseparable from their subject and from one another, may be disjoined in our conception; one *cannot exist* without the other, but one *can be conceived* without the other." So far is this from being a matter of *certainty*, that in every possible sense in which we can understand the word *conception*, it apppears to us as evidently *false*, as that *three* and *two* are equal to *nine*. It is indeed not difficult to distinguish *in* a body its solidity from its extension, and its weight from both: but can we distinguish them *out* of the body? or, to speak in plain language, can we conceive *solidity* as separated from *all extension* and *all weight*? Unless this can be done, and by *us* it cannot be done, there is no *abstraction strictly so called*. It is indeed easy to conceive *solidity* or *extension* abstracted from *any one* individual object: but how is it done? Why, by transferring your attention to some other *individual object*. Thus, we can easily conceive *solidity* or *extension* separated from a guinea, for instance; but it is only by transferring our thoughts to another body, *a piece of silver*, or a *ball of lead*, &c. and our conceptions in both cases are *particular* and *concrete*.

As we think this opinion of Dr Reid's respecting ABSTRACTION both ill-founded and of dangerous consequences, we have expressed our dissent from it in strong terms; and in doing so we have only followed the example set us by himself when dissenting from the theories of Hume and Berkeley. But we are so thoroughly convinced that the Doctor's acuteness is superior to our own (L), that we are not without our fears that we may have mistaken his meaning. We are conscious that we have not wilfully misrepresented it; and to enable our readers to judge for themselves between him and us, we shall lay before them his definition of *general conceptions* in his own words.

83 Terms, how they are

That there are in every language *general terms*, is known to all mankind: for such are all substantives, proper names excepted; and all adjectives. But "it is impossible (says the Doctor*) that words can have a general signification, unless there be conceptions in the

* *Essay on the Intellectual Powers of Man.*

(L) "If such an extraordinary faculty (abstraction) were possible, I cannot for my part conceive what purpose it could serve. An idea hath been defined by some logicians, the form or resemblance of a thing in the mind; and the whole of its power and use in thinking is supposed to arise from an exact conformity to its archetype. What then is the use or power of that idea, to which there neither is nor can be any archetype in nature, which is merely a creature of the brain, a monster that bears not the likeness of any thing in the universe!"—— *Philosophy of Rhetoric*, vol. ii. p. 110.

(L) Notwithstanding this declaration, which is made with the greatest sincerity, we do not apprehend that we are guilty of presumption when we examine the Doctor's opinions. Berkeley and Hume were certainly as acute as any metaphysician who has succeeded them; yet their opinions have been canvassed without ceremony, and to much advantage. *Aliquando bonus dormitat Homerus.*

Of Abstraction and general Ideas.

the mind of the ſpeaker and of the hearer, of *things* (M) that are *general*. It is to ſuch that I give the name of *general conceptions*: and it ought to be obſerved, that they take this denomination, not from the act of the mind in conceiving, which is an individual act; but from the object or thing conceived, which is general." Now, whatever is conceived, muſt be either *external* to the mind, or *preſent* with it. But the Doctor himſelf acknowledges, "That all the objects we perceive are individuals. Every object of ſenſe, of memory, or of *conſciouſneſs*, is an individual object. All the good things we enjoy or deſire, and all the evils we feel or fear, muſt come from individuals; and I think we may venture to ſay, that every creature which God has made in the heavens above, or in the earth beneath, or in the waters under the earth, is an individual." If this be ſo, and no man can call it in queſtion, it is obvious that we can have no *general* conception of any thing *external*. The *act* of conceiving is *an individual act*; and therefore the only thing which can be *general*, muſt be ſomething preſent with the mind, and different from the *mere act of conceiving*: But what can this be, if not what Berkeley and others call an *idea*? and how can we have an *idea* of which we are not *conſcious*? yet every thing of which we are conſcious Dr Reid himſelf acknowledges to be an *individual*.

89 Of general ſignification.

But if the doctrine generally received reſpecting abſtract ideas be ſo very abſurd as it has appeared in our repreſentation, how comes it to be ſo prevalent among the acuteſt philoſophers? To this we anſwer, that thoſe philoſophers have certainly in this inſtance been impoſed upon by the ſtructure of language. Every adjective and every ſubſtantive, proper names excepted, are words of general ſignification; and all ſcience is converſant about general truth: but as words are ſaid to be ſignificant, not of things, but of ideas; and as truth reſults from the agreement or coincidence of ideas; it has been haſtily ſuppoſed, that without general ideas there could have been neither general terms nor general truth. This is plauſible, but it is not ſolid. Every object which affects our ſenſes is an individual object; but we perceive that two or more objects which affect ſome of our ſenſes very differently, affect others of them in preciſely the ſame way. Thus, the paper upon which one writes, the ſnow which he perceives from his window, and the milk which he may uſe at breakfaſt, affect his ſenſes of touch and taſte very differently, but they preſent the ſame appearance to his eye. This diverſity in the one caſe he believes to proceed from different powers or qualities in the ſeveral objects; and the ſameneſs of appearance in the other, from ſimilar qualities in theſe objects. To the ſimilar qualities, though he can frame no idea of them abſtracted from every individual object, he gives one common name; and calls every object which preſents the ſame appearance to his eye that ſnow does, a *white* object; where the word *white* does not ſtand for an abſtract idea, but for a quality inherent in one or more objects. Hence the origin of adjectives in language, which denote more than can be expreſſed by any claſs of ſubſtantives; for every adjective, beſides the power of a name, includes in itſelf the force of a conjunction. See GRAMMAR.

The other claſs of general terms comprehends ſubſtantives: of which the origin is as follows. The objects about which we have occaſion to ſpeak or write are ſo numerous and ſo fluctuating, that if every individual had a proper name, a complete language could never be formed. But as there are not perhaps in nature two objects that appear to us ſimilar in all reſpects, ſo are there not in nature two objects which affect *all* our ſenſes differently. The mind, therefore, either actually perceiving two or more objects at once, or contemplating the *ideas* left by two or more objects in the memory, perceives, by its intellective power, in what reſpects they agree and in what they diſagree. If the agreement be ſtriking, and in more qualities than one, it combines the ſeveral individuals into one claſs or ſpecies, giving to the whole a common name, which equally denotes the ſpecies and every individual belonging to it. Thus, obſerving that Peter, James, and John, agree in having the ſame erect form, in walking on two legs, in having hands, &c. and in being endowed with reaſon, we combine theſe three, and all other individuals which we perceive to agree in the ſame ſtriking and important qualities, into one ſpecies, to which we give the name of *man*—a word which equally denotes the whole ſpecies and every individual of it. Again, contemplating ſeveral figures, which all agree in the circumſtance of being bounded by three ſtraight lines meeting one another ſo as to form three angles, we call the whole claſs of figures and each individual by the name of *triangle*—though it may be impoſſible to contemplate any number of triangles without perceiving that all the angles of one are acute; that one angle of another is a right angle; and that in the third there is one angle obtuſe: but the word *triangle*, unleſs it is limited in its ſignification by the addition of an adjective, is equally expreſſive of an acute-angled triangle, a right-angled triangle, and an obtuſe-angled triangle. By thus arranging individuals according to their moſt conſpicuous qualities, we may combine all the objects exiſting into ſo many claſſes or ſpecies, which ſhall be afterwards known by as many names; but of each ſpecies we neither have, nor can have, any other idea than that of a multitude of ſimilar individuals.

As our acquaintance with nature enlarges, we diſcover reſemblances ſtriking and important between one ſpecies and another, which naturally begets the notion of a higher claſs called a *genus*. From comparing man with beaſts, birds, fiſhes, and reptiles, we perceive that they are all alike poſſeſſed of life, or a principle of ſenſation and action, and of an organiſed body: hence we rank them all under a higher claſs or genus, to which we give the name of *animal*; which equally denotes the whole *genus*, each *ſpecies* comprehended under the *genus*, and every *individual* of every *ſpecies*. Thus, *animal* is a *genus*; *man*, *beaſt*, *bird*, are ſo many *ſpecies* comprehended under that *genus*; and *Peter*, *James*, and *John*, are *individuals* of the ſpecies *man*. *Peter*, *James*, and *John*, are proper names, denoting each an *individual*;

(M) He tells us ſoon afterwards, that there are *no things general*. How is the one paſſage to be reconciled with the other?

Of Abstraction and general Ideas.

dual; *man*, *beaſt*, *bird*, are *ſpecific* terms, denoting each a *whole ſpecies* compriſing many *individuals*; and *animal* is a *general term*, becauſe it denotes a *whole genus*, comprehending under it *ſeveral ſpecies*, of which each conſiſts of *many individuals*; and the general term denotes either the whole *genus*, all the *ſpecies*, or any *individual* of all the ſpecies. This is the whole myſtery of *abſtraction*: they are merely *terms*, that in ſtrictneſs of ſpeech are *general* and *abſtract*; and even theſe are general only as *ſigns*, of which the full ſignification cannot always be repreſented by any conceivable *idea*.

90 Ideas and often mere signs.

"It is a received opinion (ſays Biſhop Berkeley), that language has no other end but the communicating of our ideas, and that every ſignificant name ſtands for an idea. This being ſo; and it being withal certain, that names, which yet are not thought altogether inſignificant, do not always mark out particular conceivable ideas; it is ſtraightway concluded that they ſtand for abſtract notions. That there are many names in uſe amongſt ſpeculative men, which do not always ſuggeſt to others determinate particular ideas, is what nobody will deny: and a little attention will diſcover, that it is not neceſſary, even in the ſtricteſt reaſonings, that ſignificant names, which ſtand for ideas, ſhould every time they are uſed excite in the underſtanding the ideas they are made to ſtand for. In reading and diſcourſing, names are for the moſt part uſed as letters in algebra; in which, though a particular quantity be marked by each letter, yet to proceed right, it is not requiſite that in every ſtep each letter ſuggeſt to our thoughts that particular quantity it was appointed to ſtand for." The ſame thing is true of ideas, which as well as names are often uſed merely as ſigns repreſenting a whole claſs; and on that account they may be called *general*, though every idea is in itſelf ſtrictly particular. Thus, "An idea, which conſidered in itſelf is particular, becomes general by being made to repreſent or ſtand for all other particular ideas of the ſame ſort. To make this plain by an example, ſuppoſe a geometrician is demonſtrating the method of cutting a line in two equal parts: He draws, for inſtance, a black line of an inch in length: this, which in itſelf is a particular line, is nevertheleſs, with regard to its ſignification, general; ſince, as it is there uſed, it repreſents all particular lines whatſoever: ſo that what is demonſtrated of it is demonſtrated of all lines, or, in other words, of a line in general. And as that particular line becomes general by being made a ſign; ſo the *name* line, and the *idea* of a line in the imagination, either of which taken abſolutely is particular, by being ſigns are made general likewiſe. And as the former owes its generality, not to its being the ſign of an abſtract or general line, but of all particular right lines that may poſſibly exiſt; ſo the latter, the name and the idea, muſt be thought to derive their generality from the ſame cauſe, namely, the various particular lines which each of them indifferently denotes." Again, when one demonſtrates any propoſition concerning triangles, it is to be ſuppoſed that he has in view to demonſtrate an univerſal truth; yet the particular triangle which he conſiders muſt be either equilateral, iſoſceles, or ſcalenon; for a plain triangle, which is none of theſe, can neither exiſt nor be conceived. But whether it be of this or that ſort is of no importance, as any of them may equally ſtand for and repreſent all rectilineal triangles, and on that account be denominated *univerſal*.

This doctrine reſpecting names and ideas being uſed merely as *ſigns*, has been adopted by almoſt every ſubſequent philoſopher; and by Principal Campbell it has been illuſtrated with perſpicuity and acuteneſs every way worthy of the author of the Diſſertation on Miracles. "In confirmation of this doctrine (ſays he *), it may be obſerved, that we really think by *ſigns*, as well as ſpeak by them. All the truths which conſtitute ſcience, which give exerciſe to reaſon, and are diſcovered by philoſophy, are general; all our ideas, in the ſtricteſt ſenſe of the word, are particular. All the particular truths about which we are converſant are properly hiſtorical, and compoſe the furniture of memory. Nor do I include under the term *hiſtorical* the truths which belong to natural hiſtory; for even theſe too are general. Now, beyond particular truth or hiſtorical facts, firſt perceived and then remembered, we ſhould never be able to proceed one ſingle ſtep in thinking any more than in converſing, without the uſe of ſigns.

* *Philoſophy of Rhetoric.*

"When it is affirmed that *the whole is equal to all its parts*, there cannot be an affirmation which is more perfectly intelligible, or which commands a fuller aſſent. If, in order to comprehend this, I recur to ideas, all that I can do is to form a notion of ſome individual whole, divided into a certain number of parts of which it is conſtituted; ſuppoſe of the year, divided into the four ſeaſons. Now all that I can be ſaid to diſcern here is the relation of equality between this particular whole and its component parts. If I recur to another example, I only perceive another particular truth. The ſame holds of a third and of a fourth. But ſo far am I, after the perception of ten thouſand particular ſimilar inſtances, from the diſcovery of the univerſal truth, that if the mind had not the power of conſidering things as ſigns, or particular ideas as repreſenting an infinity of others, reſembling in one circumſtance though totally diſſimilar in every other, I could not ſo much as conceive the meaning of an univerſal truth. Hence it is that *ſome ideas*, to adopt the expreſſion of Berkeley, *are particular in their nature, but general in their repreſentation.*"

91 Which, though particular in themſelves, ſerve to demonſtrate general truths; becauſe

But if in univerſal propoſitions, ideas particular in themſelves be uſed only as the ſigns of others, it may be demanded, how we can know any propoſition to be true of all the ideas which are repreſented by the ſign? For example, having demonſtrated that the three angles of an iſoſceles rectangular triangle are equal to two right ones, how can we conclude that this affection therefore agrees to all other triangles which have neither a right angle nor two equal ſides? To this queſtion Biſhop Berkeley and Principal Campbell give the following anſwer: Though the idea we have in view whilſt we make the demonſtration be that of an iſoſceles rectangular triangle, whoſe ſides are of a determinate length, we may yet be certain that the demonſtration extends to all other rectilineal triangles of what ſort or bigneſs ſoever; for this plain reaſon, that neither the equality nor determinate length of the ſides, nor the right angle, are at all concerned in the demonſtration. It is true, the idea or diagram we have in view includes all theſe particulars; but then there is not the leaſt mention made of them in the

proof

Of Abstraction and general Ideas.

proof of the propofition. It is not faid the three angles are equal to two right angles, *becaufe* one of them is a *right angle*, or becaufe the fides comprehending it are of equal length; which fufficiently fhows that the right angle might have been oblique and the fides unequal; and for all that the demonftration have held good. In every one of Euclid's theorems, a particular triangle, and a particular parallelogram, and a particular circle, are employed as figns to denote all triangles, all parallelograms, and all circles. When a geometrician makes a diagram with chalk upon a board, and from it demonftrates the property of a ftraight-lined figure, no fpectator ever imagines that he is demonftrating a property of nothing elfe but that individual white figure, five inches long, which is before him.—Every one is fatisfied that he is demonftrating a property of all of that order, whether more or lefs extenfive, of which it is both an example and a fign; all the order being underftood to agree with it in certain characters, however different in other refpects. Nay, what is more, the mind with the utmoft facility extends or contracts the reprefentative power of the fign as the particular occafion requires. Thus the fame equilateral triangle will with equal propriety ferve for the demonftration, not only of a property of all equilateral triangles, but of a property of all ifofceles triangles, or even of a property of all triangles whatever. Nay, fo perfectly is this matter underftood, that if the demonftrator in any part fhould recur to fome property belonging to the particular figure he hath conftructed, but not effential to the kind mentioned in the propofition, and which the particular figure is folely intended to reprefent, every intelligent obferver would inftantly detect the fallacy: So entirely for all the purpofes of fcience doth a particular ferve for a whole fpecies or genus. Now, why one *vifible* individual fhould in our reafonings ferve without the fmalleft inconvenience as a fign for an infinite number, and yet one *conceivable* individual, or a particular idea of imagination, fhould not be adapted to anfwer the fame end, it will, we imagine, be utterly impoffible to fay (N).

It muft, however, be confeffed, that there is a confiderable difference in kind, between *ideas* ufed as figns and the *general* terms of any language. Amongft all the individuals of a fpecies, or even of the higheft genus, there is ftill a natural connection, as they agree in the fpecific or generic character; and when the mind makes ufe of any pofitive idea as the fign of the fpecies or genus, that idea appears in the imagination as an exact refemblance of fome one individual. But the connection which fubfifts between words and things, or even between words and ideas, is in its origin arbitrary; and yet its effect upon the mind is much the fame with that of the natural connection between ideas and things. For having often had occafion to obferve particular words ufed as figns of particular things, and fpecific terms ufed as figns of a whole fpecies, we contract a habit of affociating the fign with the thing fignified, infomuch that either being prefented to the mind neceffarily introduces or occafions the apprehenfion of the other. Cuftom in this inftance operates precifely in the fame manner as natural refemblance in the other; fo that certain founds, and the ideas of things to which they are not naturally related, come to be as thoroughly linked in our conceptions as the ideas of things and things themfelves. Nay, fo completely are they linked together, that we often ufe, through long chains of reafoning, certain founds or words, without attending at all to the ideas or notions of which they are figns. "I believe (fays the author of *A Treatife on Human Nature*), that every one who examines the fituation of his mind in reafoning will agree with me, that we do not annex diftinct and complete ideas to every term we make ufe of; and that in talking of *government*, *church*, *negotiation*, *conqueft*, we feldom fpread out in our minds all the fimple ideas of which the compound notions fignified by thefe terms are compofed. It is, however, obfervable, that notwithftanding this imperfection, we may avoid talking nonfenfe on thefe fubjects, and may perceive any repugnance among the ideas as well as if we had a full comprehenfion of them." This remark generally holds true; but then it is to be obferved, that all the words ufed as figns, and which yet do not denote any one conceivable determinate *idea*, muft be capable of definition. Thus, in matters that are perfectly familiar, in fimple narration, or in moral obfervations on the occurrences of life, a man of common underftanding may be deceived by fpecious falfehood, but is hardly to be gulled by downright nonfenfe or a repugnance of ideas. Almoft all the poffible applications of the terms (in other words, all the acquired relations of the figns) have become cuftomary to him. The confequence is, that an unufual application of any of them is inftantly detected; this detection breeds doubt, and this doubt occafions an immediate recourfe to *definition*; which, proceeding through fpecies and genera, refolves complex terms into others lefs complex, till it ends at laft in fimple ideas and relations, which can neither be defined nor mifunderftood (O). See LOGIC.

Thus

(N) Were it poffible to frame an *abftract general idea* of a triangle, which is neither equilateral, ifofceles, nor fcalenon, even *that idea* muft be ufed merely as a fign as much as any particular triangle whatever: and the queftion might ftill be afked, How we can know any propofition to be true of all the triangles reprefented by the fign? For example: having demonftrated that the three angles of an ideal triangle, which is neither equilateral, ifofceles, nor fcalenon, are equal to two right angles, how can we conclude that this affection agrees to triangles which are equilateral, &c.? To this queftion it is not eafy to conceive what anfwer could be given other than that of Berkeley and Campbell, in the cafe of ufing particular and conceivable triangles as figns.

(O) Since this article was written, fome excellent obfervations on the common doctrine concerning abftraction have been given to the public by profeffor Dugald Stewart of Edinburgh. See *Elements of the Philofophy of the Human Mind.*

Abſtraction and general ideas.

Thus then we ſee, that though there are no ideas, properly ſpeaking, general and abſtract, a man may by *terms* and *particular* ideas, uſed as *ſigns*, arrive at the knowledge of general truth. In neither caſe is it the

92
It is not the matter but the power of the ſign that is regarded by the mind.

matter, if we may be allowed the expreſſion, but the *power* of the ſign, that is regarded by the mind. We find, that even in demonſtrative reaſonings, ſigns the moſt arbitrary, or mere ſymbols, may be uſed with as little danger of error as ideas or natural ſigns. The operations both of the algebraiſt and arithmetician are ſtrictly of the nature of demonſtration. The one employs as *ſigns* the letters of the alphabet, the other certain numerical characters. In neither of theſe arts is it neceſſary to form ideas of the quantities and ſums ſignified; in ſome inſtances it is even impoſſible without reſolving the quantity or ſum into parts, in a manner analogous to definition; and then the mind comprehends not the whole quantity or number at once, but the ſeveral parts of which it is compoſed, which it connects (P) by the relation of junction or addition. Yet without this reſolution, the equations and calculations carried on by means of the letters and figures ſignificant of the whole quantity or the whole ſum, are not the leſs accurate or convincing. And ſo much for *abſtraction*, *generalization*, and the power of *ſigns*, whether *natural* or artificial.

Chap. V. *Of the* Association *of* Ideas.

93
A continued train of thought in the mind.

Every man whilſt awake is conſcious of a continued train of thought ſpontaneouſly ariſing in his mind and paſſing through it; nor could a ſingle now or inſtant be pitched upon in which ſome idea is not preſent in his memory or imagination. No one idea, however, unleſs detained by a voluntary exertion of the mind, or unleſs productive of intenſe pleaſure or pain, remains long in the imagination; but each haſtens off the ſtage to make way for another, which takes its turn and is ſucceeded by a third, &c. We are not to imagine that this train of thought is altogether fortuitous and incoherent. "It is evident (ſays Mr Hume *), that there is a principle of connection between different thoughts or ideas of the mind; and that, in their appearance to the memory or imagination, they introduce each other with a certain degree of method and regularity. In our more ſerious thinking or diſcourſe this is ſo obſervable, that any particular thought which breaks in upon the regular tract or chain of ideas, is immediately remarked and rejected. Even in our wildeſt and moſt wandering reveries, nay, in our very dreams, we ſhall find, if we reflect, that the imagination ran not altogether at adventures, but that there was ſtill a connection upheld among the different ideas which ſucceeded each other. Were the looſeſt and freeſt converſation to be tranſcribed, there would immediately be obſerved ſomething which connected it in all its tranſitions: Or, where this is wanting, the perſon who broke the thread of diſcourſe might ſtill inform you, that there had ſecretly revolved in his mind a ſucceſſion of thoughts, which had gradually led him from the ſubject of converſation. Among different languages, even where we cannot ſuſpect the leaſt connection or communication, it is found, that words expreſſive of ideas the moſt compounded, do yet nearly correſpond to each other; a certain proof that the ſimple ideas comprehended in the compound ones, were bound together by ſome univerſal principle, which had an equal influence on all mankind."

* Eſſays.

Aſſociation of Ideas.

94
Principles of aſſociation.

That theſe obſervations are well founded, every man may be ſatisfied by looking attentively into his own thoughts; but when the author reduces the principles of this aſſociation of ideas to *three*, viz. *reſemblance*, *contiguity* in time and place, and *cauſe* or *effect*, he certainly contracts them within too narrow a compaſs. That theſe principles often ſerve to connect ideas, will not indeed be denied. A picture leads our thoughts to the original: the mention of one apartment in a building introduces an inquiry or diſcourſe concerning the others: and if we think of a wound, we can hardly forbear reflecting on the pain which follows it. But ſurely ideas ſometimes ſucceed each other without *reſemblance*, without *contiguity* in time or in place, and without being connected by the relation of a *cauſe* to its *effect*. Beſides all this, there are other aſſociations than of *ideas*. Ideas are aſſociated with paſſions and emotions, and paſſions and emotions are aſſociated together. A particular idea is aſſociated with a proper name, and often with the general name of the ſpecies. General conceptions, ſuch as thoſe which Mr Locke calls mixed modes (ſee Mode), are aſſociated with ſigns both audible and viſible, and ſigns are aſſociated with each other. Surely virtue, as it conſiſts in action and intention, does not reſemble the *ſound* virtue, is not *contiguous* to it in time or in place, and is neither its *cauſe* nor its *effect*; nor is it conceivable, that the arbitrary ſigns of different things ſhould have any natural relation to one another.

But were the enumeration complete, the bare mention of theſe principles does not account for the phenomena: For, granting the fact, it may ſtill be aſked, Why does a picture lead our thoughts to the original; or the mention of one apartment in a building introduce an inquiry concerning the others? To theſe queſtions our author has given no anſwer; nor are we acquainted with any writer who can be ſaid to have attempted it, except Dr Hartley and his ingenious editor. There may be ſome of our readers whom the names of theſe men will prejudice againſt their theory; but, doubtleſs, the greater part are willing to adopt truth, or to examine an ingenious ſpeculation, from whatever quarter it comes. To ſuch as feel themſelves otherwiſe diſpoſed, we beg leave to ſay, that if they allow the name of *Prieſtley* to diſguſt them at what follows, they will furniſh him with a new proof of the truth of the doctrine which they reject.

That

(P) No man, we think, will pretend that he can perceive at one view a million of individual men, or that he can imagine or conceive at once a million of ideal men: yet he may divide the million into parts, which in the one caſe may be eaſily viewed, and in the other may be eaſily conceived, in ſucceſſion. Thus, 100+100+100, &c.

Association of Ideas.

95 How they operate.

That *ideas* should be associated together, seems to be inevitable from the manner in which the mind acquires them. All our ideas, properly speaking, are of sensible objects, and by far the greater part of them of *visible* objects. But every sensible object conveys at once various sensations and perceptions to the mind, which appear not only united in fact, but inseparable in imagination. Thus, when a man looks at any particular object, a tree for instance, he perceives the *trunk*, *branches*, *leaves*, *size*, *shape*, and *colour*, &c. of the whole at *once:* he does not first perceive the *figure* of the trunk, then its *size*, then its *colour*, then the *branches*, &c. all in succession; but a perception of the *whole* is conveyed to the mind by one simultaneous impression (q.) We have already seen, that the senses, in fact, convey nothing to the mind but their respective sensations; and that the perception of the external object instantly follows the sensation. We have likewise seen, that sensation is occasioned by some impression, concussion, or vibration, given to the nerves and brain, and by them communicated to the mind or percipient being. We have likewise seen, that memory depends as much upon the brain as original sensation, and is always attended or occasioned by similar concussions or vibrations, &c. These are facts proved by universal experience, and which, we believe, no thinking man has ever called in question. It follows, therefore, that every actual sensation must leave some effect in the brain, either an actual print, which seems to be impossible, or a tendency to vibrate or be agitated in the same way as when the original impression was made. This being the case, it is natural to conclude, that when any part of the original perception is revived in the memory, the whole perception should be revived at once, so as that we cannot have an idea of the trunk of a tree without perceiving the ideas of the branches associated with it. This is indeed not merely natural, but the contrary seems to be impossible; for as the original agitation or vibration was occasioned by the whole tree, it is evident, that whatever effect or tendency that agitation or vibration left behind it, must be left by the whole vibration, and therefore be equally related to the whole tree.

But no object stands single in nature. When we view a tree, or any thing else, we always notice, however transiently, the field where it grows and the objects around it. These too leave effects in the brain at the same time that the tree does so; and therefore make their appearance with it in the memory or imagination: but if the tree was the object to which we principally attended during the actual sensation, the idea of it will be much more vivid than the idea of its adjuncts, and remain much longer in the imagination or memory; because the original sensation by which it was perceived, was struck much deeper than the sensations by which its adjuncts were perceived. All this must be intelligible to every one who attends to what we have already said of sensation, perception, and memory.

Thus we see why a picture leads our thoughts to the original, and why the mention of one apartment in a building introduces an inquiry concerning the others. It is not merely because the picture *resembles* the original, and because the apartments of a building are *contiguous*. Between a plain surface, variously coloured and shaded, and the contour of the human face, there is certainly very little real resemblance, as any man may be convinced who places his eye within six inches of a good picture. But the painter, having by his skill in perspective, contrived to lay his colours on the plain canvas in such a manner as that they reflect the same rays of light with the original; provided the spectator stand at the proper distance; these rays proceeding from the picture fall upon the eye in the same direction, and therefore give to the nerves and brain the very same impulse which was given by the original. When one apartment of a building is mentioned, we inquire concerning the others from the very same cause that, when we think of the trunk of a tree which we have seen, we cannot avoid thinking likewise of its branches.

96 Association gives meaning to words and language.

But the principle of association takes place among things not naturally connected, as the apartments of a building and a substance and its attributes and adjuncts. It is association which is the original source of all the general or complex conceptions which we have, and which even gives meaning to the words of every language. Between sounds considered in themselves, and things, or the ideas of things, every one knows that there is no natural connection; yet the idea of every known object is in the mind of every man so strictly associated with the name that it bears in his native tongue, that the presence of the one always suggests the other. It cannot indeed be otherwise, if we attend to the manner in which a child learns to affix a meaning to the words which he hears.—A child knows his mother and nurse, and indeed almost every visible object in the family, long before he acquires the power of articulation. The impressions made

(q.) This is certainly the case with adults, but it may be doubted whether it be so with very young children. It has been shown already, that the sensation communicated by the eye from any visible object, has not the least resemblance to that object; and that in looking at a tree or any thing else, a full grown man pays not the least attention to the appearance which the tree really makes to his eye; nay, that he is not even conscious of that appearance, farther than as it consists in colour. It is by the sense of touch only that we acquire ideas of figure, even of plain figure; and we imagine that we perceive them by the eye only, because different figures, as distinguishable by touch, are so closely associated with their corresponding visible sensations, that long before we are capable of inquiry, these two things are inseparable in the imagination. It is otherwise with children, who, when they first begin to distinguish objects by the sense of sight, appear to do it with great deliberation, as if they first felt the proper sensation of light and colours so or so modified, and afterwards acquired, by something like a mental inference, a notion of the figure at which they are looking.

Association of Ideas. made by these objects, and repeated daily and hourly on his brain, every one of which excites a sensation, must soon become so deep as not to be easily effaced. Numbers of them too are associated together, so that the presence of one introduces the other. It has been already observed, that ideas of sight are the most vivid and the most lasting; but the child having the same sound often repeated, even that sound comes in time to leave in his memory a permanent idea. He then hears the sound *nurse*, for instance, uttered at the time when he is looking earnestly at the person of the nurse, with whom he is well acquainted, and to whom he is strongly attached; and having the two ideas repeatedly excited together, they soon become so associated, that the one necessarily excites the other: the *word nurse* calls into view the *idea* of the *woman* treasured up in his imagination.

But we need not have recourse to children for the proof of our assertion. It is obvious that the name of every simple and uncompounded idea can be significant only by association. Of a complex conception the name may be made intelligible by a definition; but simple ideas cannot be defined, and between ideas and sounds there is no natural connection, so as that the one previous to association should suggest the other. Even of complex conceptions and mixed modes, the meaning of the names is generally acquired by association; for though it is certainly true, that all such names are capable of definition, they are yet used with sufficient propriety by thousands who know not what a definition is. Were a plain unlettered man asked to define virtue, it is not probable that he could do it so as to make himself understood; yet having ideas of the *practice of justice*, *charity*, *fortitude*, &c. strictly associated in his mind with the *word virtue*, he may know the general meaning of that word as well as the most acute grammarian or the most profound philosopher.

An *alms* is a donation to a poor man; but a child who never heard of this definition knows perfectly what an *alms* is, from having often seen his parents give money to a beggar, and call what they were doing by the name *alms*. The sound of the word, after having seen the first alms given, will excite in his mind an idea of the *individual* object who received it, and of the *action* of him by whom it was given; but after having seen several poor men relieved, he comes to associate with the word *alms* any thing given to any person who needs it or appears to be in want.

So completely does this association take place between ideas or clusters of ideas, and the words by which they are expressed, that even men of letters hear and understand perfectly many words without reviewing in their minds all the ideas and relations of which they are the signs. It has been already observed, that in talking of *government*, *church*, *negotiation*, *conquest*, we seldom spread out in our minds all the simple ideas of which the compound notions signified by these terms are composed; and we now add, that the terms may be used with sufficient propriety, and be perfectly understood by those who never attempted to analyse the notions of which they are significant into their primary and constituent parts. Every man has read numberless details of the transactions of one court with another; he has heard such transactions universally called by the term *negotiation*. The term and the transactions signified by it are so closely associated in his mind, that they are in a manner inseparable; and by this association he knows the meaning of the term better than he could have done by the most complete definition; which, perhaps, he would find it difficult to give, or even to comprehend.

97 and is the source of our first notions of virtue.

We have said that the *meaning* of the word *virtue* is acquired by association, by having often heard that sound applied to certain *actions*; but it is extremely probable, that the very *notion* of virtue, simple and uncompounded as it appears to be, is acquired in the very same manner. The *first* rudiments of the notions of *right* and *wrong* and *obligation* seem to be acquired by a child when he finds himself checked and controled by superior power. At first he feels nothing but mere *force*, and consequently has no notion of any kind of restraint but that of necessity. He finds he cannot have his will, and therefore he submits. Afterwards he attends to many circumstances which distinguish the commands of a *father*, or of a *master*, from those of any other person. Notions of *reverence*, *love*, *esteem*, and *dependence*, are connected with the idea of him who gives those commands; and by degrees the child experiences the peculiar *advantages* of filial subjection. He sees also that all his companions, who are noticed and admired by others, obey their parents; and that those who are of a refractory disposition are universally disliked. These and other circumstances now begin to alter and modify the notion of mere necessity, till by degrees he considers the commands of a parent as something that *must not* be resisted or disputed, even though he has a power of doing it; and all these ideas coalescing, form the notions of *moral right* and *moral obligation*, which are easily transferred from the commands of a parent to those of a magistrate, of God, and of conscience. This opinion of the gradual formation of the ideas of moral right and wrong, from a great variety of elements associated together, perfectly accounts for that prodigious diversity in the sentiments of mankind respecting the objects of moral obligation; nor do we see that any other hypothesis can account for the facts. If the notion of moral obligation were a simple uncompounded idea, arising from the view of certain actions or sentiments; or were it acquired, as it certainly might be, by a chain of reasoning from the nature of God and the nature of man; why should it not in the one case be as invariable as the perception of colours or sounds, and in the other as our judgements of mathematical or physical truths? But though the shape and colour of a flower appear the same to every human eye; though every man of common understanding knows, that if a billiard ball be struck by another, it will move from its place with a velocity proportioned to the force of the impulse; and though all mankind who have but dipt into mathematics, perceive that any two sides of a triangle must be greater than the third side; yet one man practises as a moral duty what another looks upon with abhorrence, and reflects on with remorse. Now a thing that varies with education and instruction, as moral sentiments are known to do, certainly has the appearance of being generated by a series of different impressions and associations in some such manner as we have endeavoured to describe. Let not any man imagine that this account of the origin of moral sentiments endangers the cause of virtue; for whether those

Association of Ideas.

those sentiments be instinctive or acquired, their operation is the very same, and in either case their rectitude must often be tried by the test of reason, so that the interests of virtue are equally safe on this as on any other scheme. See *Moral Philosophy*.

98 It ought, therefore, to be attended to in the education of youth.

This principle of association has so great an influence over all our actions, passions, reasonings, and judgments, that there is not perhaps any one thing which deserves more to be looked after in the education of youth. Some of our ideas—such as those of a substance and its attributes, a genus and the species contained under it, a species and its several individuals, have a real connection with each other in nature. These it is the office of our reason to trace out and to hold together in that union and order in which nature presents them to the view of the mind; for such associations constitute perhaps the greatest part of necessary and of useful truths. But there are others formed by custom and caprice, which are too often the sources of error, superstition, vice, and misery—of errors the more dangerous, and of vice the more deplorable; that if the associations have been long formed without an attempt to dissolve them, they generally become at last too strong to be broken by the most vigorous effort of the best disposed mind. Thus, let a foolish maid* amuse or rather frighten children with stories of ghosts appearing in the dark, let her repeat these fictions till they have made a deep impression on the young minds, and the notion of ghosts will in time become so closely associated with the idea of darkness, that the one shall always introduce the other; and it may not be in the power of the children, after they have become men, and are convinced in their judgments of the falsehood and absurdity of the tales which originally frightened them, to separate entirely the notion of ghosts from the idea of darkness, or with perfect ease to remain alone in a dark room. Again, let the idea of *infallibility* be annexed to any person or society, and let these two inseparably united constantly possess the mind; and then one body in ten thousand places at once shall, unexamined, be swallowed for an incontrovertible fact, whenever that infallible person or society dictates or demands assent without inquiry.

* *Locke's Essay*, and *his Conduct of the Understanding*.

Some such wrong and unnatural combinations of ideas will be found to establish the irreconcileable opposition that we find between different sects in philosophy and religion; for we cannot imagine every individual of any sect to impose wilfully on himself, and knowingly to reject truth offered by plain reason. That which leads men of sincerity and good sense blindfold, will be found, when inquired into, to be some early and wrong association. Ideas independent and of no alliance to one another, are by education, custom, and the constant din of their party, so linked together in their minds, that they can no more be separated from each other than if they were but one idea; and they operate upon the judgment as if they really were but one. This gives sense to jargon, the force of demonstration to absurdities, and consistency to nonsense: it is the foundation of the greatest and most dangerous errors in the world; for as far as it obtains, it hinders men from seeing and examining.

Before we dismiss the subject of association, it may be proper to inquire, how far it is agreeable to the account which we have given of the manner in which external objects are perceived by means of the senses, and the ideas of such objects retained in the memory.

99 The principle of association operates in perception of external objects.

—It has been proved, we think, by arguments unanswerable, that by the organs of sense nothing is conveyed immediately to the mind but sensations which can have no resemblance to external objects, and that the perception of an object may be resolved into a process of reasoning from effects to causes.—But children, it will be said, do not reason from effects to causes, and yet they soon acquire the faculty of perceiving and distinguishing the objects with which they are surrounded. This is an undoubted truth, and it can be accounted for only by the principle of association. A child has as much the use of his senses as a full grown man. By his eye he has the sensation of colour; by his nose, that of smell; by his ear he has the sensation of sound; and by his hand he feels heat and cold, resistance and bounded resistance. Every object which is presented to him, impresses his mind with various sensations: and these sensations combined together are probably all that he perceives for some years; for there is no reason to imagine that a boy of one or two years old has the slightest notion of what we mean by solidity, hardness, softness, or indeed of that which is termed *substance*. Yet when two or more objects are present, he may easily distinguish the one from the other, because the sensations excited by the one must differ from those excited by the other, as much as the real qualities of the one are different from the real qualities of the other; and by distinguishing between his own sensations, he in effect distinguishes between the objects which produce these sensations. His sensations too being frequently excited, leave behind them ideas in his memory or imagination; and those ideas, from having been imprinted together and never separated, become in time so closely associated, that whenever one of them is called into view, the others necessarily make their appearance with it. Thus a child has a set of combined sensations excited in his mind by the presence of his nurse; he has a different cluster excited, suppose, by the presence of his mother. These are often repeated, and leave deep traces behind them; so that when the mother or the nurse makes her appearance, she is immediately recognised as a known object; or, to speak more correctly, the child feels the very same sensations which he has felt before, from which he has experienced pleasure, and of which he has the ideas treasured up in his memory or imagination. A stranger, on the other hand, must affect him with a set of new sensations, and of course will be distinguished from a known object as accurately as if the child were possessed of the notions of solidity, substance, qualities, and distance. A man born blind, who knew not that such things as fire and snow had ever existed, would yet distinguish the one from the other the moment that he should be brought within their influence. He could not indeed apply their names properly, nor say which is the fire and which the snow, nor would he at first have any notion of either of them as a real, external, and distant object; but he would certainly distinguish his own sensations, the sensation of heat from that of cold. It is just so with a child: At first he perceives nothing but different sensations. These he

Aſſociation of Ideas.

can diſtinguiſh; and as they are cauſed by different objects, in diſtinguiſhing between the ſenſations he will appear to diſtinguiſh between the objects themſelves. In a ſhort time, however, he acquires, by the following proceſs, ſome inaccurate notions of diſtance. He looks, for inſtance, earneſtly in his nurſe's face, and at the ſame time touches her cheek perhaps by accident. He repeats this operation frequently, till the ſenſation communicated by his eye comes to be aſſociated with that of his touch, and with the extending of his arm; and being all treaſured up as aſſociated ideas in the memory, the ſight of his nurſe makes him ever afterwards ſtretch out his hands with a deſire to touch her. All this while there is not the ſlighteſt probability that the child has any notion of *ſubſtance* or *qualities*, or of any thing beyond his own *ſenſations*, and the means by which he has experienced, that ſenſations which are pleaſant may be obtained, and that ſuch as are painful may be avoided. The preciſe time at which a child begins to think of external things we cannot pretend to aſcertain; but we are perſuaded that it is later than many perſons imagine, and certainly not till he has made conſiderable progreſs in the exerciſe of reaſon. Prior to that period the things which men know to be bodies, are known to children only as ſenſations and ideas ſtrongly bound together by the tie of aſſociation.

100 Seems to diſtinguiſh memory from imagination;

But if aſſociation be of ſuch importance in the act of ſenſation, it is of ſtill greater in that of retention; for it ſeems to conſtitute the whole difference that there is between imagination and memory. By many of the ancients, as well as by ſome modern philoſophers, theſe two faculties ſeem to have been confounded with each other; but between them there is certainly a great difference, though they likewiſe reſemble each other in ſome reſpects. An idea of memory, conſidered by itſelf, makes the very ſame appearance to the intellect as an idea of imagination. We contemplate both as if they were actual, though faint and diſtant perceptions: but the one is attended with the conviction, that it is the idea of an object which has really been perceived at ſome period of paſt time; whilſt the other is attended with no conviction, except that the idea itſelf is actually preſent to the mind. Mr Hume has ſaid, that ideas of memory differ from thoſe of imagination only in being more vivid and diſtinct; but certainly this is not always the caſe. An idea of imagination has ſometimes been taken for a real perception, which an idea of memory can never be. The difference between theſe two kinds of ideas, we are perſuaded, ariſes chiefly, if not wholly, from aſſociation. Every idea of memory is aſſociated with many others, and thoſe again with others down to the very moment of the energy of remembrance; whereas ideas of imagination are either the voluntary creatures of the fancy at the moment of their appearance, in which caſe we ſhould call them conceptions; or they are ideas which we have actually received from ſenſation, but which, on account of ſome link being broken in the vaſt chain of aſſociation, we cannot refer to any real objects. What gives probability to this conjecture is, that ideas often appear in the mind which we know not whether to refer to the memory or imagination, nothing being more common than to hear a perſon ſay, I have in my head the idea of ſuch or ſuch an object; but whether I remember or only imagine the object, I am very uncertain. Afterwards, however, by turning the idea over and over in the mind, he finds other ideas make their appearance, till at laſt cluſters of them come into view, and aſſociate ſo cloſely with the principal idea, which was the object of doubt, as to convince the judgment that it is an idea of memory.

Aſſociation of Ideas.

101 and to be the ground of our belief of what we remember.

It has been aſked, Why we believe what we diſtinctly remember? and to that queſtion it has been ſuppoſed that no anſwer can be given. But it appears to us, that aſſociation is the ground of belief in this as it will be found to be in other inſtances; and that a man believes he waſhed his hands and face in the morning, becauſe the idea of that operation is ſo ſtrongly linked in his mind to the whole train of ideas which have ariſen in it through the day, that he cannot ſeparate the firſt from the laſt, that which was a ſenſation in the morning from the ſenſations which are preſent at the inſtant of remembrance. As thoſe ideas are aſſociated by nature, each muſt paſs in review in its proper order; ſo that in ſo ſhort a ſpace of time there is no danger, and hardly a poſſibility, of taking the firſt for the laſt, or the laſt for the firſt. Nay more, we will venture to hazard an opinion, that every paſt event of a man's life, which he diſtinctly remembers, is tied by the chain of aſſociation to his preſent perceptions. That this is poſſible is certain, ſince it is not difficult to conceive how it may be done. The principal events of a ſingle day may ſurely be ſo linked together as to be all diſtinctly reviewed in a cluſter of ideas on the morrow. Of theſe events ſome one or other muſt be the moſt important, which will therefore make its appearance as an idea more frequently than the reſt, and be more cloſely aſſociated with the events of next day. Some event of that day will, for the ſame reaſon, be more cloſely aſſociated with it than the others; and theſe two, dropping perhaps all the reſt of their original companions, will paſs on together to the third day, and ſo on through weeks and months and years. In the compaſs of a year, ſeveral things muſt occur to make deep impreſſions on the mind. Theſe will at firſt be aſſociated together by events of little importance, like the occurrences of a ſingle day. Whilſt theſe feeble chains, however, continue unbroken, they will be ſufficient to link the one important event to the other, and to bring them both into view at the ſame time, till at laſt theſe two, from appearing ſo often together, will in time unite of themſelves, and the intermediate ideas be completely effaced. Thus may two or three important events of one year be aſſociated with ſuch a number of ſimilar events of another year, ſo that the ideas of the one ſhall always introduce to the mind the ideas of the other; and this chain of aſſociation may paſs from the earlieſt event which we diſtinctly remember through all the intermediate years of our lives down to the inſtant when memory is exerted.

To this account of memory it may perhaps be objected, that it gives us no diſtinct notion of time. Every thing that is remembered is neceſſarily believed to have been preſent in ſome portion of paſt time; but aſſociation brings into view nothing but a ſeries of events. This objection will be ſeen to have no weight when we have inquired into the nature of time, and aſcertained what kind of a thing it is. It will

then

Association of Ideas.

then perhaps appear, that duration itself, as apprehended by us, is not distinguishable from a series of events; and that if there were no train of thought passing through our minds, nor any motion among the objects around us, time could have no existence. Meanwhile, whatever become of this opinion, we beg leave to observe, that our theory of remembrance is perfectly consistent with the commonly received notions respecting time; and indeed, that it is the only theory which can account for numberless phenomena respecting past duration. It is universally allowed, that if motion or a succession of events do not constitute time, it is the only thing by which time can be measured. Now it is a fact which no man will deny, that the distance of time from the present *now* or instant to the earliest period which he distinctly remembers, appears to his view extremely short, much shorter than it is said to be in reality; and that one year, when he looks forward, appears longer than two, perhaps longer than ten, when he looks backward. Upon our principles this fact is easily accounted for. We remember nothing which is not linked by a chain of associations with the perceptions of the present moment; and as none but a few of the most important events of our lives can be linked together in this manner, it hence follows, that events which, in the order of succession, were far *distant* from each other, must thus be brought *together* in the memory, and the whole chain be contracted within very short limits. But when we figure to ourselves a series of future events, we employ the active power of fancy instead of the passive capacity of retention; and can therefore bring within the compass of one periodical revolution of the sun a longer series of imaginary events succeeding each other, than is preserved of real events in our memory from the earliest period of our existence. So perfectly does our theory accord with this well-known fact. On the other hand, if memory be an original faculty of the mind totally independent of association, and of which no other account is to be given than that it necessarily commands our belief, why is it a faculty which, with regard to duration, thus uniformly deceives us? and how comes it to pass, that to a man whose memory is tenacious, who has read much, seen many countries, and been engaged in various occurrences, any determinate portion of past time always appears longer than to another man whose memory is feeble, and whose life has been wasted in ease and idleness? To these questions we know not what answer can be given upon any other principle than that which makes the evidence of memory depend upon association. But if we remember nothing but what is linked to the perception or idea which is present with us at the time of remembrance, and if duration be measured by the succession of events, it is obvious that any portion of past time must necessarily appear longer to him who has many ideas associated in his mind than to him who has but few.

102 The importance of association in the philosophy of the human mind.

There is not perhaps a single fact of greater importance in the philosophy of the human mind than the *association of ideas*; which, when thoroughly understood, accounts for many of those phenomena which some late writers of name have, with injury to science and with danger to morality, attributed to a number of distinct and independent instincts. It is for this reason that we have considered it so minutely, and dwelt upon it so long; and in addition to what we have said on the subject, we beg leave to recommend to our more philosophical readers the diligent study of Hartley's Observations on Man (R). In that work we think several things are taken for granted which require proof; and some which, we are persuaded, have no foundation in nature: but, with all its defects, it has more merit than any other treatise on the sensitive part of human nature with which we are acquainted.

Chap. VI. *Of* Consciousness *and* Reflection.

103 Consciousness, what it is, and what are its objects.

Sensation, remembrance, simple apprehension, and conception, with every other actual energy or passion of the mind, is accompanied with an inward feeling or perception of that energy or passion; and that feeling or perception is termed *consciousness*. *Consciousness* is the perception of what passes in a man's own mind at the *instant* of its passing there; nor can we *see*, *hear*, *taste*, *smell*, *remember*, *apprehend*, *conceive*, employ our faculties in any manner, enjoy any pleasure, or suffer any pain, without being *conscious* of what we are doing, enjoying, or suffering. *Consciousness* is only of things *present* *; and to apply it to things *past*, is to confound *consciousness* with memory or *reflection*. One cannot say that he is conscious of what he has seen or heard and now remembers: he is only conscious of the act of remembrance; which, though it respects a past event, is itself a present energy. It is likewise to be observed, that consciousness is only of things in the mind or conscious being, and not of things external. It is improper in any person to say that he is *conscious* of the table before him: he perceives it, he *sees* it; and he may with great propriety say that he is *conscious* he perceives or sees it; but he cannot say that he is conscious of the table itself, for it is only his immediate energy of perception that can be the object of consciousness. All the operations of our minds are attended with consciousness; which is the only evidence that we have or can have of their existence. Should a man take it into his head to think or to say that his consciousness may deceive him, and to require a proof that it cannot, we know of no proof that can be given him: he must be left to himself as a man that denies first principles, without which there can be no reasoning. Every attempt to prove this point, or to set it in a clearer light, would only serve to render it more dark and unintelligible. I *think*, I *feel*, I *exist*, are first truths, and the basis of all human knowledge.

* *Reid's Essays on the Intellect. Powers of Man.*

104 Des Cartes's argument from consciousness for his own existence.

This has given rise to the question, whether Des Cartes did not fall into an absurdity when, inferring his own existence from his actual thought, he said, *Cogito, ergo sum?* This argument has been called a pitiful sophism, and a *petitio principii*; because, before a man

(R) Since this was written Mr Stewart's *Elements of the Philosophy of the Human Mind* have been published; in which the reader will find many excellent remarks on the nature and influence of the associating principle.

Of Conſciouſneſs and Reflection.

man take it for granted that he thinks, he muſt alſo, it is ſaid, take it for granted that he exiſts, ſince there cannot be thought where there is no exiſtence. Now it muſt be confeſſed, that if Des Cartes pretended by this argument to give us a freſh conviction of our own exiſtence, his endeavours were uſeleſs and puerile; becauſe a man capable of being convinced by the arguments of another, muſt have a previous conviction of his own exiſtence: but the argument itſelf is certainly neither a ſophiſm nor a *petitio principii*. Thoſe*, who defend Des Cartes aſſert, and there is no reaſon to doubt the truth of their aſſertion, that his only view in urging ſuch an argument was not to prove the truth of our exiſtence, but to exhibit the order of that proceſs by which we arrive at the knowledge of the fact; and this he has very clearly done by analyſing the truth into its firſt principles. A ſtone exiſts as well as the human mind; but has the ſtone any knowledge of its own exiſtence? No man will ſay that it has; neither ſhould we have any knowledge of ours, did we think as little as the ſtone. We certainly *might* exiſt without thinking, as it is probable we do in very ſound ſleep; and in that ſtate our exiſtence might be known to other beings, but it could not poſſibly be known to ourſelves: for the only things of which the mind is conſcious, or has immediate knowledge, are its own operations. I *exiſt* is therefore a legitimate inference from the propoſition I *think*; and the obſervation that it is ſo may be uſeful to ſhow us the procedure of the mind in the acquiſition of knowledge; but it has little merit as an argument, and ſtill leſs as a diſcovery, though, being ſtrictly true and juſt, it ſhould never have been expoſed to ridicule.

* See Buffier's Firſt Truths.

105 *Reflection, what it is, how different from conſciouſneſs.*

It is to be obſerved, that we are conſcious of many things to which we give very little attention. We can hardly attend to ſeveral things at the ſame time; and our attention is commonly employed about that which is the *object* of our thought, and rarely about the thought itſelf. It is in our power, however, when we come to the years of underſtanding, to give attention to our own thoughts and paſſions, and the various operations of our minds. And when we make theſe the objects of our attention, either while they are preſent, or when they are recent and freſh in our memory, we perform an act of the mind which is properly called *reflection*. This *reflection* ought to be diſtinguiſhed from *conſciouſneſs* *, with which it is confounded ſometimes by Locke, and often by the learned author of Ancient Metaphyſics. All men are *conſcious* of the operations of their own minds at all times while they are awake, nor does it appear that brutes can be wholly deſtitute of conſciouſneſs; but there are few men who *reflect* upon the operations of their minds, or make them the objects of thought; and it is not probable that any ſpecies of brutes do ſo.

* [illegible]

From infancy, till we come to the years of underſtanding, we are employed ſolely about ſenſible objects. And although the mind is conſcious of its operations, it does not attend to them; its attention is turned ſolely to the objects about which theſe operations are employed. Thus, when a man is angry, he is *conſcious* of his paſſion; but his *attention* is turned to the *perſon* who offended him and the *circumſtances* of the *offence*, while the *paſſion of anger* is not in the leaſt the object of his attention. The difference between *conſciouſneſs* and *reflexion*, is like the difference between a ſuperficial view of an object which preſents itſelf to the eye while we are engaged about ſomething elſe, and that attentive examination which we give to an object when we are wholly employed in ſurveying it. It is by conſciouſneſs that we immediately acquire all the knowledge which we have of mental operations; but attentive reflexion is neceſſary to make that knowledge accurate and diſtinct. *Attention* is a voluntary act; it requires ſome exertion to begin and continue it; and by great exertion it may be continued for a conſiderable time; but *conſciouſneſs* is involuntary, and of no continuance, changing with every thought. The power of reflexion upon the operations of their own minds does not at all appear in children. Men muſt have come to ſome ripeneſs of underſtanding before they are capable of it. Of all the powers of the human mind it ſeems to be the laſt that unfolds itſelf. Moſt men ſeem incapable of acquiring it in any conſiderable degree; and many circumſtances conſpire to make it to all men an exerciſe of difficulty. The difficulty, however, muſt be conquered, or no progreſs can be made in the ſcience of our own or of other minds.

106 *All our notions of mental energies got by reflection.*

All the notions which we have of mind and of its operations are got by reflection; and theſe notions are by Mr Locke called *ideas of reflection*. This term we think extremely ill choſen; and we believe it has been the ſource of much error and confuſion among Locke's followers. A man, by attending to the operations of his own mind, may have as diſtinct *notions* of remembrance, of judgment, of will, of deſire, as of any object whatever: but if the ſecondary perception of a ſenſible object, that appearance which it has to the mind when viewed in the memory or imagination, be properly called an *idea*, it is certain that of the operations of the mind itſelf there can be no ideas; for theſe operations, when reflected on, make no appearance without their objects either in the memory or in the imagination. Nothing is more evident, in fact, than that we have no *ideas*, in the original and proper meaning of the word, but of ſenſible objects, upon which the mind exerts its firſt operations. Of theſe operations we have indeed a conſciouſneſs; but abſtracted from their objects we cannot frame of them any idea or reſemblance. We are *conſcious* to ourſelves of *thinking*, *willing*, *remembering*, *diſcerning*, *reaſoning*, *judging*, &c. but let any one look into himſelf, and try whether he can there find any *idea* of *thinking* or *willing*, &c. entirely ſeparate and abſtracted from the *object* of thought or will. Every man who has ſeen a tree or a houſe, will find in his mind ideas of theſe objects, which he can contemplate by themſelves, independent of every thing elſe; but no man can contemplate the *idea* of thinking or deſiring without taking into view the thing thought on or deſired. It is plain, therefore, that the energies of *thinking*, *willing*, and *deſiring*, with all their various modifications, are not themſelves *ideas*, or capable of *communicating* ideas to be apprehended, as the ideas of bodies are apprehended by the pure intellect. They are the *actions* and *workings* of the *intellect itſelf* upon ideas which we receive from the objects of ſenſe, and which are treaſured up in the memory or imagination for the very purpoſe of furniſhing the intellect with materials to

work

work upon. Between *ideas* and the *energies of thinking* there is as great and as obvious a difference as there is between a *stone* and the *energies* of him by whom it is cast. Ideas are the passive subjects; the energies of thinking are the operations of the agents. Ideas are relicts of sensation, and have a necessary relation to things external; the energies of thinking are relicts of nothing, and they are wholly and originally internal.

107 Our knowledge of the operations of intellect immediate, and not by the intervention of *ideas*.

That we can in no sense of the word be said to have *ideas* of the operations of the intellect, will be still more evident if we consider by what means we acquire the knowledge which we have of those operations. It has been already observed, that when our thoughts are employed upon any subject, though we are conscious of thinking, yet our *attention* is commonly employed upon the *object* of our thought, and not upon the *thought* itself: and that if we would give attention to our thoughts and passions, we must do it by a reflex act of the mind, whilst the act of thinking is still recent and fresh in our memory. Thus, if a man wishes to know what perception is, it is not the time to make the inquiry while he is looking at some rare or beautiful object; for though he is *conscious* of the energy of perceiving, the *object* of perception employs all his *attention*. But the time to make this inquiry is either when the object has become familiar to him, or presently after it is removed from his sight. In the former case, he can look upon it without emotion, pay attention to every step in the process of perception, and be immediately conscious what perception is. In the latter case, by turning his attention inwards, and reflecting on what he did or felt when the object was before him, he will find clear and vivid ideas of every thing which he perceived by his sense of sight; but he will find no *idea* of the act of *seeing* or *perceiving*. On the contrary, if he be capable of sufficient attention, he will observe that his intellect is employed in the very same manner upon the *ideas* that it was upon the original *sensations;* and of that employment, and the manner of it, he will be equally conscious as he was of the original energy exerted in sensation. There is indeed this difference between the two, without which reflection could make no discoveries, that the most vivid ideas being still faint when compared with actual sensations, the intellect is not so wholly engrossed by them as it was by the original objects, nor is it so rapidly carried from idea to idea as it was from sensation to sensation. It is thus at leisure to attend to its own operations, and to know what they are; though to form *ideas* of them as separate from their objects, is absolutely impossible. Every man capable of paying attention to what passes within himself when he sees, hears, and feels, &c. may have very accurate *notions* of *seeing*, *hearing*, and *feeling*, &c. but he cannot have *ideas* of them as he has of the *objects* of *sight*, *hearing*, and *touch*.

The same is the case with respect to the exertion of our reasoning faculties. A man must have distinct and clear *ideas* to reason upon, but he can have no *idea* of reasoning itself, though he must be conscious of it, and by attention may know what it is. When a man sits down to study for the *first time* a proposition in the Elements of Euclid, he certainly employs his reasoning faculty, and is conscious that he is doing so; but his attention is wholly turned to the diagram before him, and to the several ideas which the diagram suggests. Afterwards, when he has mastered the proposition, he may go over it again, with a view to discover what reasoning is; but he will not find he has any *idea* of reasoning as he has of the diagram. He will only exert that faculty a second time, and perceive one truth linked to and depending upon another in such a manner that the whole taken together forms a complete demonstration. In a word, the operations of our own minds, when attention is paid to them, are known immediately by consciousness; and it is as impossible that we should have ideas of them, as that a living man should be a picture upon canvas. He who attends to what passes in his own mind when he perceives, remembers, reasons, or wills, must know by consciousness what these operations are, and be capable of forming very accurate notions of them, as connected with their objects; and he who does not attend to what passes in his own mind will never acquire any notions of them, though he were to read all that has been written on the subject from the days of Pythagoras to those of Dr Reid.

As we acquire ideas of external objects by means of our senses; and notions of perceiving, remembering, reasoning, and willing, &c. by reflecting on the operations of our own minds; so are there other things of which we acquire notions, partly by sensation, partly by reflection, and partly by means of that faculty of which it is the more peculiar office to compare ideas and to perceive truth. Such are *substance*, *body*, *mind*, with their several qualities, adjuncts, and relations; the knowledge of which, as has been already observed, constitutes what in strictness of speech is termed the science of *metaphysics*. These shall be considered in order, after we have investigated the nature of truth, and inquired into the several sources of evidence; but there is one notion, about the origin and reality of which there have been so many disputes, which in itself is of so great importance, and which will be so intimately connected with all our subsequent inquiries, that it may not be improper to consider it here.—The notion to which we allude is of POWER.

108 There are things which we know partly by sensation and partly by reflection, &c.

109 Our notion of power how acquired.

Among the objects around us we perceive frequent changes, and one event regularly succeeding another. Gold thrown into the fire is changed from a fixed to a fluid body. Water exposed to a certain degree of cold is changed from a fluid to a fixed body. Night succeeds to day, and summer succeeds to winter. We are conscious of new sensations in ourselves every hour. We are likewise conscious of reasoning, willing, and desiring; and we know that by an exertion of will we can rise or sit, stand still or walk, call one idea into view, and dismiss others from our contemplation. Experience teaches us, that it is not occasionally, but always, that gold is changed into a fluid by being thrown into the fire, and water into a fixed body by being exposed to a certain degree of cold; that night succeeds to day, and summer to winter. These changes have regularly taken place since the creation of the world; and it has never once been observed that water was fixed by fire, or gold rendered liquid by cold. Were we not assured by experience that our own voluntary motions are produced by exertions of our minds, of which we are conscious, and that without such

Of Consciousness and Reflection.

such exertions those motions would never have taken place, we should probably have considered the liquifaction of gold as an event equally independent of fire, though uniformly conjoined with it, as night is independent of day, and day of night. But having experienced that we can move or not move our bodies as we please; that when it is our will to sit, we never get up to walk; and that when we wish to walk, we always do it except prevented by external violence; having likewise experienced, that by a thought, by some internal and inexplicable exertion of our minds, we can call up in our memory or imagination one idea and dismiss others from our mental view; we are led to believe with the fullest conviction, that all those motions of our bodies which in common language are termed *voluntary*, and that succession of ideas which follows a conscious exertion of the mind, depend upon ourselves. In other words, we are necessitated to believe that we have a *power* to move or not move our bodies in many cases, and a *power* to turn our attention to one idea in preference to others.

It is thus that we acquire the notion of *power* in ourselves, which we easily transfer to other objects. Knowing that the various motions of our bodies thus effected proceed from power, we are naturally led to inquire whether the changes which we perceive in other bodies may not proceed from *power* likewise, *i. e.* from something analogous to that power, of the exertions of which we are conscious in ourselves. Now uniform experience teaching us that gold is liquified by being thrown into the fire, and that water is fixed by being exposed to cold; we infer with the utmost certainty that there are *powers* in fire and cold to produce these changes, and that without the exertion of such *powers* these changes would not be produced. We cannot indeed say of external powers, as we can of our own, in what substance they inhere. We know with the utmost certainty that the voluntary motions of our hands, &c. are produced by a power not inherent in the hands but in the mind, for of the exertion of that power we are conscious; but we do not know whether the power which liquifies gold be inherent in that sensible object which we call *fire*, or in something else to which fire is only an instrument. We learn by observation, that the minute particles of fire or heat insinuate themselves between the particles of gold, and, if we may use the expression, tear them asunder; but whether they do this in consequence of a *power* inherent in themselves, or only as instruments impelled by another *power*, is a question which *observation* cannot enable us to answer.

Were we not conscious of the exertion of our own powers, it seems not conceivable that we could ever have acquired any notion of power at all; for power is not an object of sense, nor, independent of its operations, is it indeed an object of consciousness. In external operations, all that we perceive is *one thing*, in which we suppose the *power* to reside, followed by another, which is either the *change* or that on which the change is *produced*; but the exertion of the power itself we do not perceive. Thus we perceive gold, after it has been some time in the fire, converted from a fixed to a fluid body; but we perceive not by our senses either the power or the energy of the power which operates to this conversion. In the exercise of our own powers, the case is otherwise. When a man puts his hand to his head, and afterwards thrusts it into his bosom, he not only perceives by his senses the change of position, but is also conscious of the energy or exertion by which the change was produced.

"Suppose (says Mr Hume †) a person, though endowed with the strongest faculties of reason and reflection, to be brought on a sudden into this world; he would indeed immediately observe a continual succession of objects, and one event following another, but he would not be able to discover any thing farther. He would not at first by any reasoning be able to reach the idea of cause and effect; since the particular powers by which all natural operations are performed never appear to the senses. The impulse of one billiard ball is attended with motion in the second. This is the whole that appears to the *outward* senses. The mind feels no sentiment or *inward* impression from this succession of objects; consequently there is not, in any single particular instance of cause and effect, any thing which can suggest the idea of power or necessary connection. From the first appearance of an object, we never can conjecture what effect will result from it: but, were the power or energy of any cause discoverable by the mind, we could foresee the effect even without experience; and might at first pronounce with certainty concerning it by the mere dint of thought and reasoning. It is impossible, therefore, that the idea of power can be derived from the contemplation of bodies in single instances of their operations; because no bodies ever discover any power which can be the original of this idea."

† *Essays.*

There is a sense in which this reasoning is unquestionably just. A man who had never been conscious of exerting power in himself, would certainly not acquire the notion of power from observing a continual succession of external objects. The impulse of one billiard ball being followed by the motion of another, would no more lead him to the notion of power in the former, than the succession of night to day would lead him to the notion of a power in light to produce darkness. When Mr Hume says, "that from the *first* appearance of an object *we* can never conjecture what effect will result from it," he uses language that is ambiguous, and utters an assertion which is either true or false according to the sense in which it is understood. If it be meant, that after having reflected on the operations of our own minds, and learned by experience that motion is communicated by impulse from one ball of ivory to another, we could not conjecture whether a similar effect would be produced by the impulse of balls made of other hard bodies which we had never before seen, the assertion is manifestly false. A man who had but once seen motion communicated in this manner from one *ivory* ball to another, would certainly conjecture that it might be communicated from one *wooden* ball to another; and if he had seen it repeatedly communicated from one ball to another of different substances, he would infer, with the utmost confidence, that it might be communicated from ball to ball of whatever substance composed, provided that substance be hard, or of a similar texture with the balls to the impulse of which he had formerly paid attention.

Of Conſciouſneſs and Reflection.

attention. If by this ambiguous phraſe the author only means, as is probably the caſe, that from the firſt appearance of an object to which we had never before obſerved any thing in any reſpect ſimilar, we could not conjecture what effect would reſult from it; or if his meaning be, that a man ſuddenly brought into the world, who had never acquired ſuch a notion of power as may be had from attention to the energies and operations of our own minds, would not, by obſerving an effect to reſult from one body, conjecture from the firſt appearance of another ſimilar body what effect would reſult from it; in either of theſe caſes his aſſertion is certainly true, and tends to prove, that without the conſciouſneſs of the operations of our own minds we could never acquire a notion of power from the changes perceived by our ſenſes in external objects.

110
Mr Hume attempts to prove that we can have no notion whatever of power.

But Mr Hume, not contented with denying, which he might juſtly do, that we could ever have derived the idea of power merely from obſerving the continual ſucceſſion of external objects, labours hard to prove that we have no notion of power at all, and that when we uſe the word *power*, we do nothing more than utter an inſignificant ſound. To pave the way for the arguments by which ſo extravagant a paradox is to be ſupported, he lays it down as a "propoſition which will not admit of much diſpute, that all our ideas are nothing but copies of our impreſſions; or, in other words, that it is impoſſible for us to *think* of any thing that we have not antecedently *felt* either by our external or internal ſenſes." As this propoſition, however, will admit, it ſeems, of *ſome* diſpute, he takes care, before he applies it to the purpoſe of demoliſhing all power, to ſupport it by two arguments. "Firſt (ſays he), when we analyſe our thoughts or ideas, however compounded or ſublime, we always find that they reſolve themſelves into ſuch ſimple ideas as were copied from a precedent feeling or ſentiment. Thoſe who would aſſert, that this poſition is not univerſally true nor without exception, have only one, and that an eaſy, method of refuting it; by producing that idea, which, in their opinion, is not derived from this ſource. Secondly, If it happen, from a defect of the organ, that a man is not ſuſceptible of any ſpecies of ſenſation, we always find that he is as little ſuſceptible of the correſpondent ideas. A blind man can form no notion of colours, a deaf man of ſounds. And tho' there are few or no inſtances of a like deficiency in the mind, where a perſon has never felt, or is wholly incapable of a ſentiment or paſſion that belongs to his ſpecies; yet we find the ſame obſervation to take place in a leſs degree. A man of mild manners can form no idea of inveterate revenge or cruelty; nor can a ſelfiſh heart eaſily conceive the heights of friendſhip and generoſity."

111
His reaſoning ſophiſtical.

As theſe propoſitions are the engines by which all power is baniſhed from the world, it may not be improper, before we proceed to inquire by what means they perform ſo arduous a taſk, to conſider their own inherent ſtrength; for if they be weak in themſelves, their work, however dexterouſly they may be employed, can have no ſtability. We have already noticed the perverſeneſs of this writer's language, when it confounds *ſenſations* with *impreſſions*; but here it is ſtill more perverſe, for paſſions, ſentiments, and even *conſciouſneſs*, are ſtyled *impreſſions*. When ſenſations are confounded with impreſſions, the effect is only miſtaken for the cauſe, it being univerſally known that ſenſations proceed from impreſſions made upon the organs of ſenſe. When conſciouſneſs is confounded with an impreſſion, one thing is miſtaken for another, to which it is univerſally known to have neither reſemblance nor relation. But, not to waſte time upon theſe fallacies, which, though dangerous if admitted, are yet too palpable to impoſe upon a reader capable of the ſlighteſt attention, let us examine the propoſitions themſelves. The moſt important, and that for the ſake of which alone the others are brought forward, is, that it is impoſſible for us to *think* of any thing that we have not immediately *felt*, either by our external or internal ſenſes." Did Mr Hume then never *think* of a mathematical *point*, or a mathematical *line*? Neither of theſe things is capable of being *felt* either by making an impreſſion upon the organs of ſenſe or as an object of conſciouſneſs; and therefore it is impoſſible that he ſhould ever have had ideas of them ſuch as he doubtleſs had of ſenſible objects; yet in the moſt proper ſenſe of the word *think* (s), he certainly thought of both points and lines; for he appears to have made conſiderable progreſs in the ſcience of geometry, in which he could not have proceeded a ſingle ſtep without a perfect knowledge of theſe things, on which the whole ſcience is built. It is not therefore true, that our thoughts or ideas, when analyſed, always reſolve themſelves into ſuch ſimple ideas as were copied from a precedent feeling or ſentiment; for every mathematical figure of which we can think reſolves itſelf into a point and motion; and a point having no parts and no magnitude, cannot poſſibly be the object of feeling to any of our ſenſes. If, therefore, ideas alone be the objects of thought, we have refuted Mr Hume's poſition by the very method which he himſelf lays down; for we have produced an idea which is not derived either from a precedent feeling or a precedent ſentiment. By ſentiment, we ſuppoſe to be here meant that which by other philoſophers is denominated conſciouſneſs; and of conſciouſneſs it is undeniable that nothing is the object but the actual energies of our own minds.

112
Things which we can have no ideas may themſelves be the objects of thought.

But ideas are not the only objects of thought. We have already given our reaſons for reſtricting the word *idea* to that appearance which an object of ſenſe, when reflected on, makes either in the memory or imagination. Such was undoubtedly its original ſignification; and had it never been uſed to denote other and very different objects, much error and perplexity would have been avoided, which now diſgrace the ſcience of metaphyſics. Things may *themſelves* be the objects of thought; and

(s) *Thinking*, in the propriety of the Engliſh tongue, ſignifies that ſort of operation of the mind about its ideas wherein the mind is active; where it, with ſome degree of voluntary attention, conſiders any thing. *Locke*.

Of Conſciouſneſs and Reflection.

and when that is the caſe, to think of their *ideas*, were it poſſible to do ſo, would be worſe than uſeleſs; for we may certainly know a man better by looking at himſelf than by looking at his picture. Of things which are *themſelves* the objects of thought, we have either a *direct* or a *relative* knowledge. We know directly the actual operations of our own minds by the moſt complete of all evidence, that of conſciouſneſs; and we have a *relative* notion of mathematical points and lines: but neither of mental energies nor of theſe external things (T) can we poſſibly have any *idea*.

113 We have only relative notions of some things,

It is well obſerved by Dr Reid †, that our notions both of body and mind are nothing more than relative. "What is body? It is, ſay philoſophers, that which is extended, ſolid, and diviſible. Says the querist, I do not aſk what the properties of body are, but what is the thing itſelf? let me firſt know directly what body is, and then conſider its properties. To this demand I am afraid the querist will meet with no ſatisfactory anſwer; becauſe our notion of body is not direct, but relative to its qualities. We know that it is ſomething extended, ſolid, and diviſible, and we know no more. Again, if it ſhould be aſked, what is mind? It is that which thinks. I aſk not what it does, or what its properties are, but what it is? To this I can find no anſwer; our notion of mind being not direct, but relative to its operations, as our notion of body is relative to its qualities (U)."

† Eſſays on the Active Powers of Man.

114 But which, however, we can reason with utmost preciſion:

Our notion of a mathematical point is of the very ſame kind. What is a point? It is, ſays Euclid, that which hath no parts and no magnitude. Replies the queriſt, I aſk not either what it has or what it has not let me firſt know what it is? To this ſecond queſtion, it might perhaps be anſwered, that a mathematical point is that which by motion generates a line. But, rejoins the queriſt, I am not inquiring what it generates; give me a direct idea of the point itſelf? or, if that cannot be done, as ſurely it cannot, tell me what its offspring a line is? A line, ſays Euclid, is length without breadth. I have no idea, replies the queriſt, of length without breadth. I never felt an *impreſſion* from a ſenſible object which did not ſuggeſt length, breadth, and thickneſs, as inſeparably united; and I can have no idea which is not the *copy* of a *former impreſſion*. To aſſiſt the queriſt's conception, it may be ſaid that lines are the boundaries of a ſuperficies, and that ſuperficies are the boundaries of a ſolid body; but of a ſolid body every man has a clear and direct idea, in the moſt proper ſenſe of the word. Here then are ſeveral things, viz. points, lines, and ſuperficies, of not one of which is it poſſible to form a direct notion; and yet we know them ſo thoroughly, from the relation which they bear to other objects, that we can reaſon about them with a preciſion and certainty which only the mathematical ſciences admit.

115 And ſuch is power.

The great advantage of theſe ſciences above the moral, Mr Hume himſelf expreſsly admits: but he attributes it to a wrong cauſe, when he ſays it conſiſts in this, that the "ideas of the former being *ſenſible* are always clear and determinate;" for we ſee that the notion of a point or of a line is merely relative, and cannot poſſibly be the copy of a ſenſation, or, in his language, of a ſenſible impreſſion. If then we have clear and determinate notions of points and lines, and may reaſon about them without ambiguity, as he acknowledges we may, what is there to hinder us from having an equally clear and determinate notion of power, or from reaſoning about it with as little ambiguity (V)? Why, ſays he, we are not conſcious of power. And to prove this poſition, which needs no proof, he makes

(T) By calling mathematical points and lines external things, we do not mean to attribute to them any corporeal exiſtence. We know well that they are merely creatures of the mind, and that if there were no mind, they could have no exiſtence. But twenty men may at the ſame inſtant have a notion of the ſame lines and the ſame points; and therefore theſe lines and points have an exiſtence independent of, and external to, any *one* mind, at leaſt to any one *human* mind. The objects, however, of which a man is conſcious, are in no ſenſe whatever external, for they are preſent to no human mind but his own.

(U) The opinions of philoſophers concerning corporeal and ſpiritual ſubſtances ſhall be conſidered more fully hereafter. In quoting from Dr Reid on another ſubject, we have been obliged to anticipate his opinion, which will be found to be not more modeſt than juſt.

(V) "There are ſome things of which we can have both a direct and relative conception. I can directly conceive ten thouſand men, or ten thouſand pounds, becauſe both are objects of ſenſe, and may be ſeen. But whether I ſee ſuch an object, or directly conceive it, my notion of it is indiſtinct; it is only that of a great multitude of men, or of a great heap of money; and a ſmall addition or diminution makes no perceptible change in the notion I form in this way. But I can form a relative notion of the ſame number of men or of pounds by attending to the relations which this number has to other numbers greater or leſs. Then I perceive that the relative notion is diſtinct and ſcientific; for the addition of a ſingle man, or a ſingle pound, or even of a penny, is eaſily perceived. In like manner, I can form a direct notion of a polygon of a thouſand equal ſides and equal angles. This direct notion cannot be more diſtinct when conceived in the mind, than that which I get by ſight when the object is before me; and I find it ſo indiſtinct that it has the ſame appearance to my eye, or to my *direct* conception, as a polygon of a thouſand and one, or of nine hundred and ninety-nine ſides. But when I form a *relative* conception of it, by attending to the relation it bears to polygons of a greater or leſs number of ſides, my notion of it becomes diſtinct and ſcientific, and I can demonſtrate the properties by which it is diſtinguiſhed from all other polygons. From theſe inſtances it appears, that our relative conceptions of things are not always leſs diſtinct, nor leſs fit materials for accurate reaſoning, than thoſe that are direct; and that the contrary may happen in a remarkable degree."

Reid's Eſſays on the Active Powers of Man.

Of Consciousness and Reflection.

makes many observations that, however just, might certainly have been spared. Of these one is, that "a man suddenly struck with a palsy in the leg or arm, or who had now lost these members, frequently endeavours at first to move them, and employ them in their usual offices. Here he is as much conscious of power to command such limbs, as a man in perfect health is conscious of power to actuate any member which remains in its natural state and condition. But consciousness never deceives. Consequently, neither in the one case nor in the other are we ever conscious of any power." This is true; we never are conscious of any power; but we are frequently conscious of actual energies: and the man who, after being suddenly struck with a palsy, endeavours in vain to move his leg or arm, is as conscious of energy as he who in health makes the attempt with success. Nor let it be imagined that his consciousness deceives him; for, as Mr Hume justly observes, consciousness never deceives. He is certain of the *energy*, but finds by experience that the *instrument* of this energy has suddenly become disordered and unfit for its usual office. In this and this alone consists the difference between the paralytic and the man whose limbs are sound. The one may be as conscious of energy as the other, and his consciousness may be equally infallible. What then is this energy? Mr Hume will not say that it is an *idea*, for it is not the copy of any antecedent impression; besides, he has somewhere allowed that ideas are never active. Is it then a substance? Impossible! for it is not permanent: and we believe no man will venture to affirm, or even to suppose, that the same substance can be repeatedly annihilated, and as often created. Is it then the occasional exertion of some substance? This must be the truth; for no other supposition remains to be made. If so, that substance must be possessed of *power;* for a capacity of exerting actual energy is all that is meant by the word *power*. —"Wherever there is a *capability* of energy or exertion, there must be *power;* for though there can be no exertion without power, there may be power that is not exerted *. Thus a man may have *power* to speak when he is silent; he may have power to rise and walk when he sits still. But though it be one think to *speak* and another to have the *power* of speaking, we always conceive of the power as something which has a certain relation to the effect; and of every power we form our notion by the effect which it is able to produce. Nor is it only in speaking and moving his limbs that a man is conscious of energy. There is as much energy, though of a different kind, in *thinking* as in *acting*. Hence the powers of the human mind have been divided into active and speculative. By the former we move the body; and by the latter we see, hear, remember, distinguish, judge, reason, and perform upon our notions and ideas every other operation which is comprehended under the general word *to think*."

* *Reid's Essays on the Active Powers of Man.*

116 Locke's passive power an improper expression.

Mr Locke† has introduced into his theory of power another distinction than that which we have made between active and speculative powers. Observing by our senses, under which on this occasion memory is certainly included, various changes in objects, we collect, says he, a possibility in one object to be changed, and in another a possibility of making that change, and so come by that idea which we call power. Thus we say that fire has a power to melt gold, and that gold has a power to be melted. The first he calls *active*, the second *passive*, power. But to say that the *possibility* of being changed is *power*, seems to be a very improper mode of speaking, and such as may lead to consequences which the excellent author certainly held in abhorrence. It tends to make unwary readers imagine that the passive subject is as necessary to the existence of power, as the active being of which power is an attribute; but if the universe had a beginning, and if its Creator be immutable, two propositions which Mr Locke firmly believed, there certainly was power when there was no change, nor any thing existing which was capable of change. He owns, indeed, that active power is more properly called power than the other; but we see no propriety at all in passive power. "It is (in the language of Dr Reid) a powerless power, and a contradiction in terms."

† *Essay*, book ii. chap. 21.

117 Just observations of the same author respecting power as belonging to body or mind.

But though Locke here uses improper terms, he has other observations with which we have the honour fully to agree, and which lead to consequences the reverse of that impiety which seems to follow from the notion of *passive* power. He observes, that "we have from body no idea at all of thinking, nor any idea of the beginning of motion. A body at rest affords us no idea of any active power to move; and when it is set in motion itself, that motion is rather a passion than an action in it. For when the ball obeys the stroke of a billiard stick, it is not any action of the ball, but a passion: also, when by impulse it sets another ball in motion that lay in its way, it only communicates the motion it had received from another, and loses in itself so much as the other received; which gives us but a very obscure idea of an active power of moving in body, whilst we observe it only to transfer, but not to produce any motion. So that it seems to me, we have from the observation of the operation of bodies by our senses but a very imperfect obscure idea of active power, since they afford us not any idea in themselves of the power to begin any action either of motion or thought." He thinks it evident, however, "that we find in ourselves a power to begin or forbear, continue or end, several actions of our minds and motions of our bodies, barely by a thought or preference of the mind ordering, or, as it were, commanding, the doing or not doing such or such a particular action. This power which the mind has thus to order the consideration of any idea, or the forbearing to consider it, or to prefer the motion of any part of the body to its rest, and *vice versa* in any particular instance, is that which we call *will*. The actual exercise of that power, by directing any particular action, or its forbearance, is that which we call *volition* or *willing*.

118 Whence it follows, that only such beings as have will and understanding can possess real power.

According to Mr Locke, therefore, the only clear notion or idea we have of power is taken from the power which we find in ourselves to give certain motions to our bodies, or certain directions to our thoughts; and this power in ourselves can be brought into action only by willing or volition. This is exactly our doctrine; where we have endeavoured to prove, that without the consciousness of actual energy in ourselves, we never could have acquired any notion at all of power from observing the changes which take place among external objects. But if this be so, if the *power*, of which alone we know any thing, can be brought into

Of Consciousness and Reflection.

into action only by willing or volition, and if will necessarily implies some degree of understanding, as in us it certainly does, it comes to be a question of the first importance, whether any being which possesses not will and understanding can be possessed of real power, or be the efficient cause of any action. This question we feel ourselves compelled to answer in the negative. If *we* had not will, and that degree of understanding which will necessarily implies, it is evident that we could exert no power, and consequently could have none: for power that cannot be exerted is no power. It follows also, that the power, of which alone we can have any distinct notion, can be only in beings that have understanding and will. Power to produce any effect, implies power not to produce it; and we can conceive no way in which power may be determined to one of these rather than the other in a being that has not will. We grow from infancy to manhood; we digest our food, our blood circulates, our heart and arteries beat; we are sometimes sick and sometimes in health: all these things must be done by the power of some agent, but they are not done by our power. And if it be asked how we know this? the answer is, because they are not subject to our will. This is the infallible criterion by which we distinguish what is our doing from what is not; what is in our power from what is not. Human power can be exerted only by will: and we are unable to conceive any active power to be exerted without will. If, therefore, any man affirms that a being may be the efficient cause of an action which that being can neither conceive nor will, he speaks a language which we do not understand. If he has a meaning, he must take the words *power* and *efficiency* in a sense very different from ours; for the only distinct notion, indeed the only notion which we can form, of real efficiency, is a relation between the cause and the effect similar to that between us and our voluntary actions. It seems therefore most probable, that such beings only as have some degree of understanding and will can possess active power, and that inanimate beings must be merely passive. Nothing which we perceive without us affords any good ground for ascribing active power to any inanimate being; and we can as little conceive such a being possessed of power as we can conceive it capable of feeling pain. On the other hand, every thing which we discover in our own constitution, leads us to think that active power cannot be exerted without will and intelligence; and to affirm that it can, is to affirm what to us at least is a contradiction in terms.

9 Objection obviated.

To this reasoning, which is Dr Reid's*, and which to us appears unanswerable, we have heard it objected, that a man born blind has the same evidence for the non-existence of colour that is here urged for the impossibility of power being exerted without will and understanding. If the objection had not been made by a very acute man, we should have deemed it altogether unworthy of notice; for between the two cases supposed to be similar there is hardly any analogy. A man born blind has no notion whatever of colour. If you describe it to him in the best manner that you can, and refer it to any of the senses which he possesses; if you say that it is the object of feeling, and that by feeling it one may perceive things at the distance of many miles; the blind man has reason to say that you are uttering a proposition which he knows with the utmost certainty cannot possibly be true. But if you tell him that colour is the object of the sense of sight, a sense which he possesses not; that it has not the least resemblance to the objects of the other senses; and that persons endowed with the sense of sight perceive coloured objects at the distance of many miles; the blind man cannot know whether what you say be true or false, because he has no idea or conception of the things of which you speak. This is not the case with respect to power; for every man who has reflected on the operations of his own mind has a very distinct notion of power, and knows perfectly, that to the actual exertion of the only power which he can conceive, will and understanding are necessary. Should it be said that there may be power altogether different from that of which we have a distinct conception, we think it sufficient to reply, that of a thing which cannot be conceived nothing can be either affirmed or denied; that activity exerted without will and understanding ought not to be called an exertion of *power*, because power is the name already appropriated to the attribute of a being by which he can do certain things if he wills; that as we can form no notion of a real efficient cause which has not will and understanding, so we have no reason to believe that such a cause any where exists; and to say that power, such as we can conceive, may be exerted without will and understanding, is as great an absurdity as to say that there may be velocity without space.

But if active power, in its proper meaning, requires a subject endowed with will and intelligence, what shall we say of those active powers which philosophers teach us to ascribe to matter, the powers of corpuscular attraction, magnetism, electricity, gravitation, and others? These powers, as they are called, shall be considered when we treat of the nature and source of corporeal motion. In the mean time, it is sufficient to observe, that whatever the agents may be in the operations of nature, whatever the manner of their agency or the extent of their power, they depend upon the first cause, and are all under his control.

Chap. VII. *Of* Truth, *and the different* Sources *of* Evidence.

Sect. I. *Of Truth.*

By pursuing these inquiries in the order which to us appears most natural, we are now led to the contemplation of those faculties of the human mind of which *truth* is properly the object. But what is *truth*? This was a famous question among the Greek sophists; which had been so often agitated, and to which so many absurd answers had been given, that it came at last to be doubted by men of the world whether a satisfactory answer could be given, or indeed whether the matter was worthy of investigation. It is well known, that among the ancient philosophers there was a sect called from their principles *Sceptics*, and from their founder *Pyrrhonians*, who openly avowed their opinion that *truth*, like virtue, is nothing but a name; that all things are equally true, or rather equally doubtful; and that it is in vain for man to hope for certainty in any inquiry in which he can be engaged. Such scepticism

* *Essays, Active powers.*

Of Truth.

scepticism as this no modern philosopher has professed; but many have had enough of it to make sober men hesitate about defining truth, and even insinuate that of truth no definition can be given. This surely is a mistake. If truth cannot be defined, it still wanders at large and in disguise, and vain must be the pursuit of every man who endeavours to obtain it; he is pursuing he knows not what.

120
Truth defined.

So obvious and so solid is this reflection, that almost every philosopher of merit who has lately written on the nature of evidence has begun his work, if not with a formal definition, with something at least equivalent to a definition of the object of his pursuit. To repeat all these definitions could serve no other purpose than to swell this article to a disproportioned bulk, and to perplex perhaps the mind of the reader. We shall therefore content ourselves with that which is given by Mr Wollaston. "Those propositions (says he) are true which represent things as they are: or, truth is the conformity of those words or signs by which things are expressed to the things themselves." Notwithstanding the objections of a very learned and acute writer (w), this is the best definition of *truth* which we have met with in any language. It is concise and perspicuous. It comprehends all kinds of truth, as well that which is merely mental, the subject of silent contemplation, as that which is communicated either by written language or by the living voice: and it makes truth itself immutable, as depending not upon the arbitrary constitution of this or that individual, or even of the whole human race (x), but upon the nature of things as established by their Almighty Creator.

121
Every proposition either true or false.

According to this definition, every proposition which

(w) Dr Tatham having asked, with a contemptuous air, How imperfect and illogical is the definition of truth given by Wollaston? proceeds, though not to define, to describe or characterise it himself. "Truth (says he) is of the nature and essence of God, like him *incomprehensible* in the whole, and *ineffable* in its sublimer parts. For these and other reasons it cannot admit of an *adequate definition*. And who, in the beginning of his researches, should presume to define that which, after all his longest and best conducted labours, he can only hope partially, and often imperfectly, to comprehend; and of which an important part can neither be *directly* expressed nor *directly* understood? We may indeed esteem ourselves highly favoured by the Author and finisher of all truth, if, at the end of our researches, we shall be able any way to understand, to define, and to apply, a few particular portions and detachments of it, and to guard them from ERROR and corruption. When upon a solemn occasion the question was put to our Lord by a Roman governor, *What is* TRUTH? though it was what he fully and perfectly knew, and what he came purposely and professedly to teach, he did not define it. He knew that definition was never the best method of instruction; and that in its common use and application it was seldom the friend of truth. Philosophically viewed, words do not constitute truth; they are only the vocal instruments by which it is communicated, or the written signs by which it is recorded. By an inquirer, therefore, things are to be examined rather than words defined. By a teacher, things are to be conveyed by words in some form or other, which are doubtless to be explained to the understanding, if not sufficiently understood before. But *explanation* is one thing, and *definition* quite another. Explanation is the *first* office of a teacher: Definition, if it be good, is the *last* of the inquirer, after the truth be found; and is then the most *advantageously* employed by the teacher, when his previous instructions have prepared him for it. GOD is a mind, and TRUTH is consequently an *attribute* of MIND. To the SUN, declaring at his rising a marvellous instrument, He, by whom all things were made, hath delegated the power of enlightening the *material* system; whilst he hath reserved to HIMSELF the office which is more suitable to his nature, of giving light and knowledge, by his eternal TRUTH, to the *mind* of man. But whether he act through the instrumentality of his creatures, or more *immediately* from himself, he is uniform and consistent in his operations; so that one part of his divine economy is always illustrative of another. As the SUN sheds his *light* over the material creation to be apprehended by the eye, TRUTH is the *light* shed down from heaven to be apprehended by the intellect, given to illumine every subject, natural and moral, corporeal and spiritual, so far as they are qualified by their different natures to convey it to the human mind, or rather perhaps so far as the human mind is qualified to receive it from them." *The Chart and Scale of Truth*, vol. I.

This passage, of which some parts are certainly not remarkable for perspicuity, seems to be descriptive, not of *truth* in the common acceptation of the word, but of *all knowledge* human and divine, of which indeed no adequate definition can be given. *Truth*, as here used, seems to be opposed to *ignorance*; as used by Mr Wollaston and others it is opposite to *falsehood*. In this last sense it may certainly be *explained*, if not defined: and if the learned lecturer will allow that Mr Wollaston has given a good *explanation* of the word *truth* as opposed to *falsehood*, we shall not quarrel with him or any man about the propriety of an expression. We have called it a *definition* of truth; because it was so called by the author from whom it is taken.

(x) Dr Beattie, in his elegant essay, has given a definition of truth very different from this, though it is possible that his meaning may be the same with Mr Wollaston's. "I account that to be *truth* (says he) which the constitution of our nature determines us to believe; and that to be *falsehood* which the constitution of our nature determines us to disbelieve." But if truth be really *immutable*, as he teaches or wishes to teach, it must depend upon the nature of things, and not upon the instinctive impulse of any particular constitution. It is always difficult, often impossible, to distinguish between the constitution of our nature, as it came from the hand of God, and the same constitution as it is moulded by arbitrary and capricious associations of our own. A sincere member of the Church of Rome certainly believes the doctrine of transubstantiation. How he may do so we have already shown. Were all mankind sincere members of that church, it would be said an which can be expressed or apprehended is necessarily either true or false, whether its truth or falsehood be perceived or not either by him who hears or by him who utters it. All propositions are either affirmative or negative; but before any thing can with certainty be affirmed or denied of another, we must know those things as they are in themselves, as well as the established use of the signs by which they are expressed. He who affirms or denies without this knowledge, speaks at random, and has no distinct meaning.

12 ...l.u ...aculty ...rned ...isition ...th.

Every faculty which we possess is in some way or other an instrument of knowledge; for we know by our senses, by our memory, and by our intellect. Every one of our faculties, therefore, is concerned in the acquisition of truth, and furnishes the mind with the materials of propositions. These propositions are indeed of various kinds; but they are all certainly true or certainly false, though the *certainty* of the truth or falsehood of every one it is not always in our power to perceive.

13 ...ity of ...f- ...ot ...th ...it is ...d.

When a man affirms that red is a quality inherent in a soldier's coat, he utters a proposition which every one of the vulgar firmly believes to be true, but which every philosopher knows to be false. This diversity of belief, however, affects not the truth of the proposition itself. All mankind know that it is either true or false, independent of them or their perceptions; and it is easy, by a few optical experiments and by an explanation of terms, to convince them all, that what they have agreed to call *red* is no quality inherent in external objects, but only a sensation caused by the impulse of certain rays of light reflected from certain objects to the eye of the percipient. The contrariety therefore in this case of vulgar to philosophical belief, does not result from any ambiguity in the nature of truth itself, but from the different means of perception which the clown and the philosopher possess.

Again, were a man looking at a red and a green object, to affirm that they are both of the same colour, he would affirm what in one sense may be true, what in another is undoubtedly false, and what in a third may be either true or false. If it be his meaning that the two objects give to him the same sensation, he may know with the utmost certainty that what he says is true; if he mean that they affect all mankind precisely as they affect him, he utters what all mankind with the most absolute certainty know to be false; if he mean that the texture of the two bodies (that particular disposition of parts on their surfaces which makes them reflect certain rays of light and absorb others) is exactly similar, so as that the one must reflect the very same kind of rays with the other, he utters what all mankind must *believe* to be false, though still it is *possible* that what he affirms may be true. This diversity of belief affects not the truth itself. The two objects are what they are by whomsoever perceived, or whether perceived or not; the rays of light reflected by each are what they are, whether they fall upon this, upon that, or upon any eye; and the sensation communicated to this singular man is certainly what he is conscious it is, as those of the rest of mankind are with equal certainty what they are conscious of. This being the case, it is obvious and undeniable, that the organs of sight in this individual of the human race are somehow differently formed from those of other men: and the only question which can occasion a doubt in the mind of the sceptic is, whether his or their eyes be so formed as to represent things falsely? for that by the one or the other things are falsely represented, is as evident as that two contradictory propositions cannot both be true. Now, though, for any thing we know it is certainly possible, as to us it appears not to imply any contradiction, that the eyes of but one man are formed in a manner suitable to their objects, whilst the eyes of all other men are formed to deceive them; yet the contrary is so highly probable, that no man really doubts of it any more than he doubts whether three and two be equal to five.

124 Why some truths are said to be absolutely and others morally certain.

This last proposition is indeed said to express a truth absolutely certain, whilst the former expresses a truth which is called morally certain: not that there is any difference or degrees of certainty in the nature of truths themselves; the only difference is in our power of perceiving them. That three and two are equal to five, is said to be an absolute truth; because we perceive the whole of it as it is in itself, and are convinced that every intelligence from the highest to the lowest who understands the terms in which it is expressed perceives it as we do: whereas of *moral* or *physical* truths, as they are called, we only perceive a part, and may therefore mistake for want of evidence. Thus, in the case of the two objects exhibiting the same colour to one man, whilst they exhibit different colours to all other men, could we see into the objects themselves, and comprehend them immediately with our intellect as we comprehend our own ideas, it might, and no doubt would, appear as palpable a contradiction to say that the particular disposition of the parts on their surfaces, which reflect the rays of light, are the same in both, as it is now to affirm that three and two are not equal to five. Between truth and falsehood there is no medium. All truths are in *themselves* equally certain; and to the Supreme Being, who knows the nature of every thing more fully and intimately than we know our own ideas, they all *appear* equally certain: but yet we may without absurdity speak of *probable* truth as well as of *certain* truth, provided always that we make the difference to result, not from the nature of things, but from the power of our understanding, which comprehends the one kind of truth wholly and the other only partially.

125 Why some truths are said to be eternal and necessary, whilst others are considered as temporary and contingent.

There is another division made of truth into that which is eternal and necessary, and that which is temporary and contingent. Though we do not approve of

7

and thought, "that the constitution of human nature determines men to believe transubstantiation:" a doctrine which, though it is rejected by millions, Pere Buffier has laboured hard to reconcile with common sense. Yet it is certain that the same body cannot be in different places at the same time; and that therefore transubstantiation must be false, though believed by all mankind. Our *believing* any thing does not make it true, nor our *disbelieving* any thing make it false. We must, indeed, *act* according to our belief; but in every instance truth and falsehood would have been what they are, though we had never existed.

Of Truth.

of applying the epithets *temporary* and *eternal* to any thing but real exiſtences, yet as this manner of ſpeaking has been uſed by all philoſophers, we ſhall give inſtances of each kind of truth, and endeavour to aſcertain in what the diſtinction conſiſts. "The three angles of a plain triangle are equal to two right angles," is a propoſition expreſſive of a neceſſary and eternal truth. "The world exiſts," is a contingent and temporary truth. Here it is obvious, that if both theſe propoſitions be true, there is no diſtinction between them, ſo far as mere *truth* is concerned; for truth admits not of degrees of compariſon. It is however ſaid, that the firſt propoſition depends not upon time, or will, or any thing elſe; and that the Supreme Being himſelf could not make it falſe: whereas it is certainly poſſible, that he who created the world could annihilate it, and thus reduce what is now a truth to an abſolute falſehood. This difference between the two propoſitions is thought a ſufficient ground for calling the former a *neceſſary* and *eternal* truth, and the latter a *temporary* and *contingent* truth. But is the difference itſelf real? In the preſent inſtance we cannot think that it is: for if the right angles and triangles, which conſtitute the materials of the former propoſition, be real corporeal things, they may be annihilated as well as the reſt of the world; and then the truth of the propoſition will ceaſe, for there can be neither equality nor inequality between nonentities. If the angles and triangles be merely ideas in the mind of a rational being, it is not to be denied that the propoſition muſt be true, independent of all *will*, whenever thoſe ideas exiſt, *i. e.* whenever right angles and triangles are *thought upon*; but if all reaſonable creatures were to be annihilated, and the Supreme Being never to think of triangles, the propoſition would unqueſtionably ceaſe to be either true or falſe. The world may indeed be annihilated; but it certainly is not annihilated whilſt any one creature exiſts to contemplate even that which is called *neceſſary* and *eternal* truth: and therefore whilſt any truth exiſts in a mind not divine, it muſt be neceſſarily true that the world exiſts; for the individual being by which truth is perceived would then conſtitute the whole world.

But if in a ſomewhat different manner we compare the former of theſe propoſitions with this—"The ſolar ſyſtem conſiſts of the ſun and at leaſt ſeven primary planets"—we ſhall at once perceive the difference between neceſſary and contingent truths. Both propoſitions we know to be true at this moment: but there is this difference between them, that a plain triangle can neither actually exiſt at any period of duration, nor be conceived by any one mind divine or human, of which the three internal angles are not preciſely equal to two right angles; whereas the ſolar ſyſtem may eaſily be conceived, and might certainly have been formed, with a ſmaller number of primary planets rolling round the central fire. This needs no proof; as it is well known, that till very lately we conceived the ſyſtem to conſiſt of the ſun and only ſix primary planets; and it has been already ſhown, that whatever we can poſitively conceive may poſſibly exiſt. Thus, then, every propoſition, of which the contrary is clearly and diſtinctly perceived to be impoſſible, is a *neceſſary* truth; and it may likewiſe be ſaid to be *eternal*, becauſe at every period of duration it muſt of neceſſity when thought upon be perceived to be true: On the other hand, every propoſition of which the contrary may be clearly and diſtinctly conceived, is, if true, only a *contingent* truth, becauſe its contrary might have exiſted; and it may likewiſe be called *temporary*, becauſe what might have been falſe in time paſt may yet be falſe in time future.

Though all our faculties (our ſenſes, our memory, and our intellect) furniſh materials for propoſitions, and are therefore all ſubſervient to the inveſtigation of truth; yet the perception of truth, as it is in itſelf, is commonly aſcribed to our rational faculties; and theſe have by Locke and others been reduced to two—reaſon and judgment. The former is ſaid to be converſant about certain truths, the latter chiefly about probabilities.

Some late philoſophers of great merit, diſſatiſfied with this analyſis of the intellect, have added to reaſon and judgment a third faculty, to which they have given the name of *common ſenſe*, and of which the proper object is ſuch truths as neither admit nor ſtand in need of evidence. By *common ſenſe* they mean, "that degree of judgment which is common to men with whom we can converſe and tranſact buſineſs." Whether the introduction of ſuch a term into metaphyſics was proper or improper, we do not think it of importance to inquire. According to this definition of it, which is Dr Reid's, it differs not from the *reaſon* (x) and *judgment* of Locke; agreeing with the former when its

(x) This is expreſsly acknowledged by Dr Reid. "It is abſurd (ſays that able and candid writer) to conceive that there can be any oppoſition between reaſon and common ſenſe. It is indeed the firſt-born of reaſon; and as they are commonly joined together in ſpeech and in writing, *they are inſeparable in their nature*. We aſcribe to reaſon two offices or two degrees: The firſt is to judge of things ſelf-evident; the ſecond to draw concluſions that are not ſelf-evident from thoſe that are. The firſt of theſe is the province, and the ſole province, of common ſenſe; and therefore it *coincides with reaſon in its whole extent*, and is only *another name* for one branch or one degree of reaſon." Pere Buffier talks nearly the ſame language; but Dr Beattie expreſſes himſelf very differently. "That there is a real and eſſential difference between theſe two faculties; that common ſenſe cannot be accounted for by being called the *perfection of reaſon*, nor reaſon by being reſolved into *common ſenſe*; will appear (he thinks) from the following remarks. 1. We are conſcious, from internal feeling, that the energy of underſtanding, which perceives intuitive truth, is different from that other energy which unites a concluſion with a firſt principle by a gradual chain of intermediate relations. 2. We cannot diſcern any neceſſary connection between reaſon and common ſenſe." Nay, he ſays, "That we often find men endued with the one who are deſtitute of the other:" and he inſtances dreams and certain kinds of madneſs where this is the caſe; adding, that a man who believes himſelf its object is certain truth, and with the latter when it is conversant about probabilities. Nothing indeed is more evident, than that in the assent of the mind to every proposition, some energy of the judgment is exerted; and upon every proposition not self-evident, reasoning of some kind or other must be employed to procure that assent. Instead therefore of perplexing ourselves and our readers with various analyses of the human understanding, or rather with various names to what after all is perhaps but one individual power, it will surely be of more importance to the cause of truth to examine the different sources of evidence by which the assent of the reason, or judgment, or common sense, is determined.

Under the article Logic it was observed, that *intuition*, *experience*, and *testimony*, are each a sufficient *ground of judgment*; but they are not the only grounds. *Consciousness* is certainly one source of evidence, perhaps the most complete of any; and, in a low degree, *analogy* is another. Of *consciousness* we have already treated, but of *analogy* we have yet said nothing: and though we might (for an account of *intuition*, *experience*, and *testimony*) refer our readers to the article Logic, where they are accurately though concisely explained, we shall, without repeating what has been already said, add a few words on each, as well to complete the present article as to supply the deficiencies of the former.

Sect. II. *Of Intuitive Evidence and Demonstration.*

Intuitive evidence is that which arises from the comparison of two or more ideas or notions when their agreement or disagreement is perceived immediately, without the intervention of any third idea or notion. Of this kind is the evidence of these propositions: One and four make five*; things equal to "the same thing are equal to one another; the whole is greater than any of its parts;" and in a word, all the axioms in arithmetic and geometry. All these are in reality propositions in which the subject and predicate appear upon comparison to be nothing more than the same thing taken in different views or expressed by different terms. In fact, they are all in some respect reducible to this axiom, "Whatever is, is." We do not say that they are deduced from it; for they have in themselves that original and intrinsic evidence which makes them, as soon as the terms are understood, to be perceived intuitively. And if they be not thus perceived, no deduction of reason will ever confer on them any additional evidence. But though not deduced from the general axiom, they may be considered as particular exemplifications of it; inasmuch as they are all implied in this, that the properties and relations of our clear and adequate ideas can be no other than what the mind clearly perceives them to be. Of Intuitive Evidence and Demonstration

129 Every demonstration a series of propositions intuitively evident.

It may perhaps be thought, that if axioms were propositions perfectly identical, it would be impossible by their means to advance a single step beyond the simple ideas first perceived by the mind. And it would indeed be true, that if the predicate of the proposition were nothing but a repetition of the subject under the same aspect, and in the same or synonymous terms, no conceivable advantage could be made of it for the furtherance of knowledge. Of such propositions as these, for instance, "seven are seven, eight are eight, the three angles of a triangle are the three angles of a triangle, two right angles are two right angles," it is manifest that we could never avail ourselves for the improvement of science: But when the thing, though in effect coinciding, is considered under a different aspect; when that which is single in the subject is divided in the predicate, and conversely; or when what is a whole in the one is regarded as a part of something else in the other; such propositions lead to the discovery of innumerable and apparently remote relations. It is by the aid of such simple and elementary principles that the arithmetician and the algebraist proceed to the most astonishing discoveries. Nor are the operations of the geometrician essentially different: for to this class belong all propositions relating to number and quantity; that is, all which admit of mathematical demonstration. If the truth of a mathematical proposition be not self-evident; in other words, if the subject and predicate do not appear at first sight to be different names for the same thing, another term must be found that shall be synonymous to them both. Thus, to prove that the three internal angles of a right-lined triangle are equal to two right angles, I produce the base of the triangle; and by a very short process I discover that the exterior angle so formed is equal to the two interior and opposite angles. By a process equally plain and short, I perceive that the exterior angle and the interior adjacent angle are equal to two right angles: But I have already seen, that the exterior angle is neither more nor less than the two interior and opposite angles under a different aspect; whence it appears that the three internal angles of the triangle are nothing else than two right angles under a different aspect. In a word, all demonstration is founded on first principles or primary truths, which neither

self made of glass, shall yet reason very justly concerning the means of preserving his supposed brittleness from flaws and fractures." Surely these are strange remarks. Dreams and madness have hitherto been supposed to originate in the imagination, or, as it was denominated by the ancient philosophers, the *phantasia*: and when the ideas or forms which are there treasured up are disarranged or absurdly compounded, a dreaming sane man or a waking madman, if he reason at all, must reason from absurd principles; not, however, through any defect of common sense, but from a disorder in that region of the brain, upon which the phantasia more immediately depends. Of his first remark, we can only say, that to us it appears to be the reverse of truth. In every proposition which admits of demonstration, *we* are conscious that the conclusion is united with the first principle by a repetition of the very same energy of the understanding which perceives intuitive truth. That this is the case in every one of Euclid's demonstrations, we appeal to every mathematical reader; and why it must be so, we shall by and by endeavour to evince.

Of Intuitive Evidence and Demonſtration

neither admit nor ſtand in need of proof, and to which the mind is compelled to give its aſſent by a bare intuition of the ideas or terms of which theſe primary truths are compoſed. Nothing is ſuſceptible of demonſtration, in the rigid ſenſe of the word, but general, neceſſary, and eternal truths; and every demonſtration is built upon intuition, and conſiſts in a ſeries of axioms or propoſitions of the very ſame kind with the firſt principle or truth from which the reaſoning proceeds. That propoſitions formerly demonſtrated are taken into the ſeries, doth not in the leaſt invalidate this account; inaſmuch as theſe propoſitions are all reſolvable into axioms, and are admitted as links in the chain; not becauſe neceſſary, but merely to avoid the uſeleſs prolixity which frequent and tedious repetitions of proofs formerly given would occaſion. But it is obvious that ſuch truths only as reſult from the compariſon of ideas and notions are neceſſary; and of courſe that ſuch truths only are capable of ſtrict demonſtration. The truths which relate to real exiſtences are all contingent, except that which affirms the exiſtence of the Supreme Being, the Parent of all truth.

The mathematical ſciences, categorical logic, and that part of metaphyſics which demonſtrates the being of God, are therefore the only branches of human knowledge which admit of ſtrict demonſtration. The longeſt demonſtration in the mathematical ſciences may be traced to this general and neceſſary truth, "Whatever is, is," or to ſome particular exemplification of it: the longeſt train of categorical ſyllogiſms terminates in this general principle, "What is affirmed or denied of a whole *genus*, may be affirmed or denied of all the *ſpecies* and all the *individuals* belonging to that genus:" and the metaphyſical demonſtration of the being of God reſts upon this foundation, "Whatever had a beginning, had a cauſe." That theſe are truths abſolutely certain, which can neither be proved nor called in queſtion, every man may be ſatiſfied, merely by attending to the ideas or notions which the terms of each propoſition expreſs. The two firſt are merely identical propoſitions, of the truth of which no man has ever pretended to doubt; and though the laſt is not identical, it is a neceſſary and ſelf-evident truth, as its contrary implies, that in the ſame thing there is power and no power, change and no change, action and inaction, at the ſame inſtant.

130
It is by intuition that we acquire all our notions of relation.

Before we diſmiſs the ſubject of intuition, it may not be improper to obſerve, that it is by this faculty or power of the mind contemplating its ideas, and comparing one idea with another, that we acquire all our notions of relation; ſuch as *identity* and *diverſity*, *reſemblance*, *coexiſtence*, relations of *ſpace* and *time*, relations of *quantity* and *number*, of a *cauſe* to its *effect*, and many more which it would be uſeleſs as well as tedious to enumerate.

Sect. III. *Of Experience and Analogy.*

131
Experience, the reſult of repeated obſervations.

It has been juſt obſerved, that intuition and demonſtration are applicable only to general and neceſſary propoſitions, of which the contrary are not only falſe, but abſurd and impoſſible. The great buſineſs of life, however, is with facts and contingent truths, which admit not of demonſtration, but reſt upon other evidence. The ſenſes, external and internal, are the inlets to all our knowledge of facts; and the memory is the ſtorehouſe where that knowledge is preſerved. Of what a man ſees or feels, he can at the inſtant of ſeeing or feeling entertain no doubt; and whilſt the ideas of what he has ſeen or felt, with all their aſſociated circumſtances, remain vivid and diſtinct in his memory, he is conſcious that he poſſeſſes ſo much real knowledge. But all our knowledge, as it is derived from the ſenſes, is of particular facts or particular truths; and the man who has in certain circumſtances obſerved one particular phenomenon, for the exiſtence of which he perceives no *neceſſity*, has not ſufficient ground to conclude, that in ſimilar circumſtances ſimilar phenomena will always occur. Milton, who ſurpaſſed the greater part of his contemporaries in philoſophical ſcience almoſt as far as he has ſurpaſſed all ſucceeding poets in the ſublimity of his genius, repreſents Adam, when firſt falling aſleep, as under apprehenſions that he was about to ſink into his original ſtate of inſenſibility:

> ———————— " Gentle ſleep
> " Firſt found me, and with ſoft oppreſſion ſeiz'd
> " My drouſed ſenſe, untroubled; though I thought
> " I then was paſſing to my former ſtate
> " Inſenſible, and forthwith to diſſolve."

Apprehenſions ſimilar to theſe would take place in his mind when he firſt perceived that darkneſs had overſpread the earth. In his circumſtances, he could have no ground to expect that the ſun when once ſet would riſe again to relume the world, as he had not then experienced the alternate ſucceſſion of light and darkneſs, and probably knew not whence light proceeds. After ſome time, however, having obſerved day and night regularly to ſucceed each other, theſe two appearances, or the ideas of them, would be ſo aſſociated in his mind, that each ſetting ſun would ſuggeſt the idea of next ſun-riſing, and lead him to expect that glorious event with the utmoſt confidence. He would then conſider the alternate ſucceſſion of day and night as a law of nature, which might be affirmed in a propoſition expreſſive of a certain truth.

1[...]
Is the only evidence that we have for the general truths in phyſics, even for those which we think intuitively certain

This continued obſervation of the ſame event happening in the ſame or ſimilar circumſtances, is what we call *experience;* and it is the only evidence which we have for all the general truths in phyſics, even for thoſe which we are apt to think intuitively certain *. Thus, that *milk* is white, and that *gold* is yellow, are ſuppoſed to be univerſal and neceſſary truths: but for any thing that we know, they may be particular truths; and they are certainly contingent, as the contrary to either of them may be ſuppoſed without abſurdity. We have indeed always obſerved the milk of animals of every ſpecies *white;* and therefore the idea of *white* becomes a neceſſary part of our *idea* of the ſubſtance milk, of which we call whiteneſs an eſſential property. This, however, reſpects only the milk of thoſe animals with which we are acquainted. But ſince the milk of all the animals with which we are acquainted, or of which we have heard, is white, we can have no reaſon to ſuſpect that the milk of any new and ſtrange animal is of any other colour. Alſo, ſince, wherever there has been the ſpecific gravity, ductility, and other properties of *gold*, the colour has always been *yellow;* we conclude that theſe circumſtan-

* Ca[...] Philoſ[...] of Rh[...] and [...] ley's [...] marks [...] Drs [...] &c.

ces are neceſſarily united, though by ſome unknown bond of union, and that they will always go together.

53 The proper proof, therefore, of ſuch univerſal propoſitions as "that milk is white," "that gold is yellow," or "that a certain degree of cold will freeze water," conſiſts in what is called an induction of *particular facts* of preciſely the ſame nature. Having found, by much and various experience, that the ſame events never fail to take place in the ſame circumſtances, the *expectation* of the ſame conſequences from the ſame previous circumſtances is neceſſarily generated in our minds; and we can have no more ſuſpicion of a different event than we can ſeparate the *idea* of *whiteneſs* from that of the other properties of *milk*.—When the previous circumſtances are preciſely the ſame, we call the proceſs of proof by the name of *induction*, and expect the event from *experience*: but if they be not preciſely the ſame, but only bear a conſiderable reſemblance to the circumſtances from which any particular appearance has been found to reſult, we call the argument *analogy*; and it is ſtronger in proportion to the degree of reſemblance in the previous circumſtances. Thus the milk of all the cows that we have ſeen, or upon which we have made the experiment, having been found nouriſhing, we confidently expect that the milk of all other cows will prove nouriſhing likewiſe; and this confidence of expectation is the reſult of uniform experience. But if, from having found the milk of all the animals with which we are acquainted to be nouriſhing, however different the nature of theſe animals; we infer that the milk of any ſtrange animal will likewiſe be nouriſhing; the inference is drawn by analogy, and by no means carries with it the conviction of experience. A proof from *real* experience can leave no doubt in the mind (B); an argument from analogy always muſt. In the one caſe, we only infer that two events of preciſely the ſame nature and in preciſely the ſame circumſtances have been produced by the ſame kind of cauſe; in the other, we infer that two events ſimilar in moſt reſpects, though for any thing that we know diſſimilar in others, have been produced by the ſame kind of cauſe; and it is obvious that between theſe caſes the difference is great.

4. Thus, after having obſerved that all the projectiles to which we have paid any attention—a ſtone thrown from the hand, a ball from a gun, and an arrow from a bow—deſcribe a certain curve, and are impelled in that curve by two powers acting in different lines of direction which form with each other a certain angle, we infer that all projectiles which on the ſurface of the earth deſcribe the ſame curve are impelled by the ſame or ſimilar powers acting in the ſame or ſimilar lines of direction. This inference is the reſult of experience, and carries with it the fulleſt conviction to the mind. But when, from having obſerved that the curves deſcribed by the planets are of the ſame kind with thoſe deſcribed by projectiles on the earth, Sir Iſaac Newton inferred that theſe vaſt bodies are impelled in their orbits by forces of the very ſame kind, and acting in the ſame manner with the forces which impel a ball from a cannon or an arrow from a bow, his argument was founded only on analogy; and even that analogy is very remote. We know by experience that all projectiles which fall under our immediate cogniſance are of the very ſame kind and in the very ſame circumſtances; that every one of them has a tendency, from whatever cauſe, to the centre of the earth, and is preſerved from falling by the force of projection; we know likewiſe that they are all moved thro' the medium of the atmoſphere, which at the ſurface of the earth is conſiderably denſe, and that a denſe medium muſt occaſion much reſiſtance: But we do not *know* that the planets have a tendency to the centre of the ſun, that they are preſerved from falling into that luminary by a projectile force, or whether they move through a *medium* or *in vacuo*: ſo that we are not *certain* that the motion of the planets is perfectly ſimilar to that of terreſtrial projectiles in any other circumſtance than the form of the curve which they all deſcribe; and from this ſingle caſe of coincidence no inference can be drawn which carries to the mind abſolute conviction.

When a man reaſons from *experience*, he infers, that what has uniformly happened hitherto, will happen always in the very ſame circumſtances; or that what is known to be the cauſe of *various phenomena of the ſame kind* is the cauſe of every other phenomenon in *all reſpects* ſimilar to theſe. Such an inference is founded on the united and complete evidence of ſenſe, memory, and reaſon. When a man reaſons from *analogy*, he infers, that what has *generally* happened hitherto, will

Of Experience and Analogy.

(z) We ſay from *real* experience; becauſe what is often taken for *experience*, and to human eyes has that appearance, is in fact nothing more than *analogy*. Thus a phyſician may have preſcribed to ninety-nine patients labouring under the ſame diſeaſe the ſame remedy, and always with the ſame ſucceſs. If ſo, he will think that he has experience of its utility, and will preſcribe it again with the fulleſt confidence. Yet in this caſe he may be diſappointed; for though the medicine be the ſame and the diſeaſe the ſame, there may be ſomething in the conſtitution of the hundredth patient ſo different from that of the ninety-nine, that what was ſalutary to them may be pernicious to him. This does not detract from the evidence of experience: it only ſhows, that the circumſtances of the caſe in which the medicine failed were different from thoſe in which it ſucceeded. In ſuch concluſions as are founded on a complete induction and uniform experience, every man expects the event with the laſt degree of aſſurance, and regards his paſt experience as a full *proof* of the future exiſtence of that event: In other caſes, where experience has been variable—or apparently variable—he knows that the induction has been incomplete, and therefore proceeds with caution. He weighs the oppoſite experiments; takes as complete a view as he can of the circumſtances in which they were made; conſiders which ſide is ſupported by the greater number of experiments, and inclines to that ſide with doubt and heſitation. And when at laſt he fixes his judgment, the evidence exceeds not what is called *probability*. All probability, then, ſuppoſes an oppoſition of experiments and obſervations, where the one ſide is found to overbalance the other, and to produce a degree of evidence proportioned to the ſuperiority.

will happen again in circumſtances *nearly ſimilar*; or that what is known to be the cauſe of various phenomena of the ſame kind, is the cauſe of other phenomena in *ſome reſpects* ſimilar to theſe. This inference is likewiſe founded on the united evidence of ſenſe, memory, and reaſon: but here the evidence of ſenſe is not complete, and it can be ſtrengthened only by finding more facts of the ſame or of a ſimilar nature.

Sect. IV. *Of Teſtimony.*

135 Mankind ready to believe the teſtimony of each other.

The laſt ſource of evidence which we propoſed to conſider is *teſtimony*, or the report of men concerning events which have fallen under the obſervation of their ſenſes. That we are all ready to believe the information which we receive from the teſtimony of our fellow creatures is undeniable; and indeed without ſuch belief every man's knowledge of facts and events would be confined to thoſe only of which he himſelf had been a perſonal witneſs. In that caſe, no man who had not travelled would believe that there are ſuch cities as Rome and Conſtantinople; and no man whatever could now believe that ſuch heroes as Hannibal and Ceſar had ever exiſted.

Between words and things there is no natural connection; and though we are all accuſtomed to give to things the names by which they are known in the language that we ſpeak, and to expreſs their mutual relations by the words appropriated for that purpoſe; yet it is obviouſly impoſſible to denote one thing by the name of another, and to expreſs by words relations that have no exiſtence. This being the caſe, it may be aſked upon what principle we give credit to human teſtimony? To this queſtion various anſwers have been given, which have produced much controverſy on one of the moſt important ſubjects which can employ the mind of man.

136 The reaſon aſſigned by Hume for this propenſity

"We may obſerve (ſays Mr Hume*), that there is no ſpecies of reaſoning more common, more uſeful, and even neceſſary to human life, than that which is derived from the teſtimony of men and the reports of eye-witneſſes and ſpectators. This ſpecies of reaſoning perhaps one may deny to be founded on the relation of cauſe and effect. I ſhall not diſpute about a word. It will be ſufficient to obſerve, that our aſſurance in any argument of this kind is derived from no other principle than our obſervation of the veracity of human teſtimony, and of the uſual conformity of facts to the reports of witneſſes. It being a general maxim that no (A) objects have any diſcoverable connection together, and that all the inferences which we can draw from one to another are founded merely on our experience of their conſtant and regular conjunction; it is evident that we ought not to make an exception to this maxim in favour of human teſtimony, whoſe connection with any event ſeems in itſelf as little neceſſary as any other. Were not the memory tenacious to a certain degree; had not men commonly an inclination to truth, and a principle of probity; were they not ſenſible to ſhame when detected in falſehood: Were not theſe, I ſay, diſcovered by *experience* to be qualities inherent in human nature, we ſhould never repoſe the leaſt confidence in human teſtimony. And as the evidence derived from witneſſes and human teſtimony is founded on paſt experience, ſo it varies with the experience, and is regarded either as a *proof* or *probability*, according as the conjunction between any particular kind of report and any kind of object has been found to be conſtant or variable. There are a number of circumſtances to be taken into conſideration in all judgments of this kind; and the ultimate ſtandard by which we determine all diſputes that may ariſe concerning them, is always derived from experience and obſervation. The reaſon why we place any credit in witneſſes and hiſtorians, is not derived from any *connection* which we perceive *à priori* between teſtimony and reality, but becauſe we are accuſtomed to find a conformity between them. But when the fact atteſted is ſuch a one as has ſeldom fallen under our obſervation, here is a conteſt of two oppoſite experiences; of which the one deſtroys the other as far as it goes, and the ſuperior can only operate on the mind by the force which remains. The very ſame principle of experience which gives us a certain degree of aſſurance in the teſtimony of witneſſes, gives us alſo, in this caſe, another degree of aſſurance againſt the fact which they endeavour to eſtabliſh; from which contradiction there neceſſarily ariſes a counterpoiſe, and mutual deſtruction of belief and authority."

* Eſſay on Miracles.

This account of the origin of faith in teſtimony has been controverted with much ſucceſs by the Doctors Campbell and Reid. "That the evidence of teſtimony is derived ſolely from experience (ſays the former of theſe writers §), is at leaſt not ſo inconteſtable a truth as Mr Hume ſuppoſes it; that, on the contrary, teſtimony hath a natural and original influence on belief antecedent to experience, will, I imagine, eaſily be conceived. For this purpoſe, let it be remarked, that the earlieſt aſſent which is given to teſtimony by children, and which is previous to all experience, is, in fact, the moſt unlimited; that by a gradual experience of mankind, it is gradually contracted, and reduced to narrower bounds. To ſay, therefore, that our diffidence in teſtimony is the reſult of experience, is more philoſophical, becauſe more conſonant to truth, than to ſay that our faith in teſtimony has this foundation. Accordingly, youth, which is unexperienced, is credulous; age, on the contrary, is diſtruſtful. Exactly the reverſe would be the caſe were this author's doctrine juſt." This is a complete confutation of the reaſoning of Mr Hume: but in order to prevent all cavilling, it is to be wiſhed that the very acute author had explained more fully what he means by ſaying, that teſtimony hath a *natural* and *original* influence on belief; for theſe words may be taken in different ſenſes, in one of which what he affirms is true, and in another falſe. 137 confuted

§ Diſſertation on Miracles, and The Philoſophy of Rhetoric

Dr

(A) Is there then no diſcoverable connection between a tree and the field in which it grows; between a man and his cloaths; between an author and his work; between a ſceptic and paradoxes? Surely all theſe are correlates, and neceſſarily ſuggeſt the ideas of each other.

Of Teſtimony.

Dr Campbell's omiſſion is amply ſupplied by Dr Reid, who gives § the following account of teſtimony, and of the credit which it obtains. "The wiſe and beneficent Author of nature, who intended that we ſhould be ſocial creatures, and that we ſhould receive the greateſt and moſt important part of our knowledge by the information of others, hath, for theſe purpoſes, implanted in our nature two principles that tally with each other. The firſt of theſe principles is a propenſity to ſpeak truth, and to uſe the ſigns of language ſo as to convey our real ſentiments. This principle has a powerful operation even in the greateſt liars; for where they lie once, they ſpeak truth a hundred times. Truth is always uppermoſt, and is the natural iſſue of the mind. It requires no art or training, no inducement or temptation, but only that we yield to a natural impulſe. Lying, on the contrary, is doing violence to our nature, and is never practiſed even by the worſt men without ſome temptation. Speaking truth is like uſing our natural food, which we would do from appetite, although it anſwered no end; but lying is like taking phyſic, which is nauſeous to the taſte, and which no man takes but for ſome end which he cannot otherwiſe attain.—When we are influenced by any motive, we muſt be conſcious of that influence, and capable of perceiving it upon reflection. Now, when I reflect upon my actions moſt attentively, I am not conſcious that in ſpeaking truth I am influenced on ordinary occaſions by any motive moral or political. I find that truth is always at the door of my lips, and goes forth ſpontaneouſly if not held back. It requires neither good nor bad intention to bring it forth, but only that I be artleſs and undeſigning. There may indeed be temptations to falſehood, which would be too ſtrong for the natural principle of veracity, unaided by principles of honour or virtue; but where there is no ſuch temptation, we ſpeak truth by *inſtinct*. By this inſtinct, a real connection is formed between our words and our thoughts; and thereby the former become fit to be ſigns of the latter, which they could not otherwiſe be."

§ Inquiry into the Human Mind,

Such is the account which Dr Reid gives of the truth of human teſtimony: and he adds, that there is another original principle implanted in us by the Supreme Being, to tally with it, viz. a diſpoſition to confide in the veracity of others, and to believe what they tell us. "This (he ſays) is the counterpart to the former; and as that may be called the *principle of veracity*, we ſhall, for the want of a more proper name, call this the *principle of credulity*. It is unlimited in children, until they meet with inſtances of deceit and falſehood; and retains a very conſiderable degree of ſtrength through life."

It is ever with extreme reluctance that we controvert the opinions of this able writer; and that reluctance cannot be leſſened in the preſent inſtance, when we are conſcious that great part of what he ſays is unanſwerable. That truth is always at the door of the lips; that it requires no effort to bring it forth; that in ordinary caſes men ſpeak truth uninfluenced by any motive moral or political; that the greateſt liars ſpeak truth a hundred times where they lie once; and that lying is never practiſed by the worſt men without ſome temptation, are poſitions which daily experience renders it impoſſible to queſtion: But notwithſtanding this, we do not think that truth is ſpoken by an *inſtinctive* principle; becauſe it is inconceivable that inſtinct ſhould teach the uſe of arbitrary and artificial ſigns, ſuch as the words of every language undoubtedly are; or that between ſuch ſigns and ideas any *inſtinctive* connection ſhould ever be formed. "Truth (as we have defined it) is the conformity of thoſe words or ſigns by which things are expreſſed, to the things themſelves;" and things themſelves are what they are, independent of us, our inſtincts, and perceptions. When we have preciſe and adequate ideas of objects, and when thoſe ideas are related to one another as the objects themſelves are related, we are in poſſeſſion of mental truth; and in this caſe there is a *real* and *natural* connection between the ſigns and the things ſignified: for we cannot frame original and ſimple ideas which have no archetype in nature; nor can *one* object, diſtinctly perceived, generate in our minds the ideas that are generated by *other* objects. Here external things are the objects, and ideas are the ſigns, which, when they are in conformity to the things ſignified by them, conſtitute truth.

158 The true reaſon aſſigned.

But in human teſtimony, the ideas in the mind of the ſpeaker are the things ſignified, and the words of language are ſigns by which they are expreſſed; and when theſe things and ſigns are in conformity to each other, the words uttered expreſs ſo much truth.—Now, though in this caſe there is no *natural* connection between the ſign and the thing ſignified, yet it is obvious, that without a violent effort of the ſpeaker to the contrary they muſt always be in conformity with each other, becauſe, in every language, there are words appropriated for the purpoſe of denoting every idea and relation which can be expreſſed; and in the mind of every man theſe ideas, relations, and *words*, have been conſtantly aſſociated from the time that he learned to ſpeak. So intimate is this aſſociation, and ſo impoſſible to be broken, that whoever will pay ſufficient attention to the operations of his own mind, will find that he *thinks* as well as *ſpeaks* in ſome language; and that in cogitation he ſuppoſes and runs over, ſilently and habitually, thoſe ſounds which in ſpeaking he actually utters (B). If this be ſo, it is impoſſible that a man without ſome effort ſhould ever ſpeak any thing but truth: for the *ideas* of what he has ſeen or heard, &c. are not of his manufacture;

(B) This ſeems to have been *Plato's* opinion; for he calls *thinking* [illegible], "the language by which the ſoul explains itſelf to itſelf when it conſiders any thing." And *Plotinus* ſays, [illegible], "the vocal words are an imitation of thoſe of the ſoul." To ſay that vocal words are an imitation of thoſe of the ſoul, is to ſpeak inaccurately, and to reverſe the proceſs of aſſociation; but it affords ſufficient evidence, that in the opinion of Plotinus men think as well as ſpeak in words.

Of Teſtimony.

nufacture; they are generated by external objects; and till they be effaced from the memory, they muſt always, by the law of aſſociation, make their appearance there with all their mutual relations, and in their proper dreſs. In the very act of learning to ſpeak, we neceſſarily learn to ſpeak the *truth:* for were we not to employ words exactly as they are employed by thoſe with whom we converſe, our language (if language it might be called) would be unintelligible; and we could neither declare our wants nor aſk relief with any hopes of ſucceſs. *Children* beginning to ſpeak, may indeed utter untruths without any motive, and merely from miſtake; becauſe the ideas and words of children have neither been long nor cloſely aſſociated: but it is impoſſible that a *man*, however wicked, ſhould habitually and without motives lie on ordinary occaſions, unleſs the fundamental principles of his nature have been totally altered; unleſs his brain has been diſordered by diſeaſe; unleſs his ideas have been diſarranged, and all his original aſſociations broken.

We know indeed by woful experience, that immoral men occaſionally utter falſehoods with a view to deceive. But on theſe occaſions they are influenced by ſome motive either of hope or terror: the falſehood is always uttered with an effort: and ſo ſtrong is the aſſociation between words and ideas, that the truth will at times break out in ſpite of all their endeavours to ſuppreſs it; ſo that the end or middle of a falſe narrative, if it be of any length, is commonly inconſiſtent with the beginning. We entertain a ſuſpicion concerning any matter of fact, when thoſe who relate it contradict each other—when they are but few in number, or of doubtful character—when they have an intereſt in what they affirm—when they deliver their teſtimony with heſitation—or, on the contrary, with too violent aſſeverations; becauſe theſe are circumſtances which we have generally experienced to accompany falſe witneſs. It is likewiſe with reluctance that we admit a narrative of events entirely different from every thing which hitherto we have ſeen or heard; becauſe we may not be certain that the narrator is not under ſome influence to deceive us in matters concerning which we have nothing but his teſtimony on which to ground our judgment. But in every caſe where the fact recorded is in itſelf poſſible, and attributed to an adequate cauſe; where a competent (c) number of witneſſes had ſufficient means of information, and are certainly under no inducement to deceive; teſtimony is complete evidence, however extraordinary the fact may be; becauſe no fact which is known to have an adequate cauſe can be ſo incredible, as that a number of men of ſound underſtandings ſhould act contrary to the fundamental principles of human nature, or be able, if ſo diſpoſed, to diſſolve aſſociations which had been formed in the mind of each from his infancy, and form new ones, all agreeing exactly with one another, but all contrary to truth.

Part II. Of BODY with its ADJUNCTS.

Chap. I. *Of the* Composition *of* Bodies; *or, of* Matter *and* Form.

HITHERTO we have contemplated only the powers of our own minds by which we acquire a ſtock of ideas, and the various operations of the intellect upon thoſe ideas, as treaſured up in the memory or imagination. In the courſe of the inquiry we have found, that every idea and notion which we have was ſuggeſted by ſomething independent of us; and in order to diſcover what thoſe things are, we have inveſtigated the nature of each ſenſe, as it is by the ſenſes only that we have any communication with the external world. By touch we perceive heat and cold, hardneſs and ſoftneſs, figure, ſolidity, motion, and extenſion; by the organ of ſmell, we perceive odours; by the tongue and palate, taſtes; by the ear, ſounds; and by the ſight, colours. We have likewiſe ſeen, that heat and cold, odours, taſtes, ſounds, and colours, are mere ſenſations which have no exiſtence but while they are perceived. On the other hand, hardneſs and ſoftneſs, figure and ſolidity, motion and extenſion, are neither ſenſations, nor like ſenſations; but are conceived to be ſomething external and independent of us, and to be the cauſes of certain ſenſations. Even of heat and cold, odours, taſtes, ſounds, and colours, we know with certainty that there is ſome cauſe independent of our faculties, which may operate in a deſart wilderneſs as well as in a populous city, though, for want of ſentient beings to operate upon, it cannot in the wilderneſs produce the ſame effects as in the city.

139 Of things perceived by the ſenſes the greater part always united.

Of things perceived by the ſenſes we find the greater part always united; for when a man perceives a piece of ſealing-wax, if he makes uſe of all his ſenſes, he perceives at once cold, taſte, colour, hardneſs, roughneſs or ſmoothneſs, figure, ſolidity, motion or reſt, and extenſion. That the powers or qualities, which in this inſtance produce the ſenſations of heat or cold, taſte, odour, and colour, are ſo united to the hardneſs, figure, ſolidity, and extenſion of the wax, as that they cannot exiſt alone, is evident; becauſe it is impoſſible to remove any one of theſe things, or to conceive it removed, without removing with it all the reſt.

(c) Should it be aſked what number we call competent, we beg leave to ſay, that it will be greater or leſs according to circumſtances. In caſes where they are not liable to the deceptions of ſenſe, two men of integrity and intelligence deſerve equal credit with two thouſand; but where there is particular occaſion for good organs, whether of ſight, hearing, or touch, the greater the number the greater is our ſecurity. To this muſt be added, that as one man is influenced by that which to another would be no motive, a great number of witneſſes concurring in the ſame teſtimony is always an additional ſecurity that they are not under the influence of any latent bias.

reſt. What then is the bond of this union? Do theſe things neceſſarily accompany one another, ſo as that one of them cannot exiſt without bringing all the reſt along with it? No; there is no neceſſary connection among them: for by the operation of fire the wax may be rendered liquid, when the *hardneſs* and *cold* are gone, tho' every thing elſe remains the ſame, or nearly the ſame, as it was before. By a ſtill further operation of fire the appearance may be entirely changed; and that which was formerly a piece of hard red wax, may be reduced to ſmoke and aſhes, in which there is neither hardneſs, colour, odour, nor figure; at leaſt there is not in the ſmoke and aſhes *ſuch* hardneſs, colour, odour, or figure, as was in the wax. The ſolidity and extenſion, however, remain; for we perceive aſhes and ſmoke to be extended and ſolid as much as wax or an adamant; nor is it poſſible to do any thing with the wax, or with any other ſenſible object, which ſhall deprive it of extenſion or ſolidity.

10 Thus, then, extenſion and ſolidity may exiſt and be perceived when ſeparated from hardneſs, colour, and odour; but none of theſe can exiſt, or be conceived to exiſt, independent of extenſion and ſolidity. Hardneſs, colour, odour, taſte, and figure, or the things which ſuggeſt theſe notions to us, have with great propriety been termed accidents or qualities; becauſe they cannot exiſt or be conceived to exiſt by themſelves, but require for their ſupport one common ſubject. Extenſion and ſolidity can exiſt independent of them, but they cannot exiſt independent of ſolidity and extenſion.

11 Is then ſolidity the baſis of theſe qualities, ſo that they neceſſarily reſult from it? No; there are many things ſolid and extended which are neither hard, nor coloured, nor odorous, nor ſapid; which could not be if theſe qualities were the neceſſary effect of ſolidity. Beſides, all mankind conceive of ſolidity and extenſion as qualities of ſomething elſe; for we never ſay that ſolidity is extended or coloured, or hard or odorous, but that ſomething ſolid has theſe qualities: whence it is evident that we conſider ſolidity as a quality itſelf. In what then does ſolidity and all the other ſenſible qualities inhere, ſince they cannot exiſt ſeparately, and do not ſupport each other? This is a queſtion which modern philoſophers pretend not to anſwer: but ſome of the ancients were not ſo modeſt. Ariſtotle and his followers reſolved every bodily ſubſtance into *matter* and *form*, making matter the baſis or *ſubſtratum*, and under form comprehending all ſenſible qualities.

As attempts have been lately made to revive this philoſophy, it may not be improper to give a ſhort view of the doctrine of *matter* and *form*, if it were only to diſcover whether the ſpeculations of Ariſtotle and his adherents on this ſubject deſerve to be preferred to thoſe of Newton and Locke.

The moſt perſpicuous, and by far the moſt elegant writer among the moderns who has adopted the ancient philoſophy, is Mr Harris; and leſt we ſhould be accuſed by others of doing injuſtice to a ſubject above the reach of ordinary comprehenſion, we ſhall tranſcribe ſo much of what he has ſaid of *matter* and *form* in his philoſophical arrangements as ſeems neceſſary to make our readers underſtand his meaning as far as it is intelligible.

Of the Compoſition of Bodies.

142 The Peripatetic doctrine concerning matter;

"Matter (ſays this writer) is that elementary conſtituent in compoſite ſubſtances which appertains in *common* to them all, without diſtinguiſhing them from one another. Every thing generated or made, whether by nature or art, is generated or made out of ſomething elſe; and this ſomething elſe is called its ſubject or matter. Such is iron to the ſaw; ſuch is timber to the boat. Now this *ſubject* or *matter* of a thing being *neceſſarily previous* to that thing's exiſtence, is *neceſſarily different* from it, and *not the ſame*. Thus iron, as iron, is not a ſaw; and timber, as timber, is not a boat. Hence, then, one character of every *ſubject* or *matter*, that is, the character of *negation* or *privation*. [He means *negation* or privation of what is to be made out of it.]

143 Which is deſcribed as deſtitute of every attribute or quality,

"Again, though the *ſubject* or *matter* of a thing be not that thing, *yet*, were it incapable of becoming ſo, it could not be called its ſubject or matter. Thus iron is the *ſubject* or *matter* of a ſaw; becauſe, though *not* a ſaw, it may ſtill *become* a ſaw. On the contrary, timber *is not* the ſubject or matter of a ſaw; becauſe it not only (as timber) is no ſaw, but can never be made one from its very nature and properties. Hence, then, beſides *privation*, another character of every *ſubject* or *matter*, and that is the character of *aptitude* or *capacity*. [He means aptitude or capacity to be that which is made out of it.]

"Again, when one thing is the *ſubject* or *matter* of *many* things, it implies a *privation* of them *all*, and a *capacity* to them *all*. Thus iron being the ſubject or matter of the ſaw, the axe, and the chiſſel, implies *privation* and *capacity* with reſpect to *all three*. Again, we can change a ſaw into a chiſſel, but not into a boat; we can change a boat into a box, but not into a ſaw. The reaſon is, there can be no change or mutation of one thing into another where the two changing beings do not participate the ſame matter (D). But even here, were the boat to moulder and turn to earth, and that earth by natural proceſs to metalliſe and become iron; through ſuch progreſſion as this we might ſuppoſe even the boat to become a ſaw. Hence therefore it is, that *all change* is by immediate or mediate participation of the *ſame matter*. Having advanced thus far, we muſt be careful to remember, firſt, that every *ſubject* or *matter* implies, as ſuch, *privation* and *capacity*; and next, that *all change* or *mutation* of beings into one another is *by means of their participating the ſame common matter*. This we have choſen to illuſtrate from works of art, as falling more eaſily under human cogniſance and obſervation. It is, however, no leſs certain as to the productions of nature, though the ſuperior ſubtlety in theſe renders examples more difficult. The queſtion then is, whether in the world which we inhabit, it be not admitted from experience, as well as from the confeſſion of all philoſophers, that ſubſtances

(D) In a note he ſays: This reaſoning has reference to what the ancients called υλη προσεχης, *the immediate matter*, in oppoſition to υλη πρωτη, *the remote* or *primary matter*.

Of the Compoſition of Bodies.

ſubſtances of every kind (E), whether natural or artificial, either immediately or mediately, paſs into one another; and whether, in that caſe, there muſt not be ſome one *primary matter* common to *all things*. I ſay ſome *one primary matter*, and that common to *all things*, ſince without ſome *ſuch* matter, *ſuch mutation* would be wholly impoſſible. But if there be ſome *one primary matter*, and that *common to all things*, this *matter* muſt imply, not (as particular and ſubordinate matters do) a *particular* privation and a *particular* capacity, but, on the contrary, *univerſal* privation and *univerſal* capacity. If the notion of ſuch a being appear ſtrange and incomprehenſible, we may farther prove the *neceſſity* of its exiſtence from the following conſiderations: Either there is no ſuch general change as here ſpoken of; which is contrary to fact, and would deſtroy the ſympathy and congeniality of things: Or, if there be, there muſt be a matter of the character *here* eſtabliſhed; becauſe without it (as we have ſaid) ſuch change would be *impoſſible*. Add to this, however hard *univerſal* privation may appear, yet had the *primary matter*, in its proper nature, any one particular attribute, ſo as to prevent its *privation* from being unlimited and univerſal, ſuch *attribute would run through all things*, and be conſpicuous in all. If it were white, all things would be white; if circular, they would be circular; and ſo as to other attributes; which is contrary to fact. Add to this, that the *oppoſite* to ſuch attribute could *never* have exiſtence, unleſs it were poſſible for the ſame thing to be at *once* and in the ſame inſtance both white and black, circular and rectilineal, &c. ſince this inſeparable attribute would neceſſarily be *every where*; becauſe the *matter*, which implies it, is itſelf *every where*, at leaſt may be found in all things that are generated and periſhable.

144 And to be apprehended only by abſtraction and analogy.

"Here then we have an idea (ſuch as it is) of that ſingular being ὕλη πρώτη, the *primary matter*; a being which thoſe philoſophers who are immerged in ſenſible objects know not well how to admit, though they cannot well do without it; a being which flies the perception of every *ſenſe*, and which is at beſt, even to the *intellect*, but a negative object, no otherwiſe *comprehenſible* than either by *analogy* or *abſtraction*. We gain a glimpſe of it by *abſtraction*, when we ſay that the *firſt matter* is *not* the lineaments and complexion which make the beautiful face; *nor yet* the *fleſh* and *blood* which make thoſe lineaments and that complexion; *nor yet* the liquid and ſolid aliments which make that fleſh and blood; *nor yet* the ſimple bodies of earth and water which make thoſe various aliments; but *ſomething*, which being *below* all theſe, and ſupporting them all, is yet *different* from them all, and eſſential to their exiſtence. We obtain a ſight of it by *analogy*, when we ſay, that as is the braſs to the ſtatue, the marble to the pillar, the timber to the ſhip, or any one *ſecondary matter* to any one *peculiar form*; ſo is the *firſt* and *original matter* to all *forms in general*."

Such is the doctrine of the Peripatetics concerning the *primary matter*, or the baſis of bodily ſubſtances. We forbear to make any remarks upon it till we have ſeen what they ſay of *form*, the other eſſential part of every body; for what is meant by *matter* and *form* will be moſt completely ſeen when they are viewed together.

145 The peripatetic doctrine concerning form.

"FORM (ſays the ſame elegant writer) *is that elementary conſtituent in every compoſite ſubſtance, by which it is* DISTINGUISHED, *and* CHARACTERISED, *and known, from every other*. But to be more explicit: The *firſt* and moſt ſimple of all *extenſions* is a *line*: this, when it exiſts, united with a *ſecond* extenſion, makes a *ſuperficies*; and theſe two, exiſting together with a *third*, make a *ſolid*. Now this *laſt* and *complete* EXTENSION we call the *firſt* and *ſimpleſt* FORM; and when this *firſt* and *ſimpleſt form* accedes to the *firſt* and *ſimpleſt matter*, the union of the two produces *body*; which is for that reaſon defined to be *matter triply extended*. And thus we behold the riſe of *pure* and original *body* (F). It muſt be remembered, however, that *body*, under this character, is ſomething *indefinite and vague*, and ſcarcely to be made an *object* of *ſcientific contemplation*. It is neceſſary to this end that its extenſion ſhould be *bounded*; for as yet we have treated it without ſuch regard. Now, the *bound* or *limit* of *ſimple body* is *figure*; and thus it is that *figure*, with regard to *body*, becomes the next *form* after *extenſion*.

146 The three original forms which, [...]ed to matter, constitute body physical.

"But though the *boundary* of body by *figure* is one ſtep towards rendering it *definite* and *knowable*, yet is not this ſufficient for the purpoſes of nature. It is neceſſary *here*, that not only its *external* ſhould be duly bounded, but that a ſuitable regard ſhould likewiſe be had to its *internal*. This *internal adjuſtment*, diſpoſition, or *arrangement* (denominate it as you pleaſe), is called ORGANIZATION, and may be conſidered as the *third* form which appertains to body. By its acceſſion we behold the riſe of BODY PHYSICAL or NATURAL; for every ſuch body is ſome way or other *organized*. And thus may we affirm, that theſe *three*, that is to ſay, *extenſion*, *figure*, and *organization*, are the *three original forms* to *body phyſical* or *natural*; *figure* having reſpect to its *external*, *organization* to its *internal*, and *extenſion* being common both to one and to the other. It is more than probable, that from the variation in theſe *univerſal* and (as I may ſay) *primary forms*, ariſe moſt of thoſe *ſecondary* forms uſually called *qualities ſenſible*, becauſe they are the proper objects of our ſeveral ſenſations. Such are roughneſs and ſmoothneſs, hardneſs and ſoftneſs; the tribes of colours, ſavours, odours; not to mention thoſe powers of character more *ſubtle*, the powers electric, magnetic (G), medicinal, &c.

(E) He muſt mean only bodily ſubſtances; for it is not admitted by ſuch philoſophers as make a diſtinction between mind and body, that the one ever paſſes into the other.

(F) "Original body (he ſays), when we look *downward*, has reference to the *primary matter*, its ſubſtratum: when we look *upwards*, it becomes itſelf a *matter* to *other things*; to the *elements*, as commonly called, air, earth, water, &c. and in conſequence to all the variety of *natural productions*."

(G) That it is from the *extenſion*, *figure*, and *organization* of bodies, that their *medicinal* powers ariſe, ſeems to be undeniable; for medicines operate by contact: but it is not ſo clear that the ſame *forms*, to uſe the author's language, are the ſource of *magnetical* powers. If the magnet be ſurrounded with an atmoſphere extending to a certain diſtance, ſuch may be the caſe; but if not, the author's conjecture muſt be ill founded. See MAGNETISM.

Of the Composition of Bodies.

"Here therefore we may anſwer the queſtion, how *natural* bodies are *diſtinguiſhed*. Not a ſingle one among them conſiſts of *materia's in chaos*, but of materials wrought up after the moſt exquiſite manner, and that conſpicuous in their *organiſation*, or in their *figure*, or in *both*.—As therefore every *natural body* is diſtinguiſhed by the *differences* juſt deſcribed, and as theſe *differences* have nothing to do with the *original matter*, which being every where ſimilar can afford no diſtinction at all; may we not here infer the expediency of ESSENTIAL FORMS, that every *natural ſubſtance* may be eſſentially *characteriſed?* Theſe *forms*, though they differ from matter, can yet *never ſubſiſt without it;* but *united* with it, they help to produce every *compoſite* being, that is to ſay, in other words, every *natural ſubſtance*, in the viſible world. It muſt be remembered, however, that it is the FORM in this union which is the *ſource of all diſtinction*. It is by *this* that the *ox* is diſtinguiſhed from the *horſe*, not by that graſs on which they ſubſiſt, the *common matter* to both. To which alſo may be added, that as figures and ſenſible qualities are *the only objects of our ſenſations*, and theſe are all *parts* of *natural form;* ſo therefore (contrary to the ſentiment of the vulgar, who dream of nothing but of matter) *it is form, which is in truth the whole that we either hear, ſee, or feel;* nor is *mere matter* any thing better than an *obſcure imperfect being*, knowable only to the *reaſoning faculty* by the two methods already explained, I mean that of *analogy* and that of *abſtraction*. Here therefore we conclude with reſpect to *ſenſible forms*, that is to ſay, *forms immerged in matter* and *ever inſeparable* from it. In *theſe* and *matter* we place the ELEMENTS OF NATURAL SUBSTANCE."

If this extract appear long, let it be remembered that it contains the fulleſt and moſt perſpicuous detail which is to be found in the Engliſh language, of a doctrine of which the author of *Ancient Metaphyſics* ſuppoſes Locke to have been ignorant; and for which ignorance he affects to treat the Engliſh philoſopher with ſupercilious contempt. Had Locke really been ignorant of the ancient doctrine of *matter* and *form*, it is probable that moſt people will be of opinion that the *contempt* expreſſed by his cenſurer might have been ſpared; but if it ſhould appear, that, as far as this theory is intelligible, it differs not, except in words, from the doctrine laid down in the *Eſſay concerning human underſtanding*, what ſhall we think of that zeal for ancient phraſes, which had influence ſufficient to make one reſpectable philoſopher pour contempt upon another who was an ornament to his country?

147
Matter cannot be deſtitute of ſolidity.

What Mr Harris has ſaid of *matter* and *form* reſpecting works of art, is ſufficiently intelligible, and extremely juſt. Nor ſhould we object to the account which he gives of the origin of natural body, if he had not diveſted his firſt matter of every power and every quality, ſolidity and extenſion not excepted. But though we can ſuppoſe body diveſted of any one particular figure and of every ſenſible quality, ſuch as colour, odour, taſtes, &c. and the *ſubſtratum* or *baſis* or *matter* of it ſtill to remain, yet it ſeems impoſſible to conceive it diveſted of *ſolidity* without ſuppoſing it totally annihilated. Nay, if we have any juſt notion at all of ſolidity, it is evidently inſeparable from the ſubſtratum of body, whatever that ſubſtratum be; and indeed, though Mr Harris diveſts his firſt matter of every attribute, the argument by which he proves the neceſſary exiſtence of ſuch a being does not require its privation to be ſo univerſal. "Had the *primary matter* (ſays he), in its proper nature, any one particular attribute, ſo as to prevent its privation from being unlimited and univerſal, *ſuch attribute would run through all things* and be conſpicuous in all." This indeed is obvious and undeniable: but *ſolidity* and *extenſion* do in *fact* run through *all things* into which the *ſubſtratum* or *matter* of body is ever formed or ever can be conceived to be formed; and therefore there is no neceſſity for ſuppoſing the firſt matter diveſted of theſe attributes (H).

Mr Harris ſays, that both Timæus and Plato drop ex-

(H) Nor does it appear that it was diveſted of them by all the ancient philoſophers. We learn from Cudworth, that "the atomical phyſiology, the moſt ancient perhaps of any, teaches that body is nothing elſe but μεγεθος αντιτυπον, *extended bulk;* and that nothing is to be attributed to it but what is included in the nature and idea of it, viz. greater or leſs magnitude with diviſibility into parts, figure, and poſition, together with motion or reſt, but ſo as that no part of body can ever move itſelf. And conſequently, this philoſophy ſuppoſes, that there is no need of any thing elſe beſides the ſimple elements of magnitude, figure, ſite, and motion (which are all clearly intelligible, or different modes of extended ſubſtance), to ſolve the corporeal phenomena by; and therefore not of any ſubſtantial *forms* diſtinct from the matter; nor of any other qualities really exiſting in the bodies without, beſides the reſults or aggregates of thoſe ſimple elements, and the diſpoſition of the inſenſible parts of bodies in reſpect of figure, ſite, and motion; nor of any intentional *ſpecies* or *ſhows* propagated from the objects to our ſenſes; nor, laſtly, of any other kind of motion or action really diſtinct from local motion (ſuch as generation and alteration), they being neither intelligible as modes of extended ſubſtance, nor any way neceſſary: Foraſmuch as the forms and qualities of bodies may well be conceived to be nothing but the reſult of thoſe ſimple elements of magnitude, figure, ſite, and motion, variouſly compounded together; in the ſame manner as ſyllables and words in great variety reſult from the different combinations and conjunctions of a few letters, or the ſimple elements of ſpeech; and the corporeal part of ſenſation, and particularly that of viſion, may be ſolved only by local motion of bodies; that is, either by corporeal effluvia (called *ſimulacra*, *membranæ*, and *exuviæ*), ſtreaming continually from the ſurface of the objects, or rather, as the later and more refined atomiſts conceived, by preſſure made from the object to the eye, by means of light in the medium. So that ως δια βακτηριας του τασιν, αερος το βλεπομενον αναγγελλεται, the ſenſe taking cognizance of the object by the ſubtile interpoſed medium, that is tenſe and ſtretched (thruſting every way from it upon the optic nerves), doth by that, as it were by a ſtaff, touch it. Again, generation and corruption may be ſufficiently explained by concretion and ſecretion, or local motion, without ſubſtantial forms and qualities expreſſions as if they conſidered *matter* to be *place;* but place, as will be ſeen afterwards, can be the baſis of nothing. He likewiſe quotes a paſſage from Ammonius on the predicaments, in which it is ſaid "that there never was in *actuality* either matter without body, or body without quality;" and we appeal to our readers if it be not abſolutely impoſſible to contemplate ſuch a being even in *idea*. To the queſtion, Whether the firſt matter has a ſeparate exiſtence by itſelf, diſtinct from all the qualities of body, the author of *Ancient Metaphyſics* anſwers thus:—"We have no idea of it exiſting ſeparately, becauſe we find no ſuch thing in nature, from which we draw all our ideas; but whether there may not be ſuch a thing exiſting in the regions of infinite ſpace, as *matter* without *form* and *dimenſions*, is what I think no man can take upon him to decide." But with all ſubmiſſion, if a man cannot decide this queſtion with the utmoſt certainty, his three ponderous volumes are nothing better than uſeleſs paper: for the ſubject of them is things *exiſting;* and concerning exiſtence we know nothing with greater certainty, than that a being of which nothing poſitive can be affirmed, cannot poſſibly have any exiſtence.

148 Some firſt matter common to all bodies.

That, in the world which we inhabit, bodily ſubſtances of every kind, whether natural or artificial, either immediately or mediately paſs into one another, is a truth which cannot be denied; and therefore it follows, that there muſt be ſome one primary matter common to all things. In modern philoſophy this primary matter is conſidered as ſolid, and as the *ſubſtratum* of all bodies; and all thoſe things which, in the language of Mr Harris, are comprehended under the appellation of *form*, are called *qualities:* ſo that on this ſubject the ancient and modern philoſophy differ in nothing but in the latter uſing the word *qualities* inſtead of the word *form;* and defining the firſt matter to be a "*ſolid* ſubſtance every where the ſame," whilſt the ancient philoſophy conſiders it as void of ſolidity.

149 Of the nature of which men are equally ignorant.

Of the nature of this firſt matter all philoſophers are equally ignorant: for, as Mr Harris ſays, it is in truth *form;* or, as modern philoſophers would ſay, they are in truth *qualities*, which are the whole that we either hear, or ſee, or feel, or of which we have either idea or conception. Mr Locke ſays expreſsly, "That if any one will examine himſelf concerning his notion of pure ſubſtance in general, he will find that he has no other idea of it at all, but only a ſuppoſition of he knows not what ſupport of ſuch qualities as are capable of producing ſimple ideas in us."

150 How we know that the things immediately perceived are qualities.

But how, it has been aſked, do we know that the things which we perceive are qualities, and cannot exiſt without a ſubject? We anſwer, Becauſe every one of them, except ſolidity, may be changed or deſtroyed, and the ſubject in which they inhere ſtill remain. Thus, though wax may be melted or burnt, and be no longer a hard red ſubſtance of ſuch a figure and ſuch a ſmell, the matter which ſupported the hardneſs, figure, colour, and ſmell, ſtill remains; for melted wax or aſhes is as much a ſolid ſubſtance as is that which may be uſed for the ſealing of letters, &c.

It has been ſaid that ſolidity (1) is the *ſubſtratum* of

---

lities. And laſtly, thoſe ſenſible ideas of light and colours, heat and cold, ſweet and bitter, as they are diſtinct things from the figure, ſite, and motion of the inſenſible parts of bodies, ſeem plainly to be nothing elſe but our own fancies, paſſions, and ſenſations, however they be vulgarly miſtaken for qualities in the bodies without us." *Cudworth's Intellectual Syſtem*, Book i. chap. 1.

This, as will be ſeen by and by, is the philoſophy of Newton, Locke, and all their followers: and that it is the genuine philoſophy of the ancient atomiſts, we may ſafely take the word of the author whom we have quoted; for no modern has been more converſant with their writings, more completely maſter of their language, or has given their ſenſe with greater accuracy. Thoſe authors, therefore, who in their zeal for ancient metaphyſics would explode the phyſiology of Newton and Locke, and ſubſtitute in its place the Ariſtotelian doctrine of *matter* and *form*, belie their own pretences; for the theory which they would baniſh is more ancient than that which they wiſh to introduce; and we appeal to our readers if it be not more intelligible.

(1) The philoſophers of moſt eminence who have maintained this opinion are, *Dr Watts;* the author of the *Procedure, Extent, and Limits, of the Human Underſtanding*; and *Dr Law* late biſhop of Carliſle, who in a note upon *King's origin of evil* gives the opinion of the triumvirate in the following words:—"We find by experience, that a thing will always exhibit the ſame appearances in ſome reſpects, though it admit of changes in others: or, in Mr Locke's language, that certain numbers of ſimple ideas go conſtantly together, whereas ſome others do not. The former of theſe we call the *ſubſtance*, thing, or being, itſelf; the latter are termed its modes or *accidents*. Thus the ſubſtance of *body*, as far as we know of it, conſiſts in ſolidity and extenſion; which being neceſſarily finite, it alſo becomes capable of diviſion, figure, and motion. Theſe are its original inſeparable qualities, which conſtitute the thing, and ſeem not to depend on any thing elſe as a *ſubject*. But a particular figure, motion, &c. are only accidents or modes of its exiſtence; which do not neceſſarily attend it, though they themſelves cannot be ſuppoſed to exiſt without it. The ſubſtance of *ſpirit* conſiſts in the powers of thinking and acting, which likewiſe admit of various modifications. This ſeems to be all that we can learn concerning the nature of things from obſervation and experience. To inquire into the *manner* how theſe, which we call *properties*, exiſt together, or to attempt to explain the *cauſe*, ground, or reaſon, of their union, is in vain. To aſſign the word *ſubſtance* for a repreſentation of it, is ſaying nothing: it is ſetting a mere word for what we have neither any idea of nor occaſion for. Indeed if we conſider theſe primary qualities as needing ſomething to inhere in, we are obliged to ſeek for ſomething to ſupport them: and by the ſame way of reaſoning, we may ſeek for ſomething elſe to ſupport that other ſomething, and ſo on; and at laſt ſhall find no other ſupport for the whole but the cauſe which produced it." "Dr Watts (continues the biſhop) is of opinion, that it is introducing a needleſs *ſcholaſtic* notion into the real nature of things, and then fancying it to have a real exiſtence;" (*Logic*, p. 14.) The author of the *Procedure, Extent*, &c. affirms, "That as far as we directly know the eſſential properties of any ſubſtance, ſo far we have a *direct* knowledge of the ſubſtance

[Of the Compoſition of Bodies.] of body; and men have been probably led into this notion from a conviction that ſuch *ſubſtratum*, whatever it be, is and muſt be ſolid; but that ſolidity is only a quality inſeparable from the firſt matter, and not that matter itſelf, muſt be evident from this conſideration, that ſolidity is the ſame in all bodies, and incapable of producing by itſelf any other effect than that of excluding from the place occupied by it every other ſolid ſubſtance. It could not of itſelf be the *ſubſtratum* of colour, taſte, or ſmell, otherwiſe all bodies would be coloured, ſapid, and odorous; and as, according to all our notions of it, it is incapable of any change, it could not by itſelf be ſo modified as to excite in us theſe ſenſations.

151 [Our] notion [of m]atter [relat]ive and [obſc]ure.

The things then immediately perceived by us, or of which we have any adequate idea or conception, are only qualities which muſt belong to a ſubject; and all that we know about this ſubject is, that it is that to which ſuch qualities belong. From this it is evident, that our notion of matter, as diſtinguiſhed from its qualities, is a relative § and obſcure notion, and muſt remain obſcure till men have other faculties. In this the philoſopher ſeems to have no advantage above the vulgar: for as they perceive colour, and figure, and motion, by their ſenſes, as well as he does; and as both are equally certain that there is a ſubject of thoſe qualities; ſo the notions which both have of this ſubject are equally obſcure; or, to ſpeak more properly, they have no *poſitive* notion of it all. When a philoſopher calls it the *firſt matter*, a *ſubſtratum* or a *ſubject* of *inheſion*, thoſe learned words convey no meaning but what every man underſtands and expreſſes, by ſaying in common language, that it is a thing extended, ſolid, and moveable.

[§ Reid's Eſſays on Intellectual Powers of Man.]

They are therefore *qualities*, or in the language of ancient philoſophy, *forms* alone, about which, in corporeal ſubſtance, we can reaſon with preciſion and certainty; and it is ſufficient for all the purpoſes of life that we have of them an adequate knowledge. For as the *firſt matter* or original *ſubſtratum* of all bodies ſeems to be the ſame, though we know not what it is; and as one body is diſtinguiſhed from another only by its *qualities* or *powers*: a knowledge of the nature of theſe is all that can be neceſſary to direct our conduct with reſpect to the various objects with which we are ſurrounded.

152 [Qua]lities, [prim]ary.

Qualities thus conſidered in bodies, are, firſt, ſuch as are utterly inſeparable from the body, in what ſtate ſoever it is; ſuch as in all the changes and alterations which it ſuffers, and under all the force which can be employed upon it, it conſtantly keeps. Thus, in the inſtance already given, a ſtick of ſealing-wax may, by the operation of fire, be rendered liquid or reduced to ſmoke and aſhes; and when it has undergone theſe changes, it has loſt many of the ſenſible qualities which it had when a long round ſubſtance fit for the purpoſe of ſealing letters; but other qualities which were then perceivable in it ſtill remain: for not only liquid wax, but every particle of ſmoke and aſhes, is ſolid and extended, as well as the hardeſt or largeſt body; and every ſuch particle has likewiſe ſome figure, and is capable of motion or reſt. Again, if a grain of wheat or any other corporeal ſubſtance be divided into two parts, and each part be again divided without end, ſtill the ſmalleſt particle of it will be ſolid, extended, of ſome figure, and capable of further diviſion. *Solidity*, *extenſion*, *diviſibility*, and *motion* or *reſt*, are therefore qualities inſeparable from *body*, and have on that account been with great propriety called its *original* or *primary qualities*.

153 Secondary.

There are other qualities, which in truth are nothing in the bodies themſelves, but powers ariſing from the magnitude, figure, texture, and motion, of their inſenſible parts, to produce in us various ſenſations; ſuch are *colours*, *ſounds*, *taſtes*, and *odours*. Theſe have been denominated *ſecondary qualities*: and to them may be added a third ſort, which are univerſally allowed to be barely *powers*, though they are in fact as much real qualities in the ſubject as thoſe we have juſt mentioned. Thus the power in fire to produce by its primary qualities a new colour or conſiſtency in wax or clay, is as much a quality in the fire as the power which it has to produce in us a new ſenſation of warmth or burning. That *colours*, *taſtes*, *ſounds*, and *odours*, as they are perceived by us, are mere ſenſations, has been already proved: and that the powers in the bodies which produce theſe ſenſations are not, like *ſolidity* and *extenſion*, inſeparable from the body to which they may belong, is evident; becauſe a piece of *red* wax may be reduced to *black* aſhes; and becauſe by pounding an almond we may change its clear white colour into a dirty hue, and its pleaſant taſte into one that is oily and rancid; and a ſingle rent through the body of a bell deſtroys its ſound.

The primary qualities of body have a real exiſtence, independent of us and of every other creature. Thus the particular *bulk*, *number*, *figure*, and *motion*, of the *parts* of *fire* or *ſnow* are *really in the fire or ſnow*, whether any man's ſenſes perceive them or not; and therefore theſe may be called *real qualities*, becauſe they really exiſt in the bodies: But *light*, *heat*, *whiteneſs*, or *cold* (as they are perceived by us), are no more *really in fire or ſnow*, than ſickneſs is in *tartar* or pain in a *ſword*. Take away the ſenſations of them: let not the eyes ſee light or colours, nor the ears hear ſounds; let not the palate taſte nor the noſe ſmell; and all colours, taſtes, odours, and ſounds, as they are ſuch particular ſenſations, vaniſh and ceaſe, and are reduced to their cauſes, *i. e.* to the bulk, figure, and motion of the parts of the body.

154 Bodily qualities are of three ſorts.

The qualities then that are in bodies, rightly conſidered, are of three ſorts. 1. The *bulk*, *figure*, *number*, *ſituation*,

ſubſtance *itſelf*: and if we had a direct knowledge of *all* the eſſential properties of any ſubſtance, we ſhould have an *adequate* knowledge of that ſubſtance; for ſurely, if there be any meaning in words, the knowing any thing of the eſſential properties of a thing is knowing *ſo much* of its very ſubſtance."

That the ſubſtance of body conſiſts in *ſolidity* and *extenſion*, and nothing more; and that theſe depend not upon any thing elſe as a *ſubject*; cannot be true: for *ſolidity*, in our conception, is nothing but *impenetrability*; but whoever uſes the word *impenetrability*, certainly means that there is *ſomething* impenetrable. That there is ſome real thing or being different from ſolidity and extenſion, which impreſſes us with the notion that it is ſolid and extended, is ſelf-evident to all mankind: if it be not matter, theſe conceptions muſt be communicated

Of the Constitution of Bodies.

situation, and *motion* or *rest*, of their *solid* parts. Of these, as they are in themselves, we have clear and distinct notions. We know that they are in the body whether we perceive them or not, and we call them *primary* or *essential qualities*. 2. The power that is in any body, by reason of its internal texture and insensible primary qualities, to operate upon our senses in a peculiar manner, producing in us the different sensations of *colours*, *sounds*, *tastes*, or *smells*, &c. These we have called *secondary qualities*, but they are often termed *sensible qualities*. 3. The *power* that is in any body, by reason of the particular constitution of its primary qualities, to make such a *change* in the *bulk*, *figure*, *texture*, and *motion* of *another body*, as to make it operate on our senses differently from what it did before. Thus, the sun has a power to make wax white, and fire to make lead fluid. These are universally called *powers*; but we have no such notions of them as we have of the *primary qualities* of bodies. We know that they exist, but we know not what they are. It has indeed been discovered, that the sensation of smell is occasioned by the effluvia of bodies †; that of sound, by their vibration. The disposition of bodies to reflect a particular kind of light occasions the sensation of colour; and the operation of the minute parts of bodies upon the nerves of the tongue and palate is the cause of tastes. Very curious discoveries have been made of the nature of heat and its manner of operation, and an ample field still remains. We are likewise intuitively certain, that body can operate upon body only by impulse; but how certain impulses upon certain organs should produce sensations in us to which there is nothing similar in the impelling body, is equally unknown to the clown and the philosopher.

155
The doctrine of the ancient atomists respecting qualities.

Such is the distinction which in modern philosophy is made between primary and secondary qualities; but it is a distinction which was likewise well known to that sect of ancient philosophers who were denominated *atomists*. At the head of these were Thales and Pythagoras (K); and we may infer from Aristotle, that the sect comprehended almost all the physiologists who taught before himself and Plato: for he says*, Δημοκριτος και οι πλειστοι των φυσιολογων ατοπωτατον τι ποιουσι, παντα γαρ τα αισθητα απτα ποιουσι, και εις σχηματα αναγουσι τους χυμους: "Democritus, and *most* of the *physiologists*, fall into a great absurdity; for they make all sense to be touch, and resolve sensible qualities into the figures of insensible atoms." And he adds, that "the former physiologists (without exception) said not well, that there is no black and white without the sight, nor bitter and sweet without the taste." He elsewhere § tells us, that those philosophers explained generation and alteration without forms and qualities, by figures and local motion." Δημοκριτος και Λευκιππος ποιησαντες τα σχηματα την αλλοιωσιν και την γενεσιν εκ τουτων ποιουσι, διακρισει μεν και συγκρισει γενεσιν και φθοραν, ταξει δε και θεσει αλλοιωσιν. "Democritus and Leucippus having made figures (or variously figured atoms) the first principles, make generation and alteration out of these; namely, generation together with corruption from the concretion and secretion of them, but alteration from the change of their order and position." By the atomic physiologists the name of *quality* was generally applied only to those things which we have called *secondary qualities*. The *primary* being considered as *essential* to *matter*, were seldom, if ever, called *qualities*. That the atoms, which they held to be the first principles of bodies, were figured, solid, extended, and moveable, is apparent, not only from the short view of their system which we have given from Cudworth, but likewise from the passages which we have just quoted from Aristotle: but the question debated between them and their antagonists was, whether those atoms had *smell*, *taste*, and *colour*; or, as it was commonly expressed, whether they had *qualities*? Democritus, Leucippus, and the other atomists, we see, maintained that they had not; and the following account of the doctrine of Protagoras, another philosopher of that school, shows, that on this subject at least the ancient advocates for the atomic system reasoned as justly as any of the moderns, and much more justly than the Peripatetics and Platonists by whom they were opposed. Plato having in his Theætetus first said in general that the philosophy of Protagoras made all things to consist of a commixture of atoms and local motion, represents his doctrine concerning colours in particular, after this manner: "First, as to that which belongs to the sight, you must conceive what is called a white or black colour, not to be any thing absolutely existing either without your eyes or within your eyes; but black and white, and every other colour, is caused by different motions made upon the eye, from objects differently modified; so that it is nothing either in the agent or patient absolutely,

* *Lib. de Sensu et Sensibili*, cap. 4.

§ *De Generatione et Corruptione*, lib. i. cap.

ated to us by the immediate agency of the Deity, which seems to have been the real opinion of the Bishop of Carlisle. But this differs not from the theory of Berkeley, which we shall consider by and by.

(K) This is denied by Bishop Warburton, who thinks nothing better settled than that Democritus and Leucippus were the authors of the atomic physiology. We highly respect the learning and ingenuity displayed in the Divine Legation of Moses; but on this point we are convinced that its author is mistaken. Strabo expressly affirms, that Moschus the Phenician was the author of the atomic physiology; and Cudworth has proved, by arguments which to us are perfectly satisfactory, that Thales and Pythagoras were both atomists, and that they derived the doctrine from Phœnicia or Egypt. They did not, indeed, speculate in physics, but delivered their doctrines as they had received them from tradition, and they referred all motion to mind as its cause. Leucippus and Democritus, we believe, were the first speculative atomists: but though they refined upon, and perhaps improved, the mere mechanical part of the physiology of their masters, they unhappily dropt the better part of it; and, banishing mind from their system of the universe, they became materialists and atheists. With the sober and pious part of philosophers this brought the atomic theory into disrepute, and Plato and Aristotle, who were theists, when they opposed that theory, always pointed their arguments against Leucippus and Democritus, which is probably what led the learned bishop to consider these atheists as the authors of the atomic physiology.

Of the Composition of Bodies.

solutely, but something which arises from between them both (L)." From this passage it is plain that Protagoras thought of colours exactly as Mr Locke thought, that they are not *real qualities* existing in bodies, but merely sensations excited in our minds; and indeed he is presently after represented as having called them τινα ιδια φασματα, *certain fancies* or *appearances in us*. But there is in the Theœtetus another passage, in which a fuller account is given of the atomic philosophy, to this purpose: "The principle upon which all these things depend is this, That the whole universe (M) is motion of atoms and nothing else; which motion is considered two ways, and is accordingly called by two names, *action* and *passion*. From the mutual congress, and, as it were, attrition of these together, are begotten innumerable offsprings, which, though infinite in number, yet may be reduced to two general heads, *sensibles* and *sensations*, which are both generated at the same time. The *sensations* are *seeing*, *hearing*, and the like; and the corresponding *sensibles* are *colours*, *sounds*, &c. Wherefore, when the eye and its proper object meet together, both the αισθητον and the αισθησις, the *sensible idea* of white and black, and the *sensation* of seeing, are generated together, neither of which would have been produced if those two had not met. The like is to be conceived of all other *sensibles*, as hot and cold, &c. None of these are absolute things in themselves, or real qualities in external objects; but they are begotten from the mutual congress of agent and patient, and that by motion. So that neither the agent has any such thing in it before its congress with the patient, nor the patient before its congress with the agent. But the agent and patient meeting together, and begetting *sensation* and *sensibles*, both the object and the sentient are forthwith made to be so and so qualified; as when honey is tasted, the sensation of tasting, and the quality of sweetness, are begotten together, though the sensation be vulgarly attributed to the taster, and the quality of sweetness to the honey." The conclusion of all which is summed up thus, ουδεν ειναι αυτο καθ αυτο, αλλα τινι αει γιγνεσθαι: "Not one of these sensible things is any thing absolutely in the object without, but they are all generated or made relative to the sentient (N)."

The language of ancient philosophy was defective in precision; terms were used vaguely and improperly, so that the meaning of the author is often to be collected only from the context. When Protagoras is here made to say, that when the agent and patient meet together, both the object and the sentient are forthwith made to be so and so *qualified*; as when honey is tasted, the sensation of tasting and the *quality* of sweetness are begotten together; it could not be his meaning, that any real change is made upon the external object merely by our tasting it, but only that the actual sensation and the sensible *idea* of sweetness are produced at once; just as he had said before, that the sensible idea of white or black, and the sensation of seeing, are generated together. If his words be thus interpreted, they express a noble truth; and the whole passage shows, that the ancient Atomic theory differed not from the theory of Des Cartes, Newton, and Locke, being the most rational as well as the earliest system of physics with which we have any acquaintance. By divesting body of *essential forms* distinct from matter and motion, and by giving to the first matter extension and solidity, it renders the corporeal world intelligible; and accounts for those appearances which are called secondary qualities, in a manner perfectly satisfactory. Aristotle indeed opposed the Atomic philosophy, and had influence enough to bring it into disrepute for many ages; but when he insisted that the two constituent principles of body are *matter* and *form*, both independent of all sentient beings, and which may be conceived as existing distinct from each other, he substituted for a simple and sublime theory an absurd and incomprehensible fiction.

Of the Essences of Bodies.

CHAP. II. *Of the* ESSENCES *of* BODIES.

156 The essences of bodies result,

HAVING treated of the substance, qualities, and powers of body, we may seem to have exhausted this part of our subject; but there is still more to be done. Metaphysicians, ancient and modern, have introduced another term into the science, to denote that which distinguishes one species or sort of bodies from all other species or sorts; and this term we shall briefly explain. Gold is apparently different from lead, and from every other species of metal; a horse is apparently different from an ox, and from every other species of animals; and all animals apparently differ from all vegetables, as vegetables differ from metals.

157 According to the Peripatetics and Platonists, from essential forms;

It is only with the *bodies*, not the minds of animals, that we are at present concerned; and we have seen that all bodies are composed of the same matter.—What then is it that makes different bodies exhibit to us such different appearances; or, in other words, how come they to be possessed of such different qualities and powers? It is (say the followers of Plato and Aristotle) from their having different *essential forms*, by which every natural substance is essentially characterised; for of every animal, vegetable, or metal, &c. there is a *form* conceived, as existing before the individuals in which it is incorporated, from which result all the properties of that animal, vegetable, or metal, such as *figure*, *size*, *colour*, and the other qualities

---

(L) Υπολαβε τοινυν ουτωσι κατα τα ομματα πρωτον, ὁ δη καλεις χρωμα λευκον μη ειναι αυτο ἑτερον τι εξω των σων ομματων, μηδ' εν τοις ομμασι, αλλα μελαν τε και λευκον και ὁτιουν αλλο χρωμα εκ της προσβολης των ομματων προς την προσηκουσαν φοραν φανειται γεγενημενον, και ὁ δη ἑκαστον ειναι φαμεν χρωμα, ουτε το προσβαλλον ουτε το προσβαλλομενον αλλα μεταξυ τι ἑκαστῳ ιδιον γεγονος.

(M) Protagoras was a follower of Leucippus and Democritus in every thing, and of course an atheist.—This, however, does not hinder him from having been a correct physiologist with respect to the composition of body; and as such only is he quoted by us. It is, indeed, melancholy to think, that there was hardly a sect of ancient philosophers in which there were not many atheists.

(N) Αρχη δε εξ ἡς και ἁ νυν δη ελεγομεν παντα ηρτηται ἡδε αυτων, ὡς το παν κινησις ην και αλλο παρα τουτο ουδεν, της δε κινησεως δυο ειδη, πληθει μεν απειρον ἑκατερον, δυναμιν δε το μεν ποιειν εχον, το δε πασχειν, &c.——See the *Theætetus*; see also *Cudworth's Intellectual System*, Book I. chap. i.

Of the Essences of Bodies.

ties perceptible by our senses: but this *internal and essential form* itself, from which all other forms result, is not perceptible by our senses, nor even by our understanding directly and immediately, nor otherwise than by the analogy formerly mentioned. These essential forms, we are told, mean something, which, though different from matter, can yet never subsist without it; something which, united with it, helps to produce every *composite* being, that is to say, in other words, every natural substance in the visible world.

158 But these forms have no existence.

This assertion Mr Harris submits with deference to his contemporaries; because (says he) "I speak perhaps of spectres as shocking to some philosophers as those were to Æneas which he met in his way to hell—*Terribiles visu formæ.*" The elegant author's unwillingness to frighten his contemporaries, was a proof of his amiable and benevolent disposition; but he needed not to have suffered from any such apprehension. Those spectres, apparently so dreadful, had long before been laid to rest by the incomparable Cudworth, who has demonstrated, that *essential forms* different from matter and motion, as they have no real existence, had no place in the most ancient philosophy; and that the different appearances or sensible qualities which different bodies exhibit, are the result of the different contexture of their insensible parts. Thus, gold and lead are composed of the same primary matter, but the atoms or minute parts of that matter are in the one substance differently combined from what they are in the other; and this different combination is the sole cause that gold is specifically heavier than lead, more ductile, and of a different colour, &c. For the very same reason, iron is harder than either gold or lead, specifically lighter, and possessed of many other sensible qualities which are not found in either of these substances. One vegetable differs from another externally in size, colour, taste, smell, rapidity of growth, and proportion of parts, &c. but all vegetables are composed of the same matter; and the external difference which prevails among them is the result of a different structure and motion of their insensible parts. The same is to be said of the differences which prevail among the bodies of animals; they all result from internal organization and motion, and from nothing else, whatever be the immediate cause of that motion.

159 The real essences of bodies unknown to us.

This particular internal texture and motion of insensible parts, is that which makes one sort of bodies differ externally from every other sort of bodies; and it is by modern metaphysicians called the *real essence* of bodies. Thus, that internal texture of minute parts, which makes gold of a bright yellow, extremely ductile, specifically heavier than all other metals, and soluble in *aqua regia*, is the real essence of gold; but what that essence is in itself no man can tell, as we perceive only the qualities which result from it. We are, however, certain, that it is different from the real essences of lead and iron, because it produces different effects from those which are produced by these essences; and different effects are never produced in the same circumstances by the same cause.

We have called the internal texture and motion of the insensible parts of bodies their *real essences*, to distinguish them from other *essences* which are only *nominal*, and with which we are perfectly acquainted, because they are the fabrication of our own minds.—Thus, a beautiful bright yellow, a certain specific gravity, extreme ductility, and solubility in *aqua regia*, are the qualities by which we distinguish gold from all other metals. Of these qualities we frame a sort of general conception, which we call the *essence* of gold; and every substance in which we find this essence, we class under the specific name gold. For though it is obvious that our conceptions cannot be the *real essences* of things external, yet are they sufficient guides to these essences, as we know that bodies which, being all formed of the same matter, have the very same sensible qualities, must likewise have the same internal organization or texture of parts, because it is only in that organization or texture that one body can differ from another.—And so much for bodily substance, qualities, and essences.

Of the Existence of Matter.

160 Nominal essences what they are.

Chap. III. *Of the* Existence *of* Matter.

We have endeavoured to prove, that all corporeal substances consist of minute atoms, solid and extended; and that the sensible qualities of every body result from the combination and motion of the atoms of which that body is composed. The celebrated Berkeley, Bishop of Cloyne, however, attempted to demonstrate that these atoms have no real existence; and that the very supposition of a solid, extended, and inert substance, being the archetype of our ideas, involves in it an absurdity and contradiction.

16[?] Berkeley attempts to demonstrate that matter has no existence.

It is universally allowed, that all our knowledge of matter is derived through the senses, either immediately in the very act of sensation, or mediately by an association which is resolvable into a process of reasoning. According to the principles which we have stated, and laboured to establish, matter itself is no immediate object of the senses; and as these are the principles upon which the Bishop erected his demonstration, it will be incumbent upon us to consider his theory, because it has been represented as in the highest degree pernicious, and as leading to universal scepticism.

161 The view of his system given by his antagonists.

The author of the *Essay on the Nature and Immutability of Truth*, represents Berkeley as teaching us, "that external objects (that is, the things which we take for external objects) are nothing but ideas in *our* minds; in other words, that they are in *every respect* different from what they appear to be; that matter exists not but in *our* minds; and that independent on *us* and *our* faculties, the earth, the sun, and the starry heavens, have no existence at all; that a lighted candle hath not *one* of *those qualities* which it *appears to have*; that it is not white, nor luminous, nor round, nor divisible, nor extended; but that, for any thing we know, or can ever know to the contrary, it may be an Egyptian pyramid, the king of Prussia, a mad dog, the island of Madagascar, Saturn's ring, one of the Pleiades, or nothing at all." With respect to the consequences of this theory, he affirms, that "it is subversive of man's most important interests, as a moral, intelligent, and percipient being; and not only so, but a so, that if it were universally and seriously adopted, ed, the diffolution of fociety, and the deftruction of mankind, would neceffarily enfue within the compafs of a month."

The diffolution of fociety and the deftruction of mankind are indeed difmal confequences—enough to make a man fhudder in his clofet. But do they really flow from Berkeley's fyftem? They certainly do, if it be the aim of that fyftem to prove that a candle has not any one quality which it appears to have, and that it may be a *mad dog*; for fhould all philofophers, by fome means or other, become converts to the theory of Berkeley, as we know that the bifhops Sherlock, Smalridge, and others, actually did, the diffolution of fociety and the deftruction of mankind would indeed be inevitable. The fcribbling race, by ufing mad dogs for candles, would all become infected with the hydrophobia; and having their natural irritability augmented by the canine rabies, they would bite and tear till not a human being were left alive.

But to drop this ludicrous ftyle, fo unfuitable to philofophical inveftigation and calm inquiry, we beg leave to affirm, that the theory of Berkeley is here totally and grofsly mifrepresented, and that not one of thofe dangerous confequences which flow from that mifreprefentation can be fairly deduced from any thing taught in *The Principles of Human Knowledge* and the *Dialogues on the Exiftence of Matter*. So far is Berkeley from teaching that external things are nothing but ideas in *our* minds, and that they are in every refpect different from what they appear to be, that he teaches the very reverfe of this in the plaineft language poffible. "I am of a vulgar caft (fays he), fimple enough to believe my fenfes, and leave things as I find them. It is my opinion, that the real things are thofe very things I fee and feel and perceive by my fenfes. That a thing fhould really be perceived by my fenfes, and at the fame time not really exift, is to me a plain contradiction. When I deny fenfible things an exiftence out of the mind, I do not mean *my* mind in particular, but *all* minds Now it is plain they have an exiftence exterior to my mind, fince I find them by experience to be independent of it. There is therefore fome other mind wherein they exift during the intervals between the times of my perceiving them; as likewife they did before my birth, and would do after my annihilation. And as the fame is true with regard to all other finite created fpirits, it neceffarily follows there is an *omnipotent eternal mind*, which knows and comprehends all things, and exhibits them to our view in fuch a manner, and according to fuch rules, as he himfelf hath ordained, and are by us termed the laws of nature."

So far is Berkeley from teaching that, independent on *us* and *our* faculties, the earth, the fun, and the ftarry heavens, have no exiftence at all, and that a lighted candle has not one of thofe qualities which it appears to have, that he over and over affirms the direct contrary; that the univerfe has a real exiftence in the mind of that infinite God in whom, according to the fcriptures, we all live, and move, and have our being; that a lighted candle has not only all thofe qualities which it appears to have, but that, with refpect to us, it has nothing elfe; that fo far from being continually deceived by our fenfes, we are never deceived by them; and that all our miftakes concerning matter are the refult of falfe inferences from true fenfations.

Of the Exiftence of Matter.

The Bifhop makes the fame diftinction that we have made between ideas and notions; reftraining the ufe of the former term to denote the relicts of fenfation, and employing the latter to denote our knowledge or conception of fpirits and all fuch objects as are not perceived by fenfe. He likewife affirms, that we can have no *idea* of an external inert fubftance; becaufe an idea can be like nothing but another idea, or the fenfation of which it is a relict: and as all mankind admit that ideas and fenfations can have no exiftence but in the mind of a percipient being, he therefore infers that we can have no *idea* of any thing exifting unperceived, and by confequence can have no idea of matter in the philofophical fenfe of that word. Solidity, extenfion, divifibility, motion, figure, colour, tafte, and all thofe things which are ufually called qualities primary and fecondary, being according to him mere ideas, can have no exiftence but in a mind perceiving them; but fo far is he from fuppofing their exiftence to depend upon the perception of our minds, that he fays exprefsly, "When in broad day-light I open my eyes, it is not in my power to choofe whether I fhall fee or no, or to determine what particular objects fhall prefent themfelves to my view; and fo likewife as to the hearing and other fenfes, the ideas imprinted on them are not creatures of my will There is therefore fome other will or fpirit that produces them. The queftion between the materialifts and me is not, Whether things have a real exiftence out of the mind of *this* or *that* perfon? but, Whether they have an abfolute exiftence, diftinct from being perceived by *God*, and exterior to *all minds?* I affert, as well as they, that fince we are affected from without, we muft allow powers to be without in a being diftinct from ourfelves. So far we are agreed. But then we differ as to the kind of this powerful being. I will have it to be fpirit; they matter, or I know not what third nature. Thus I prove it to be fpirit: From the effects I fee produced, I conclude there are actions; and becaufe actions, volitions (for I have no notion of any action diftinct from volition); and becaufe there are volitions, there muft be a will. Again, the things I perceive muft have an exiftence, they or their archetypes, out of my mind: but being ideas, neither they nor their archetypes can exift otherwife than in an underftanding: there is therefore an underftanding. But will and underftanding conftitute in the ftricteft fenfe a mind or fpirit. The powerful caufe, therefore, of my ideas is, in ftrict propriety of fpeech, a fpirit."

164 That theory, however improbable, certainly poffible, and

This is a faithful abftract of Berkeley's theory given in his own words. Matter, according to him, cannot be the *pattern* or *archetype* of ideas, becaufe an idea can refemble nothing but another idea, or the fenfation of which it is a relict. Matter, he thinks, cannot be the *caufe* of ideas; for every caufe muft be active, and matter is defined to be inert and incapable of action. He therefore infers, that all our fenfations of what we call the qualities of body are the effect of the immediate agency of the Deity upon our minds; and that corporeal fubftance has no exiftence, or at leaft that we have no evidence of its exiftence. That fuch may *poffibly* be the origin of our fenfations, we

that

Of the Exiſtence of Matter

man will deny who reflects upon the infinite power and wiſdom of the Agent from whom they are ſaid to proceed. Dr Reid himſelf, the ableſt of all Dr Berkeley's opponents, frankly acknowledges that no man "can ſhow, by any good argument, that all our ſenſations might not have been as they are, though no body or quality of body had ever exiſted."

165 In its conſequences harmleſs.

In its conſequences we do not perceive that this theory can be hurtful either to religion, to virtue, or to the buſineſs of common life; for it only explodes the notion of a ſubſtratum, which, though it may have a real exiſtence, was never thought of by the generality of mankind in any nation under heaven. Dr Beattie indeed affirms, that in "leſs than a month after the nonexiſtence of matter ſhould be univerſally admitted, he is certain there could not, without a miracle, be one human creature alive on the face of the earth." But this aſſertion muſt be the conſequence of his miſtaking Berkeley's nonexiſtence of matter for the nonexiſtence of ſenſible objects, the reality and exiſtence of which the Biſhop never denied. On the contrary, he expreſsly ſays, "We are ſure that we really ſee, hear, feel; in a word, that we are affected with ſenſible impreſſions; and how are we concerned any farther? I *ſee* this cherry, I *feel* it, I *taſte* it; and I am ſure *nothing* cannot be ſeen, or felt, or taſted: it is therefore *real*. Take away the ſenſations of ſoftneſs, moiſture, redneſs, tartneſs, and you take away the cherry." All this is equally true and equally conceivable, whether the combined ſenſations which indicate to us the exiſtence of the cherry be the effect of the immediate agency of God or of the impulſe of matter upon our minds; and to the lives of men there is no greater danger in adopting the former than the latter opinion.

166 A conſequence of Berkeley's theory; which

But it has been ſaid, that Berkeley's doctrine neceſſarily leads to ſcepticiſm in religion, as the ſame kind of reaſoning which he employs to prove the non-exiſtence of matter, operates equally againſt the exiſtence of mind, and conſequently againſt the poſſibility of a future ſtate of rewards and puniſhments. "The rational iſſue of this ſyſtem (we are told) is ſcepticiſm with regard to every thing excepting the exiſtence of our ideas and their neceſſary relations. For ideas being the only objects of thought, and having no exiſtence but when we are conſcious of them, it neceſſarily follows, that there is no object of our thought which can have a continued and permanent exiſtence. Body and ſpirit, cauſe and effect, time and ſpace, to which we were wont to aſcribe an exiſtence independent of our thought, all are turned out of exiſtence by this ſhort dilemma: Either thoſe things are ideas of ſenſation or reflection, or they are not: If they are ideas of ſenſation or reflection, they can have no exiſtence, but when we are conſcious of them: If they are not ideas of ſenſation or reflection, they are words without any meaning."

This ſophiſm was advanced as a conſequence from Berkeley's principles by Mr Hume; and upon theſe principles it has been deemed unanſwerable by ſubſequent philoſophers of great merit. But is it really a part of Berkeley's ſyſtem, or can it be fairly inferred from the principles on which that ſyſtem is built? Theſe queſtions it is fit that Berkeley ſhould anſwer for himſelf: and we ſhall venture to aſſert, that his anſwer will be perfectly ſatisfactory to every reader who attends to the diſtinction, which, after the Biſhop, we have ſtated between ideas and notions.

Of the Exiſtence of Matter.

167 That the author ſaw and

Though we believe this dangerous inference from Berkeley's principles is commonly attributed to Hume as its author, it did not eſcape the ſagacity of the Biſhop himſelf. In the third dialogue, *Hylas*, who pleads for the exiſtence of matter, thus objects to the reaſoning of his antagoniſt. "Notwithſtanding all you have ſaid, to me it ſeems, that according to your own way of thinking, and in conſequence of your own principles, it ſhould follow, that you are only a ſyſtem of floating ideas, without any ſubſtance to ſupport them. Words are not to be uſed without a meaning. And as there is no more meaning in ſpiritual ſubſtance than in material ſubſtance, the one is to be exploded as well as the other."

168 Obviated but

To this *Philonous* anſwers: "How often muſt I repeat, that I know or am *conſcious* of my own being; and that I myſelf am not my ideas, but ſomewhat elſe; a thinking active principle, that perceives, knows, wills, and operates about ideas? I know that I, one and the ſame ſelf, perceive both colours and ſounds; that a colour cannot perceive a ſound, nor a ſound a colour; that I am therefore one independent principle, diſtinct from colour and ſound; and, for the ſame reaſon, from all other ſenſible things and inert ideas. But I am not in like manner *conſcious* either of the exiſtence or eſſence of matter. Farther, I know what I mean, when I affirm that there is a ſpiritual ſubſtance or ſupport of ideas; *i. e.* that a ſpirit knows and perceives ideas. But I do not know what is meant, when it is ſaid that an unperceiving ſubſtance hath inherent in it, and ſupports, either ideas or the archetypes of ideas. In the very notion or definition of material ſubſtance there is included a manifeſt repugnance and inconſiſtency. But this cannot be ſaid of the notion of ſpirit. That ideas ſhould exiſt in what doth not perceive, or be produced by what doth not act, is repugnant. But it is no repugnancy to ſay, that a perceiving thing ſhould be the ſubject of ideas, or an active being the cauſe of them. That I, who am a ſpirit or thinking ſubſtance, exiſt, I know as certainly as I know that my ideas exiſt. I know likewiſe what I mean by the terms *I* and *myſelf*; and I know this immediately or intuitively; though I do not perceive it as I perceive a triangle, a colour, or a ſound. Ideas are things inactive and perceived; and ſpirits a ſort of beings altogether different from them, by which they are perceived. I do not, therefore, ſay, that my ſoul is an idea, or like an idea. However, taking the word *idea* in a large ſenſe, my ſoul may be ſaid to furniſh me with an idea, that is, an image or likeneſs of God, though indeed extremely inadequate. For all the notion I have of God is obtained by reflecting on my own ſoul, heightening its powers, and removing its imperfections. I have, therefore, though not an inactive idea, yet in myſelf ſome ſort of an active thinking image of the Deity. And though I perceive him not by ſenſe, yet I have a notion of him, or know him, by reflection and reaſoning. My own mind and my own ideas I have an immediate knowledge of; and by the help of theſe do immediately apprehend the *poſſibility* of the exiſtence of other ſpirits and ideas. Farther, Of the Existence of Matter.

from my being, and from the dependency I find in myself and my ideas, I do by an act of reason *necessarily* infer the existence of a God, and of all created things in the mind of God. It is granted that we have neither an immediate evidence, nor a demonstrative knowledge, of the existence of *other finite spirits*; but it will not therefore follow, that such spirits are on a footing with material substances: if, to suppose the one be inconsistent, and if it be not inconsistent to suppose the other; if the one can be inferred by no argument, and there is a probability of the other; if we see signs and effects indicating distinct finite agents like ourselves, and see no sign or symptom whatever that leads to a rational belief of matter. I say, lastly, that I have a *notion* of spirit, though I have not, strictly speaking, an *idea* of it. I do not perceive it as an idea, or by means of an idea; but know it by reflection. Whereas, I neither perceive matter objectively as I do an idea, nor know it as I do myself by a reflex act; neither do I mediately apprehend it by similitude of the one or the other, nor yet collect it by reasoning from that which I know immediately. All which makes the case of matter widely different from that of the Deity and all spirits."

9 ...tia- ...ith the en- ...urst the ...nce of ...r im- ...le.

Thus far we think Berkeley's theory tenible, and its consequences harmless. That by the immediate agency of the Deity all our sensations *might* be what they are though matter had no existence, we think he has proved by arguments unanswerable; and we are likewise of opinion, that by admitting the evidence of sense, consciousness, and reason, in their fullest extent, and by distinguishing properly between those things of which we have *ideas*, and those of which we have *notions*, he has sufficiently secured the existence of spirits or percipient beings, and obviated the irreligious sophistry of Hume before it was conceived by that author. But the good Bishop stops not here. Not satisfied with proving that all our sensations lead us immediately to the Deity, and that, for aught we know, matter, as defined by philosophers, may have no separate existence, he proceeds farther, and endeavours to prove that matter cannot possibly exist. This appears even in the extracts which we have quoted from his book, in which he talks of the repugnance and inconsistency of the notion. In this part of his system, we think he errs greatly, and advances an opinion altogether inconsistent with his own just principles.

10 ...fon.

The repugnance of which he speaks, arises solely from considering solidity and extension as relicts of sensation, or ideas of the same kind with those of heat and cold, tastes and sounds. "Light, and colours, heat and cold, extension and figures; in a word, the things we see and feel; what are they (says his Lordship), but so many sensations, notions, ideas, or impressions, on sense? and is it possible to separate even in thought any of these from perception? Some there are who make a distinction betwixt *primary* and *secondary* qualities: by the former, they mean extension, figure, motion, rest, solidity or impenetrability, and number: by the latter, they denote all other sensible qualities, as colours, sounds, tastes, and so forth.—The ideas we have of these they acknowledge not to be the resemblances of any thing existing without the mind, or unperceived; but they will have our ideas of the primary qualities to be patterns or images of things which exist without the mind, in an unthinking substance which they call *matter*. But it is evident that extension, figure, and motion, are only ideas existing in the mind; that without extension solidity cannot be conceived; that an idea can be like nothing but another idea; and that consequently neither they nor their archetypes can exist in an unperceiving substance. Hence it is plain, that the very notion of what is called *matter* or *corporeal substance*, involves a contradiction in it."

11 fallacious.

This account of extension and solidity affords a striking instance how much the most vigorous and upright mind is liable to be warped by prejudice in behalf of a darling theory, and how apt the clearest understanding is to be blinded by the equivocal use of terms. That Bishop Berkeley possessed a vigorous and perspicacious mind, his most vehement antagonists are eager to admit; and that his intentions were good, is known to all Europe. Yet by the equivocal use of the word *idea*, which the writings of Locke had then introduced into the language of philosophy, he has here suffered himself to lose sight of a very proper and accurate distinction, which, so far as we know, was among the moderns first made by himself between *ideas* and *notions*. According to the Bishop, "we have a *notion* of power and a *notion* of spirits, but we can have no *idea* either of the one or the other; for all ideas being passive and inert, they cannot represent unto us by way of image or likeness that which acts. Such is the nature of *spirit* or that which acts, that it cannot be of itself perceived, but only by the effects which it produceth. It must be owned, however, that we have some *notion* of soul, spirit, and the operations of the mind, such as willing, loving, hating, inasmuch as we know or understand the meaning of these words."

Now we beg leave to affirm, that what is here said of spirits, and of which we readily admit the truth, is equally true of material or solid substances. We have no *ideas* of solidity and extension, because these things are not originally impressed upon the senses; but we have very distinct though relative *notions* of them, for they are clearly perceived by the effects which they produce. That this is at least possible, we have the acknowledgment of Bishop Berkeley himself: for he "freely owns, that from a cause, effect, operation, sign, or other circumstance, there may reasonably be inferred the existence of a thing not immediately perceived; and that it were absurd for any man to argue against the existence of that thing, from his having no direct and positive notion of it." This is exactly the case with respect to solid substances. These substances we do not immediately perceive; but we infer their existence from effects, signs, and other circumstances, and we have of them very clear though relative notions. Thus a man can open and shut his empty hand; but when he grasps an ivory ball of three or four inches diameter, he feels, that though the same power be exerted, his hand cannot then be shut. He is conscious that there is no change in himself; and being intuitively certain that every effect must have a cause, he infers with the utmost confidence, that the cause which prevents his hand from shutting is in the ball; or, in other words, that

that the thing which communicates to his eye the ſenſation of colour, and impreſſes upon his hand a ſenſation of touch, muſt be ſolid or impenetrable. Solidity, however, is not the ſenſation itſelf; it is only the cauſe of the ſenſation; and therefore it is ſo far from being an idea in our minds, that we are conſcious our notion of it is of a thing totally different from all our ideas, of a thing external, at leaſt to our minds. Indeed the notion itſelf is not poſitive; it is only relative, and inferred from the effects which are produced on our ſenſes. That it is the *ſame* thing which communicates to our eye the ſenſation of colour, and has the power of reſiſting the compreſſion of our hand, is evident; becauſe, when the ball is thrown away, the reſiſtance as well as the actual ſenſation vaniſh at once.

172 The idea of colour and the notion of ſolidity not naturally inſeparable.

From this fact, which a leſs acute man would think a proof that the reſiſtance was not occaſioned by the immediate agency of the Supreme Being, but by the impenetrability of a ſolid ſubſtance of ſmall dimenſions, the Biſhop argues thus againſt the *poſſibility* of ſuch a ſubſtance: "They who aſſert that figure, motion, and the reſt of the primary or original qualities, do exiſt without the mind in unthinking ſubſtances, do at the ſame time acknowledge, that colours, ſounds, heat, cold, and ſuch like ſecondary qualities, do not; which they tell us are ſenſations exiſting in the mind alone, that depend on and are occaſioned by the different ſize, texture, and motion, of the minute particles of matter. This they take for an undoubted truth, which they can demonſtrate beyond all exception. Now if it be certain, that thoſe original qualities are inſeparably united with the other ſenſible qualities, and not even in thought capable of being abſtracted from them, it plainly follows, that they exiſt only in the mind. But I deſire any one to reflect and try whether he can by any abſtraction of thought conceive the extenſion and motion of a body, without all other ſenſible qualities. For my own part, I ſee evidently that it is not in my power to frame an idea of a body extended and moved, but I muſt withal give it ſome colour or other ſenſible quality, which is acknowledged to exiſt only in the mind. In ſhort, extenſion, figure, and motion, abſtracted from all qualities, are inconceivable. Where, therefore, the other ſenſible qualities are, there muſt be theſe alſo, to wit, in the mind, and no where elſe."

In this reaſoning, though plauſible, there is an unintended fallacy. It is indeed true, that we cannot contemplate in imagination a ſolid ſubſtance without conceiving it to have ſome colour; but there is ſufficient reaſon to believe, that this union of colour and ſolidity in our minds is not the effect of nature as it operates at firſt upon our ſenſes, but merely the conſequence of early and deep-rooted aſſociation. Biſhop Berkeley himſelf has taught us, that the objects of ſight are not at a diſtance; and that if a man born blind were ſuddenly made to ſee, he would conceive the objects of his ſight as exiſting either in his eye or in his mind. This is a truth which no man will controvert who has dipt into the ſcience of optics, or who has even paid the ſlighteſt attention to the perceptions of infants; and if ſo, it follows, that to a man born blind and ſuddenly made to ſee, colour and ſolidity would not appear united. Were ſuch a perſon to lay hold of an ivory ball and raiſe it to the elevation of his eye, he would perceive whiteneſs as a new ſenſation exiſting in his eye or his mind, but he would feel reſiſtance at the extremity of his arm. He would not have the leaſt reaſon to conclude, that this whiteneſs was inſeparably united to the cauſe of this reſiſtance; and he would, in fact, draw no ſuch concluſion, till experience had taught him, that by removing the ball or cauſe of reſiſtance from his hand, he at the ſame time removed the ſenſation from his eye. After repeated experiments, he would indeed diſcover, that the cauſe of colour to the eye, was likewiſe by ſome means or other the cauſe of reſiſtance to the hand; and he would ſo aſſociate theſe in his mind, that the one would never afterwards make its appearance as an idea or a notion without bringing the other along with it. The whole difficulty, therefore, in this caſe, is to break an early and deep-rooted aſſociation; for it is plain that the aſſociated ideas were not originally united, and that ſolidity and colour were at firſt conceived as ſeparate.

If the reader perceive not the force of this reaſoning, we beg leave to recommend to him the following experiment, which, if we miſtake not, will carry conviction to his judgment, that in the laſt quoted paſſage Biſhop Berkeley has argued fallaciouſly, and that extenſion and colour are not *inſeparably* united as ideas in the mind. Let him go into a dark room, containing a number of ſpherical bodies of various colours; let him take one of them into his hand; and he will inſtantly *feel* reſiſtance, and have a *notion* of extenſion and ſolidity; but will he likewiſe have the *idea* of colour inſeparably united with this notion? The Biſhop ſays he will: and if ſo, it muſt be the idea of ſome *particular* colour; for his Lordſhip has taught us, that the *abſtract* and *general* idea of colour, which is neither *red*, nor *green*, nor *blue*, &c. cannot poſſibly be formed. The man, then, we ſhall ſuppoſe, whilſt he feels reſiſtance, conceives the reſiſting body to be *green*; and holding it ſtill in his hand, walks into the light of day. The *reſiſtance*, and conſequently the *cauſe* of reſiſtance, remains unchanged; but what becomes of the inſeparable union of thoſe with colour, when the body, upon being actually ſeen, proves to be *black*, i. e. to have no colour at all?—It appears, therefore, undeniable, that ſolidity and colour are not united in nature; that the one is an eſſential quality of ſomething external to us, of which we have no *idea*, but a very diſtinct though relative *notion*; and that the other is an actual ſenſation in our minds, cauſed by the impreſſion of ſomething external on the organ of ſenſe, which leaves behind it in the memory or imagination a poſitive and direct *idea* that exiſts no where elſe.

173 Matter exiſts, b[ut]...

Solid ſubſtance, therefore *may* exiſt, for though it is not immediately perceived by the ſenſes, and is a thing of which we can have no *idea*, we acquire a clear and diſtinct *notion* of it, by the very ſame means which Biſhop Berkeley thinks ſufficient to give us diſtinct notions of power and of ſpirits; and, therefore, that notion can involve in it no contraction. Still, however, we would not ſay with Dr Beattie, "that we could as eaſily believe, that two and two are equal to

ten;

the Existence of Matter.

ten; or, that whatever is, is not; as that matter has no separate existence:" for it is certainly *possible*, that the Supreme Being, without the instrumentality of matter, could communicate to our minds all the sensations and notions from which we infer the reality of solid substance. All that we contend for, as having the evidence of demonstration, is the *possibility* of solid and extended substance; and if the thing be *possible*, the general voice of mankind proclaims its *probability*.— We are *conscious* of our actual sensations, and we know by *experience* that they are caused by something distinct from ourselves. When a man grasps an ivory ball, he *feels* that he cannot shut his hand, and he knows that the resistance which prevents him proceeds *not* from *himself*. Thus far all mankind are agreed. But Bishop Berkeley says, that the resistance proceeds immediately from the Supreme Being or some other spirit; whilst we, without pretending that his scheme is impossible, think it more natural to suppose that the man's hand is kept from shutting by the resistance of a solid substance of four inches diameter; of which substance, though we have no *idea* of it, we have as distinct a *notion* as Berkeley had of spirits. From one or other of these causes this effect must proceed; and it is of little importance to life or happiness which of them be the true cause, since it is with the effect only that we are immediately concerned. Still, however, a philosopher would choose to adopt the easiest and most natural side of every alternative; which, if our notion of solidity be just, is certainly, in the present case, the existence of matter.

4 Whether some philosophers have denied the solidity of matter.

After treating so largely of the composition of bodies, and showing the general agreement of metaphysicians ancient and modern with respect to the notion of their solidity, it will appear strange to the less philosophical part of our readers, that we should now express a doubt of that notion's being well-founded.— We have ourselves no doubt, but on the contrary are fully convinced, that solidity is essential to matter. This, however, has of late been denied by philosophers of great merit. Dr Priestley, after Mr Mitchell and Father Boscovich, affirms that matter is *not solid* or impenetrable to other matter; and that it has, in fact, no properties but those of *attraction* and *repulsion* ‡. The proofs of this position, which appears so paradoxical, he draws from optical experiments, from electricity, and from the effects of heat and cold upon substances usually conceived to be solid.

‡ Disquisitions on Matter and Spirit.

Arguments used for and against this hypothesis.

The appearances from which the solidity of matter is inferred, are nothing more, he says, than superficial appearances, and therefore have led to superficial and false judgments, which the *real appearances* will not authorise. "*Resistance*, on which alone our opinion concerning the solidity or impenetrability of matter is founded, is never occasioned by *solid matter*, but by something of a very different nature, viz. a *power of repulsion*, always acting at a real, and in general an assignable distance, from what we call the body itself. When I press my hand against the table, I naturally imagine that the obstacle to its going through the table, is the *solid matter* of which it consists; but a variety of philosophical considerations demonstrate that it generally requires a much greater power of pressure than I can exert to bring my fingers into actual contact with the table. Electrical appearances show that a considerable weight is requisite to bring into seeming contact even the links of a chain hanging freely in the air, they being kept asunder by a repulsive power belonging to a very small surface, so that they do not actually touch, though they are supported by each other. It has been shown, from optical considerations, that a drop of water rolls upon a cabbage leaf without ever coming into actual contact with it; and indeed all the phenomena of *light* are most remarkably unfavourable to the hypothesis of the solidity or impenetrability of matter. When light is reflected back from a body on which it seems to strike, it was natural to suppose that this was occasioned by its impinging against the *solid parts* of the body; but it has been demonstrated by Sir Isaac Newton, that the rays of light are always reflected by a *power of repulsion* acting at some distance from the body. Again, when part of a beam of light has overcome this power of repulsion, and has entered any transparent substance, it goes on in a right line, provided the medium be of a uniform density, without the least interruption, and without a single particle being reflected, till it comes to the opposite side, having met with no solid particles in its way, not even in the densest transparent substances, as glass, crystal, or diamond; and when it is arrived at the opposite side, it is solely affected by the laws of attraction and repulsion.

Of the Existence of Matter.

"Nay, that the component particles of the hardest bodies themselves do not actually touch one another, is demonstrable from their being brought nearer together by cold, and by their being removed farther from each other by heat. The power sufficient to overcome these internal forces of repulsion, by which the ultimate particles of bodies are prevented from coming into actual contact, is what no person can pretend to compute. The power requisite to break their cohesion, or to remove them from the sphere of each other's attraction, may in some measure be estimated; but this affords no *data* for ascertaining the force that would be necessary to bring them into actual contact, which may exceed the other almost infinitely."

From these facts, Dr Priestley infers, that the mutual resistance of bodies proceeds in all cases from powers of repulsion acting at a distance from each body: that the supposition of the *solidity* or *impenetrability* of matter is destitute of all support whatever; and that matter itself is nothing but powers of attraction and repulsion, and several spheres of them, one within another. As other philosophers have said, "Take away solidity, and matter vanishes;" so he says expressly, "Take away attraction and repulsion, and matter vanishes."

To illustrate this strange notion, "Suppose (says he) that the Divine Being, when he created *matter*, only fixed certain *centres of various attractions and repulsions*, extending indefinitely in all directions, the whole effect of them to be upon each other; these centres approaching to, or receding from each other, and consequently carrying their peculiar spheres of attraction and repulsion along with them, according to certain definite circumstances. It cannot be denied that these spheres may be diversified infinitely, so as to correspond to all the kinds of bodies that we are acquainted with, or that are possible. For all effects in which

bodies

Of the Existence of Matter.

bodies are concerned, and of which we can be sensible by our eyes, touch, &c. may be resolved into attraction or repulsion. A compages of these centres, placed within the spheres of each other's attraction, will constitute a body that we term *compact*; and two of these bodies will, on their approach, meet with a repulsion or resistance sufficient to prevent one of them from occupying the place of the other, without a much greater force than we are capable of employing; so that to us they will appear perfectly hard.

"As, in the constitution of all actual bodies that we are acquainted with, these centres are placed so near to each other, that in every division that we can make we still leave parts which contain many of these centres; we, reasoning by analogy, suppose that every particle of matter is infinitely divisible; and the *space* it occupies is certainly so. But, strictly speaking, as those centres which constitute any body are not absolutely infinite, it must be naturally possible to come by division to one single centre, which could not be said to be divisible, or even to occupy any portion of space, though its sphere of action should extend ever so far; and had only *one* such centre of attraction, &c. existed, its existence could not have been known, because there would have been nothing on which its action could have been exerted; and there being no *effect*, there could not have been any ground for supposing a *cause*."

In answer to this reasoning against the solidity of matter, Dr Priestley was frequently asked by his candid and masterly antagonist *, "What it is that attracts and repels, and that is attracted and repelled?" But to the question he was never able to give a satisfactory answer. Indeed, how could he have been able? for, as Dr Price argues, "Exclusive of attraction and repulsion, he affirms matter to be absolutely nothing; and therefore, though we were to allow it the power of attracting and repelling, yet as it is nothing but this power, it must be the power of nothing, and the very idea of it be a contradiction."

* *Free Discussion between Dr Price and Dr Priestley.*

176

founded on fallacious appearances and contrary to an intuitive and necessary truths.

If there be any class of truths intuitively certain, that class comprehends the two following propositions: POWER CANNOT BE WITHOUT A SUBJECT; and NOTHING CAN ACT WHERE IT IS NOT. If, therefore, there be powers of attraction and repulsion, (which shall be considered afterwards in the Chapter of MOTION), there must be a subject of those powers; and if matter, whether solid or unsolid, be the subject, it cannot possibly attract or repel at a *distance*. Sir Isaac Newton, in his letters to Dr Bentley, calls the notion that matter possesses an innate power of attraction, or that it can act upon matter at a distance, and attract and repel by its own agency, "an absurdity into which, he thought, no one could possibly fall." Hence it follows, that the appearances from which Dr Priestley infers the penetrability of matter must be fallacious appearances, since they contradict an intuitive and necessary truth. The facts which he instances are, indeed, such as would make most other men suspicious of fallacy, and in his reasonings from them he sometimes takes for granted the truth to be proved. The links of a chain used for electrical purposes, supposing them to be in contact with each other, can touch only with very small surfaces. The electrical fluid is of considerable density, and incapable of being absorbed within a very narrow compass. This is evident, because it passes not through paper and other porous bodies without making a passage for itself, and leaving a visible aperture behind it; and though it assimilates with metals, and passes through them more easily than through other bodies, yet is it plain that it requires a certain quantity of metal to conduct it; for when the conductor falls short of the necessary quantity, it is melted or dissipated by the force of the fluid. This being the case, it follows that the links of a chain *may be* in actual contact (we do not positively affirm that they *are*), and yet the fluid become visible in passing from link to link; for if the point of contact be too small to absorb the *whole* fluid, *part* of it must pass without any metallic conductor through the atmosphere, and thus become apparent to the eye of the spectator.

With respect to light, it is obvious that there cannot possibly be any *demonstration*, in the logical sense of the word, that it is reflected by a power of repulsion acting at some distance from the body; for, in the opinion of all mankind, the primary and solid atoms of matter are too minute to fall under the cognisance of our senses, however assisted by art; and therefore, if light *appears* to be reflected at a distance from the surface of the body, we must conclude, either that between the point of reflection and the apparent surface of the body, there are solid atoms unperceived by us, or that light is reflected by the agency of some other substance than matter. One of these conclusions, we say, *must* be drawn, because they are both *possible*, and there is no other alternative but to admit one of them, or to suppose that a thing may act where it is not; which is as clearly absurd and *impossible* as that *whatever is, is not*. Again, when part of a beam of light has entered any transparent substance, how does Dr Priestley know that it goes on in a right line, without the least interruption, till it comes to the opposite side? This he can know only by his senses; but the beam may meet with ten thousand interruptions from objects which the senses cannot perceive, and may describe a zig-zag line, of which the deflections are so small as to elude the keenest eye aided by the most powerful glass.

That the component particles of the hardest bodies do not *all* actually touch one another, is indeed evident from the effects of cold and heat upon those bodies: but it does not therefore follow that those bodies have no component particles; but only, that they are fewer in number than we are apt to imagine; that all the solid matter in the universe might possibly be compressed within a very narrow sphere; and that it is held together in different bodies and different systems by a power foreign from itself. These are truths which all philosophers have admitted who have thought sufficiently on the subject; but who will admit Dr Priestley's proposition, when it is translated into common English: "That the component *nothings* of the hardest bodies do not actually touch one another, is demonstrable from their being brought nearer together by cold, and by their being removed farther from each other by heat?"

Dr Priestley owns, that if matter be solid it could act upon other matter by impulse. We are certain, that, whatever it be, it can act upon nothing in the manner

manner which he describes; and therefore, to use the words of Dr Price, "matter, if it be any thing at all, must consist of solid particles or atoms occupying a certain portion of space, and therefore *extended*, but at the same time *simple* and *uncompounded*, and incapable of being resolved into any other smaller particles. It must likewise be the different form of these *primary* particles, and their different combinations and arrangement, that constitute the different bodies and kinds of matter in the universe." This is exactly agreeable to the doctrines of Newton; who, after considering the question in every point of view, concludes, that "in the beginning God formed matter in solid, massy, hard, impenetrable, moveable particles, of such sizes and figures, and with such other properties, as most conduced to the end for which he formed them; and that those primary particles being solid, are incomparably harder than any porous bodies compounded of them; even so very hard as never to wear or break in pieces: no ordinary power being able to divide what God himself made one in the creation." To talk, as Dr Priestley does, of matter's being certain *centres of various attractions and repulsions* extending indefinitely in all directions, and to describe these centres as *not* being *physical points* or *solid atoms*, is either to say, that *nothing* attracts and repels; or it is to introduce the divine agency as the immediate cause of all our sensations. The former of these alternatives Dr Priestley disclaims; the latter he seems willing to admit. But if it be his meaning that all our sensations are caused by the immediate agency of God or created spirits, his scheme differs not from that of Berkeley, except in being less elegantly expressed and less ingeniously supported. Berkeley's scheme is evidently *possible*. The commonly received scheme is likewise possible. It remains therefore with the reader, whether he will adopt the system of the Bishop of Cloyne; or admit, with all other philosophers, that matter exists; that it consists of parts actually distinct and separable; and that each of these parts is a *monad* or solid atom, which requires no foreign agency to keep it united.

Chap. IV. *Of* Space *and its* Modes.

Having considered bodies in their substance, essences, and qualities, and proved that they have a real existence independent of us and our conceptions, we proceed now to inquire into the nature of *space*, *motion*, *number*, and *duration*. These are commonly called the *adjuncts* of body, and are supposed to be absolutely inseparable from its existence. It does not indeed appear that *actual motion* is a necessary adjunct of body, considered as a mere solid, extended, and figured substance; but it is certainly necessary to the existence of organized and animated bodies; and the capability of being moved enters into our conceptions of all bodies whatever. Of these adjuncts, that which first demands our attention is *space*; for without a knowledge of its nature we could not have an adequate idea of motion, and without motion we could have no idea of time.

Every body is extended; and between two bodies not in actual contact, we perceive that a third body may be easily introduced. That which admits of the introduction of the third body is what we call *space*: and if it be totally void of matter, it is called *pure space*. Whether there be any space absolutely pure, has been disputed; but that such space is possible, admits of no dispute. Were any one body (a cannon ball for instance) to be annihilated, and the circumambient air, with every other material substance, kept from rushing into the space which the ball had occupied, that portion of space, with respect to matter, would be empty or pure space: whether it would necessarily be filled with mind shall be considered afterwards. Pure space, therefore, is conceivable; and it is conceived as having three dimensions, length, breadth, and depth, which are generally called the three simple modes of space. In this respect it agrees with body: but the agreement proceeds no farther; for space is conceived as destitute of solidity, without which the existence of body is inconceivable. It has been formerly observed, that whatever may be distinctly conceived may possibly exist; but with respect to the existence of pure space, whatever is possible is real: for it shall be shown in the next section, that were there no space absolutely pure or void of matter, there could be no motion. Our business at present is to inquire what the nature of space is, and what notion we ought to have of its existence.

180 Space supposed to be something different from body and mind, and to be eternal and infinite, &c.

Many modern philosophers consider space as something entirely distinct both from body and mind: some of them ascribe to it no less than four of the attributes of the Deity—*eternity*, *immobility*, *infinity*, and *necessary existence*; and a few of them have gone so far as to call *infinite space* the *sensorium* of the Deity. "The supposal of the existence of *any thing whatever* (says Dr Clarke *) necessarily includes a *presupposition* of the existence of *space*. Nothing can possibly be conceived to exist without thereby presupposing space; which, therefore, I apprehend to be a *property* or *mode* of the self-existent Substance; and that, by being evidently necessary itself, it proves, that the substance of which it is a property must be also necessary." Elsewhere he says, that "space is a property or mode of the self-existent Substance, but not of any other substances. All other substances are *in* space, and are *penetrated* by it; but the self-existent Substance is not in space, nor penetrated by it, but is itself (if I may so speak) the *substratum* of space, the *ground* of the existence of *space* itself." He acknowledges, however, that such expressions as "the self-existent Substance is the *substratum* of space, or space is a property of the self-existent Substance, are *not*, perhaps, very proper: but what I mean (says he), is this: The idea of *space* (as also of *time* or *duration*) is an abstract or partial idea; an idea of a certain *quality* or *relation*, which we evidently see to be necessarily existing; and yet (which not being itself a *substance*) at the same time necessarily *presupposes* a substance, without which it could not exist."

* *Demonstration of the Being and Attributes of God, and Correspondence with a Gentleman in Gloucestershire, passim.*

These opinions respecting space have been adopted by succeeding philosophers of great merit, and particularly by Dr Price; who says, that "it is a maxim which cannot be disputed, that *time* and *place* are necessary to the existence of all things. Dr Clarke (continues he) has made use of this maxim, to prove that infinite space and duration are the essential properties of the Deity; and I think he was right."

Had authority any weight in philosophy, we know not what modern writers we could oppose to the celebrated

Of Space and its Modes.

brated names of Clarke and Price, unless it were Bishop Berkeley, Dr Law late bishop of Carlisle, and the author of Ancient Metaphysics. But the question is not to be decided by authority. Learned and acute as Dr Clarke was, his assertions respecting space are contradictory and inconsistent. If nothing can possibly be conceived to exist without thereby presupposing the existence of *space*, how can space be a property or mode of the self existent Substance? Are properties prior in the order of nature, or even in our conceptions, to the substances in which they inhere? Can we frame an abstract idea of figure, or extension, or solidity, before we conceive the existence of any one figured, extended, or solid substance? These are questions which every man is as capable of answering as the Doctors Clarke and Price, provided he can look attentively into his own mind, and trace his ideas to their source in sensation: and if he be not biassed by the weight of great names, we are persuaded he will find, that if it be indeed true, that the supposal of the existence of any thing whatever necessarily includes a *presupposition* of the existence of space, *space* cannot possibly be a *property* or *mode* of the self-existent substance, but must of necessity be a *substance* itself.

181 This supposition controverted.

182 Space necessary to the existence of every thing.

It is, however, *not* true, that the supposal of the existence of any thing whatever necessarily includes a presupposition of the existence of space. The idea of space is indeed so closely associated with every visible and most tangible objects, that we cannot see the one nor feel the other without conceiving them to occupy so much of space. But had we never possessed the senses of sight and touch, we could not have supposed the existence of space necessary to the existence of any thing whatever. The senses of smelling, tasting, and hearing, together with our internal powers of consciousness and intellect, would certainly have compelled us to believe in our own existence, and to suppose the existence of other things; but no object either of consciousness, smelling, tasting, or hearing, can be conceived as occupying space. Space and every thing which fills it are conceived as of three dimensions; but who ever supposed or can suppose an *odour*, *taste*, or *sound*, to have *length*, *breadth*, and *depth*; or an object of consciousness to be an ell or an inch long?

Let us suppose that body and all the visible world had a beginning, and that once nothing existed but that Being which is alone of necessary as well as eternal existence; *space*, say the followers of Dr Clarke, would then exist likewise without bounds or limits. But we desire to know of these gentlemen what sort of a being this space is. It certainly is not *substance*; neither is it a property; for we have seen that the very notions of it, which lead men to suppose its existence *necessary*, render it impossible to be a property of the self-existent Being. Is it then nothing? It "is in one sense*: it is nothing *actually* existing; but it is something *potentially*; for it has the *capacity* of receiving body whenever it shall exist. It is not, and cannot, become any thing itself, nor hath it any actual existence; but it is that without which nothing corporeal could exist." For this reason it was that Democritus and Epicurus made space one of the principles of nature; and for the same reason Aristotle has made *privation* one of his three principles of natural things, *matter* and *form* being the other two. But though the privation of *one* form be doubtless necessary before matter can receive another (for a piece of wax or clay cannot receive the form of a *globe* before it lose the form of a square), yet Aristotle never dreamed that the privation of the square was any property of the globe, or that *privation* itself was to be reckoned a real being. On the contrary, he expresly calls it *το μη ον*, or *the no being*. In this way, if we please, we may consider space, and call it the *privation of fulness* or of body. We have indeed a positive idea of it, as well as of silence, darkness, and other privations: but to argue from such an idea of space, that space itself is something real, seems altogether as good sense as to say, that because we have a different idea of *darkness* from that of *light*, of *silence* from that of *sound*, of the *absence* of any thing from that of its *presence*; therefore *darkness*, *silence*, *absence*, must be real things, and have as positive an existence as *light*, *sound*, and *body*: and to deny that we have any positive idea, or, which is the very same thing, any idea at all, of the privations above mentioned, will be to deny what is capable of the most complete proof (see n° 19), and to contradict common sense and daily experience. There are therefore ideas, and simple ones too, which have nothing *ad extra* correspondent to them; no proper *idiatum*, archetype, or objective reality: and we do not see why the idea of space may not be reckoned of that number. To say that *space* must have existence, because it has some properties (for instance, *penetrability*, or the *capacity* of receiving body), seems† to be the same thing as to urge that *darkness* must be *something* because it has the capacity of *receiving light*; *silence* the property of admitting *sound*; and *absence* the property of being supplied by *presence*. To reason in this manner is to assign absolute negations; and such as, in the same way, may be applied to *nothing*, and then call them *positive properties*; and so infer that the chimera, thus cloathed with them, must needs be *something*.

183 Space a thing the property existence of body.

But it is said, that as we cannot conceive space to be annihilated, it must be some real thing of eternal and necessary existence. If this argument had not been used by writers of great merit, and with the best intention, we should not have scrupled to call it the most contemptible sophism that ever disgraced the page of philosophy. Whatever now has an *actual* existence, must from eternity have had a *possible* existence in the ideas of the Divine mind. Body, as an extended substance, has now an *actual* existence; and therefore it must from eternity have had a *possible* existence in the ideas of the Divine mind: but the *possible existence of body* is all that we can conceive by *space*; and therefore this argument, upon which so much stress has been laid, amounts to nothing more, than that what has from eternity been possible, can at no period have been impossible. It is evident that the *capacity* or *potentiality* of every thing existing must have been from eternity; but is capacity or potentiality a real being? All the men and women who shall succeed the present generation to the end of time, have at this moment a possibility of existence, nor can that possibility be conceived as an impossibility; but is it therefore any thing actually existing either as a substance or a quality?

It has been urged, that space must be something more than the mere absence of matter; because if nothing

* *Ancient Metaphysics.*

† See *Law on King's Origin of Evil*, and *Law's Inquiry into the Idea of Space*, &c.

Of Space and its Modes.

thing be between bodies, such as the walls of a room, they must necessarily touch. But surely it is not *self-evident* that bodies must necessarily touch if nothing be between them; nor of the truth of this proposition can any thing like a proof be brought. It is indeed intuitively certain, that "things, when they are in contact, have nothing between them;" and hence it has been rashly inferred, that things, when they have nothing between them, are in contact; but this is an illegitimate conversion of the proposition. Every logician knows, that to convert a proposition, is to infer from it another whose *subject* is the *predicate*, and whose *predicate* is the *subject*, of the proposition to be converted: but we are taught by Aristotle and by common sense, that an *universal* affirmative can be converted only into a *particular* affirmative "Things, when they are in contact, have nothing between them," is an *universal* affirmative proposition; and therefore it can be converted only into the following *particular* affirmative: "Some things, when they have nothing between them, are in contact;" a proposition which by no means includes in it the contact of the walls of an empty room. The reason why the walls of an empty room do not touch, is that they are *distant*; but is *distance*, in the abstract, any thing really existing? Two individuals differ, or there is a difference between them; but is *difference* itself any real external thing? Bodies are long, broad, thick, heavy; but are *length*, *breadth*, *density*, *weight*, properly any thing? Have they any real separate archetypes or external idiata? Or can they exist but in some substance?

The reason why so many philosophers have considered space as a real external thing, seems to be this: Every bodily substance is extended; but space is conceived to be that which contains body, and therefore to space we likewise attribute extension. Extension is a quality which can have no existence but as united with other qualities in some substance; and it is that of which, abstracted from all substances, we can, properly speaking, form no *idea*. We understand the meaning of the word, however, and can reason about that which it denotes, without regarding the particular substance in which extension may inhere; just as we can reason about whiteness without regarding any one white object, though it is self-evident that whiteness, abstracted from all objects, cannot figure in the mind as an idea. Qualities considered in this manner are general and relative notions, the objects of pure intellect, which make no appearance in the imagination, and are far less, if possible, to be perceived by sense: but it is extremely painful to the mind to dwell upon such notions; and therefore the ever-active fancy is always ready to furnish them with imaginary *substrata*, and to make that which was a *general* and *invisible notion* be conceived as a *particular ideal object*. In the case of extension this is the more easily done, that the notion which we have of a *real substratum* or substance, the support of real qualities, is obscure and relative, being the notion of *something* we know not what. Now, by leaving, if we can, solidity and figure out of our conception, and joining the notion of *something* with the notion of *extension*, we have at once the *imaginary substratum* of an *imaginary* quality, or the general notion of extension particularised in an imaginary subject; and this subject we call *space*, vainly fancying that it has a real external and independent existence. Whether this be not all that can be said of space, and whether it be not absurd to talk of its having any real properties, every man will judge for himself, by reflecting upon his own ideas and the manner in which they are acquired. We ourselves have no doubt about the matter. We consider pure space as a mere notion relative to the existence of corporeal substance, as nothing more than the absence of body, where body is possible; and we think the usual distinction between *absolute* and *relative* space, if taken as real, the grossest absurdity. We do not, however, pretend to dictate to others; but recommend it to every man to throw away all respect for great names, to look attentively into his own thoughts, and on this as on all metaphysical subjects to judge for himself.

135 Place, what it is.

Having said so much of space in general, we need not waste much time upon its modes Indeed the only mode of space, after considering it with respect to the three dimensions of body, which now demands our attention, is that which we call *place*. As in the simplest mode of space we consider the relation of distance between any two bodies or points; so, in our idea of *place*, we consider the relation of distance betwixt any thing, and any two or more points, which, being considered as at rest, keep the same distance one from another. Thus, when we find any thing at the same distance now at which it was yesterday from two or more points with which it was then compared, and which have not since the comparison was made changed their distance or position with respect to each other, we say that the thing hath kept its *place*, or is in the *same place*; but if it hath sensibly altered its distance from either of those points, we then say that it hath changed its *place*.

From this view of the nature of place, we need not observe that it is a mere relation; but it may be worth while to advert to this circumstance, that a thing may without falsehood be said to have continued in the same place, and at the same time to have changed its place, according to the different objects with which it is compared. Thus, if two persons find a company of chess-men standing each upon the same square of the chess-board where they left them, the one may with truth affirm that they are all in the *same place*, or unmoved; and the other may with equal truth affirm that they have all changed *place*. The former considers the men only with respect to their distances from the several parts of the chess-board, which have kept the same distance and position with respect to one another. The latter must consider the men with respect to their distance from something else: and finding that the chess-board, with every thing upon it, has been removed, we shall suppose from one room to another, he cannot but say that the chess-men have changed their place with respect to the several parts of the room in which he formerly saw them.

This modification of distance, however, which we call *place*, being made by men for their common use, that by it they may design the particular position of objects where they have occasion for such designation, they determine this *place* by reference to such adjacent things as best serve their present purpose, without regarding other things which, for a different purpose, would better determine the place of the same object.

Of Space and its Modes.

Thus in the cheſs-board, the uſe of the *deſignation of the place* of each cheſs-man being determined only within that chequered piece of wood, it would croſs that purpoſe to meaſure it by any thing elſe: but when theſe very cheſs-men are put up in a box, if any one ſhould aſk where the black king is, it would be proper to *determine the place* by reference to ſomething elſe than the cheſs-board; ſuch as the parts of the room or cloſet which contain the box.

186 The universe has no place.

That our idea of *place* is nothing but ſuch a relative poſition of things as we have mentioned, will be readily admitted, when it is conſidered that we can have no idea of the place of the *univerſe*. Every *part* of the univerſe has place; becauſe it may be compared with reſpect to its diſtance from other parts ſuppoſed to be fixed. Thus the earth and every planet of our ſyſtem has a place which may be determined by aſcertaining its diſtance from the ſun and from the orbits of the other planets; and the place of the ſyſtem itſelf may be aſcertained by comparing it with two or more fixed ſtars: but all the ſyſtems taken as *one whole* can have no *place*; becauſe there is nothing elſe to which the diſtance and poſition of that whole can be referred. It is indeed true, that the word *place* is ſometimes uſed, we think improperly, to denote that *ſpace* or portion of *ſpace* which any particular body occupies; and in this ſenſe, no doubt, the univerſe has place, as well as the earth or ſolar ſyſtem: but to talk of the place of the univerſe in the other and proper ſenſe of the word, is the groſſeſt nonſenſe.

Chap. V. *Of* Motion.

187 Mobility eſſential to every corporeal ſubſtance, but not natural motion.

Mobility, or a capacity of being moved, is eſſential to every corporeal ſubſtance; and by actual motion are all the operations of nature performed. Motion, therefore, if it may be called an *adjunct* of body, is certainly the moſt important of all its adjuncts; and to aſcertain its nature and origin demands the cloſeſt attention of the metaphyſician, as well as of the mechanic and aſtronomer. With the *laws* of motion, as diſcovered by experience, we have at preſent no concern: they are explained and fully eſtabliſhed in other articles of this work (ſee Mechanics, Motion, &c.). The principal queſtions which we have to conſider are, "What is motion? and, By what power is it carried on?"

For an anſwer to the firſt of theſe queſtions, the modern metaphyſician refers every man to his own ſenſes; becauſe, in his apprehenſion, the word motion denotes a ſimple idea which cannot be defined. Among the ancients, the Peripatetics were of a different opinion; and Ariſtotle, whoſe love of dialectic made him define every thing, has attempted to give two definitions of *motion*. As ſome learned men are at preſent labouring to revive this ſyſtem, we ſhall, out of reſpect to them, mention thoſe definitions, and make upon them ſuch remarks as to us appear proper.

188 The Peripatetic definitions of motion

The author of *Ancient Metaphyſics* having obſerved, that both nature and art propoſe ſome end in all their operations; that when the end is obtained, the thing operated upon is in a ſtate of perfection or completion; and that in the operations of both nature and art there is a progreſs, and by conſequence a *change*, from one thing to another; adds, that this change is *motion*. Motion, therefore, according to him, is a change or progreſs to the end propoſed, or to that ſtate of perfection or completion which Ariſtotle calls ἐντελέχεια. It is not enough, however, that we know *to what* the change or progreſs is made: to have an adequate idea of motion, we muſt likewiſe know *from what* it proceeds. Now it is evident that every thing exiſting, whether by nature or art, was, before it exiſted, poſſible to exiſt; and therefore, adds the ſame author, things do in ſome ſort exiſt even before they exiſt. This former kind of exiſtence is ſaid by Ariſtotle to be ἐν δυνάμει, that is, in *power* or *capacity*. In this way, plants exiſt in their ſeeds; animals in the embryo; works of art in the idea of the artiſts and the materials of which they are made; and, in general, every thing in the cauſes which produce it. From this power or capacity there is a progreſs to *energy* or actual exiſtence; ſo that we are now able to anſwer the queſtion, "*from what*, and *to what*, motion is a change?" for it is univerſally true of all *motion*, that it is a change from *capacity* to *energy*.

"Having thus diſcovered that *motion* lies betwixt *capacity* and *energy*, it is evident (he ſays) that it muſt have a connection with each of them: and from this double connection Ariſtotle has given us two definitions of it; one of them taken from the *energy*, or end to which it tends; the other from the *capacity* from which it begins. The firſt is expreſſed in two words, viz. ἐνέργεια ἀτελής, or *imperfect energy*; the other is ἐντελέχεια τοῦ ἐν δυνάμει ᾗ ἐν δυνάμει; which may be tranſlated thus, *The perfection of what is in capacity, conſidered merely as in capacity*. The meaning of the laſt words is, that nothing is conſidered in the thing that is moved but merely its *capacity*; ſo that motion is the perfection of that capacity, but not of the thing itſelf. It is ſomething more (adds the learned author) than mere *capacity*; for it is capacity exerted, which when it has attained its end, ſo that the thing has arrived at that ſtate to which it is deſtined by nature or art, ceaſes, and the thing begins to exiſt ἐνεργείᾳ, or *actually*."

189 unintelligible.

By all the admirers of Ariſtotle, this latter definition has been preferred to the former; for what reaſon, it is difficult to ſay. They both involve in the thickeſt obſcurity that which, viewed through the ſenſes, is very eaſily underſtood; and on this, as on many other occaſions, Ariſtotle was certainly guilty of darkening counſel by words without knowledge. The author, whoſe comment on this wonderful definition we have faithfully abridged, admits that it is not intelligible till we know what *change* and *progreſs* are; but is it poſſible to conceive any *change* to take place in bodily ſubſtances without *motion*? or, if we were called upon to explain what progreſs is, could we do it better than by ſaying that it is motion *from* ſomething *to* ſomething? It is likewiſe very obvious, that before we can have an adequate idea of *motion*, we muſt, according to this definition, know perfectly what the words *capacity*, *energy*, and *perfection* denote; and yet nothing can be more true than that *perfection* denotes a complex conception, which may be eaſily defined by reſolving it into the ſimple ideas and notions of which it is compounded, whilſt *motion* is ſuſceptible of no ſuch reſolution. The perfection of a knife is compounded of the temper of the ſteel and the

Of Motion.

the ſharpneſs of the edge; the perfection of a ſyſtem of philoſophy conſiſts of the importance of the ſubjects treated, the ſtrength of the author's arguments, and the perſpicuity of his ſtyle and manner; but of what is the *motion* of a ball, or *an atom*, or any thing elſe, compounded? We are aware that to this queſtion the modern Peripatetics will reply, that it is not the motion of a *ball*, or an *atom*, or any *one thing*, that their maſter has ſo learnedly defined, but motion abſtracted from *all individuals*, and made an object of pure intellect; and they will likewiſe affirm, that by the word *perfection* uſed in the definition, he does not mean *any one kind* of perfection as adapted to any particular *object* or *end*, but perfection abſtracted from *all objects* and *all ends*. The perfection of *nothing* and the motion of *nothing*, for ſuch ſurely are that motion and that perfection which are abſtracted from *all objects* and *ends*, are ſtrange expreſſions. To us they convey no meaning; and we have reaſon to think that they are equally unintelligible to men of greater acuteneſs (o). In a word, *motion* muſt be ſeen or felt; for it cannot be defined. To call it the *act of changing place*, or a *paſſage from one place to another*, gives no information; for *change* and *paſſage* cannot be conceived without previouſly conceiving *motion* (p).

190 Peripatetic division of motion absurd.

The Peripatetics having idly attempted to *define* motion, proceed next to *divide* it into four kinds or claſſes. This diviſion was by the father of the ſchool pretended to be made from the effects which it produces, and was ſaid by him to belong to three categories, viz. *quality*, *quantity*, and *where* (ſee CATEGORY). The firſt kind is that well known *motion* from *place* to *place*, which falls under the category laſt mentioned; the ſecond is *alteration*, by which the quality of any thing is changed, the ſubſtance remaining the ſame. This belongs to the category of *quality*. The third is *increaſe*, and the fourth *diminution*, both belonging to the category of *quantity*. The ancient atomiſts, and all the modern metaphyſicians of eminence, have with great propriety rejected this diviſion as being nothing but a collection of abſurd diſtinctions where there is in nature no difference. It has been already ſhown, that body has no other real qualities than *ſolidity*, *extenſion*, and *figure*: but of theſe the firſt cannot be altered without deſtroying the ſubſtance; for every thing which is material is equally ſolid. The extenſion of a body may indeed be enlarged, and its figure may be altered, while the ſubſtance remains the ſame; but that alteration can be made only by moving from their *places* the ſolid atoms of which the body is compoſed. Ariſtotle's ſecond kind of motion therefore differs not from the firſt; nor do the third and fourth differ from theſe two. For a body cannot be *increaſed* without acquiring new matter, nor diminiſhed without loſing ſome of the matter of which it was originally compoſed: but matter can neither be added nor taken away without motion from place to place; for there is now no creation *de novo*; and we have no reaſon to imagine that, ſince the original creation, a ſingle atom has been ever annihilated. It is therefore paſt diſpute, that local motion is the only motion conceivable; and indeed, as far as we are capable of judging from what we know of body, it is the only motion poſſible.

191 Whether, if but one body exiſted, there could be motion?

This has given riſe to a queſtion which has been debated among modern philoſophers, though, as far as we know, it was never agitated among the ancients, viz. "Whether if there were but one ſolid body exiſting, that body could poſſibly be moved." Biſhop Berkeley ſeems to be of opinion that it could not; becauſe no motion can be conceived but what has a direction towards ſome *place*, and the relation of place neceſſarily ſuppoſes the exiſtence of two or more bodies. Were all bodies, therefore, annihilated except one globe, it would be impoſſible (he thinks) to conceive that globe in motion (q.) With reſpect to

(o) "Nunc dicendum de natura motus. Atque is quidem, cum ſenſibus clare percipiatur, non tam natura ſua, quam doctis philoſophorum commentis obſcuratus eſt. Motus nunquam in ſenſus noſtros incurrit ſine mole corporea, ſpatio et tempore. Sunt tamen qui motum, tanquam ideam quandam ſimplicem et abſtractam, atque *ab omnibus aliis rebus ſejunctam*, contemplari ſtudent. Verum idea illa tenuiſſima et ſubtiliſſima *intellectus aciem eludit*: id quod quilibet ſecum meditando experiri poteſt. Hinc naſcuntur magnæ difficultates de natura motus, et definitiones, ipſa re quam illuſtrare debent longe obſcuriores. Hujuſmodi ſunt definitiones illæ Ariſtotelis et ſcholaſticorum, qui motum dicunt eſſe *actum mobilis quatenus eſt mobile*, vel, *actum entis in potentia quatenus in potentia*. Hujuſmodi etiam eſt illud viri inter recentiores celebris, qui aſſerit *nihil in motu eſſe reale præter momentaneum illud quod in vi ad mutationem nitente conſtitui debet*. Porro conſtat, horum et ſimilium definitionum auctores in animo habuiſſe abſtractam motus naturam, ſecluſa omni temporis et ſpatii conſideratione, explicare: ſed qua ratione abſtracta illa motus quinteſſentia (ut ita dicam) intelligi poſſit non video."

Berkeley de Motu.

(p) "Multi etiam per *tranſitum* motum definiunt, obliti ſcilicet tranſitum ipſum ſine motu intelligi non poſſe, et per motum definiri oportere: Veriſſimum adeo eſt definitiones, ſicut nonnullis rebus lucem, ita viciſſim aliis tenebras afferre. Et profecto, quaſcumque res ſenſu percipimus, eas clariores aut notiores definiendo efficere vix quiſquam potuerit. Cujus rei vana ſpe allecti res faciles difficillimas reddiderunt philoſophi, menteſque ſuas difficultatibus, quas ut plurimum ipſi peperiſſent, implicavere." *Id. ibid.*

(q) Having proved that *place*, in the proper ſenſe of the word, is merely relative, and affirmed that all *motion* is relative likewiſe, the Biſhop proceeds thus: "Veruntamen ut hoc clarius appareat, animadvertendum eſt, motum nullum intelligi poſſe ſine determinatione aliqua ſeu directione, quæ quidem intelligi nequit, niſi præter corpus motum, noſtrum etiam corpus, aut aliud aliquid, ſimul intelligatur exiſtere. Nam ſurſum, deorſum, ſiniſtrorſum, dextrorſum, omneſque plagæ et regiones in relatione aliqua fundantur, et neceſſario corpus a moto diverſum connotant et ſupponunt. Adeo ut, ſi, reliquis corporibus in nihilum redactis, globus, exempli gratia, unicus exiſtere ſupponatur; in illo motus nullus concipi poſſit: uſque adeo neceſſe eſt, ut detur

Of Motion.

the origin of our *ideas* of motion, his reaſoning appears unanſwerable; but we do not perceive how it concludes againſt the poſſibility of motion itſelf as exiſting in a ſingle body. It has been already ſhown in the chapter of *ſimple apprehenſion and conception*, that though nothing can be conceived which may not poſſibly exiſt, yet many things may be poſſible which we have not faculties or means to conceive. In the preſent inſtance, were this ſolitary globe animated as our bodies are, were it endowed with all our ſenſes and mental powers, it certainly would not acquire any *idea* of motion though impelled by the greateſt force. The reaſon is obvious; it would have no objects with which to compare its place and ſituation at different periods of time; and the experience of a ſhip at ſea in calm weather, affords ſufficient proof that motion which is equable cannot be perceived by any other means than by ſuch a compariſon. When the waves ſwell and the ſhip pitches, it is indeed impoſſible that thoſe who are on board ſhould not perceive that they are actually in motion; but even this perception ariſes from comparing their poſition with that of the waves riſing and falling around them: whereas in the regions of empty ſpace the animated globe could compare its poſition with nothing; and therefore, whether impelled by equal or unequal forces, it could never acquire the *idea* of motion. It may perhaps be thought, that if this ſolitary globe were a *ſelf*-moving animal, it might acquire the *idea* of motion by inferring its exiſtence from the energy which produced it. But how, we would aſk, could an animal in ſuch circumſtances be *ſelf*-moving? Motion is the effect of ſome cauſe; and it has been already ſhown (ſee n° 118. of this article), that we have no reaſon to ſuppoſe that any being can be the *real* and *primary* cauſe of any effect which that being can neither conceive nor will: but as motion can be perceived only by the ſenſes, a ſolitary animal could have no idea of motion previous to its own exertions; and therefore could neither conceive, nor will, an exertion to produce it. Let us, however, ſuppoſe, that without any end in view it might ſpontaneouſly exert itſelf in ſuch a manner as would produce *ſenſible* motion, were it ſurrounded with other corporeal objects; ſtill we may venture to affirm, that ſo long as it ſhould remain in abſolute ſolitude, the being itſelf would acquire no *idea* of motion. It would indeed be *conſcious* of the *mental* energy, but it could not infer the exiſtence of motion as a conſequence of that energy; for the idea of motion can be acquired only by ſenſe, and by the ſuppoſition there are no objects from which the ſenſes of this ſpherical animal could receive thoſe impreſſions, without which there can be no perception, and of courſe no ideas.

Let us now ſuppoſe, that, while this animated globe is under the influence either of external impulſe or its own ſpontaneous energy, other bodies are ſuddenly brought into exiſtence: would it then acquire the idea of motion? It certainly would, from perceiving its own change of place with reſpect to thoſe bodies; and though at firſt it would not perhaps be able to determine whether itſelf or the bodies around it were moving, yet a little experience would decide this queſtion likewiſe, and convince it that the motion was the effect either of its own *mental energy*, or that external *impulſe* which it had felt before the other bodies were preſented to its view. But it is obvious, that the creation of new bodies at a diſtance, can make no real alteration in the ſtate of a body which had exiſted before them: and therefore, as this animated globe would now *perceive* itſelf to be moving, we may infer with the utmoſt certainty that it *was moving* before; and that the motion of a ſingle body, though not *perceivable* by the ſenſes, might poſſibly be produced in empty ſpace.

19 Whether motion would be poſſible in ſpace abſolutely full.

Having thus ſeen that a ſingle body is capable of motion in empty ſpace, the next queſtion that occurs on this ſubject is, Whether it would be poſſible to move a body in ſpace that is abſolutely full? Such are the terms in which this queſtion is uſually put; and by being thus expreſſed, it has given riſe to the diſpute among natural philoſophers about the exiſtence of a *vacuum*. Perhaps the diſpute might have been avoided had the queſtion been more accurately ſtated. For inſtance, had it been aſked, Whether motion would be poſſible, could matter be ſuppoſed abſolutely infinite without any the leaſt interſtice or vacuity among its ſolid parts? we apprehend that every reflecting man would have anſwered in the negative. At any rate, the queſtion ought to be thus ſtated in metaphyſics; becauſe we have ſeen that ſpace, though a poſitive term, denotes nothing really exiſting. Now it being of the very eſſence of every ſolid ſubſtance to exclude from the place which it occupies every other ſolid ſubſtance, it follows undeniably, that not one particle of an infinite ſolid could be moved from its place without the previous annihilation of another particle of equal extent; but that annihilation would deſtroy the infinity. Were matter extended to any degree *leſs* than infinity, the motion of its parts would undoubtedly be poſſible, becauſe a ſufficient force could ſeparate thoſe parts and introduce among them vacuities of any extent; but without vacuities capable of containing the body to be moved, it is obvious that no force whatever could produce motion. This being the caſe, it follows, that however far we ſuppoſe the material univerſe extended, there muſt be vacuities

---

detur aliud corpus, cujus ſitu motus determinari intelligatur. Hujus ſententiæ veritas clariſſima elucebit, modo corporum omnium tam noſtri quam aliorum, præter globum iſtum unicum, annihilationem recte ſuppoſuerimus.

"Concipiantur porro duo globi, et præterea nihil corporeum, exiſtere. Concipiantur deinde vires, quomodocunque applicari: quicquid tandem per applicationem virium intelligamus, motus circularis duorum globorum circa commune centrum nequit per imaginationem concipi. Scilicet cum motus natura ſua ſit relativus, concipi non potuit priuſquam darentur corpora correlata. Quemadmodum nec ulla relatio alia ſine correlatis concipi poteſt." *De Motu*.

Mo- n.

vacuities in it sufficient to permit the motion of the planets and all the other heavenly bodies, which we plainly perceive to revolve round a centre: and if so, the next question to be determined is, What can *in vacuo* operate upon such immense bodies, so as to produce a regular and continued motion?

4 c- in- ot to hand t.

That all bodies are equally capable of motion or rest, has by natural philosophers been as completely proved as any thing can be proved by observation and experience. It is indeed a fact obvious to the most superficial observer; for if either of these states were essential to matter, the other would be absolutely impossible. If rest were essential, nothing could be moved; if motion were essential, nothing could be at rest, but every the minutest atom would have a motion of its own, which is contrary to universal experience. With respect to motion and rest, matter is wholly passive. No man ever perceived a body inanimated begin to move, or when in motion stop without resistance. A billiard ball laid at rest on the smoothest surface, would continue at rest to the end of time, unless moved by some force extrinsic to itself. If such a ball were struck by another ball, it would indeed be moved with a velocity proportioned to the impetus with which it was struck; but the impelling ball would lose as much of its own motion as was communicated to that upon which the impulse was made. It is evident, therefore, that in this instance there is no *beginning* of motion, but only the communication of motion from one body to another; and we may still ask, Where had the motion its origin? If the impelling ball was thrown from the hand of a man, or struck with a racket, it is plain that by a volition of the man's mind the motion was first given to his own arm, whence it proceeded through the racket from one ball to another; so that the ball, racket, and arm, were mere instruments, and the mind of the man the only agent or first mover. That motion can be *begun* by any being which is not possessed of life, consciousness, and will, or what is analogous to these, is to us altogether inconceivable. Mere matter or inanimated body can operate upon body only by impulse: but impulse, though from the poverty of language we are sometimes obliged to talk of its agency, is itself merely an effect; for it is nothing more than the contact of two bodies, of which one at least is in motion. An infinite series of effects without a cause is the grossest absurdity; and therefore motion cannot have been communicated from eternity by the impulse of body upon body, but must have been originally produced by a being who acts in a manner analogous to the energies of the human will.

Of Motion.

195 Motion produced by impulse can only be in a straight line.

But though motion could not have been begun but by the energy of mind, it is generally believed that it might be continued by the mere passivity of body; and it is a law of the Newtonian philosophy, that a body projected in empty space would continue to move in a straight line for ever. The only reason which can be assigned for this law is, that since body continues to move at all after the impetus of projection has ceased, it could not of itself cease to move without becoming active; because as much force is required to stop a body in motion as to communicate motion to the same body at rest. Many objections have been made to this argument, and to the law of which it is the foundation; but as we do not perceive their strength, we shall not fill our page with a formal examination of them (R). If a single body could exist and have motion communicated to it *in vacuo* by the force of projection, we are persuaded, that from the very passivity of matter, that motion would never have an end; but it is obvious that it could be moved only in a straight line, for an impulse can be given in no other direction.

196 The Newtonian doctrine respecting the causes of the motion of the heavenly bodies.

The heavenly bodies, however, are not moved in straight lines, but in curves round a centre; and therefore their motion cannot have been originally communicated merely by an impressed force of projection. This is admitted by all philosophers; and therefore the Newtonians suppose that the planets are moved in elliptical orbits by the joint agency of two forces acting in different directions. One of these forces makes the planet tend directly to the centre about which it revolves; the other impels it to fly off in a tangent to the curve described. The former they call *gravitation*, which some of them have affirmed to be a property inherent in all matter; and the latter, which is a projectile force, they consider as impressed *ab extra*. By the joint agency of such forces, duly proportioned to each other, Sir Isaac Newton has demonstrated, that the planets must necessarily describe such orbits as by observation and experience they are found actually to describe. But the question with the metaphysician is, Whether such forces be real?

197 Mutual attraction among the heavenly bodies impossible.

With respect to projection, there is no difficulty; but that bodies should mutually act upon each other at a distance, and through an immense vacuum, seems at first sight altogether impossible. If the planets are moved by the forces of gravitation and projection, they must necessarily move *in vacuo*; for the continual resistance

(R) By much the strongest and best urged of these objections which we have seen, is made by Dr Horsely, a man equally learned in mathematics and in ancient and modern philosophy. "I believe with the author of Ancient Metaphysics (says he), that some active principle is necessary for the continuance as well as for the beginning of motion. I know that many Newtonians will not allow this: I believe they are misled, as I myself have formerly been misled, by the expression *a state of motion*. Motion is a change; a continuance of motion is a farther change; a farther change is a repeated effect; a repeated effect requires a repeating cause. State implies the contrary of change; and motion being change, a *state of motion* is a contradiction in terms." See *Ancient Metaphysics*, Vol II.

If our readers think this reasoning conclusive, they may be in the right; and in that case they will see the necessity of admitting, even for the continuance of rectilineal motion, the *plastic nature*, or something equivalent to it, without which we have endeavoured to prove that the heavenly bodies could not revolve round their respective centres in elliptical curves.

Of Motion.

resistance of even the rarest medium would in time overcome the force of the greatest impetus: but if they move *in vacuo*, how can they be attracted by the sun or by one another? It is a self-evident truth, that nothing can act but where it is present, either immediately or mediately; because every thing which operates upon another, must perform that operation either by its own immediate agency or by means of some instrument. The sun and planets are not in contact; nor, if the motion of these bodies be *in vacuo*, can any thing material pass as an instrument from the one to the other. We know indeed by experience, that every particle of unorganised matter within our reach has a tendency to move towards the centre of the earth; and we are intuitively certain, that such a tendency must have some cause: but when we infer that cause to be a power of attraction inherent in all matter, which mutually acts upon bodies at a distance, drawing them towards each other, we talk a language which is perfectly unintelligible (s). Nay more, we may venture to affirm that such an inference is contrary to fact. The particles of every elastic fluid fly *from* each other; the flame of a fire darts *upwards* with a velocity for which the weight of the circumambient air cannot account; and the motion of the particles of a plant when growing, is so far from tending toward the *centre* of the earth, that when a flowerpot is inverted, every vegetable in it, as soon as it is arrived at a sufficient length, bends itself over the side of the pot, and grows with its top in the natural position.

198 The heavenly bodies cannot be moved by two forces impressed *ab extra*;

Sensible of the force of these arguments against the possibility of an attractive power in matter which operates at a distance, other philosophers have supposed that the heavenly bodies are moved in elliptical orbits by means of two forces originally impressed upon each planet impelling it in different directions at the same time. But if the tendency of the planets towards the centre of the sun be of the same kind with that of heavy bodies towards the centre of the earth (and if there be such a tendency at all, we have no reason to suppose it different), it cannot possibly be the effect of impulse. A body impelled or projected *in vacuo* would continue to be moved with an equable velocity, neither accelerated nor retarded as it approached the object towards which it was directed; but the velocity of a body tending towards the centre of the earth is continually accelerated: and as we cannot doubt but that the same thing takes place in the motion of a body tending towards the centre of the sun, that motion cannot be the effect of impulse or projection.

Some of the Newtonians therefore have supposed, "That all kinds of attraction consist in fine imperceptible particles or invisible effluvia, which proceed from every point in the surface of the attracting body, in all right-lined directions every way; which in their progress lighting on other bodies, urge and solicit them towards the superior attracting body; and therefore (say they) the force or intensity of the attracting power in general must always decrease as the squares of the distances increase." The inference is fairly drawn from the fact, provided the fact itself were real or possible: but it is obvious, that if fine imperceptible particles or invisible effluvia were thus issued from every point in the surface of the sun, the earth and other planets could not move *in vacuo*; and therefore the projectile motion would in time be stopped by the resistance

(s) Since this article was finished for the press, Professor Stewart's *Elements of the Philosophy of the Human Mind* have been given to the public; a work of which the merit is such as to make it painful to us to differ in any important opinion from the ingenious author. We shall, however, claim the same liberty of dissenting occasionally from him that he has claimed of dissenting from Newton, Locke, Clarke, and Cudworth, from whom he differs widely in thinking it as easy to conceive how bodies can act upon each other at a distance, as how one body can communicate motion to another by impulse. "I allow (says he, p. 79.), that it is impossible to conceive in what manner one body acts upon another at a distance through a vacuum; but I cannot admit that it removes the difficulty to suppose, that the two bodies are in actual contact. That one body may be the efficient cause of the motion of another body placed at a distance from it, I do by no means assert; but only that we have as good reason to believe that this may be possible, as to believe that any one natural event is the efficient cause of another."

If by *efficient* cause be here meant the *first* and *original* cause of motion, we have the honour to agree with the learned Professor; for we are persuaded that body inanimated is not, in this sense of the word, the cause of motion either at hand or at a distance: but if he mean (and we think he must, because such was the meaning of Newton, from whom he professes to differ), that we can as easily conceive one body to be the instrumental cause of the motion of another from which it is distant, as we can conceive it to communicate motion by impulse, we cannot help thinking him greatly mistaken. We will not indeed affirm, with the writer whom he quotes, "that although the experiment had never been made, the communication of motion by impulse might have been predicted by reasoning *à priori*;" because we are not certain, that without some such experiment we should ever have acquired adequate notions of the solidity of matter: But if all corporeal substances be allowed to be solid and possessed of that negative power to which philosophers have given the name of *vis inertiæ*, we think it may be easily proved *à priori*, that a sufficient impulse of one hard body upon another *must* communicate *motion* to that other; for when the *vis inertiæ*, by which alone the one body is kept in its place, is less than the *vis impetus* with which the other rushes to take possession of that place, it is evident that the former body *must* give way to the latter, which it can do only by motion, otherwise the two bodies would occupy one and the same place, which is inconsistent with their solidity. But that a substance possessed of a *vis inertiæ* should make another substance possessed of the same negative power quit a place to which itself has no *tendency*, is to us not only *inconceivable*, but apparently impossible, as implying a direct contradiction.

Of Motion.

ance of this powerful medium. Besides, is it not altogether inconceivable, nay impossible, that particles issuing *from* the sun should draw the planets *towards* that centre? would they not rather of necessity drive them to a greater distance? To say, that after they have reached the planets, they change their motion and return to the place whence they set out, is to endue them with the powers of intelligence and will, and to transform them from passive matter to active mind.

These difficulties in the theories of attraction and impulse have set philosophers upon fabricating numberless hypotheses: and Sir Isaac Newton himself, who never considered gravitation as any thing more than an effect, conjectured that there might be a very subtle fluid or ether pervading all bodies, and producing not only the motion of the planets, and the fall of heavy bodies to the earth, but even the mechanical part of muscular motion and sensation. Others (T) again have supposed fire, or light, or the electric fluid, to be the universal agent; and some few (U) have acknowledged, that nothing is sufficient to produce the phenomena but the immediate agency of mind.

With respect to the interposition of any material fluid, whether ether, fire, light, or electricity, it is sufficient to say that it does not remove any one difficulty which encumbers the theory of innate attraction. All these fluids are elastic; and of course the particles of which they are composed are distant from each other. Whatever motion, therefore, we may suppose to be given to one particle or set of particles, the question still recurs, How is it communicated from them to others? If one body can act upon another at the distance of the ten-thousandth part of an inch, we can perceive nothing to hinder its action from extending to the distance of ten thousand millions of miles. In the one case as well as the other, the body is acting where it is not present; and if that be admitted to be possible, all our notions of action are subverted, and it is vain to reason about the cause of any phenomenon in nature.

200
The hypothesis of Plato, Aristotle, and Cudworth,

This theory of the intermediate agency of a subtle fluid differs not essentially from the vortices of Des Cartes; which appeared so very absurd to Cudworth, that with a boldness becoming a man of the first genius and learning, he rejected it, and adopted the plastic nature of Plato, Aristotle, and other Greek philosophers. That incomparable scholar observes, that matter being purely passive, the motion of the heavenly bodies, the growth of vegetables, and even the formation of animal bodies, must be the effect either of the immediate agency of God, or the agency of a *plastic nature* used as an instrument by divine wisdom. That they are not the effect of God's immediate agency, he thinks obvious from several circumstances. In the first place, they are performed slowly and by degrees, which is not suitable to our notions of the agency of almighty Power. Secondly, Many blunders are committed in the operations of nature, such as the formation of monsters, &c. which could never be were things formed by the immediate hand of God. He is therefore of opinion, that, after the creation of matter, God employed an inferior agent to give it motion and form, and to carry on all those operations which have been continued in it since the beginning of the world. This agent he calls *plastic nature;* and considers it as a being incorporeal, which penetrates the most solid substance, and, in a manner which he pretends not to explain otherwise than by analogy, actuates the universe. He does not look upon it as a being endued with perception, consciousness, or intelligence; but merely as an instrument which acts under divine wisdom according to certain laws. He compares it to art embodied; and quoting from Aristotle, says, Ει ενην εν τω ξυλω ἡ ναυπηγικη ὁμοιως αν τῃ φυσει εποιει· *If the art of the shipwright were in the timber itself, operatively and effectually, it would there act just as nature doth.* He calls it a certain lower life than the animal, which acts regularly and artificially for ends of which it knows nothing. It may be, he says, either a lower faculty of some conscious soul, or else an inferior kind of life or soul by itself, but depending in either case upon a higher intellect. He is aware with what difficulty such a principle will be admitted by those philosophers who have divided all being into such as is extended and such as is cogitative: but he thinks this division improper. He would divide beings into those which are solid and extended, and those which have life or internal energy. Those beings which have life or internal energy he would again divide into such as act with consciousness, and such as act without it: the latter of which is this plastic life of nature. To prove that such an instrument is possible, or that a being may be capable of operating for ends of which it knows nothing, he instances *bees* and other animals, who are impelled by *instinct* to do many things necessary to their own preservation, without having the least notion of the purpose for which they work. (See INSTINCT.) He observes, that there is an essential difference between reason and instinct, though they are both the attributes of mind or incorporeal substance: and that therefore, as we know of two kinds of mind differing so widely, there is nothing to hinder us from inferring a third, with powers differing as much from instinct as instinct differs from reason. Mankind are *conscious* of their own operations, *know* for what *purpose* they generally act, and can by the power of *reflection* take a *retrospective* view of their actions and thoughts, making as it were the mind its own object. Brutes are *conscious* of their own operations, but they are ignorant of the *purposes* for which they operate, and altogether *incapable* of *reflecting* either upon their past conduct or past thoughts. Between their intellectual powers and those of man, there is a much greater difference than there is between them and a plastic nature, which acts as an instrument of divine wisdom without any consciousness of its own operations. Aristotle, from whom principally the

(U) Cudworth, Berkeley, and the author of Ancient Metaphysics.

Of Motion.

the learned author takes his notion of this plastic nature, compares it, with respect to the divine Wisdom which directs and superintends its operations, to a mere builder or mechanic working under an architect, for the purpose of which the mechanic himself knows nothing. The words of the Stagyrite are: Τους αρχιτεκτονας περι εκαστον τιμιωτερους και μαλλον ειδεναι νομιζομεν των χειροτεχνων, και σοφωτερους ὅτι τας αιτιας των ποιουμενων ισασιν οἱ δ' ὥσπερ και των αψυχων ενια, ποιει μεν, ουκ ειδοτα δε ποιει, οἷον καιει το πυρ· τα μεν ουν αψυχα φυσει τινι ποιειν τουτων εκαστον τους δε χειροτεχνας δι εθος *. "We account the architects in every thing more honourable than the mere workmen, because they understand the reason of the things done; whereas the other, as some inanimate things, only work, not knowing what they do, just as the fire burns: the difference betwen them being only this, that inanimate things act by a certain nature in them, but the workman by habit."

* Metaphys. Lib i. chap. 1.

201 Shown to be possible.

Still further to prove that a being may be endowed with some vital energy of a subordinate kind, and yet be destitute of consciousness and perception, the learned author observes, that there is no reason to think that the souls of men in sound sleep, lethargies, or apoplexies, are conscious of any thing; and still less, if possible, to suppose that the souls of embryos in the womb are from the very first moment of their arrival there intelligent and conscious beings: neither can we say, how we come to be so differently affected in our souls by the different motions made upon our bodies, nor are we conscious always of those energies by which we impress fantastic ideas on the imagination. But if it be possible for the souls of men to be for one instant void of consciousness and intelligence, it follows, that consciousness is not absolutely necessary to those energies and motions by which life is preserved. To this it may be added, upon the best authority ‡, "that where animal or vegetable life is concerned, there is in every case a different relation between the cause and effect, and seemingly depending upon the concurrence or influence of some farther principle of change in the subject, than what subsists in inanimate matter, or in the causes and effects that are the objects of mechanichal and chemical philosophy." Now to this principle of vegetable life, without which, in a seed or in a plant, vegetation will neither begin nor continue, tho' light, heat, air, earth, and water, should concur in the utmost perfection, Cudworth expressly compares his plastic nature in the universe. It is so far (says he) from being the first or highest life, that it is indeed the last and lowest of all lives, being really the same thing with the vegetative.

‡ Gregory's Philosophical and Literary Essays.

202 Argument for it; but

These arguments, if the phenomena of elective attractions in chemistry be added to them, demonstrate, we think, the *possibility* of such a principle: and to those who are inclined to affirm that no such thing can exist, because, according to the description of it given by Cudworth and the ancients, it is neither body nor spirit, in the proper sense of the words; we beg leave to ask in the words of Locke, "Who told them that there is and can be nothing but solid beings which cannot think, and thinking beings that are not extended? which is all that they mean by the terms body and spirit." All the Greek philosophers who were not materialists, and even the inspired writers of the Old and New Testaments, constantly distinguish between the *spirit* and the *soul* of a man, calling the former sometimes νους and sometimes πνευμα, and the latter ψυχη; and St Paul, who before he was a Christian was learned in philosophy, describes the constituent parts of man as three, πνευμα, ψυχη, σωμα, *spirit*, *soul*, and *body*. This distinction, setting aside the *authority* with which it comes to us, seems to be well founded; for there are many operations carried on in the human body without any conscious exertion of ours, and which yet cannot be accounted for by the laws of mechanism. Of these, Cudworth instances the motion of the diaphragm and other muscles which causes respiration, and the systole and diastole of the heart; neither of which, he thinks, can be the effect of mere mechanism. But, as we are not conscious of any energy of soul from which they proceed, even while we are awake, and still less, if possible, while we are asleep; he attributes them, not to the intellect or rational mind, but to this inferior vital principle called ψυχη (v); which, in his opinion, acts the

(v) The existence of this plastic nature was warmly debated between Monsieur Le Clerc and Monsieur Bayle. Mosheim, who was inclined himself to admit such a principle, gives the following view of Le Clerc's sentiments from *Bibliotheque choisie*, tom. ii. p. 113. "Respiratio, inquit et motus cordis, actiones sunt, quorum nihil ad animam pertinet. Interim mechanice eas fieri, nullo modo probabile est. In voluntariis commotionibus nesciunt animi nostri, quid facto opus sit, ut membra commoveantur: imperant illi tantum. Est vero aliud nescio quid, quod fideliter, si modo organa recte sint affecta, mandata ejus exsequitur. Quidni igitur suspicemur, esse *naturam* in corpore nostro *viventem*, præter animam nostram, cujus sit animæ præceptis et jussis morem gerere? quamquam potentia ejus ita sit definita, ut obedire nequeat animo, nisi recte sese habeant organa. Eadem forte natura, corporis nostri motibus impulsa, animam edocet, quid factum sit, ut ille possit præcipere, quæ ad conservationem corporis necessaria judicat. Anima, pergit, si hæc vera esse putes, similis erit domino, sibimet ipsi servire nescio, nec ulla facultate alia, quam imperandi et jubendi instructo. Hæc vero natura fictrix non dissimilis erit mancipii cui nihil eorum, quæ dominus meditatur, notum est, quodque nihil aliud facit, quam ut jussis pareat, et dominum de illis rebus admoneat, quæ ad salutem ipsius pertinent." Mosheim proceeds,—Si quis huic loco sic occurrat, Hæc ratione tria fingi in homine principia; respondet vir doctus: "Nullis constares argumentis, binis tantum hominem partibus constare. Eos, qui hominem ex binis tantum partibus component, nulla ratione explicare posse naturam conjunctionis animi et corporis, nisi ipsum Deum statuant cunctis actionibus hominum intervenire: hoc vero Divina Majestate prorsus indignum esse. Definitionem accuratam mediæ hujus naturæ postulantibus sese talem dare non posse definitionem respondet: Hoc unum sese scire: esse eam naturam interiori agendi virtute instructam, quæ ex se et animam et corpus afficere queat; naturam, quæ doceat animam quid rerum

Of Motion.

the same part in the system of the human body which the plastic nature acts in the system of the world.—To make the resemblance more striking, he observes, that even the voluntary motion of our limbs, though it proceeds ultimately from an energy of will, seems to be the effect of that energy employing some *instrument* which pervades the sinews, nerves, and muscles of the body; and if the human spirit or πνευμα employ the instrumentality of a plastic nature or ψυχη in moving the small machine of the body, it seems to be far from incredible that the Divine Wisdom should employ the instrumentality of a plastic nature in moving the great machine of the universe.

103 Whether it be necessary for the motions of the heavenly bodies are carried on by the agency of some e-thing immaterial.

But we need not insist further on the *possibility* of such an instrument. Whatever may be thought of the arguments of Cudworth, of which some are, to say the least of them, plausible, though others appear to us to have very little strength, Dr Clarke has proved, with a force of reasoning not inferior to mathematical demonstration, that the motions of the heavenly bodies are carried on by the agency of something very different from matter, under every possible form. "For, not to say that, seeing matter is utterly incapable of obeying any *laws* in the proper sense of the word, the very original laws of motion themselves cannot continue to take place, but by something superior to matter, *continually* exerting on it a certain force or power according to such certain and determinate laws; it is now evident beyond question, that the bodies of all *plants* and *animals* could not possibly have been formed by mere matter according to any general laws of motion. And not only so, but that most universal principle of *gravitation* itself, the spring of almost all the great and regular inanimate motions in the world, answering not at all the *surfaces* of bodies, by which alone they can act upon one another, but entirely to their *solid contents*, cannot possibly be the result of any motion originally impressed upon matter." For though it is true, that the most solid bodies with which we are acquainted are all very porous; and that, therefore, a subtle material fluid might penetrate the bodies of the planets, and operate upon them with a force exerted internally; still it is self-evident, that the *greatest* quantities of such a fluid could not enter into those bodies which are *least* porous, and where the greatest force of *gravitation* resides: "and, therefore, this motion must of necessity be caused by something which penetrates the very *solid substance* of all bodies, and continually puts forth in them a force or power entirely different from that by which matter acts upon matter †." Which is, as the same able writer observes, an evident demonstration, not only of the world's being originally made by a supreme intelligent Cause; but moreover, that it depends every moment upon some superior Being, for the preservation of its frame; and that all the great motions in it are caused by some immaterial power *perpetually* and *actually* exerting itself every moment in every part of the corporeal universe. This preserving and governing power, whether it be the immediate power and action of the same Supreme Cause that created the world, or the action of some subordinate instruments appointed by him to direct and preside respectively over certain parts thereof, gives us equally in either way a very noble idea of Providence. We know with certainty, that *real* and *original power* can belong only to a being endowed with intelligence and will; and, therefore, if the existence of Cudworth's (w) plastic nature be

† *Evidence of Nat. and Reveal'd Religion.*

---

rerum geratur in corpore; naturam denique, quæ animi mandatis, quorum tamen caussas nesciat, fideliter obtemperet." Reliqua, quæ illustrandæ hujus rei caussa CLERICUS affert, prætereo. Satis copiosa est in illis, quæ produximus, meditandi materia. *Mosheim. ed. Syst. Intellect.* p. 173.

Such a principle actuating the universe, if it be divested of intelligence, and considered as a second or inferior cause, under the direction of the Supreme, is acknowledged by a very able judge to be a rational hypothesis; and such, if properly pursued, would certainly open a most entertaining scene of natural philosophy. See *Jones's Answer to an Essay on Spirit.*

(w) Besides Cudworth, we have mentioned Berkeley and the author of *Ancient Metaphysics*, as holding all motion to be an effect of the immediate agency of mind or incorporeal substance. The opinion of the last of these philosophers is not essentially different from Cudworth's; and therefore it is needless to quote from him: Berkeley was better acquainted with the principles of the Newtonian philosophy, as well as an abler mathematician, than either of these pupils of the ancients; and being likewise a man who on all subjects thought for himself, it may be worth while to lay before our readers a short abstract of his reasoning respecting the origin of motion. His words are: "Totum id quod novimus, cui nomen *corpus* indidimus, nihil in se continet quod motus principium seu causa efficiens esse possit. *Vis*, *gravitas*, *attractio*, et hujusmodi voces, utiles sunt ad ratiocinia et computationes de motu et corporibus motis; sed non ad intelligendam simplicem ipsius motus naturam, vel ad qualitates totidem distinctas designandas. Attractionem certe quod attinet, patet illam ab Newtono adhiberi, non tanquam qualitatem veram et physicam, sed solummodo ut hypothesin mathematicam. Quin et Leibnitius, nisum elementarem seu solicitationem ab impetu distinguens, fatetur illa entia non re ipsa inveniri in rerum natura, sed abstractione facienda esse. Similis ratio est compositionis et resolutionis virium quarumcunque directarum in quascunque obliquas, per diagonalem et latere parallelogrammi. Hæc mechanicæ et computationi inserviunt: sed aliud est computationi et demonstrationibus mathematicis inservire, aliud rerum naturam exhibere. Revera corpus æque perseverat in utrovis statu, vel motus vel quietis. Ista vero perseverantia non magis dicenda est actio corporis, quam existentia ejusdem actio diceretur. Cæterum resistentiam, quam experimur in sistendo corpore moto, ejus actionem esse fingimus vana specie delusi. Revera enim ista resistentia quam sentimus, passio est in nobis, neque arguit corpus agere, sed nos pati: constat utique nos idem passuros fuisse, sive corpus illud a se moveatur, sive ab alio principio impellatur.—Actio et reactio dicuntur esse in corporibus: nec incommode ad demonstrationes mechanicas. Sed cavendum, ne propterea suppo-

Of Motion.

be admitted, (and we see not (x) why it should be called in question), it can be considered only as an instrument employed by Divine Wisdom, as a chizzel or a saw is employed by the wisdom of the mechanic.

204 This theory not inconsistent with the principles of Newton.

Nor let it be imagined, that this ancient theory of motion is in any degree inconsistent with the mathematical principles of Sir Isaac Newton's astronomy, or with the calculations raised from those principles. Having founded his astronomy on analogy between the phænomena of projectile and planetary motions, he assigned the same or similar *forces* existing in nature as the efficient causes of both. And indeed, both in the act of deriving his *principles* from the projectile phenomena, and afterwards for the purpose of applying them to the planetary, it was necessary to analyze the elliptical motion of the heavenly bodies into a compound of two simple motions in right lines, produced by the action of these different forces; and this might also be useful for the purposes of teaching and demonstration, just as we find it necessary, in all parts of science, to separate what in nature is inseparable, for the convenience and assistance of the understanding. The planetary motions, however, are very probably simple and uncompounded, for no experiments can be tried in those distant regions; and the astronomy of Newton, which is only the application of his mathematical principles to their mensuration from their *analogy* to projectile motions, does not at all require that the forces of gravitation and projection be assigned as their real existent causes (Y). It is sufficient for the *analogy*, on which the whole philosophy is founded, that the phenomena of motion are known from experiments and observations to be the *same* in *both* instances; that the *principles* or *general laws* mathematically established from the *forces* of the *one* are transferred to the *phenomena* of the *other*; and that the proofs and operations deduced from these principles in the latter case, are confirmed by *facts* and *experience*, the first and final test of truth.*

CHAP. VI. *Of* NUMBER.

205 Unity an idea, cannot

" AMONGST all the ideas that we have, as there is none (says Mr Locke‡) suggested to the mind by more ways, so there is none more simple than that of UNITY or one. It has no shadow of variety or composition in it. Every object our senses are employed about, every idea in our understandings, every thought of our minds, brings this idea along with it: and there-

‡ Essay, Book ii. chap. 16

supponamus virtutem aliquam realem, quæ motus causa sive principium sit, esse in iis. Etenim voces illæ eodem modo intelligendæ sunt ac vox *attractio*: et quemadmodum hæc est hypothesis solummodo mathematica, non autem qualitas physica; idem etiam de illis intelligi debet, et ob eandem rationem.

" Auferantur ex idea corporis extensio, soliditas, figura, remanebit nihil. Sed qualitates istæ sunt ad motum indifferentes, nec in se quidquam habent, quod motus principium dici possit. Hoc ex ipsis ideis nostris perspicuum est. Si igitur voce *corpus* significatur id quod concipimus, plane constat inde non peti posse principium motus: pars scilicet nulla aut attributum illus causa efficiens vera est, quæ motum producat. Vocem autem proferre, et nihil concipere, id demum indignum esset philosopho.

" Præter res corporeas, alterum est genus rerum cogitantium: in iis autem potentiam inesse corpora movendi, propria experientia didicimus, quando quidem anima nostra pro lubitu possit ciere et sistere membrorum motus, quacunque tandem ratione id fiat. Hoc certe constat, corpora moveri ad nutum animæ, eamque proinde haud inepte dici posse principium motus; particulare quidem et subordinatum, quodque ipsum dependeat, a primo et universali principio.

" Ex dictis manifestum est eos qui vim activam, actionem, motus principium, in corporibus revera inesse affirmant, sententiam nulla experientia fundatam amplecti, eamque terminis obscuris et generalibus adstruere, nec quid sibi velint satis intelligere. E contrario, qui mentem esse principium motus volunt, sententiam propria experientia munitam preferunt, hominumque omni ævo doctissimorum suffragiis comprobatam.

" Primus Anaxagoras τον νουν introduxit, qui motum inerti materiæ imprimeret: quam quidem sententiam probat etiam Aristoteles, pluribusque confirmat, aperte pronuncians primum movens esse immobile, indivisibile, et nullum habens magnitudinem. Dicere autem, omne motivum esse mobile, recte animadvertit idem esse ac siquis diceret, omne ædificativum esse ædificabile. Plato insuper in Timæo tradit machinam hanc corpoream, seu mundum visibilem, agitari et animari a mente, quæ sensum omnem fugiat. Et Newtonus passim nec obscure innuit, non solummodo motum ab initio a numine profectum esse, verum adhuc systema mundanum ab eodem actu moveri. Hoc sacris literis consonum est: hoc scholasticorum calculo comprobatur."

De Motu, passim.

(x) This we say upon the received opinion, that there are beings wholly incorporeal. The truth of the opinion itself will be considered in a subsequent chapter.

(Y) Indeed Sir Isaac himself is very far from positively assigning them as the *real* causes of the phenomena. The purpose for which they were introduced into his philosophy he clearly explains in the following words: " Eadem ratione qua projectile vi gravitatis in orbem flecti posset et terram totam circumire, potest et luna, vel vi gravitatis, *si modo gravis sit*, vel alia quacunque vi qua in terram urgeatur, retrahi semper a cursu rectilineo terram versus et in orbem suum flecti: et absque tali vi luna in orbe suo retineri non potest. Hæc vis, si *justo minor* esset, non satis flecteret lunam a cursu rectilineo; si *justo major*, plus satis flecteret, ac de orbe terram versus deduceret. Requiritur quippe ut sit *justæ magnitudinis*: et mathematicorum est invenire vim, qua corpus in dato quovis orbe data cum velocitate accurate retineri possit; et vicissim invenire viam curvilineam, in quam corpus e dato quovis loco data cum velocitate egressum data vi flectatur."——*Principia Mathem.* Def. V.

Of Number.

therefore it is the most intimate to our thoughts, as well as it is, in its agreement to all other things, the most universal idea we have; or number applies itself to men, angels, actions, thoughts, every thing that either doth exist or can be imagined. "He seems likewise to be of opinion that we have the idea of *unity* before that of *many;* and that it is by repeating the simple idea of unity in our own minds that we come by the *complex ideas* of *two, three,* &c." In this opinion he is joined by Pere Buffier *; who observes that it is impossible to explain the nature of *unity,* because it is the most simple idea, and that which perhaps *first* occurred to the mind.

That *unity* is a simple idea, must be granted; but it certainly did not first occur to the mind, nor can it be abstracted from all individuals, and apprehended in Locke's sense of the word as a *general idea.* Let any man look into his own mind, and then say whether he has a general idea of *one* or *unity* as abstracted from every individual object mental and corporeal. In particular, when he thinks he has completely abstracted it from body and mind, sensations, ideas, actions, and passions, &c. let him be sure, before he pronounce it a general *abstract* idea, that he is not all the while contemplating the idea of its *name,* or of that numerical *figure* by which it is marked in the operations of arithmetic. Both these ideas are in themselves particular; and become general in their import, only as representing every individual object to which unity is in any sense applicable. But in the chapter *of abstraction,* we have said enough to convince every person capable of conviction that they are used as signs for whole classes of objects.

Instead of being an abstract general idea, *unity,* as the basis of number, is in fact nothing but a mere *relation,* which cannot be conceived without the related objects; and so far is it from being the *first* idea that occurred to the mind, that it is certainly the result of a comparison, made by the intellect, of two or more objects. The ideas which first occur to the mind are, beyond all doubt, those which are called *ideas of sensation;* and many such ideas every child receives before he is capable of comparing objects and forming to himself notions of number. *Unity,* or the idea of *one,* is indeed the element of the science of *arithmetic,* just as a mathematical *point* is the element of the science of *geometry;* but accurate notions of these elements are, in the progress of knowledge, subsequent to ideas of *many* and of *surfaces.* There is reason to believe that persons totally illiterate have no notion at all of *mathematical points;* and we think it possible to conceive an intelligent and conscious being in such a situation as that he could not acquire a notion of *unity* or *one.* Were a child never to see or feel two objects of the *same kind,* we doubt if he would think of numbering them, or of making such a comparison of the one with the other as would suggest to his mind the relations of *one* and *two;* for these relations imply both a sameness and a difference of the objects beyond the power of a child to ascertain. The difference indeed would be perceptible to the senses, but the senses would perceive no sameness or agreement. A guinea, a shilling, and a ball of lead, impress upon the mind different sensations; and therefore a child undoubtedly distinguishes these objects from one another: but what could make him derive from them his first idea of the relation of number? A guinea, a shilling, and a ball of lead, are not *one, two, three,* in any sense which a child can comprehend. To be convinced of this, let any man throw a guinea, a shilling, and a ball of lead upon a table, and ask a *clown* what is their number. From being accustomed to retail the *names* of number as signs, without affixing to them any idea of the things signified, he will probably answer with quickness *three,* or perhaps *one, two, three:* but if he be further asked in what *respect* they are *one, two, three,* we believe his answer will not be so ready: They are not *one, two, three guineas,* or *shillings,* or *balls of lead.* A philosopher knows them to be three pieces of the same first matter under different forms, and can therefore apply to them the relation of number with truth and propriety; but of the first matter a *clown* is entirely ignorant, and of course cannot call them *one, two, three,* in any sense which is at once true and to him intelligible.

To make it still more evident, that it is only by comparing together things of the *same kind* that our *first* ideas of unity and number are formed, let us suppose no created being to have hitherto existed except the animated and intelligent globe mentioned in the last chapter, and we think it will be granted that such a being in solitude could never acquire the idea of *unity.* Let us next suppose a *cubical* body to be created and exhibited to the senses of this spherical man; the consequence would be a *sensation* or feeling entirely new: but that feeling would not be of *unity;* for, as the author of *Ancient Metaphysics* has somewhere well observed, unity is no object of sensation. The sensation would be of colour, hardness, softness, roughness or smoothness, &c. for beyond these the empire of the senses does not reach. Again, let another body be created of a colour and figure totally different from the colour and figure of the cube, and the spherical man would then experience new sensations having no agreement with those which he had formerly felt. These different kinds of sensations might be compared together; but the result of the comparison would not be the ideas which are denoted by the words *one* and *two,* but merely that which is expressed by *difference* or *dissimilarity.* Were another cube, however, of exactly the same size and colour with the former to be brought into existence, and both to be at once presented to the view of the spherical man, the rudiments of the idea of number would then be generated in his mind, because he could not but perceive the cubes to be in one respect different and in another the same; different as being distinct from each other, and agreeing in their effects upon the organs of sensation.

208
Men must have made some progress in classing things according to genera and species, before they acquired any notion of number.

It appears, therefore, that mankind must have made some progress in classing things according to their genera and species, before they acquired any correct ideas of the relation of number, or thought of using numerical names or figures as general and discriminating signs: for we say *one, two, three,* &c. only with respect to the species or genus of which each of the things denoted by these numbers is an individual; and if there be any thing which has no genus or species, neither number nor unity can, in the original sense of the

Of Number.

the words, be predicated of it (z). We say indeed that there is *one* God; but perhaps we do not always attend to the meaning of the expression. Language was formed to answer the common purposes of life; and those purposes are best answered by denoting individuals by the name of the species or genus to which they belong: but *God* belongs to no species or genus, unless he be said improperly (A) to be of the universal genus of *Being*; and therefore the true meaning of the word *one*, when joined to the verb *is*, and transferred from the creature to the Creator, in such a sentence as—"there *is one* God"—seems to be nothing more than an affirmation that God exists, and that to him the relation of number cannot be applied. In a word, *unity* and *number* are merely relations between the individuals of the same species or genus of being; and men acquire ideas of these relations at the same time and by the same means that they are led to class things into species and genera. As to the processes of addition and subtraction, and the various purposes to which number is applied, these things belong to the science of arithmetic, and fall not under the province of the metaphysician, whose sole object is to ascertain the real nature and causes of things. It may, however, be worth while to observe, that Locke, whose notions of number seem to have been different from ours, owns, that a man can hardly have any ideas of numbers of which his language does not furnish him with names. But if units were either real things, or even positive ideas, we see not how *names* could be necessary to their existence; whereas, if they be nothing more than mere relations, it is obvious that they cannot be conceived but as relative either to beings actually existing, or to names which are the signs of actual beings.

Chap. VII. *Of* Time.

209 Time, a mode of duration in contradistinction to eternity.

When St Augustine was asked what time is? he replied, "*Si non roges, intelligo.*" An answer from which it may be inferred, that he thought the nature of *time* could not be explained by a logical definition. *Time* and *eternity* are commonly considered as the two modes of *duration*; and if duration be taken in what Locke thinks its true and original sense, to denote permanence of existence with a kind of resistance to any destructive force, the distinction seems to be sufficiently proper. It is indeed the best that we can make or comprehend; for *duration*, *time*, and *eternity*, are subjects which have perplexed philosophical minds in all ages, and of which if we have adequate notions, it is very difficult to express these notions in language. Instead of attempting it by previous definitions, the method in which the ancients generally began their inquiries, we shall pursue the better course of induction recommended by Lord Bacon, and endeavour to show by what means we acquire the notion of that mode of duration which is called *time* in contradistinction to *eternity*. We begin with time; because we ourselves exist in it, and it is in some sense familiar to us. If we be able to trace our notions of this mode of duration to their source, we may then give a definition of it founded on fact and universal experience, and afterwards proceed to consider the other mode in conjunction with infinity, to which it is nearly allied.

It has been already observed (see n° 93 of this article), that every man, while awake, has a train of sensations and ideas constantly passing through his mind, in such a manner as that the one succeeds the other in a regular order. It is not possible, either, by detaining in the mind one idea to the exclusion of all others, to stop the course of this succession entirely; or, by hurrying some ideas off the stage, and calling others in their place, to quicken its progress beyond a certain degree. One man indeed has naturally a quicker succession of ideas than another; and all men can, by great exertions, accelerate or retard in a small degree the natural flow of their thoughts. A studious man lays hold, as it were, of a particular idea, which he wishes to contemplate, and detains it in the imagination, to the exclusion of all others; a man of wit calls remote ideas into view with a rapidity of which a cool and phlegmatic reasoner can form no conception; and a forcible *sensation* takes full possession of the mind, to the exclusion of all *ideas* whatever. Whilst the attention is wholly occupied by one idea, or by one sensation, the mind has no notion whatever of time; and were it possible to detain such idea or sensation alone in the mind till the hand of a clock should move from the number of one hour to that of another, the hour, as marked on the dial-plate and measured by the motion of the hand, would appear but as one instant absolutely void of duration. For the truth of this assertion we appeal to the experience of our readers. Such of them as have ever been engaged in deep study must often have had their attention

210 Whilst the mind is occupied by one idea or notion, there is no perception of time which

(z) We are happy to find our notions on this subject confirmed by an authority so respectable as that of Professor Stewart. "Without the power of attending separately to things which our senses present to us in a state of union, we never (says this able writer) could have had any idea of *number*: for before we can consider different objects as forming a multitude, it is necessary that we should be able to apply to all of them one common name; or, in other words, that we should reduce them all to the same genus. The various objects, for example, animate and inanimate, which are at this moment before me, I may class and number in a variety of different ways, according to the view of them that I choose to take. I may reckon successively the number of sheep, of cows, of horses, of elms, of oaks, of beeches; or I may first reckon the number of animals, and then the number of trees; or, I may at once reckon the number of all the organized substances which my senses present to me. But whatever be the principle on which my classification proceeds, it is evident that the objects numbered together must be considered in those respects only in which they agree with each other; and that if I had no power of separating the combinations of sense, I never could have conceived them as forming a plurality." *Elements of the Philosophy of the Human Mind*, chap. iv.

(A) We say *improperly*, because beings which were *created* can have nothing in *common* with that being which is *self-existent*, and upon whose *will* and *power* all other things depend.

attention ſo fixed upon one object, that large portions of time, as meaſured by the clock, have paſſed away wholly unheeded; and every man who has ſeen a very ſtriking and uncommon object, muſt remember, that when the ſenſation was firſt impreſſed upon his mind, all other objects, ideas, and notions, and among the reſt the notion of time, were for a while excluded.

No ſenſation, however, keeps poſſeſſion of the whole mind after it has ceaſed to be new; nor can the moſt vigorous exertions long preſerve any one idea from being driven off the ſtage by the ſucceeding train. Now this ſucceſſion of ideas appearing and diſappearing in their turns, is that which, when compared with the permanency of ourſelves and other things, gives us our firſt and juſteſt notion of time: for whilſt we are thinking, or whilſt a ſeries of ideas is ſucceſſively paſſing through our minds and vaniſhing, we know that we ourſelves and the things around us exiſt; and this exiſtence, or continuation of exiſtence, commenſurate with the train of our fleeting ideas, is what we call the *duration* of ourſelves and the things around us.

We are aware that our firſt notions of time have been often ſaid to be derived from *motion* as perceived by our ſenſes in the objects around us. It is obſerved by Euclid, that "if there were no *motion*, there could be no ſound, nor any ſenſe of hearing." "He might have added (ſays the author of Ancient Metaphyſics), nor any other perception of ſenſe. Further, without motion there would have been no viſible world, nor generation or production of any kind here below; and, among other things, *time* could have had no exiſtence." All this is certainly true; but that corporeal motion, though the original ſource of all our ideas, is not that which *immediately* ſuggeſts to us the notion of time, will be readily granted by him who conſiders that motion itſelf is perceived by us only when it excites or accompanies a conſtant ſucceſſion of perceptions and ideas. Motion, when equable and very ſlow, ſuch as that of the hour-hand of a common watch, is not perceived by us in its courſe; nor can we diſcover that the thing has moved at all, till after we have been ſenſible of the lapſe of a conſiderable portion of what is commonly called *time;* when we diſcover that the hand of the watch has changed its place with reſpect to other objects which we know to be fixed. The ſame is true of motion remarkably quick: "Let a cannon-ball (ſays Locke) paſs through a room, and in its way take with it any limb or fleſhy parts of a man; it is as clear as any demonſtration can be, that it muſt ſtrike ſucceſſively the two ſides of the room: it is alſo evident that it muſt touch one part of the fleſh firſt, and another after, and ſo in ſucceſſion: and yet I believe nobody who ever felt the pain of ſuch a ſhot, or heard the blow againſt the two diſtant walls, could perceive any ſucceſſion either in the pain or ſound of ſo ſwift a ſtroke."

Of theſe two phenomena a ſatisfactory account may be eaſily given; from which we think it will at the ſame time be apparent, that the ſucceſſion of the train of ideas in the mind is the meaſure and ſtandard of all other ſucceſſions. We know that the energy of mind which reviews a train of ſenſible ideas is of the very ſame kind with that which attends to a ſeries of paſſing ſenſations (ſee n° 69); and therefore it is natural to ſuppoſe that we can pay attention to ſenſations and ideas paſſing with nearly equal velocities. But it has been ſhown, that every ſenſation remains in the mind or ſenſorium for a very ſhort ſpace after the object which excited it is taken away: whence it follows, that a body communicating to the organs of ſenſe a ſeries of ſimilar impreſſions ſucceeding each other with remarkable rapidity, cannot excite a train of ſimilar and diſtinct ſenſations; becauſe the effects of the firſt and ſecond impreſſions not having vaniſhed when thoſe of the third and fourth arrive, the whole train of effects muſt neceſſarily coaleſce into one uniform ſenſation. This reaſoning is confirmed by experience. Similar ſounds ſucceeding each other at conſiderable intervals, are all diſtinctly perceived; and if the motion be accelerated gradually, it may be carried to a great degree of velocity before the ſounds be confounded and coaleſce into one. "Mr Herſchel having, by means of a clock, produced ſounds or clicking noiſes, which ſucceeded each other with ſuch rapidity that the intervals between them were, as far as could be judged, the ſmalleſt poſſible, found that he could evidently diſtinguiſh one hundred and ſixty of them in a ſecond of time; but beyond that he could by no effort of attention diſtinguiſh one ſound from another. The ſame philoſopher tried another experiment on viſible ſenſations. By means of the ſame handle and work of the clock, he cauſed a wheel in it to turn till it acquired the velocity of once in a ſecond. He continued to increaſe the velocity, and obſerved it while revolving at the rate of twenty times round in thirteen ſeconds, and could ſtill diſtinguiſh the teeth and ſpaces from each other; whence it appears (by a computation given at length), that he had two hundred and forty-ſix diſtinct viſible ſenſations generated by equable motion in a ſecond of time. The teeth of the wheel, he owns, were not ſo far viſible as to ſhow their ſhape diſtinctly, much leſs could they have been counted: but he very plainly diſtinguiſhed the circumference to be divided into teeth and ſpaces; and he ſuppoſes that the ſame diviſion might ſtill have been ſeen though the motion had been a little faſter, as far perhaps as two turns in a ſecond, equal to three hundred and twenty ſenſations *." The reaſon that the diviſion could not be ſeen whilſt the wheel moved more rapidly than twice round in a ſecond of time, was doubtleſs the continuance of that agitation in the brain from which each ſenſation proceeded, until a new impreſſion cauſed a new agitation, which coaleſced with the former and removed all diſtinction. Hence it is plain, that no external ſucceſſion can be perceived which moves with a greater velocity than that of which the internal train of ſenſations and ideas is capable. On the other hand, an external ſucceſſion which moves with leſs rapidity than that to which the internal flow of ideas may be reduced, either has not ſufficient force to generate ſenſations at all, or the ſucceſſive impreſſions from which the ſenſations proceed follow one another at ſuch diſtances as to permit the natural train of ideas to intervene between them, and thus deſtroy the perception of the ſucceſſion entirely.

* *Watſon's Treatiſe on Time.*

To us, therefore, it ſeems evident, that the conſtant and regular ſucceſſion of ideas in the mind of a waking man, is the meaſure and ſtandard of all other ſucceſſions; of which, if any one either exceeds the pace of which our ideas are capable, or falls ſhort of

it,

Of Time.

it, the ſenſe of a conſtant and continued ſucceſſion is loſt, and we perceive it not but with certain intervals of reſt between. So that it is not motion, but the conſtant train of ideas in our minds, that ſuggeſts to us our firſt notion of time; of which motion no otherwiſe gives us any conception, than as it cauſes in our minds a conſtant ſucceſſion of ſenſations: and we have as clear a notion of time by attending to the train of ideas ſucceeding each other in our minds, as by a train of ſenſations excited by conſtant and perceptible motion.

That it is merely by comparing the permanent exiſtence of things with the fleeting ſucceſſion of ideas in our own minds that we acquire our notions of time, may perhaps be ſtill more evident from the following narrative quoted by Dr Beattie *, from *L'Hiſtoire de l'Academie Royal des Sciences pour l'annee* 1719. "A nobleman of Lauſanne, as he was giving orders to a ſervant, ſuddenly loſt his ſpeech and all his ſenſes. Different remedies were tried without effect. At laſt, after ſome chirurgical operations, at the end of ſix months, during all which time he had appeared to be in a deep ſleep or deliquium, his ſpeech and ſenſes were ſuddenly reſtored. When he recovered, the ſervant to whom he had been giving orders when he was firſt ſeized with the diſtemper, happening to be in the room, he aſked whether he had executed his commiſſion, not being ſenſible, it ſeems, that any interval of time, except perhaps a very ſhort one, had elapſed during his illneſs." If this ſtory be true, here was a man, who, by the train of ideas vaniſhing at once from his mind, loſt the perception of what was to others ſix months of time; and had all mankind been in his ſtate, the ſame portion of time would have been irrecoverably loſt even to the annals of chronology.

* *Eſſay on Truth.*

We are aware of an objection to any inference which may be drawn reſpecting the preſent queſtion from the caſe of this nobleman. It may be ſaid, that he had loſt, together with the perception of time, the perception of every thing beſides; and that, therefore, motion may ſtill be the cauſe from which a waking man derives his notions of time. But in reply to this objection, we beg leave to aſk, Whether if a ball had been put in motion on a table, and the nobleman had been told, that a body moved with the velocity of that ball would have been carried over ſo many thouſand miles of diſtance during the time that he lay in a ſtate of inſenſibility, he could from ſuch information alone have formed any tolerable notion of the length of time in which he was inſenſible? He certainly could not, for want of a ſtandard by which to meaſure the rapidity of the motion. He would, indeed, have known inſtantly that he had been inſenſible for a conſiderable length of time, becauſe he had the evidence of former experience that a body carried by perceptible motion over a great extent of diſtance would have generated in his mind a vaſt train of ſucceſſive ſenſations; but till he had attended this ball during part of its courſe, and compared with the permanency of other objects the ſeries of ſenſations which it generated in his mind, he would not have been able to gueſs with any thing near to accuracy the length of time it would take to paſs over a thouſand miles.—The ſame inſenſibility of duration happens to every man in ſound ſleep. From having notions of time, ſuch as they are, formed in our minds, we never indeed ſuppoſe, however ſoundly we have ſlept, that the moment at which we awake in the morning is contiguous to that in which we fell aſleep at night. The reaſon is obvious; every man has been awake whilſt others were ſleeping, and has known by experience, that if they had been awake likewiſe a train of ideas would have paſſed through their minds which muſt have ſuggeſted to them the notions of time. Moſt men, too, have been frequently awake whole nights, and have thus acquired a notion of time as going on inceſſantly, whether perceived by them or not; and this notion being cloſely aſſociated with our ideas of night and morning, we inevitably ſuppoſe a portion of time to have elapſed between them, though unperceived by us in our ſleep. But were a man to ſleep without dreaming from Sunday night till Tueſday morning, and then to awake at his uſual hour as marked on the clock, there are numberleſs inſtances on record to convince us, that he would not of himſelf ſuppoſe, nor perhaps be very eaſily perſuaded, that more than one night had elapſed between his falling aſleep and the moment at which he awoke.

It being thus evident, that our notion of time is ſuggeſted by that compariſon which we inevitably make of the exiſtence of things permanent with the train of ideas inceſſantly paſſing through our minds; we may now perhaps be able to anſwer the queſtion, "What is time?" It muſt of neceſſity be one of three things, viz. either the ideal ſucceſſion itſelf; a certain quality inherent in all objects; or merely the relation of co-exiſtence between things that are permanent and the trains of fleeting ideas which ſucceed each other on the theatre of the imagination. It is not the firſt of theſe; for in every train of thought, the appearance of any one idea in the mind occupies no more of the extenſion of time, than a mathematical point occupies of the extenſion of diſtance. Ten thouſand mathematical points added together would make no part of a line; and ten thouſand ideas made to coaleſce, if that were poſſible, would occupy no part of that mode of duration which is called *time*. A point is the boundary of a line, but no part of it: the appearance of an idea in the mind is inſtantaneous; and an inſtant is the boundary, but no part of time. Hence it follows, that were every thing inſtantaneous like ideas in a train, there could be no ſuch thing as time, ſince nothing could be ſaid to have in that ſenſe of the word any duration. That time is not a quality inherent in all objects, is likewiſe plain; for we have ſeen, that were *ideas* as permanent as objects, the notion of time could never have been acquired. Succeſſion, though it does not itſelf conſtitute time, is eſſential to its exiſtence; and were all motion to ceaſe, and the attention of men to be immoveably fixed upon one invariable object or cluſter of objects, *time* would ceaſe likewiſe. It remains, therefore, that time can be nothing elſe than the relation of co-exiſtence apprehended between things that are permanent and thoſe trains of fleeting ideas which inceſſantly ſucceed each other on the theatre of the imagination. Thus whilſt a man is ſteadily looking at one object, which, from its being common, does not occupy his whole mind, he may be conſcious of a thouſand ideas ſtarting up in

21. Time mere relation of exiſtence.

Of Time. in his imagination, and each in its turn vanifhing the inftant in which it appeared. Every one of thefe ideas had an exiftence as well as the object at which he is looking; but the exiftence of each of them was inftantaneous and in fucceffion, whilft the exiftence of the external object is permanent. The object, therefore, as contrafted with the train of ideas, is faid to endure or to exift in time, whilft each idea is deftitute of duration, and exifts in no time.

Objections obviated. To this theory fome objections occur, which it will be incumbent upon us to obviate. It may be faid, that though each idea confidered by itfelf is inftantaneous, and occupies no time; yet the whole train when taken together, without being compared with any thing external, is perceived to occupy a confiderable portion of that mode of duration; and that, therefore, time itfelf muft be fomething more than a mere relation between a fleeting fucceffion of ideas and objects of more permanent exiftence. But how, we beg leave to afk, is the whole train perceived to occupy any portion of time? Is it not by being compared with our own exiftence? A man, whilft a train of ideas is paffing through his mind, may be fuddenly deprived of all his external fenfes, and then indeed it will be impoffible for him to compare the fleeting exiftence of this internal fucceffion with the more permanent exiftence of external things; but, whilft he thinks at all, he muft be confcious of his *own* exiftence, and cannot avoid perceiving, that whilft his ideas pafs in conftant fucceffion, each making an inftantaneous appearance in his mind, he himfelf remains unchanged. Now, what is it that this perception fuggefts to the mind? Evidently nothing more than the relation of co-exiftence between a fleeting fucceffion and a permanent object; for were it poffible that the man could be deprived of memory as well as of his fenfes, and ftill have ideas fucceeding each other in his mind, he would then think all objects equally fleeting; he would indeed be himfelf a mere fucceffion of inftantaneous diftinct perfons, and could have no notion whatever of time. His exiftence, though it fhould feem to endure half a century as eftimated by others, muft to himfelf appear to pafs away like a flafh of lightening.

It may be ftill further objected to our theory, that time is meafured by motion; and that it feems very abfurd to talk of meafuring a relation, efpecially a mere *ideal* relation, by a real external thing. In anfwer to this objection, which at firft fight appears formidable, we beg leave to obferve, that all relations are equally ideal; and that yet many of them may be faid to be meafured by real external things, with as much propriety as time can be faid to be meafured by motion. When a man wifhes to afcertain the relation of quantity which one body bears to another, though he knows that fuch a relation has no other than an ideal exiftence, and cannot be conceived but in conjunction with the related bodies, he applies to them fucceffively fome common ftandard; and having difcovered the relation which each bears to that, he compares the one relation with the other, and thus afcertains the relation fought. Juft fo it is with refpect to motion meafuring time. That which to each individual conftitutes real time, is the relation of co-exiftence between the fleeting fucceffion of his own ideas and other things of a more permanent nature. But a man has often occafion to afcertain the time of things external which fall not under the infpection of his fenfes; and in fociety all men have tranfactions with one another to be performed in fome determinate portion of time, though there are not, perhaps, two men exifting whofe ordinary trains of thought flow with precifely the fame rapidity. To remedy thefe inconveniences, it was neceffary to invent fome common ftandard, by means of which men might afcertain the duration of actions performed at a diftance, and be able to keep appointments made with each other. The only ftandard proper for thefe purpofes is fuch a conftant and equable motion as has fuggefted a flux of perceptions common to all men in all ages and countries; and hence the motions of the heavenly bodies have been univerfally made ufe of for the common regulators of time. Thefe motions, however, do not conftitute real and natural time, any more than a foot or a yard applied to two diftant bodies conftitutes the relation of quantity which thefe bodies bear to each other. They are merely ftated meafures, to be differently applied according to the different purpofes which we have in view.

Thus, if a man in Europe wifhes to know what would to him have been the *real* and *natural* time of an action performed in the Eaft Indies, he has only to be told, that it was co-exiftent, we fhall fuppofe, with a diurnal revolution of the earth; and by comparing this common meafure with his ufual flow of thought, he can form fome notion of the extent of that train of ideas, which, had he been prefent, would to him have been fucceffively co-exiftent with the action in queftion. But when perfons have an appointment to keep, this common meafure of motion muft be differently, or rather partially, applied. In fuch cafes, it is no part of their intention to compare their own exiftence with that of the whole train of ideas which may pafs in the mind of each; for the refult of fuch a comparifon, which alone conftitutes true and natural time, would not be the fame in perhaps any two men: but their purpofe is, to compare their own permanent exiftence only with that train of fenfations which fhall be excited in the mind by the perceptible motion of the fun, or any other body fixed upon which moves equably; and fuch a train muft confift of an equal number of inftants in all men. Neither the fun, nor the hour-hand of a common watch, moves with fuch apparent rapidity as to keep pace with the internal flow of thought of which the moft phlegmatic man is confcious. That thefe bodies move at all, is known only by their vifible change of place during the lapfe of a confiderable portion of real time; and as there is in their courfe a certain number of places diftinctly marked, to which alone it is agreed that the attention is to be turned, it is impoffible that of time fo computed two men can have different notions. Such time, however, is but partial; and the method of afcertaining it, when compared with that by which we afcertain real time, has a ftriking refemblance to that by which we afcertain the relation of partial quantity between two diftant bodies. When it is our purpofe to afcertain the relation of real quantity which one body bears to another, we apply the common ftandard to each in every dimenfion of length, breadth, Of Time.

breadth, and depth; but when we have no other view than to afcertain the relation of length which the one bears to the other, we apply the common ftandard to each in that dimenfion only. Juft fo it is with regard to real and partial time. When an individual wifhes to afcertain what would to him have been the duration of any action which he did not fee performed, he applies the common ftandard to the exiftence of that action, and to the ufual flow of his own thoughts; but when two men talk of the duration of any action, or agree to meet on fuch a day, they compare the exiftence of the action, or the diftance intervening between the prefent moment and the day of meeting, only with that partial train of fenfations which by the common ftandard is generated in an equal number, and in the fame order, in the minds of both.

215 Time muft have had a beginning.

It will be faid, that if time be nothing more than a mere relation fubfifting between trains of ideas or other fleeting objects, and things of a more permanent exiftence; and if the univerfe had a beginning; either time muft have had a beginning likewife, or the Deity cannot be immutable. We allow the force of the argument; but inftead of an objection, we confider it as a confirmation of the truth of our theory. The Deity, who is immutable, exifts not in time, but in eternity; and that thefe, though from the poverty of language they are both called modes of duration, are yet very different from each other, we fhall endeavour to prove in the next chapter.

Chap. VIII. *Of* Infinity *and* Eternity.

216 Why we treat of infinity and eternity among the adjuncts of body.

As corporeal fubftance is certainly not infinite, and as the prefent material fyftem has in itfelf every evidence of its not being eternal, it may feem ftrange, perhaps, to the reader, that we fhould treat of infinity and eternity among the adjuncts of body. But in modern metaphyfics thefe words are ufed in a vague fenfe to denote the extent of fpace and time; and in this chapter it is our intention to do little more than afcertain their meaning, and to fhow, in oppofition to fome celebrated names, of what fubjects they may not be predicated. There is a mathematical and a metaphyfical infinity, which, though often confounded, ought to be kept diftinct. In mathematics, extenfion is faid to be divifible *ad infinitum*, and number is fometimes confidered as infinite: but in metaphyfics thefe modes of expreffion are extremely improper. A pofitive and metaphyfical infinite is that which has no limits, and to which no addition can be made; but it is obvious that there is no number which may not be enlarged, nor any pofitive idea of extenfion which has not limits, and which may not be either increafed or diminifhed. The infinity of the mathematician is termed *infinity in power*, and that of the metaphyfician *abfolute infinity*. The firft confifts in this, that a being, however great or fmall it be fuppofed, may ftill be conceived to poffefs more greatnefs or minutenefs than we can form an idea of, even after the utmoft ftretch of human thought. Thus when it is faid that all extenfion as fuch is infinitely divifible, it is not meant that every extended fubftance contains an infinite number of *real parts*; for then the parts of an inch would be equal to thofe of a league: but the meaning is, that in ideal extenfion we can never reach the end of ideal divifion and fubdivifion. In like manner, when it is faid that number is infinite, the meaning is not that any pofitive number is without limits, or the poffibility of increafe, but that we might go on for ever; adding unit to unit, without approaching nearer to the end of the procefs. If, therefore, the mathematician would fpeak properly, and without the affectation of paradox, he ought to fay that all extenfion as fuch is *indefinitely* divifible, and that unit might be added to unit without end; but thefe phrafes fuggeft notions very different from that of a metaphyfical infinite, which is fomething pofitive to which nothing can be added. (B)

Of Infinity and eternity.

21[7] Space and time held to be the one infinite, the other eternal.

That there is fomething pofitively infinite, has been very feldom queftioned; but it has been warmly difputed among metaphyficians what fubjects are infinite. Dr Clarke and his adherents have contended that fpace and time are real things; that they are both of neceffary exiftence; that the former impreffes us with the idea of its infinity, and that the latter is pofitively eternal. "Time and fpace (fays the Doctor*) are the *fine qua non* of all other *things*, and of all other *ideas*. To fuppofe either of them *finite*, is an exprefs *contradiction* in the idea itfelf. No man *does* or *can* poffibly *imagine* either of them to be finite; but only either by *non-attention* or by *choice* he attends perhaps to *part* of his *idea*, and *forbears attending to* the remainder. They who fuppofe *fpace* to be nothing but a *relation between two bodies* are guilty of the abfurdity of fuppofing that which is *nothing* to have *real qualities*: *For the fpace which is between two bodies* is always unalterably juft what it was, and has the very fame dimenfions, quantity, and figure, whether *thefe* or any *other bodies* be there or any where elfe, or not at *all*. Juft as *time* or *duration* is the fame, whether you turn your *hour-glafs* or no, or whether the fun moves or ftands ftill, or whether there *was* or *was not any fun*, or any *material world* at all. To fet *bounds* to fpace is to fuppofe it *bounded* by fomething which itfelf *takes up fpace*, and that's a *contradiction*; or elfe that it is *bounded by nothing*, which is another contradiction. To fuppofe fpace *removed*, *deftroyed*, or *taken away*, amounts to the abfurd fuppofition of removing a thing away *from itfelf*; that is, if in your *imagination* you *annihilate* the *whole* of *infinite fpace*, the whole of *infinite fpace* will ftill remain; and if you annihilate any *part* of it, *that part* will ftill *neceffarily* remain, as appears by the unmoved fituation of the *reft*; and to fuppofe it *divided* or *divifible* amounts to the fame contradiction."

* *Demonftration of the Being and Attributes of God, a Correfpondence with a Gentleman of Gloucefterfhire.*

The abfurdity of confidering fpace as a real external thing has been already evinced in chap. 4th, p. 549, where it was fhown how we acquire the notion, and what kind of notion it is. Space, as was there obferved, may be conceived either as the mere abfence and poffibility of body; or as ideal extenfion, united to, and inhering in, an ideal fubftratum. Taken in the former fenfe, it is an object of pure intellect; in the latter, it is

(B) Ου γαρ ου μηδεν εξω αλλ' ου αει τι εξω εστι, τουτο απειρον εστι. *Arift. Phyf. Aufcult. Lib. 9. cap. 9. page 492, Tom. I. Oper.*

ity is an *idea* or *form* in the imagination. That the abſence of body or matter is the *ſine qua non* of all other things, and all other ideas, Dr Clarke was not diſpoſed to affirm, when he made the divine ſubſtance, to pervade every material atom in the univerſe: and to talk of the abſence of body being infinite is a palpable contradiction, unleſs Berkeley's doctrine be true, that the material world has no exiſtence. To ſay that the *poſſibility* of matter is infinite, is to uſe language which has no other meaning than that, however far the material world be on all ſides extended, its extenſion may ſtill be conceived greater and greater *ad infinitum*. This is a poſition which no philoſopher ancient or modern has ever denied; but it is ſo far from implying that we have a poſitive idea of the infinity of the material world, or of any adjunct of the material world, that it is abſolutely inconſiſtent with ſuch infinity. Whatever is capable of perpetual increaſe muſt certainly have limits, and every new addition is the limit of that to which the addition was made.

Taken in the ſecond acceptation as an ideal extenſion united with an ideal *ſubſtratum*, ſpace is ſo far from being infinite in any ſenſe of the word, that we will venture to aſſert no man ever contemplated ſuch a *form* in his own imagination, without conceiving it to be bounded. Of this, at leaſt, we are certain, that when we have attempted to frame a poſitive idea of pure ſpace, it has not been in our power to diveſt that idea of limits. Thoſe who can frame in their minds real and poſitive ideas wholly abſtracted from every individual object, may indeed perform in this way many feats above our abilities; but as we poſſeſs no ſuch powers of abſtraction, every thing which we can call an idea is limited in the ſame manner that the object itſelf is limited from which the idea was derived.—Thus, the largeſt expanſion that ever we beheld is the concave hemiſphere; and when we try to form the largeſt poſitive idea of pure ſpace, all that we can do is to figure to ourſelves that concave empty of body. We may, indeed, ſuppoſe its diameter to be either a million or ten thouſand millions of miles; and we may go on enlarging it *ad infinitum*: but when we return from this proceſs of intellect to the contemplation of the ideal forms in the imagination, none of theſe forms appear to us larger or more extended than the hemiſphere, which is the object of ſenſe, and they all appear to be bounded, and bounded in the very ſame way.

With reſpect to the eternity of time, we think Dr Clarke equally miſtaken as with reſpect to the infinity of ſpace. Of time, indeed, we cannot properly ſpeaking have any *idea* or mental *form*. Time, as we have ſeen, is a mere relation, and is in itſelf the creature of the mind which has no external *ideatum*. It is ſuggeſted, however, by the fleeting ſucceſſion of our ideas, compared with the more permanent exiſtence of other objects; and therefore ſucceſſion is eſſential to it. But nothing which has parts, whether co-exiſtent or in ſucceſſion, can be poſitively infinite. For, "in an infinite ſeries of ſucceſſive generations of men, for inſtance, there will be ſeveral infinites that are parts of one another, and by conſequence one greater than another: which (as has been well argued *) is an expreſs contradiction, ſince the greater muſt neceſſarily bound the leſs, and exceed its limits by ſo much as it is greater than it; that is, muſt make it not infinite. Infinite generations contain an infinitely greater infinity of particular men. An infinite number of men muſt have twice as many hands, and ten times as many fingers, and ſo on. Infinite time has an infinity of ages; theſe a much greater infinity of years, days, hours, &c. Space likewiſe (according to Dr Clarke) has three dimenſions, all infinite. It muſt, therefore, contain an infinity of ſurfaces, an infinitely greater infinity of lines, and a ſtill infinitely greater infinity of phyſical points. The caſe is the ſame in number itſelf, which, if we ſuppoſe it to contain an abſolute infinity of thouſands (and we may as well do that as imagine it to comprehend an infinity of units), it will contain ten times as many hundreds, fifty times as many ſcores, and ſo on. All this is only the *indefiniteneſs* of number, which we in vain attempt to turn into a poſitive infinite with which it is totally incompatible. For let us add *one* to any of theſe infinite ſeries of generations, ages, lines, or numbers, which we know to be always in our power, and if it was abſolutely infinite before, here is one more than infinite. If it only becomes infinite now, then one finite added to another finite makes infinity. If it be no larger after the addition than it was before, then one part added to another adds nothing; all which are abſurdities. The ſame will appear, if we ſubtract a part from this ſuppoſed abſolute infinite, which may be done in any of the formentioned ſubjects, as well as in every thing which admits of parts, or may be taken in pieces by the mind."

Of Infinity and Eternity.

221 The uſual reply to the foregoing reaſoning ſhown

To this kind of reaſoning Dr Clarke replies as follows: "To endeavour to prove that there cannot poſſibly be any ſuch thing as *infinite time* or *ſpace*, from the impoſſibility of an addition of finite parts ever compoſing or exhauſting an infinite; or from the imaginary inequality of the number of years, days, and hours, that would be contained in the one; or of the miles, yards, and feet, that would be contained in the other, is ſuppoſing infinites to be made up of numbers of finites; that is, it is ſuppoſing finite quantities to be *aliquot* or *conſtituent parts* of infinite, when indeed they are not ſo, but do all *equally*, whether *great* or *ſmall*, whether *many* or *few*, bear the very ſame proportion to an infinite, as mathematical points do to a line, or lines to a ſuperficies, or as moments do to time, that is, none at all. No given number or quantity can be any *aliquot* or *conſtituent* part of infinite, or be compared at all with it, or bear any kind of proportion to it, or be the foundation of any argument in any queſtion concerning it."

If it be indeed true, and it is that for which we contend, that no given number or quantity can be any aliquot or conſtituent part of infinite, or be compared at all with it; then it undeniably follows, not that miles, yards, and feet, are no conſtituent parts of ſpace; or years, days, and hours, conſtituent parts of time; but that ſpace and time cannot poſſibly be poſitive infinites. This, we ſay, follows undeniably: for nothing is more evident, than that all quantities of the ſame kind, from the largeſt to the leaſt, bear a certain proportion to each other; and upon the ſuppoſition that ſpace is a real extended thing, miles, yards, and feet are included in it, and bear to it the relation of parts to a whole. The ſame is true of time, days, and hours. To aſſum (for no proof is offered), that all

Of Infinity and Eternity.

all finite quantities, whether great or small, whether many or few, do equally bear the very same proportion to an infinite, as mathematical points do to a line, or as moments do to time, is plainly to beg the question—"that *space* considered as a real extended thing is *infinite*;" and to beg it, too, in opposition to the common sense and reason of mankind. Mathematical points we all know to be nothing real, but merely negations of extension; but supposing space to be something real and extended, can any man persuade himself that a mile or a million of miles of this space is likewise a mere negation of extension? With him who can bring himself to this persuasion, we pretend not to argue. He is possessed of faculties, whether true or false, of which we are destitute.

222 to be a *petitio principii.*

That finite quantities, whether great or small, do all equally bear the same proportion to an *infinite in power*, is indeed true; but it is no great discovery: for such an infinite, as we have seen, is nothing but the continued possibility of repeating the same mental process of addition or multiplication; and he who can go on for ever adding, in his own imagination, foot to foot, or hour to hour, will find it equally easy to add, in the same manner, league to league, or age to age. If he can perform the one operation, he must likewise have power to perform the other; and he cannot but perceive that it is as impossible to come to an end of adding league to league, or age to age, as of adding foot to foot, or hour to hour; but then he must know that these leagues, feet, ages, and hours, are not real external things, but mere ideas and notions in his mind. If such powers of ideal multiplication and addition be what Dr Clarke means by the ideas of space and time, it is indeed a contradiction to suppose either of them limited; for that is to suppose our powers different from what we know them to be by consciousness and experience. But to confound *powers* with the *objects* of those powers, is certainly very inacurate; and to suppose, because we can go on for ever adding one portion of ideal space or time to another, that therefore our ideas of space and time are in themselves positively infinite, is a contradiction: for to an idea positively infinite, it is obvious that nothing can be added. Either, therefore, space and time do not impress us with the ideas of their positive infinity; or we cannot have the power of adding league to league, and age to age, without end.

"But (says the Doctor), to suppose space removed, destroyed, or taken wholly away, amounts to the absurd supposition of removing a thing from itself; that is, if in your imagination you remove the whole of space, the whole of space will still remain." True, every man has ideas of space treasured up in his imagination, which the sound of the very word space will at all times bring into his immediate view; and whilst he has such ideas, it is impossible that he should not have them; which is all the mystery of the matter, and amounts to nothing more than that a thing cannot be and not be at the same instant. When the Doctor affirms, that if "you annihilate any part of space, that part will necessarily remain, as appears by the unmoved situation of the rest", we are not certain that we perfectly understand him. A man may surely think of a cubical inch without thinking of a foot or a yard; and he may suppose the inch taken away from the foot or the yard, and these ideal quantities so much lessened by the subtraction. But if the Doctor be here again confounding the powers of the mind with the positive ideas of space, the sentence when explained will be seen to contain nothing to his purpose. Every man has the power of contemplating in idea millions of miles, and millions of ages, and of adding mile to mile, and age to age, without end; and if he try to deprive himself of any part of this power, or to fix a limit to the mental process of addition, he will find that in spite of himself his imagination will ramble beyond the limit assigned, and that he has attempted an impossibility. This, however, is so far from being a proof that his ideas of space and time are positively infinite, that, as we have already observed, it is a proof of the contrary.

But (say this great man and his followers) "space and time are the *sine qua non* of all other things and all other ideas. The supposal of the existence of *any thing whatever* includes necessarily a *presupposition* of the existence of *space* and *time*;" and therefore, if there be any thing infinite and eternal, space and time must likewise be so.

Space and time said to be the *sine qua non* of other things

To every corporeal substance, and every idea of such substance, space and time are indeed necessary: for every body has extension and duration; and every idea of a particular body, being nothing but a secondary perception in the imagination or memory, must have the same relation to imaginary extension, that the object from which it was derived has to extension which is real. Every idea, too, which remains in the imagination whilst a train of other ideas passes successively in view, or whilst external things are perceived to change, has real time. But will any man say that *consciousness*, our notion of *power*, our acts of *willing*, or even *tastes*, *sounds*, and *smells*, are extended, or that the supposal of their existence necessarily implies a presupposition of the existence of space? We acquire our ideas of extension and space by means of our senses of touch and sight; and we learn from experience, that things external and extended are the causes of our sensations of taste, sound, and smell. The effects are in our minds closely associated with the ideas of their causes; and it is not perhaps easy to think of a particular sound, taste, or smell, without at the same time thinking of the object by which it was at first excited in the mind: but had we been originally formed with the powers of consciousness, thinking, and willing, and with no other senses than those of tasting, smelling, and hearing, it is obvious that we never could have had the idea of *space*; and therefore, that idea cannot possibly be necessary to the presupposition of every thing else. To consciousness, thinking, and willing, space is so far from being necessary, that we cannot perceive any the most distant relation between them. It is not more difficult to conceive a part greater than the whole, than it is to conceive an ell of *consciousness*, of *thought*, or of *will*; nor is it in the power of any man to make *space* and *sweetness* coalesce in his mind so as to form of the two simple ideas one complex conception. The very reverse is the case with respect to the objects of sight and touch. The idea of every thing which we see and handle necessarily

there are things which no ... space.

ly coaleſces in the mind with the idea of ſpace, nor can we poſſibly ſeparate the one from the other; but the things which we ſee and handle are neither infinite nor capable of infinity.

With reſpect to time, the ſame obſervations will be found to be juſt as with reſpect to ſpace. Whatever is liable to change, exiſts in time and cannot be eternal; but if there be any being immutable, and who views at once all things which to us are paſt, preſent, and to come, the exiſtence of that being is not commenſurable with time. That ſuch a being is poſſible no man can doubt, who reflects, that if we had one permanent idea invariably in the mind, we ſhould never have acquired the *notion* of ſucceſſion or of time; and that if there were *actually* no *change* in nature there could not poſſibly in nature be any ſuch *thing as time*. Every man, therefore, who can conceive exiſtence without change, muſt be convinced, that "the ſuppoſal of the exiſtence of any thing whatever does *not* neceſſarily include the preſuppoſition of the exiſtence of time; and that there may be an eternity diſtinct from time, as well as an infinity diſtinct from ſpace; nay that nothing which is properly infinite and eternal can poſſibly occupy either ſpace or time.

If it be aſked, what kind of infinity and eternity they are which have no relation to ſpace and time? Cudworth, treading in the footſteps of the ancients, has long ago anſwered, that they are "abſolute perfection, and neceſſary exiſtence. For (ſays he), *infinite underſtanding* and *knowledge* is nothing elſe but *perfect* knowledge, which hath in it no defect or mixture of ignorance, but knows whatſoever is knowable. In like manner, *infinite power* is nothing elſe but *perfect* power, which hath in it no defect or mixture of impotency—a power which can do every thing which is poſſible or conceivable. Laſtly, *infinity of duration*, or *eternity*, is really nothing elſe but *perfection*, as including in it *neceſſary exiſtence* and *immutability*; ſo that it is a contradiction to ſuppoſe ſuch a being to have had a beginning, to ceaſe to be, or to ſuffer or be affected by any change whatever. And becauſe infinity is perfection, therefore nothing which includes in its idea or eſſence any thing of *imperfection*, as every poſitive idea of number, corporeal magnitude, and ſucceſſive duration evidently does, can be truly and properly infinite." *

Infinity and Eternity.

It muſt indeed be confeſſed, that the idea of ſucceſſion ſo inſinuates itſelf into our uſual ideas of exiſtence, and is ſo cloſely connected with the exiſtence of all finite beings, that we find it extremely difficult to imagine the eternal exiſtence of God, any otherwiſe than as an eternally continued ſeries or ſucceſſion. Our conſtant converſation with material objects, and the aſſociations thence ariſing, make it almoſt impoſſible for us to conſider things abſtracted from time and ſpace; yet we have the evidence of experience and conſciouſneſs, that an idea may be conceived without relation to ſpace and time, and that ſpace and time cannot be made to coaleſce with ſome of our notions. The ſame muſt be true with reſpect to infinity and eternity; for we have ſeen that neither ſpace, time, nor any thing elſe which conſiſts of parts, whether continuous or ſucceſſive, can be ſuppoſed to be poſitively infinite, as the ſuppoſition implies the moſt palpable contradiction. But that there may be perfect power, perfect knowledge, and permanent invariable exiſtence, is ſo far from implying any contradiction, that even we, whoſe faculties are ſo very narrow, can yet make ſome advances towards the conception of ſuch perfections. Thus, every man of common underſtanding knows that ſome things are in themſelves poſſible, and others impoſſible, to be performed by any power. Of theſe poſſibilities and impoſſibilities a philoſopher knows more than an illiterate man; and one philoſopher knows more than another. An intellect more perfect knows more of them than any man; and that intellect which knows them all muſt be abſolutely perfect, and incapable of improvement, becauſe it knows every thing which is to be known. The ſame is true of perfect power:—but we ſhall treat of real infinity and eternity more at large when we come to demonſtrate the being and attributes of God. At preſent it is ſufficient to have ſhown, that nothing can be poſitively infinite but a being abſolutely perfect; which never was not, which can produce all things poſſible and conceivable, and upon which all other things muſt depend.

* Intellectual Syſtem.

PART III. OF MINDS AND THEIR POWERS.

CHAP. I. *Of* MIND *in* GENERAL.

THE ſcience of metaphyſics comprehends every thing into the exiſtence, nature, or cauſes, of which any inquiry may be made. But all things of which we have any notion or idea may be divided into mind and body, with their various powers, qualities, and adjuncts. By body is meant that which is ſolid, extended, inert, and diviſible; and its ſeveral adjuncts are ſpace, motion, number, and time. The only mind with which we are *intimately* acquainted is our own; and we know that it is poſſeſſed of the powers of ſenſation, perception, retention, conſciouſneſs, reflection, reaſon, and will. Theſe are totally different from extenſion, ſolidity, diviſibility, and motion; and therefore it is proper to diſtinguiſh the being of which they are powers by another name than that of body.

228 Probably minds of different orders.

Of bodies there are various kinds poſſeſſing various ſenſible qualities; and from analogy it is reaſonable to conclude, that there may be various claſſes of minds endowed with different kinds or degrees of power. For this indeed we have ſtronger evidence than that of analogy. Brute animals evidently poſſeſs the powers of perception and ſpontaneity with ſome degree of conſciouſneſs; but as they appear not to reflect upon their own conduct, or to have their actions influenced by motives, their minds are inferior to ours, though ſtill perfectly diſtinct from mere extended, inert, and diviſible ſubſtances. Mind, therefore, conſidered with reſpect to its powers, is evidently different from body conſidered with reſpect to its qualities. This is indeed

Of Mind in general.

a truth which has ſeldom if ever been controverted; but it has been long and warmly diſputed, Whether mind and body be not both compoſed of the ſame firſt matter?

229 The abſurd hypotheſis of Hobbes reſpecting mind.

Hobbes ſuppoſed, that every material atom is endowed with the faculty of ſenſation (c); but that for want of memory each ſenſation is momentaneous, being inſtantly and wholly effaced as ſoon as its cauſe is removed. Though this hypotheſis is too abſurd to require a formal and laboured confutation, it may not be improper to obſerve, that, if it were true, the hairs of a man's head would feel extreme pain when pinched by the hot iron of the hair-dreſſer; and that the nails of his fingers would be ſeverely tortured when under the operation of the knife or the raſp.

230 Other abſurd hypotheſes.

Others have ſuppoſed that each atom of matter has a *tendency towards* ſenſation and perception; and that when a ſufficient number of theſe atoms are brought together in a certain order, the *united tendencies* produce the *actual* powers which diſtinguiſh mind from groſs body. This ſuppoſition is if poſſible more abſurd than that of Hobbes. Senſation and perception are of ſuch a nature, that a mere *tendency towards* them is inconceivable. A thing muſt either be ſenſible and percipient, or inſenſible and inert: there is evidently no medium. Or if we could ſuppoſe each individual atom to have a *tendency* towards ſenſation, it would by no means follow that a number of ſuch atoms brought together in any poſſible order would become one ſentient, thinking, and active being. A number of bodies laid upon an inclined plain have each a *tendency* to roll downwards; but if the declivity of the plain be not ſuch as that their ſeparate tendencies may overcome the reſiſtance oppoſed to each individual body by friction, the *united tendencies* of all the bodies when brought together will not be able to overpower the reſiſtance of their united frictions. Juſt ſo is it with reſpect to ſenſation and perception: If the tendency of one atom cannot overcome one degree of inertneſs, the tendency of a thouſand atoms will not overcome a thouſand degrees of the ſame inertneſs.

231 Only two opinions at preſent on the ſubject.

We have juſt mentioned theſe abſurd ſuppoſitions that our article might be complete: but it is proper to inform the reader, that, ſo far as we know, neither of them has for theſe many years been maintained by any philoſopher of eminence either at home or abroad. The opinions on this ſubject, which at preſent divide the republic of letters, are two; and theſe alone are worthy of examination. One party maintains, That perception, memory, reaſon, and will, &c. are the powers of a being which muſt be immaterial and indiviſible: The other alleges, That as we know nothing of theſe powers but from our own conſciouſneſs, and as we can trace them in ourſelves to the brain and no farther, we have no reaſon to ſuppoſe that they are the powers of any ſubſtance diſtinct from matter. Both parties, however, diſtinguiſh that which in man is the ſubject of thought from his external organs of ſenſe, and agree to call it by the name of *mind*; though the one conſiders it as compoſed of the ſame firſt matter with the duſt of the ground; whilſt the other believes it to have no property whatever in common with that matter.

Were we to adopt ſome of the ancient methods of philoſophiſing, this important queſtion might be ſoon decided. A moſt reſpectable writer, who has laboured to reſtore the metaphyſics of Plato and Ariſtotle, hopes to confute the materialiſts, by laying down what they muſt think arbitrary definitions of mind and matter, and then ſhowing that the one is not the other. "In all the parts of the material world (ſays he) there is a perpetual *motion*: For the celeſtial bodies move conſtantly in one reſpect or another; and all here below is in a continual viciſſitude of generation and corruption, which cannot be without *motion*. Now, where there is *motion*, there muſt be ſomething that *moves*: What is *moved* I call *body*; what moves I call *mind*." From this definition he undertakes to prove, that mind muſt be immaterial. "That there is a relation between *moving* and *being moved* (ſays he), nobody can deny; and the relation is no other than that of *action* and *paſſion*. But the nature of relation is ſuch, that it muſt neceſſarily be between two things at leaſt; and it is further neceſſary, that the two things related ſhould exiſt together. Hence, if there be that which *moves*, there muſt be a different thing that *is moved*; and wherever the one is, the other muſt neceſſarily be; ſo that nothing can move itſelf. This being eſtabliſhed, I ſay that what *moves* muſt be either material or immaterial: for the one of theſe being the negation of the other, there can be no middle betwixt them; becauſe a thing muſt neceſſarily *be*, or not *be*. If then it be immaterial, there is an end of the queſtion: but if it be ſaid to be material, then I ſay that it muſt be *moved* itſelf before it can move any thing elſe; for it is only in that way that body can move body. If then it muſt be firſt moved itſelf, but cannot itſelf move itſelf, what is it that moves it? If it be anſwered, That it is another material mover, then I repeat the ſame queſtion, to which the ſame anſwer muſt be given: and ſo we have an infinite ſeries of *material movers*, without any beginning or *principle* of *motion*. Now this is abſurd, and contradictory to this firſt principle of natural philoſophy, admitted by all philoſophers ancient and modern, That *nothing can be produced without a cauſe* ‡."

‡ Anci. Metaſ. ...

For the immateriality of the human mind, and of every being endowed with the powers of perception and thought, the learned writer has better arguments; but it is upon this chiefly that he reſts his perſuaſion, that mind is the only *mover* in the univerſe. It is needleſs to obſerve, that in the very definitions and axioms upon which this reaſoning is built, the thing to be proved is taken for granted: for if it be ſelf-evident,

3

(c) Scio fuiſſe philoſophos quoſdam, eoſdemque *viros doctos*, qui corpora omnia ſenſu prædita eſſe ſuſtinuerunt: *Nec video*, ſi natura ſenſionis in reactione ſola collocaretur, QUOMODO *refutari poſſint*. Sed etſi ex reactione etiam corporum aliorum, phantaſma aliquod naſceretur; illud tamen, remoto objecto, ſtatim ceſſaret. Nam niſi ad retinendum motum impreſſum, etiam remoto objecto, apta habeant organa, ut habent animalia; ita tantum ſentient, ut nunquam ſenſiſſe ſe recordentur. Senſioni ergo, quæ vulgo ita appellatur, neceſſario adhæret memoria aliqua. *Hobbes's Phyſic*, cap. 25. ſect. 5.

dent, that what *moves* is, in the author's ſenſe of the word, *mind*, that what is *moved* is *body*, and that *nothing can move itſelf*, all reaſoning on the ſubject is ſuperfluous. This, however, is ſo far from being ſelf-evident, that a materialiſt may reply, "every animal moves itſelf, and yet every animal is nothing more than a ſyſtem of matter." This poſition, whether true or falſe, can neither be proved nor confuted by arguments *à priori* founded on general definitions. That animals move themſelves, and that to the ſenſes they appear to be nothing elſe than ſyſtems of matter, are facts which cannot be controverted. If we would know whether they have in them a principle of motion which is not material, we muſt ſubmit to the laws of induction (ſee Logic); and by inveſtigating the eſſential qualities of matter, endeavour to aſcertain whether a material ſyſtem can be rendered active. That we ourſelves have active powers, we know by the moſt complete of all evidence, *viz.* conſciouſneſs of their energies; and it has been already ſhown, that ſuch powers as we experience in ourſelves cannot exiſt but in a ſubject poſſeſſed of will and underſtanding. The queſtion therefore to be firſt decided between the materialiſts and immaterialiſts is, Whether the powers of conſciouſneſs, underſtanding, and will, can reſult from the particular organiſation of a ſyſtem of matter? If they can, we have no reaſon to attribute them in man to any other ſource: If theſe powers appear neceſſarily to require an immaterial principle for their ſupport, it will probably be granted, that an immaterial principle is the ſource of every power and every motion in the univerſe; and the doctrine of *mind*, in the ſtricteſt ſenſe of the word, will be ſufficiently eſtabliſhed.

Chap. II. *Of the* Substance *of the* Human Mind.

The moſt celebrated materialiſt of this or perhaps of any other age is Dr Prieſtley; who having in his own imagination diveſted matter of ſolidity, and reduced it to mere centres of attraction and repulſion, obſerves, that "if one *kind of ſubſtance* be capable of ſupporting all the known *properties* of man; that is, if thoſe properties have nothing in them that is abſolutely incompatible with one another; we ſhall be obliged to conclude (unleſs we openly violate the rules of philoſophiſing, which will not authoriſe us to *multiply cauſes* or kinds of ſubſtance *without neceſſity*), that no other kind of ſubſtance enters into his compoſition; the ſuppoſition being manifeſtly *unneceſſary*, in order to account for any appearance whatever.—All the properties that have hitherto been attributed to matter, may be compriſed under thoſe of attraction and repulſion. Beſides theſe, man is poſſeſſed of the powers of *ſenſation* or *perception*, and *thought*. But if, without giving the reins to our imaginations, we ſuffer ourſelves to be guided in our inquiries by the ſimple rules of philoſophiſing above mentioned, we muſt neceſſarily conclude, that theſe powers alſo may belong to the ſame ſubſtance that has alſo the properties of attraction, repulſion, and *extenſion* (D), which I as well as others call by the name of *matter*. The reaſon of the concluſion is ſimply this, that the powers of ſenſation or perception and thought, as belonging to man, have never been found but in conjunction with a certain *organiſed ſyſtem of matter*; and therefore that thoſe powers neceſſarily exiſt in and depend upon ſuch a ſyſtem. This at leaſt muſt be our concluſion, till it can be ſhown that theſe powers are incompatible with the other known properties of the ſame ſubſtance; and for this I ſee no ſort of pretence."

Of the Substance of the Human Mind.

This is what Dr Prieſtley calls the proper and direct proof that the ſentient principle in man is the material ſubſtance of the brain; and he enforces it by the following obſervations: "Had we formed a judgment concerning the neceſſary ſeat of thought by the circumſtances that *univerſally accompany it*, which is our rule in all other caſes, we could not but have concluded that in man it is a property of the *nervous ſyſtem*, or rather of the brain; becauſe, as far as we can judge, the faculty of thinking, and a certain ſtate of the brain, always accompany and correſpond to one another; which is the very reaſon why we believe that any property is inherent in any ſubſtance whatever. There is no inſtance of any man retaining the faculty of thinking when his brain was deſtroyed; and whenever that faculty is impeded or injured, there is ſufficient reaſon to believe that the brain is diſordered in proportion; and therefore we are neceſſarily led to conſider the latter as the ſeat of the former. Moreover, as the faculty of thinking in general ripens and comes to maturity with the body, it is alſo obſerved to decay with it; and if, in ſome caſes, the mental faculties continue vigorous when the body in general is enfeebled, it is evidently becauſe in thoſe particular caſes the *brain* is not much affected by the general cauſe of weakneſs. But, on the other hand, if the brain alone be affected, as by a blow on the head, by actual preſſure within the ſkull, by ſleep, or by inflammation, the mental faculties are univerſally affected in proportion. Likewiſe, as the mind is affected in conſequence of the affections of the body and brain, ſo the body is liable to be reciprocally affected by the affections of the mind, as is evident in the viſible effects of all ſtrong paſſions, hope or fear, love or anger, joy or ſorrow, exultation or deſpair. Theſe are certainly irrefragable arguments, that it is properly no other *than one and the ſame thing* that is ſubject to theſe affections, and that they are neceſſarily dependent upon one another. In fact, there is juſt the ſame reaſon to conclude, that the powers of ſenſation and thought are the neceſſary reſult of a particular organization, as that ſound is the neceſſary reſult of a particular concuſſion of the air. For in both caſes equally the one conſtantly accompanies the other; and there is not in nature a ſtronger

(D) When Dr Prieſtley mentions the *extenſion* of corporeal ſubſtance, it muſt be remembered that he does not mean the extenſion of any real thing poſſeſſed of an independent exiſtence. The extenſion belongs wholly to the *ſphere* or the *combination* of ſpheres of *attraction* and *repulſion*. The centre itſelf, which attracts and repels, he repeatedly affirms not to have the dimenſions even of a phyſical point; and he ſometimes ſeems to entertain a doubt whether it be any thing more than a mere relative notion.

Of the Substance of the Human Mind.

stronger argument for a necessary connection or any cause and any effect. To adopt an opinion different from this, is to form an hypothesis without a single fact to support it." *.

Though the ingenious author thinks, that if there be any foundation for the established rules of philosophising, this reasoning ought to be conclusive, he yet subjoins, for the greater satisfaction of his readers, some additional arguments, or rather, as he says, distinct illustrations of the great argument. They are as follows:

1 "That the faculty of thinking necessarily depends, for its *exercise* at least, upon a stock of ideas, about which it is always conversant, will hardly be questioned by any person. But there is not a single idea of which the mind is possessed but what may be proved to have come to it from the bodily senses, or to have been consequent upon the perceptions of sense. The notion, therefore, of the *possibility* of thinking in man, without an organized body, is not only destitute of all evidence from actual appearances, but is directly contrary to them; and yet these appearances ought alone to guide the judgment of philosophers.

2. "The only reason why it has been so earnestly contended for, that there is some principle in man that is not material, is, that it might subsist, and be capable of sensation and action, when the body is dead. But if the mind was naturally so independent of the body, as to be capable of subsisting by itself, and even of appearing to more advantage, after the death of the body; it might be expected to discover some signs of its independence before death, and especially when the organs of the body were obstructed, so as to leave the soul more at liberty to exert itself; as in a state of *sleep* or *swooning*, which must resemble the state of death; in which it is pretended that the soul is most of all alive, most active, and vigorous. But judging by appearances, the reverse of all this is the case.

3. "If the mental principle was, in its own nature, immaterial and immortal, all its particular faculties would be so too; whereas we see that every faculty of the mind without exception is liable to be impaired, and even to become wholly extinct, before death. Since, therefore, all the faculties of the mind, separately taken, appear to be mortal, the substance or principle in which they exist must be pronounced to be mortal too.

4. "If the sentient principle in man be immaterial, it can have no *extension*; it can neither have length, breadth, nor thickness; and consequently every thing within it, or properly belonging to it, must be *simple* and *indivisible*. Let us now consider how this notion agrees with the phenomena of sensation and ideas. It will not be denied, but that sensations or ideas properly exist *in the soul*, because it could not otherwise retain them, so as to continue to perceive and think after its separation from the body. Now, whatever ideas are in themselves, they are evidently produced by external objects, and must therefore correspond to them; and since many of the objects or archetypes of ideas are divisible, it necessarily follows, that the ideas themselves are divisible also. But, how is it possible that a thing (be the nature of it what it may) that is *divisible*, should be contained in a substance, be the nature of *it* likewise what it may, that is *indivisible*? If the archetypes of ideas have extension, the ideas which are expressive of them, and are actually produced by them according to certain mechanical laws, must have extension likewise; and therefore the mind in which they exist, whether it be material or immaterial, must have extension also. But how any thing can have extension and yet be immaterial, without coinciding with our idea of mere empty *space*, I know not."

* *Disquisitions on Matter and Spirit.*

To the argument, which is here chiefly insisted on as being agreeable to the established rules of philosophising, a very able reply has been made, which we shall give in the words of its elegant and spirited author. But before we attempt to dig up the foundation of the Doctor's system, it may not be improper to demolish, if possible, the additional buttresses by which it is strengthened. An experienced general, before he storm a citadel which he knows to be strongly fortified and skilfully defended, will take care to raze every less important redoubt from which the enemy might annoy him in his rear.

Answ 23

Because the faculty of thinking in general ripens, comes to maturity, and decays with the body, and the body on the other hand is affected by the affections of the mind, the Doctor affirms that we have the same reason to conclude, that the powers of sensation and thought are the necessary result of a particular organisation, as that sound is the necessary result of a particular concussion of the air. This argument is conclusive only upon the supposition that there is no *positive* evidence whatever for the immateriality of the being which is the subject of thought. If the other reasonings for the materiality and immateriality of the mind be of equal weight, this argument ought doubtless to turn the balance; but if there be the smallest preponderancy in behalf of the immaterialists, it is a mere begging of the question to attempt to counteract it by any inference which can be drawn from the mutual affections of the body and mind. If two such heterogeneous beings as an immaterial mind and an organised body can be supposed united in one person, they must necessarily affect each other; and to affirm, on account of this reciprocal affection, that they are *one and the same*, is equally absurd as to say that an electrician and his apparatus are *one and the same*. Dr Priestley himself did not at first perform his electrical experiments with so much ease as after he had acquired facility by long practice, nor could he even yet perform them so neatly with a bad as with a good apparatus.

That which the Doctor calls the first illustration of his argument might be admitted, and the force of the argument itself be consistently denied. Some kind of organised body may be necessary to the mind as an instrument without which it could not exert its faculties; but it would certainly be rash to infer that the mind must *therefore* be a system of matter. An anvil and a hammer are necessary to the exercise of the blacksmith's art; but what would be thought of him who should from this fact conclude, that the blacksmith himself must be a system of iron? This, therefore, instead of illustrating the great argument, seems to be wholly foreign from the question in debate; and it has in fact been admitted by Dr Price *, and thousands of others who reject the doctrine of materialism, as an impious absurdity. The second illustration

* Corr[espondence] with Priestl[ey]

lustration, however, is more to the purpose; and as it is not new, we shall give it an old answer.

Why do not we perceive external objects in our *sleep* or in a *swoon*? "Because (says Mr Wollaston), † the *passages* are become impracticable, the *windows* shut, and the *nerves* being obstructed, or somehow rendered for the time useless, can transmit no information to it. Why, however, does it not reason and think about *something or other*? Because, all the *marks* by which things are remembered, being for the present choked up or disordered, the remembrance of those *objects* about which it is wont to employ itself, and even of the words (or other signs) in which it uses to reason, and to preserve the deductions and conclusions it makes, is all suspended at least for the time; and so its tables being covered, its books closed, and its tools locked up, the requisites for reasoning are wanting, and no subject offers itself to exercise its thoughts, it having yet had little or no opportunity to take in *higher objects* and more *refined matter* for contemplation. And, to conclude, if it be demanded, Why any one should imagine that the *soul* may think, perceive, act, *after death*, when it doth not do this in sleep, &c.? the answer is, Because those *inclosures* and *impediments* which occasioned the forementioned intermissions, and those great limitations under which it labours at all times, will be removed with its enlargement out of the body. When it shall in its *proper vehicle* be let go, and take its flight into the open fields of heaven, it will then be bare to the immediate impressions of objects: And why should not those impressions which affected the *nerves*, that moved and affected the vehicle and soul in it, *affect the vehicle immediately* when they are immediately made upon it, without the interposition of the nerves? The hand which feels an object at the end of a *staff*, may certainly be allowed to feel the same much better by *immediate contact* without the staff."

The opinion, that the soul is united to some fine vehicle, which dwells with it in the brain, and goes off with it at death, was not peculiar to Mr Wollaston. It was thought extremely probable by Dr Hartley, and shall be shown afterwards to have been a very ancient opinion; but we do not quote it at present as either well or ill founded, but only as sufficient, in conjunction with the reasoning of its author, to obviate the force of Dr Priestley's second illustration of his argument for the materiality of mind, provided the argument itself be not more powerful than any which the immaterialists can bring against it.

The Doctor's third illustration we have already obviated, when we accounted for the mind and the body mutually affecting each other; and we might refer to Dr Price's answer (E) to the fourth, as being, in our opinion, a full confutation of it. But as that author's notions of *mind* and *ideas* differ in some respects from our own, we shall examine this objection to the doctrine of the immaterialists upon principles which we believe Dr Priestley more inclined to admit.

Of the Substance of the Human Mind.

That the sentient principle in man, if it be immaterial, can have no extension, is a truth which we think cannot be controverted; and if so, every thing in that principle must be *simple* and *indivisible*. Thus far we agree with Dr Priestley; but with respect to what follows we differ from him entirely. The agitation in the brain, which is the immediate cause of sensation, must indeed correspond to the impression *ab extra* by which it is produced, and therefore must have the property of extension; but that agitation, whatever it be, is not itself sensation any more than a bludgeon is a blow or a sword is a wound. Dr Priestley, indeed, in answer to Dr Price, affirms, that, according to Hartley's theory, ideas are only *vibrations in the brain*; but whoever shall take the trouble to examine that theory himself, will not find that its author ever advances such an opinion, or considers vibrations as any thing more than the instruments by which sensations and ideas are excited in the sentient principle. A real and proper idea, as we have often repeated, is nothing else than a fainter sensation: but no sensation, from whatever cause it may proceed, is itself extended; nor could we, without memory, the reasoning faculty, and the power of local motion, have acquired from mere sense any notion of extension at all: (See sect. 3. chap. i. Part I. Sensations and ideas are those *appearances* (if we may so say), which vibrations or some other motion in the brain excite in the mind; but a *half* appearance is an absurdity. A man may view *half a tree* with his eyes, and he may contemplate the idea of *half a tree* in his mind; but he cannot have *half a view* or *half an idea* of any thing. Sensations and ideas result from the mutual agency of the brain and sentient principle upon each other; and if the agency of the brain be vibration, more of it may vibrate at one time than at another: but surely the mere relation between its agency at any time and the agency of the mind, can neither have extension nor be divisible; for who ever thought of extending or dividing relations? On this subject it is extremely difficult to write with perspicuity and precision; and what we have said may very possibly be misunderstood. Our notion is to ourselves clear and determinate; but language which was not invented by metaphysicians, wants words in which it may be properly expressed. Perhaps the reader may understand what we mean, when we say that a sensation or an idea is the instantaneous effect of the mutual agency of the brain and sentient principle. Of this we think every man, by a little attention, may be perfectly convinced, though it may be impossible ever to discover the precise nature

3

(E) In *Disquisitions*, p. 37 and 102, it is asserted, that ideas are certainly divisible. "This seems to me very absurd. It would be as proper to assert ideas to be hard or round. The idea of an object is the apprehension, view, or notion of it; and how can this be divisible? Perception is a single and indivisible act. The object perceived may be divisible; but the *perception* of it by the mind cannot be so. It is said in page 95, *that if ideas are not things distinct from the mind, a mind with ideas and a mind without ideas would be the same.*—I maintain, that ideas are not distinct from the mind, but its conceptions; or not *things* themselves, but *notions* of things. How does it follow from hence, that a mind with or without ideas is the same? It would seem that this follows much more from the contrary assertion." *Correspondence between Dr Price and Dr Priestley.*

Of the Substance of the Human Mind.

ture of this agency; and if fo, it is plain that fenfations and ideas cannot be divided, for no inftantaneous effect of any kind is divifible. A fenfation, and of courfe a fimple and original idea, neither has extenfion itfelf, nor fuggefts the notion of extenfion *ab extra*. By running the hand or any other member along a folid body, we feel continued refiftance: this feeling, or the idea of this feeling, becomes in time fo clofely affociated with all our fenfations of touch and fight, that the one cannot be feparated from the other; and thefe affociations are what Dr Prieftley calls *extended ideas*. Upon the whole then, we think it apparent, that our fenfations, and the relicts of our fenfations, are unextended and indivifible, (F); and that though they fuggeft to us the exiftence of extended things *ab extra*, the fentient being *may* be unextended and indivifible.

Having thus examined Dr Prieftley's auxiliary arguments for the materiality of mind, we now proceed to confider his main and direct proof. To this, as we have obferved, fo able a reply has been made, that it would be injuftice to our readers not to lay it before them, in the words of its author. "I readily acknowledge (fays this fpirited effayift*), that the power of fenfation or perception never having been found but in conjunction with a certain organifed fyftem of matter, we ought, as philofophers, to conclude that this power neceffarily exifts in, and refults from, that organized fyftem, unlefs it can be fhown to be incompatible with other known properties of the fame fubftance. On the other hand, it muft be admitted, that conftant conjunction implies *neceffary* connection only when reafons cannot be difcovered to prove the conjunction to be accidental and arbitrary. In the prefent inftance, it is alleged, that difcerptibility is a property of matter abfolutely incompatible with the property of fenfation or perception; or in other words, that fenfation is a power or property incapable of divifion. But as the power of the entire fyftem is clearly nothing more than the fum or aggregate of the powers of all the parts, it neceffarily follows, that the primary particles of which the fyftem is compofed muft, upon the material hypothefis, poffefs diftinct powers of fenfation; and that thofe

* Eff. Philofophical, Hiftorical, and Literary.

2 Direct proof of the fentient principle in man to be a fet of matter.

(F) We affirm this only of *human* fenfations and ideas, becaufe thefe are the only fenfations and ideas of which we are confcious, and about which we can reafon. Other animals are fentient as well as man, and appear to have their fenfations excited by impreffions *ab extra*; but whether in every fpecies of animals a fingle impreffion excites but one fenfation common to the whole animal, or different fenfations which are felt each by a different faculty or fentient principle, is a queftion which we are not able to anfwer. We make this remark, becaufe from the phenomena of fenfation in the earth-worm and other reptiles, fome philofophers of eminence having fuppofed, that in thefe creatures the fentient faculty belongs to the material fyftem, and is divifible with it; have thence concluded, we think rafhly, that all arguments for the immateriality of the human mind are founded merely on our ignorance. We call this conclufion rafh; becaufe, though we know perfectly what a human fenfation is, we have fo little knowledge of the nature of fenfation in worms, that what may be true of the one *principle* of fenfation may be falfe of the other. Indeed, if we are to judge from the phenomena, this is actually the cafe. It appears from experiments made by Abbé Spallanzani and others, that if a certain number of rings be cut off either from the anterior or pofterior part of a worm, or even from both, the remainder will not only continue to live and be fentient, but will alfo regenerate a new head and a new tail, and become again a complete worm. Nothing like this takes place in man or in the higher orders of animals; and therefore, were it certain that the fentient principle in the worm is diffufed through the whole fyftem and divifible with it, we could not infer that the principle of fuch fenfations as we are confcious of, is likewife extended and divifible. It is, however, fo far from being certain that the fentient principle is diffufed through the whole worm, that nothing neceffarily follows from this fact, but that its feat is at fome diftance from either extremity. Nay, were it true, as perhaps it is, that a worm may be fo divided, as that each of the two fections fhall retain life, fenfation, and this reproductive power, we would not therefore be authorifed to conclude that the fentient principle is *one*, co-extended and divifible with the material fyftem. The earth worm, like many other reptiles, being an hermaphrodite, which unites in itfelf both fexes, may poffibly confift of two animated fyftems; which though united by fome bond of connection, by which fenfation is communicated from the one to the other, are yet in themfelves perfectly diftinct. Should this, upon proper inveftigation, be found to be the cafe; and fhould it likewife be found; that when a worm is divided into three or more parts, only one or two of thefe parts continue to live, there would be no room whatever for fuppofing that even in thefe creatures the principle of fenfation is extended and divifible. In the mere power of reproducing amputated parts, when that power is confidered by itfelf, there is nothing more wonderful than in the growing of the nails of our fingers or the hairs of our heads. The only thing which feems to militate againft the fimplicity of the principle of fenfation in worms, is the continuance of life, &c. with both parts of a worm when cut into two by a knife or pair of fciffars; but if a worm be found to have two feats of fenfation analogous to the brain in higher animals, and if it be likewife found that life continues only in fuch fections as retain at leaft one feat of fenfation, the fentient principle in the worm may be as fimple and indivifible as in any animal whatever. We neither wifh nor expect much ftrefs to be laid upon thefe hints and conjectures. Should they induce any of our phyfiological readers, who have leifure, and are at the fame time fkilled in philofophy, properly fo called, to inftitute a fet of experiments upon worms, and fuch reptiles, and to trace apparent effects to their heigher caufes, they might eventually lead to important difcoveries. In the mean time, it is fufficient for our purpofe to obferve, that whatever be the fentient principle or principles in the earth-worm, it is obvious that the whole animal cannot in any cafe be confcious, as man undoubtedly is, of *one individual fenfation*; and that therefore no arguments built upon the phenomena accompanying fenfation in worms, can be of any importance in the controverfy about the materiality or immateriality of the human mind.

those powers combined constitute the indivisible power of sensation belonging to the system; or, in other words, that the *indivisible* power of sensation is a *divisible* power, nay, an infinitely divisible power, if matter be, as philosophers in general allow, an infinitely divisible substance—a conclusion obviously and grossly ridiculous. We are then compelled to acknowledge, that sensation or perception is not the property of a material substance; *i. e.* if the common mode of expression be retained, it is the property of an immaterial substance; or, to avoid verbal contention, it is a property not resulting from, or necessarily connected with, the organical system, but a property wholly foreign, superinduced, and adventitious. (G)

"In opposition to this reasoning, the materialists affirm, that entire systems may possess, and they think themselves warranted to pronounce that organized systems of matter actually do possess, powers essentially different from those which inhere in the several parts. Amongst various familiar though striking illustrations of this truth, it has been said, that a rose possesses the property of sweetness or fragrance, a globe the property of sphericity, a harpsichord the property or power of producing harmony, *aqua regia* the property of dissolving gold, &c. though the component particles of these different organized systems are themselves totally destitute of the powers and properties here enumerated.

"The immaterialists, in reply, assert, that it is not only false in fact, but a direct contradiction, and an absolute impossibility in the nature of things, that a system should possess any property which does not inhere in its component parts. To assert that the power of the whole is the sum or aggregate of the powers of all the parts, is an identical and self-evident proposition, the whole and all the parts being terms precisely synonymous. Whoever, therefore, calls in question the truth of this axiom, must maintain that the power of the whole is something different from the power of all the parts, *i. e.* that the power of the whole is *not* the power of the whole.

Of the Substance of the Human Mind.

"It will be easy to demonstrate the correspondence of facts with this plain and simple theory. For this purpose, it is necessary to observe, that the properties of matter, or what are generally denominated such, may be divided into real and nominal, which Locke and others have called primary and secondary qualities. Figure, magnitude, and motion, are qualities really inherent in matter; but figure, magnitude, and motion, eternally varied, can produce only different combinations of figure, magnitude, and motion. There are also powers, or qualities, vulgarly considered as inherent properties of matter organically disposed, which are really and truly qualities or affections of the mental or percipient principle, and have no existence when not perceived. Thus the sweetness or fragrance of the rose, considered as mere sweetness and fragrance, can be nothing but an affection of the mind; considered as a quality of the rose, they can mean nothing more than a certain arrangement, configuration, and motion of parts, which in some inexplicable manner produces the sensation of sweetness. In this instance, therefore, the power of the whole is plainly the aggregate of the powers residing in the parts, by the motion and organization of which a certain effect is produced upon a foreign and percipient substance.

"But a globe, we are told, possesses the property of sphericity, though not a single particle amongst that infinite number of which the globe is constituted is itself of a spherical form. The fallacy of

---

(G) This argument is not new. It was long ago urged by Dr Clarke against Mr Dodwell; and some of our readers may not be ill pleased to see it stated by so masterly a reasoner: "That the soul cannot possibly be *material*, is demonstrable from the single consideration of bare sense or consciousness. For matter being a divisible substance, consisting always of separable, nay of actually separate and distinct parts, it is plain that unless it were essentially conscious, in which case every particle of matter must consist of innumerable separate and distinct consciousnesses, no system of it, in any possible composition or division, can be an individual conscious being. For suppose three or three hundred particles of matter, at a mile or any given distance one from another, is it possible that all these separate parts should in that state be one individual conscious being? Suppose then all these particles brought together into one system, so as to touch one another, will they thereby, or by any motion or composition whatsoever, become one whit less truly distinct beings than they were when at the greatest distance? How then can their being disposed in any possible system make them one individual conscious being? If you will suppose God by his infinite power superadding consciousness to the united particles, yet still these particles being really and necessarily as distinct beings as ever, cannot be *themselves* the *subject* in which that individual consciousness inheres; but the consciousness can only be superadded by the addition of something, which in all the particles must still itself be but one individual being. The soul, therefore, whose power of thinking is undeniably one individual consciousness, cannot possibly be a material substance." *Clarke's Letter to Mr Dodwell, 2d edition.*

That the same mode of reasoning was known to the ancients, Cudworth has shown by numerous quotations; and as an argument certainly loses nothing by antiquity, or by having occurred to thinking men in distant ages, we shall lay before our readers two passages from Plotinus, of which the extract from Clarke's letter (though we are persuaded it was not borrowed by the author) must be considered as little more than a paraphrastical translation. ——τι τοινυν φησουσιν, οἱ την ψυχην σωμα ειναι λεγοντες, πρωτον μεν περι ἑκαστου μερους της ψυχης της εν τω αυτω σωματι, ποτερον ἑκαστον ψυχη, οἱα εστι και ἡ ὁλη; και παλιν του μερους το μερος; ουδεν αρα το μεγεθος συνεβαλλετο τη ουσια αυτης· καιτοι εδει γε ποσου τινος οντος· αλλα και ὁλον πολλαχη, ὁπερ σωμασι παρειναι αδυνατον, εν πλειοσι το αυτο ὁλον ειναι, και το μερος ὁπερ το ὁλον, ὑπαρχειν· ει δε ἑκαστον των μερων, ου ψυχην φησουσιν, εξ αψυχων ψυχη αυτοις υπαρξει. *En.* IV. *Lib* 7timo. *Cap.* 5.

The same argument is elsewhere stated thus: ει δε ἑκαστον ζωην εχοι, και εν αρκει· ει δε μηδενος αυτων ζωην εχοντος ἡ συνοδος πεποιηκε ζωην, ατοπον· μαλλον δε αδυνατον συμφορησιν σωματων ζωην εργαζεσθαι, και νουν γενναν τα ανοητα. *En.* IV, *Lib.* 7. *Cap.* 2.

Of the Substance of the Human Mind.

of this illuftration is, however, as eafily demonftrable as that of the former. The fphericity of a globe is evidently the fum or aggregate of the curvilinear or convex parts which compofe its furface; and the property of the whole is neither more nor lefs than the combined properties of all its parts. No one doubts, that by new compofitions or arrangement of material particles poffeffing magnitude, figure, and motion, an endlefs diverfity of phenomena may be produced, to which it may be neceffary to apply new names. New names, however, do not conftitute new properties; and though we give to a globe the appellation of an entire fyftem, and afcribe to it the property of fphericity, we know at the fame time that it is really nothing more than a collection of thoufands of millions of particles, actually feparate and diftinct, arranged in that particular form which we denominate fpherical. But this can never be regarded as in the remoteft manner analogous to the *creation* of the power of perception, in confequence of a certain organical arrangement or difpofition of impercipient particles. Though fphericity is, indeed, the property of the entire fphere, yet every part of the fphere, if divided, poffeffes its fhare of fphericity. But if the percipient principle be divided, what would become of the power of perception? A fphere equally divided becomes two hemifpheres; does a perception, when divided in like manner, become two demi-perceptions?

"The fame reafonings may eafily be transferred, and applied to the harpfichord. Can any one be abfurd enough to affirm that the power of harmony refides in the harpfichord, as the power of perception does in the mind? After the utmoft fkill of the artificer has been exerted, we difcover nothing more in the harpfichord than new modifications of the old properties of figure, magnitude, and motion, by means of which certain vibrations are communicated to the air, which, conveyed by the medium of the auditory nerves to the fenforium, produce the fenfation of harmonic founds. Thefe new modifications are therefore attended, indeed, with new and very wonderful effects; but then thofe effects are produced upon, and are themfelves modifications of, the fentient or percipient faculty. And though it is wholly incomprehenfible to us in what manner thefe effects, that is, thefe *fenfations*, are produced, we well know, and perfectly comprehend, that they are not new powers belonging to any organized fyftem of matter; that they have no exiftence but in a mind perceiving them; and that they are far from militating againft that grand and univerfal axiom, that the power of the whole is nothing more than the united powers of all the parts.

"As to the laft inftance adduced, of the power of *aqua regia* to diffolve gold, though neither the fpirit of falt, nor the fpirit of nitre of which it is compounded, feparately poffeffes that power, it is plain, that from the union of thefe two fubftances, certain new modes of configuration and motion refult; and the folution of gold is the confequence of this new arrangement and motion of the parts. But the particles of which the menftruum is compofed were always poffeffed of the properties of figure and motion; and what is ftyled a new property, is clearly nothing more than a new effect of the old properties differently modified. In a word, the advocates for materialifm may fafely be challenged to produce, in the whole compafs of nature, a cafe which bears the leaft analogy to that which thefe inftances are moft unphilofophically adduced to prove and to illuftrate. It is an abfurdity which tranfubftantiation itfelf does not exceed, to maintain that a whole is in reality any thing different from its component parts; and all nature rifes up in confutation of an affertion fo monftrous and extravagant. To affirm that perception can arife from any combination of impercipient particles, is as truly ridiculous, as to affirm that a combination of the feven primary colours with the four cardinal virtues may conftitute a planet. It is equivalent to an affertion, that an epic poem might be compofed of parallelograms, cones, and triangles. In a word, it is an abfurdity not lefs real, and little lefs obvious, than that of the blind man who thought that the idea of a fcarlet colour refembled the found of a trumpet."

If matter be taken in the common acceptation, to be a folid, extended, and inert fubftance, this reafoning for the immateriality of the fentient principle in man appears to us to have the force of demonftration, which no difficulties or partial objections, arifing from our inability to conceive the bond of union between two fuch heterogeneous fubftances as mind and body, can ever weaken, and far lefs overturn. But the modern materialifts deny that matter is either folid or inert. "All thofe facts (fay they) which led philofophers to fuppofe that matter is impenetrable to other matter, later and more accurate obfervations have fhown to be owing to *fometl ing elfe* than folidity and impenetrability, viz. a *power of repulfion*, which for that reafon they would fubftitute in its place. The property of *attraction* or repulfion (fays Dr Prieftley) appears to me not to be properly what is *imparted* to matter, but what really *makes it to be what it is*; infomuch, that without it, it would be nothing at all; and as other philofophers have faid,—'Take away folidity, and matter vanifhes,' fo I fay, 'Take away attraction and repulfion, and matter vanifhes." If this be admitted, the ingenious author hopes that we fhall not confider matter with that contempt and difguft with which it has generally been treated, there being nothing in its real nature that can juftify fuch fentiments refpecting it.

23 Reply the m… rialist shown

We know not why, upon any hypothefis, matter fhould be viewed with contempt and difguft.—Whether penetrable or impenetrable, every confiftent theift confiders it as one of the creatures of God perfectly fitted to anfwer all the purpofes for which it was intended: but were it really deftitute of folidity, and endowed with the powers of attraction and repulfion, we fhould ftill be obliged to confider it as incapable of the powers of fenfation and thought. If we have any notion at all of what is meant by centres of attraction and repulfion (of which indeed we are far from being confident), it appears to us to be intuitively certain, that nothing can be the refult of any poffible combination of fuch centres, but new and more enlarged fpheres of attraction and repulfion. But furely confcioufnefs, fenfation, and will, are as different from attraction and repulfion, as a cube is from the found of a trumpet, or as the fenfations of a felon in the agonies of death are from the attraction of the rope by which he is hanged. If this be admitted, and

23 …o be … furd.

and we are perſuaded it will be denied by no man whoſe underſtanding is not clouded by an undue attachment to paradoxes, the ſentient principle cannot poſſibly be matter: for if, when the powers of attraction and repulſion are taken away, matter vaniſhes; and if conſciouſneſs and ſenſation are not attraction and repulſion; it is not more evident that three and two are not nine, than that the ſubſtance which attracts and repels cannot be that which is conſcious and percipient.

Locke, who was certainly no materialiſt, as he repeatedly affirmed, and indeed demonſtrated, that thought could never be the reſult of any combinations of figure, magnitude, and motion, was yet of opinion, that God by his almighty power might endow ſome ſyſtems of matter with the faculties of thinking and willing. It is always with reluctance that we controvert the opinions of ſo great a man; and it is with ſome degree of horror that we venture in any caſe to call in queſtion the power of Omnipotence.—But Omnipotence itſelf cannot work contradictions; and it appears to us nothing ſhort of a contradiction, to ſuppoſe the individual power of perception inhering in a ſyſtem which is itſelf extended and made up of a number of ſeparate and diſtinct ſubſtances. For let us ſuppoſe ſuch a ſyſtem to be ſix feet long, three feet broad, and two feet deep (and we may as well ſuppoſe a ſyſtem of theſe dimenſions to be percipient, as one that is ſmaller), then it is plain, that every idea muſt be extended, and that part of it muſt be in one place, and part in another. If ſo, the idea of a ſquare inch will be ſix feet long, three feet broad, and two feet deep; and what is ſtill harder to be digeſted, the ſeveral parts of this idea will be at a great diſtance from each other, without any bond of union among them. The being which apprehends one extremity of the idea, is, by the ſuppoſition, ſix feet diſtant from the being which apprehends the other extremity; and though theſe two diſtinct beings belong to one ſyſtem, they are not only ſeparable, but actually ſeparated from each other as all the particles of matter are. What is it then that apprehends as *one* the whole of this extended idea? Part of it may be apprehended by one particle of matter, and part of it by another; but there is nothing which apprehends, or can apprehend, the whole. Perhaps it will be ſaid, the power of apprehenſion is not divided into parts, but is the power of the one ſyſtem, and therefore apprehends at once the whole idea. But a power or faculty cannot be ſeparated from its ſubject, power which inheres in nothing being confeſſedly impoſſible; and a material ſyſtem is not *one ſubject* in which any individual power or faculty can inhere. There muſt, therefore, be united to the ſyſtem ſome *one* being, which is the ſubject of thought, and which is unextended as well as indiviſible. This, we ſay, follows undeniably. For, let us ſuppoſe, that an extended being without ſeparable parts is poſſible, and that ſuch a being is percipient; it is obvious, that the whole of any one of its perceptions could not be in one place. Now, though we ſhould grant to Dr Prieſtley and other materialiſts, that every idea of an extended ſubſtance has itſelf three dimenſions, and is incorporated and commenſurate with the whole percipient ſyſtem; what, upon this ſuppoſition, ſhall we think of conſciouſneſs and of the perception of truth? Is conſciouſneſs or truth extended? If ſo, one ſide or ſuperficies of conſciouſneſs, or of a truth, may be greater or leſs than another, above or below, to the right or to the left; and it will be very proper and philoſophical to ſpeak of the length, breadth, and depth, of conſciouſneſs or of truth. But ſurely to talk of the place, or the extenſion of theſe things, is as abſurd as to talk of the colour of ſound, or the ſound of a triangle; and we might as well ſay, that conſciouſneſs is green or red, as that it is an ell or an inch long; and that truth is blue, as that it has three dimenſions.

Of the Substance of the Human Mind.

239 *because the ſentient being cannot be extended.*

This reaſoning is ſomewhat differently ſtated by Cudworth; who obſerves, that if the ſoul be an extended ſubſtance, "it muſt of neceſſity be either a phyſical point (*i. e.* the leaſt extenſion poſſible, if there be any ſuch leaſt extenſion), or elſe it muſt conſiſt of more ſuch phyſical points joined together. As for the former of theſe, it is impoſſible that *one ſingle atom*, or *ſmalleſt point* of extenſion, ſhould be able to perceive diſtinctly all the *variety* of things, *i. e.* take notice of all the *diſtinct* and *different* parts of an *extended object*, and have a *deſcription* or *delineation* of the whole of them upon itſelf (for that would be to make it the leaſt, and not the leaſt, poſſible extenſion at the ſame time:) Beſides, to ſuppoſe every ſoul to be but one *phyſical point*, or the ſmalleſt *poſſible extenſion*, is to ſuppoſe ſuch an eſſential difference in matter or extenſion, as that ſome of the *points* thereof ſhould be *naturally* devoid of all *life*, *ſenſe*, and *underſtanding*; and others, again, naturally *ſenſitive* and *rational*. And even ſhould this abſurdity be admitted, it would yet be utterly inconceivable how there ſhould be *one*, and *but one*, *ſenſitive* and *rational* atom in every man; how this atom of ſo *ſmall* dimenſions ſhould actuate the whole ſyſtem; and how it ſhould conſtantly remain the ſame from infancy to old age, whilſt all the other parts of the ſyſtem tranſpire perpetually, and are ſucceeded by new matter (H).

"But if, according to the ſecond hypotheſis, ſouls be

(H) Should it be ſaid, that this eſſential difference between the atoms of matter is not fortuitous; that ſome of them are created intelligent for the expreſs purpoſe of animating ſyſtems of others which are unintelligent; and that theſe intelligent atoms do not operate upon the ſyſtems with which they are united, by the *vis inertiæ*, *ſolidity*, or *extenſion*, of matter, but by the energies of underſtanding and will: Should this (we ſay) be alleged, ſurely it may be aſked, for what purpoſe they are conceived to have the quality of extenſion? It is evidently of no uſe; and it has been already ſhown, and ſhall be more fully ſhown afterwards, that by our notions of conſciouſneſs and underſtanding, we are ſo far from being led to ſuppoſe the ſubject of theſe powers extended, that we cannot ſuppoſe any relation whatever between them and extenſion. But if theſe intelligent atoms be diveſted of their quality of extenſion, they will be transformed from matter to mind, and become the very things for the exiſtence of which we plead.

Of the Subſtance of the Human Mind.

be extended ſubſtances conſiſting of many points one without another, and all concurring in every ſenſation; then muſt every one of theſe points perceive either a *point* only of the object, or elſe the *whole*. Now, if every *point* of the *extended ſoul* perceives only a *point* of the *object*, then is there no *one thing* in us that perceives the whole, or that can compare one part of the object with another. On the other hand, if every *point* of the *extended ſoul* perceive the *whole object* at once, then would there be *innumerable perceptions* of the ſame object in every ſenſation; as many, indeed, as there are points in the extended ſoul — And from both theſe ſuppoſitions it would alike follow, that no man is *one ſingle percipient* or perſon, but that in every man there are innumerable diſtinct *percipients* or *perſons*; a concluſion directly contrary to the infallible evidence of conſciouſneſs (1)."

Cogent as theſe arguments for the immateriality of the ſentient principle appear to be, they have been lately treated with the moſt ſovereign contempt by a writer who profeſſes to be a diſciple of Dr Prieſtley's, but who ſeems not to have learned the modeſty or the candor of his maſter. Dr Prieſtley labours to prove, that to account for the phenomena of perception and volition, &c. it is not neceſſary to ſuppoſe an immaterial principle in man. Mr Cooper with greater boldneſs affirms, and undertakes to demonſtrate with all the parade of mathematical preciſion ‡, that ſuch a principle is impoſſible. Though the authority of this philoſopher in ſuch inquiries as depend not immediately upon the retort and the furnace, is certainly not great, he yet utters his dogmas with ſuch confidence, that it may not be improper to examine the chief arguments upon which they reſt.

Of the Subſtance of the Human Mind.

24
An attempt to prove the impoſſibility of an immaterial ſubſta[nce].

" Suppoſe (ſays he) the ſoul to have no common property with matter; then, nothing can act upon any other but by means of ſome common property. Of this we have not only all the proof that induction of known and acknowledged caſes can furniſh, but that additional proof alſo which ariſes from the impoſſibility of conceiving how the oppoſite propoſition *can* be true. But by the ſuppoſition, the ſoul has no property in common with matter; and therefore the ſoul cannot act upon matter. But by the ſuppoſition of every ſyſtem of immaterialiſm (except thoſe of Malbranche, Berkeley, and Leibnitz), it is deemed an eſſential property of the ſoul, that it acts upon the body, or upon matter; therefore the ſoul can and cannot act upon matter at the ſame time, and in the ſame reſpect. But this is a contradiction in terms; and as two contradictions cannot both be true at the ſame time, the ſuppoſition of the exiſtence of an immaterial ſoul cannot be true; that is, the ſoul does not exiſt."

25
Shown to be fut[ile].

This reaſoning, the reader will obſerve, is carried on with all the pomp of mode and figure. The propoſitions hang upon each other like the ſeveral ſteps of an algebraic proceſs: but as in ſuch proceſſes one error unwarily admitted produces a falſe reſult, ſo in demon-

(1) As the materialiſts endeavour to prejudice the public againſt the notion of an unextended ſoul, by repreſenting it as a fiction of *Des Cartes*, altogether unknown to the ancients, it may not be improper to give our readers an opportunity of judging for themſelves how far this repreſentation is juſt.— *Plotinus*, reaſoning about the nature of the ſoul from its energies of ſenſation, expreſſes himſelf in theſe words:—ειτι μελλει αισθανεσθαι τινος, ἑν αυτο δει ειναι, και τω αυτω παντος αντιλαμβανεσθαι και ει δια πολλων αισθητηριων πλειω τα εισιοντα, η πολλαι περι ἑν ποιοτητες και δι ἑνος ποικιλον, οἱον προσωπον· ου γαρ αλλο μεν ρινος αλλο δε οφθαλμων, αλλα ταυτον ὁμου παντων· και ει το μεν δι ομματων το δε δι ακοης, ἑν τι δει ειναι εις ὁ αμφω· η πως αν ειποι ὁτι ἑτερα ταυτα, μη εις το αυτο ὁμου των αισθησεων ελθοντων. "That which perceives in us, muſt of neceſſity be one thing, and by one and the ſame indiviſible perceive all; and that whether they be more things entering through ſeveral organs of ſenſe, as the many qualities of one ſubſtance, or one various and multiform thing, entering through the ſame organ, as the countenance and picture of a man. For it is not one thing in us that perceives the noſe, and another thing the eyes; but it is one and the ſelf-ſame thing that perceiveth all. And when one thing enters through the eyes, another through the ears, both theſe alſo muſt of neceſſity come at laſt to one indiviſible; otherwiſe they could not be compared together, nor one of them be affirmed to be different from the other, the ſeveral ideas of them meeting no where in one place." Purſuing the ſame argument, and having obſerved, that if what perceiveth in us be extended, then one of theſe three things muſt of neceſſity be affirmed, that either every part of this extended ſoul perceives a part only of the object, or every part of it the whole object; or elſe, that all comes to ſome one point, which alone perceives both the ſeveral parts of the object and the whole: he obſerves of the firſt of theſe ſuppoſitions,—μεγεθει οντι τουτω, ξυμμεριζοιτο αν· ωστε αλλο αλλου μερος, και μηδενα ἡμων ὁλου του αισθητου αντιληψιν εχειν· ὡσπερ αν ει εγω μεν αλλου· συ δε αλλου αισθοιο: "If the ſoul be a magnitude, then muſt it be divided, together with the ſenſible object, ſo that one part of the ſoul muſt perceive one part of the object, and another another; and nothing in it, the whole ſenſible; juſt as I ſhould have the ſenſe of one thing, and you of another." Of the ſecond ſuppoſition, he writes in this manner: ει δε ὁτιουν παντος αισθησεται· εις απειρα διαιρεισθαι του μεγεθους πεφυκοτος, απειρους και αισθησεις καθ ἑκαστον αισθητον συμβησεται γιγνεσθαι ἑκαστω οἱον του αυτου απειρους εν τω ἡγεμονουντι ἡμων εικονας: "But if every part of the extended ſoul perceive the whole ſenſible object, ſince magnitude is infinitely diviſible, there muſt be in every man infinite ſenſations and images of one object." —And as for the third and laſt part of this disjunction, Plotinus by aſſerting the infinite diviſibility of body, here ſhows that the ſuppoſition of any one phyſical point is in itſelf an abſurdity. But if it were not, he agrees with Ariſtotle in aſking πως τω αμερει το μεριστον·—thereby plainly indicating, that the ſentient principle is totally ſeparated from extenſion, and can neither be conſidered as extended like a ſuperficies or ſolid, nor unextended as a phyſical point.

demonſtrative reaſonings one unſound argument admitted into the premiſſes is neceſſarily productive of error in the concluſion. When the author affirms, "that nothing can act upon any other but by means of ſome common property," he affirms without the ſhadow of proof what is certainly not ſelf-evident. He ſays, indeed, that of this we have all the proof that induction of known and acknowledged caſes can furniſh; but unleſs conſciouſneſs be calculated to deceive us, this is unqueſtionably a miſtake. Matter, he repeatedly affirms, has no other properties than thoſe of attraction and repulſion: but a man moves his arm by a mere energy of will; and therefore, according to this demonſtrator, an energy of will muſt be either material attraction or material repulſion. If ſo, it is reaſonable to conclude, that when a man draws his hand towards his head, the centre of his brain exerts its power of *attraction;* and that when he extends his arm at full length before him, the ſame centre exerts its power of *repulſion.* We beg pardon of our readers for detaining them one moment upon ſuch abſurdities as theſe: yet we cannot diſmiſs the argument without taking the liberty to aſk our all-knowing author, How it comes to paſs that the ſame centre ſometimes attracts and ſometimes repels the ſame ſubſtance at the ſame diſtance; nay, that it both attracts and repels ſubſtances of the ſame kind, at equal diſtances, and at the very ſame inſtant of time? This muſt be the caſe, when a man puts one hand to his head, and thruſts another from him; and therefore, if theſe operations be the effect of attraction and repulſion, it muſt be of attraction and repulſion, to which induction of known and acknowledged caſes furniſhes nothing ſimilar or analogous, *i. e.* of ſuch attraction and repulſion as, according to Mr Cooper's mode of reaſoning, does not exiſt. The truth is, that we are not more certain that we ourſelves exiſt, than that an energy of will is neither attraction nor repulſion; and therefore, unleſs all matter be endued with will, it is undeniable, that, whatever be the ſubſtance of the ſoul, one thing acts upon another by a property not common to them both. In what *manner* it thus acts, we pretend not to know: but our ignorance of the *manner* of any operation is no argument againſt the *reality* of the *operation itſelf*, when we have for it the evidence of conſciouſneſs and daily experience; and when the author ſhall have explained to general ſatisfaction how material centres attract and repel each other at a diſtance, we ſhall undertake to explain how one thing acts upon another with which it has no common properties.

Suſpicious, as it ſhould ſeem, that this reaſoning has not the complete force of mathematical demonſtration, the author ſupports his opinion by other arguments. "Whatever we know (ſays he), we know by means of its properties, nor do we in any caſe whatever certainly know any thing but theſe; and we infer in all caſes the exiſtence of any thing which we ſuppoſe to exiſt from the exiſtence of its properties. In ſhort, our idea of any thing is made up of a combination of our ideas of its properties. Gold is heavy, ductile, tenacious, opake, yellow, ſoluble in *aqua regia*, &c. Now, let any one ſuppoſe for an inſtant that gold is deprived of all theſe, and becomes neither heavy, ductile, tenacious, opake, yellow, ſoluble, &c. what remains, will it be gold? Certainly not. If it have other properties, it is another ſubſtance. If it have no properties remaining, it is nothing. For nothing is that which hath no properties. Therefore, if any thing loſe all its properties, it becomes nothing; that is, it loſes its exiſtence. Now, the exiſtence of the ſoul is inferred, like the exiſtence of every thing elſe, from its ſuppoſed properties, which are the phenomena of thinking, ſuch as perception, recollection, judgment, and volition. But in all caſes of *perfect* ſleep, of the operation of a ſtrong narcotic, of apoplexy, of ſwooning, of drowning where the vital powers are not extinguiſhed, of the effects of a violent blow on the back part of the head, and all other leipothymic affections, there is neither perception, recollection, judgment, nor volition; that is, all the properties of the ſoul are gone, are extinguiſhed. Therefore, the ſoul itſelf loſes its exiſtence for the time. If any man ſhall ſay, that theſe properties are only *ſuſpended* for the time, I would deſire him to examine what idea he annexes to this ſuſpenſion; whether it be not neither more nor leſs than that *they are made not to exiſt for the time.* Either no more is meant, or it is contradictory to matter of fact; and moreover, if more *be* meant, it may eaſily be perceived to involve the archetypal exiſtence of abſtract ideas, and to contradict the axiom, *impoſſibile eſt idem eſſe et non eſſe.*"

143 For the benefit of ſhort-ſighted inquirers, it is to be wiſhed that the author had favoured the public with this *proof* which might have been ſo eaſily brought; for we can diſcern no connection whatever between the ſuſpenſion of the exerciſe of the powers of the mind, and the archetypal exiſtence of abſtract ideas, or the abſurd propoſition that it is *poſſible for the ſame thing to be and not be.* We think, however, that we underſtand enough of this reaſoning which he has given us to be able to pronounce with ſome confidence that it is nothing to the purpoſe. For, in the *firſt* place, we beg leave to obſerve, that between the properties of gold and the powers of thinking, &c. there is no ſimilarity; and that what may be true when affirmed of the one, may be falſe when affirmed of the other. The powers of the mind are all more or leſs active; the enumerated properties of gold are all paſſive. We know by the moſt complete of all evidence, that the exerciſe of power *may be* ſuſpended, and the power itſelf remain unimpaired; but to talk of the ſuſpenſion of the energies of what was never energetic, if it be not to contradict the axiom *impoſſibile eſt idem eſſe et non eſſe*, is certainly to employ words which have no meaning. Yet even this argument from the properties of gold might have led the author to ſuſpect that ſomething elſe may be meant by the ſuſpenſion of the exerciſe of powers, than that *thoſe powers are made not to exiſt for the time.* In a room perfectly dark gold is not yellow; but does it loſe any of its eſſential properties, and become a different ſubſtance, merely by being carried from light to darkneſs? Is a man while in a dark room deprived of the faculty of ſight, and one of the powers of his mind made not to exiſt for the time? The author will not affirm that either of theſe events takes place. He will tell us that gold exhibits not its yellow appearance, merely becauſe the proper medium of light paſſes not from it to the eye of the percipient, and that it is only for want of the ſame medium that nothing is ſeen by us in perfect darkneſs. Here, then,

Of the Subſtance of the Human Mind.

ſhown to be equally weak.

then, by his own confeſſion, is a power of the mind, and a property of an external object, both ſuſpended in their energies, without being annihilated; and no proof has yet been brought that all the powers of the mind may not in the ſame manner be ſuſpended in their energies without being made not to exiſt. As light is neceſſary to viſion, but is not itſelf either the thing which ſees or the thing which is ſeen; ſo may the brain be neceſſary to the phenomena of thinking, without being either that which thinks, or that which is thought upon: and as actual viſion ceaſes when light is withdrawn, though the eye and the object both continue to exiſt; ſo may the *energy* of thinking ceaſe when the brain is rendered unfit for its uſual office, though the being which thinks, and the power of thought, continue to exiſt, and to exiſt unimpaired. That this is actually the caſe every man muſt be convinced who believes that in thinking he exerts the ſame powers to-day that he exerted yeſterday; and therefore our author's ſecond demonſtration of the non-exiſtence of mind is, like his firſt, founded upon aſſertions which cannot be granted.

244 A third attempt of the ſame kind

Another of theſe pretended demonſtrations is as follows: "If the ſoul exiſt at all, it muſt exiſt ſomewhere; for it is impoſſible to frame to one's ſelf an idea of any thing exiſting, which exiſts no where. But if the ſoul exiſt ſomewhere, by the terms it occupies ſpace, and therefore is extended; but whatever has extenſion, has figure in conſequence thereof. The ſoul then, if it exiſt, hath the properties of extenſion and figure in common with matter. Moreover, by the ſuppoſition of every immaterial hypotheſis (except thoſe of Malbranche, Berkeley, and Leibnitz), it acts upon body, *i. e.* upon matter; that is, it attracts and repels, and is attracted and repelled, for there is no conceivable affection of matter but what is founded on its properties of attraction and repulſion; and if it be attracted and repelled, its re-action muſt be attraction and repulſion. The ſoul then has the properties of extenſion, figure, attraction, and repulſion, or ſolidity. But theſe compriſe every property which matter, as ſuch, has ever been ſuppoſed to poſſeſs. Therefore the ſoul is matter, or material. But by the ſuppoſition it is immaterial; therefore it does not exiſt. For nothing can exiſt whoſe exiſtence implies a contradiction."

245 ſhown to confute itſelf.

Mr Cooper, we ſee, ſtill proceeds in the direct road of mathematical demonſtration; but in the preſent inſtance we beg leave to ſtop him in the very beginning of his courſe, and to aſk *where* the univerſe exiſts? When he ſhall have given ſuch an anſwer to this queſtion as men of common ſenſe may be able to comprehend, we may perhaps attempt to tell him where an unextended ſoul exiſts. If this demonſtration be not a collection of words without meaning, the exiſtence of ſpace as a real thing is taken for granted. Space, therefore, has extenſion, and of courſe figure; but we believe Mr Cooper will find ſome difficulty in aſcertaining the figure of infinite ſpace. The mind certainly acts upon body. For this we have the evidence of conſciouſneſs and experience; but we have no evidence whatever that it muſt therefore attract and repel, and be attracted and repelled. It has been already obſerved, that the mind, whatever be its ſubſtance, acts upon the body by energies of will. What theſe are every man knows with the utmoſt certainty and preciſion, whilſt we may venture to aſſert that no man knows preciſely what corpuſcular attraction and repulſion are, ſuppoſing the exiſtence of ſuch powers to be poſſible. When we ſpeak of attraction and repulſion, we have ſome obſcure notion of bodies acting upon each other at a diſtance; and this is all that we know of the matter. But when we think of an energy of the human will, the idea of diſtance neither enters nor can enter into our notion of ſuch an energy. Theſe are facts which we pretend not to prove by a mathematical or a chemical proceſs. Every man muſt be convinced of their truth by evidence more complete than any proof, *viz.* immediate conſciouſneſs of his own thoughts and volitions. This being the caſe, we may turn Mr Cooper's artillery againſt himſelf, and, becauſe mind acts upon body by powers different from attraction and repulſion, argue that body neither attracts nor repels; and were it true, as it is certainly falſe, that nothing could act upon another but by means of ſome property common to both, we might infer that every atom of matter is endowed with the powers of volition and intelligence, and by conſequence that every man is not one but ten thouſand conſcious beings, a concluſion which our philoſopher ſeems not inclined to admit.

24[6] Objections to the doctrine of materialiſm ſtated and anſwered.

Having finiſhed his *demonſtrations*, the author ſtates other objections to the doctrine of immaterialiſm, which, as they are not his own nor new, have greater weight. "It appears no more than reaſonable (ſays he), that if the doctrine of materialiſm be rejected as inadequate to explain the phenomena, theſe latter ſhould at leaſt be explained in ſome manner or other better upon the *ſubſtituted* than the *rejected* hypotheſis; ſo that it is reaſonable to require of an immaterialiſt that his ſuppoſition of a diſtinct ſoul ſhould explain the *rationale* of the phenomena of thinking. But, ſtrange to ſay, ſo far from attempting to explain theſe phenomena on the immaterial hypotheſis, it is acknowledged on all hands that even on this hypotheſis the phenomena are inexplicable." This objection it would certainly be no difficult taſk to obviate; but from that trouble, ſmall as it is, we are happily exempted by the objector. "I would have it underſtood (ſays he), that no materialiſt ever undertook to ſay *how* perception reſults from our organization. What a materialiſt undertakes to aſſert is, that perception, *whatever* it be, or *however* it reſults from, does actually reſult from our organization." According to Mr Cooper, then, the *rationale* of thinking is equally inexplicable by materialiſts and immaterialiſts; and the truth is, that we know the *rationale* of hardly any one operation in nature. We ſee that the ſtroke of a racket produces motion in a billiard ball; but how it does ſo, we believe no man can ſay. Of the fact, however, we are certain; and know that the motion is produced by ſome power, about the effects of which we can reaſon with preciſion. In like manner we know with the utmoſt certainty, that we ourſelves have the powers of perception and volition; and that theſe powers cannot be conceived as either an ell or an inch long. How they reſult from the mutual agency of an immaterial and material ſubſtance upon each other, we are indeed profoundly ignorant; but that ſuch is the fact, and that they are not the reſult of mere organiſation, we muſt neceſſarily believe, ſo long as it is true that the power of the entire ſyſtem is nothing more than

Of the Substance of the human Mind.

the sum or aggregate of the powers of all its parts. The immaterial hypothesis contains in it something inexplicable by man: The material hypothesis likewise contains, by the confession of its advocates, something that is equally inexplicable; and is over and above burdened with this contradiction, that the whole is something different from all its parts. It is therefore *no* "singular phenomenon in literary history, that one hypothesis should be rejected as indequate to account for appearances, and that the hypothesis substituted should, even by the acknowledgement of its abettors, be such as not only not to explain the *rationale* of the appearances, but, from the nature of it, to preclude all hopes of such an explanation." This is exactly the case with respect to a *vacuum* in astronomy. That hypothesis does not in the least tend to explain the rationale of the motions of the planets; but yet it must be admitted in preference to a *plenum*, because upon this last hypothesis motion is impossible.

7 Whether any thing can be asserted of the soul [as] of the body.

"Supposing the existence of the soul, it is an unfortunate circumstance (says Mr Cooper), that we cannot properly assert positively any thing of it at all." Were this the case, it would indeed be a very unfortunate circumstance; but can we not assert positively as many things of the soul as we can of the body? Can we not say with as much propriety and certainty, that the soul has the powers of perception and volition, &c. as that the body is solid and extended, or as that matter has the powers of attraction and repulsion? We know perfectly what perception and volition are, though we cannot have *ideas* or mental images of them; and if our author knows what attraction and repulsion are, we believe he will not pretend to have of them ideas entirely abstracted from their objects. "But granting the soul's existence, it may be asked (says he), Of what use is an hypothesis of which no more can be asserted than its existence?" We have just observed, that much more can be asserted of the soul than its existence, viz. that it is something of which perception and will are properties; and he himself asserts nothing of matter but that it is something of which attraction and repulsion are properties.

"This soul, of which these gentlemen (the immaterialists) are conscious, is immaterial essentially. Now, I deny (says our author), that we can have any idea at all of a substance purely immaterial." He elsewhere says, that nothing can exist which is not extended, or that extension is inseparable from our notions of existence. Taking the word *idea* in its proper sense, to denote that appearance which external objects make in the imagination, it is certainly true that we can have no *idea* of an immaterial substance; but neither have we, in that sense, any idea of matter abstracted from its qualities. Has Mr Cooper any *idea* of that which attracts and repels, or of attraction and repulsion, abstracted from their objects? He may, perhaps, have, though we have not, very adequate ideas of bodies acting upon each other at a distance; but as he takes the liberty to substitute assertions for arguments, we beg leave in our turn to assert, that those ideas neither are, nor can be, more clear and adequate than our notion of perception, consciousness, and will, united in one being.

248 Extension not inseparable from all notions of existence.

That extension is no otherwise inseparable from our notions of existence than by the power of an early and perpetual association, is evident from this circumstance, that, had we never possessed the senses of sight and touch, we never could have acquired any idea at all of extension. No man, who has thought on the subject, will venture to affirm, that it is absolutely impossible for an intelligent being to exist with no other senses than those of smell, taste, and hearing. Now it is obvious that such a being must acquire some notion of existence from his own consciousness: but into that notion extension could not possibly enter; for neither sounds, tastes, smells, nor consciousness, are extended; and it is a fundamental article of the materialists creed, that all our ideas are relicts of sensation. Since then existence may be conceived without extension, it may be inferred that they are not inseparable from each other; and since cogitation cannot be conceived with extension, we may reasonably conclude that the being which thinks is not extended.

Mr Cooper indeed with his master talks of extended ideas and extended thoughts: but we must assert, in the words of Cudworth, that "we cannot conceive a *thought* to be of such a certain *length*, *breadth*, and *thickness*, measurable by *inches*, *feet*, and *yards*; that we cannot conceive the *half*, or *third*, or *twentieth* part of a thought; and that we cannot conceive every thought to be of some determinate *figure*, such as *round* or *angular*, *spherical*, *cubical*, *cylindrical*, or the like. Whereas if extension were inseparable from existence, *thoughts* must either be mere *non-entities*, or extended into *length*, *breadth*, and *thickness*; and consequently all truths in us (being nothing but complex thoughts) must be long, broad, and thick, and of some determinate figure. The same must likewise be affirmed of volitions, appetites, and passions, and of all other things belonging to cogitative beings; such as knowledge and ignorance, wisdom and folly, virtue and vice, &c. that these are either all of them absolute *non-entities*, or else extended into three dimensions, and measurable not only by *inches* and *feet*, but also by solid measures, such as *pints* and *quarts*. But if this be absurd, and if these things belonging to soul and mind (though doubtless as great realities at least as the things which belong to body) be *unextended*, then must the substances of souls or minds be themselves unextended, according to that of Plotinus, Νους ου, διαστατος αμεριστου, and therefore the human soul cannot be material."

249 That the human mind cannot exert its faculties but in union with some corporeal system, an opinion probable and

Mr Cooper employs many other arguments to prove the materiality of the sentient principle in man; but the force of them extends no farther than to make it in the highest degree probable, that the mind cannot exert its faculties but in union with some organised corporeal system. This is an opinion which we feel not ourselves inclined to controvert; and therefore we shall not make any particular remarks upon that part of our author's reasonings. That an immaterial and indiscerptible being, such as the soul, is not liable to be *dissolved* with the body, is a fact which cannot be controverted: for what has no parts can perish only by *annihilation*; and of annihilation the annals of the world afford no instance. That an immaterial being, endowed with the powers of perception and volition, &c. *may be capable* of exerting these powers in a state of separation from all body, and that at least one immaterial Being does actually so exert them, or other powers analogous to them, are truths which no man whose

Of the Substance of the Human Mind.

whose arrogance does not surpass his judgment will venture to deny; but the question at present between the most rigid immaterialists and their opponents, is, whether there is ground to think that the human soul is such a being?

Now, when Mr Baxter and his followers confidently affirm, that human perception must *necessarily* subsist after the dissolution of the present mortal and perishable system; and that the soul, when disencumbered of *all body*, will have its faculties greatly *enlarged*; they affirm what to us appears incapable of proof. That a disembodied soul *may* perceive, and think, and act, and that its powers of intellection *may* have a wider range than when they were circumscribed by a corporeal system, which permitted their action upon external objects only through five organs of sense, is certainly *possible*; and the argument by which the materialists pretend to prove it *not* possible, is one of the most contemptible sophisms that ever disgraced the page of philosophy. To affirm, that because our intellectual powers, in their embodied state, seem to decay with the system to which they are united, the mind, when set free, must therefore have no such powers at all, is equally absurd as to say, that because a man shut up in a room which has but one window sees objects less and less distinctly as the glass becomes more and more dimmed, he must in the open air be deprived of the power of vision. But because the human soul *may*, for any thing that we see to the contrary, subsist, and think, and act, in a separate state, it does not therefore necessarily follow that it *will* do so; and every thing that we know of its nature and its energies leads us to think, that without some kind of body by which to act as by an instrument, all its powers would continue dormant. There is not the shadow of a reason to suppose that it existed and was conscious in a prior state; and as its memory at present unquestionably depends upon the state of the brain, there is all the evidence of which the case will admit, that if it should subsist in a future state divested of all body, though it might be endowed with new and enlarged powers of *perception*, it could have no *recollection* of what it did and suffered in *this world*, and therefore would not be a fit object either of reward or of punishment. This consideration has compelled many thinking men, both Pagans and Christians, to suppose that at death the soul carries with it a fine material vehicle, which is its immediate sensorium in this world, and continues to be the seat of its recollection in the next. Such, we have seen, was the opinion of Mr Wollaston and Dr Hartley; it was likewise the opinion of Cudworth and Locke, who held that the supreme Being alone is the only mind wholly separated from matter; and it is an opinion which even Dr Clarke, one of the ablest advocates for immaterialism, would not venture positively to deny.

250 Ancient.

Nor is this opinion peculiar to a few moderns. Cudworth, after giving a vast number of quotations from Pythagoreans and Platonists, which prove to a demonstration that they held the Deity to be the only mind which perceives and acts without the instrumentality of matter, observes, that "from what hath been said, it appeareth, that the most ancient assertors of the incorporeity and immortality of the human soul, yet supposed it to be always conjoined with some body. Thus *Hierocles* plainly ἡ λογικη ουσια συμφυες εχουσα σωμα, ουτω παρα του δημιουργου εις το ειναι παρηλθεν, ως μητε το σωμα ειναι αυτην, μητε ανευ σωματος· αλλ αυτην μεν ασωματον, αποτερα τουσθαι δε εις σωμα το ὁλον αυτης ειδος. *The rational nature having always a kindred body, so proceeded from the demiurgus, as that neither itself is body, nor yet can it be without body; but though itself be incorporeal, yet its whole form is terminated in a body.* Agreeably to this the definition which he gives of a man is, ψυχη λογικη μετα συμφους αθανατου σωματος, *a rational soul, together with a kindred immortal body*; and he affirms, that our present animated terrestrial body, or mortal man, is nothing but ειδωλον ανθρωπου, *the image of the true man*, or an accession from which it may be separated. Neither does he affirm this only of human souls, but also of all other rational beings whatsoever below the supreme Deity, that they always naturally actuate some body. Wherefore a demon or angel (which by *Hierocles* are used as synonymous words), is also defined by him after the same manner, ψυχη λογικη μετα φωτεινου σωματος *a rational soul, together with a lucid body*. And accordingly *Proclus* upon *Plato's Timæus affirmeth*, παντα δαιμονα των ἡμετερων κρειττονα ψυχων, και νοεραν εχειν, ψυχην, και οχημα αιθεριον: *That every demon, superior to human souls, hath both an intellectual soul and an ætherial vehicle, the entireness thereof being made up or compounded of these two things.* So that there is hardly any other difference left between demons or angels, and men, according to these philosophers, but only this, that the former are lapsable into aerial bodies only, and no further; but the latter into terrestrial also. Now, *Hierocles* positively affirms this to have been the true cabala, and genuine doctrine of the ancient Pythagoreans, entertained afterwards by Plato: και τουτο των Πυθαγορειων ην δογμα, ὁ δε Πλατων υστερον εξεφηνεν, απεικασας ξυμφυτω δυναμει υποπτερου ξευγους τε και ἡνιοχου; πασαν θειαν τε και ανθρωπινην ψυχην. *And this was the doctrine of the Pythagoreans, which Plato afterwards declared; he resembling every both human and divine soul* (i. e. in our modern language, every created rational being) *to a winged chariot, and a driver or charioteer both together*: meaning by the chariot, an animated body; and by the charioteer, the incorporeal soul actuating it.

That this Pythagorean opinion of the Deity's being the only mind which thinks and acts without material organs was very generally received by the ancient Christians, might be proved by a thousand quotations: We shall content ourselves with producing two from the learned *Origen*. "Solius Dei (saith this philosophic father of the church), id est, Patris, Filii, et Spiritus Sancti, naturæ id proprium est, ut sine materiali substantia, et absque ulla corporeæ adjectionis societate, intelligatur subsistere †." "Materialem substantiam opinione quidem et intellectu solum separari, a naturis rationalibus, et pro ipsis, vel post ipsis affectam videri; sed nunquam sine ipsa eas vel vixisse, vel vivere: Solius namque Trinitatis incorporea vita existere putabitur ‡." Should Mr Cooper and his friends ask, What is the use of a soul which cannot act without the instrumentality of matter? or why we should suppose the existence of such a substance? we beg leave, in our turn, to ask these gentlemen, What is the use of a brain which cannot see without eyes?

5 and

and why they ſhould ſuppoſe all our ſenſations to terminate in ſuch an internal ſyſtem, ſince the vulgar certainly ſuppoſe their ſenſations to ſubſiſt in their reſpective organs? How this ancient notion, which makes body ſo eſſential a part of man, is conſiſtent with the immortality of the human ſoul, we ſhall inquire in a ſubſequent chapter; in which we ſhall endeavour to aſcertain what kind of immortality we have reaſon to expect, and upon what evidence our expectation muſt reſt. Previous to this inquiry, however, it is neceſſary to enter upon another, which is of the firſt importance, and which every materialiſt has endeavoured to perplex; we mean that which concerns *perſonal identity*: for if, as has been often ſaid, no man is the ſame perſon two days ſucceſſively, it is of no importance to us whether the ſoul be mortal or immortal.

Chap. III. *Of* Personal Identity.

Whether we are to live in a future ſtate, as it is the moſt important queſtion which can poſſibly be aſked, ſo is it the moſt intelligible one which can be expreſſed in language. Yet ſtrange perplexities have been raiſed about the meaning of that identity or ſameneſs of perſon, which is implied in the notion of our living now and hereafter, or indeed in any two ſucceſſive moments; and the ſolution of theſe difficulties hath been ſtranger than the difficulties themſelves. To repeat all that has been ſaid on the ſubject would ſwell this chapter to a diſproportionate bulk. We ſhall therefore content ourſelves with laying before our readers the ſentiments of Biſhop Butler, and the fancies and demonſtrations of the philoſopher of Mancheſter. We are induced to adopt this courſe, becauſe we think the illuſtrious Biſhop of Durham has exhauſted the ſubject, by ſtating fairly the opinions which he controverts, and by eſtabliſhing his own upon a foundation which cannot be ſhaken, and which are certainly not injured, by the objections of Mr Cooper.

"When it is aſked (ſays this philoſophical prelate†) in what perſonal identity conſiſts? the anſwer ſhould be the ſame as if it were aſked in what conſiſts ſimilitude or equality?—that all attempts to define would but perplex it. Yet there is no difficulty at all in aſcertaining the idea or notion: For as, upon two triangles being compared or viewed together, there ariſes to the mind the notion of ſimilitude; or, upon twice two and four, the notion of equality: ſo likewiſe, upon comparing the conſciouſneſs of one's ſelf or one's own exiſtence in any two moments, there as immediately ariſes to the mind the notion of perſonal identity. And as the two former compariſons not only give us the notions of ſimilitude and equality, but alſo ſhow us that two triangles are ſimilar, and that twice two and four are equal; ſo the latter compariſon not only gives us the notion of perſonal identity, but alſo ſhows us the identity of ourſelves in theſe two moments—the preſent, ſuppoſe, and that immediately paſt, or the preſent and that a month, a year, or twenty years paſt. In other words, by reflecting upon that which is myſelf now, and that which was myſelf twenty years ago, I diſcern they are not two, but one and the ſame ſelf.

"But though conſciouſneſs of what is preſent and remembrance of what is paſt do thus aſcertain our perſonal identity to ourſelves; yet, to ſay that remembrance makes perſonal identity, or is neceſſary to our being the ſame perſons, is to ſay that a perſon has not exiſted a ſingle moment, nor done one action, but what he can remember; indeed none but what he reflects upon. And one ſhould really think it ſelf-evident, that conſciouſneſs of perſonal identity preſuppoſes and therefore cannot conſtitute perſonal identity; any more than knowledge, in any other caſe, can conſtitute truth, which it preſuppoſes.

253 Theſe, however, do not make perſonal identity.

"The inquiry, what makes vegetables the ſame in the common acceptation of the word, does not appear to have any relation to this of perſonal identity; becauſe the word *ſame*, when applied to them and to perſon, is not only applied to different ſubjects, but is alſo uſed in different ſenſes. When a man ſwears to the ſame tree, as having ſtood fifty years in the ſame place, he means only the ſame as to all the purpoſes of property and uſes of common life, and not that the tree has been all that time the ſame in the ſtrict philoſophical ſenſe of the word: For he does not know whether any one particle of the preſent tree be the ſame with any one particle of the tree which ſtood in the ſame place fifty years ago. And if they have not one common particle of matter, they cannot be the ſame tree in the proper and philoſophic ſenſe of the word *ſame*; it being evidently a contradiction in terms to ſay they are, when no part of their ſubſtance and no one of their properties is the ſame; no part of their ſubſtance, by the ſuppoſition; no one of their properties, becauſe it is allowed that the ſame property cannot be transferred from one ſubſtance to another: And therefore, when we ſay that the identity or ſameneſs of a plant conſiſts in a continuation of the ſame life, communicated under the ſame organization to a number of particles of matter, whether the ſame or not; the word *ſame*, when applied to life and to organiſation, cannot poſſibly be underſtood to ſignify what it ſignifies in this very ſentence, when applied to matter. In a looſe and popular ſenſe, then, the life, and the organiſation, and the plant, are juſtly ſaid to be the ſame, notwithſtanding the perpetual change of the parts. But, in a ſtrict and philoſophical manner of ſpeech, no man, no being, no mode of being, no any thing, can be the ſame with that with which it has indeed nothing the ſame. Now ſameneſs is uſed in this latter ſenſe when applied to perſons. The identity of theſe, therefore, cannot ſubſiſt with diverſity of ſubſtance.

254 What it is.

"The thing here conſidered, and demonſtratively, as I think, determined, is propoſed by Mr Locke in theſe words: *Whether it* (i. e. the ſame ſelf or perſon) *be the ſame identical ſubſtance?* And he has ſuggeſted what is a much better anſwer to the queſtion than that which he gives it in form: For he defines perſon *a thinking intelligent being*, &c. and perſonal identity, *the ſameneſs of a rational being*; and then the queſtion is, Whether the ſame rational being is the ſame ſubſtance? which needs no anſwer; becauſe being and ſubſtance are in this place ſynonymous terms. The ground of the doubt, whether the ſame perſon be the ſame ſubſtance, is ſaid to be this, that the conſciouſneſs of our own exiſtence, in youth and in old age, or in any two joint ſucceſſive moments, is not *the ſame individual action*,

i. e.

Of Perfonal Identity.

i. e. not the fame confcioufnefs, but different fucceffive confcioufneffes. Now it is ftrange that this fhould have occafioned fuch perplexities: for it is furely conceivable, that a perfon may have a capacity of knowing fome object or other to be the fame now which it was when he contemplated it formerly; yet in this cafe, where, by the fuppofition, the object is perceived to be the fame, the perception of it in any two moments cannot be one and the fame perception. And thus, though the fucceffive confcioufneffes which we have of our own exiftence are not the fame, yet are they confcioufneffes of one and the fame thing or object; of the fame perfon, felf, or living agent. The perfon of whofe exiftence the confcioufnefs is felt now, and was felt an hour or a year ago, is difcerned to be, not two perfons, but one and the fame perfon; and therefore is one and the fame.

255 False notions of perfonal identity

"Mr Locke's obfervations upon this fubject appear hafty; and he feems to profefs himfelf diffatisfied with fuppofitions which he has made relating to it. But fome of thofe hafty obfervations have been carried to a ftrange length by others; whofe notion, when traced and examined to the bottom, amounts, I think, to this: 'That perfonality is not a permanent but a tranfient thing: That it lives and dies, begins and ends, continually: That no one can any more remain one and the fame perfon two moments together, than two fucceffive moments can be one and the fame moment: That our fubftance is indeed continually changing: but whether this be fo or not is, it feems, nothing to the purpofe; fince it is not fubftance, but confcioufnefs alone, which conftitutes perfonality; which confcioufnefs, being fucceffive, cannot be the fame in any two moments, nor confequently the perfonality conftituted by it §.'" Hence it muft follow, that it is a fallacy upon ourfelves to charge our prefent felves with any thing we did, or to imagine our prefent felves interefted in any thing which befel us, yefterday; or that our prefent felf will be interefted in what will befal us to-morrow; fince our prefent felf is not in reality the fame with the felf of yefterday, but another felf or perfon coming in its room, and miftaken for it; to which another felf will fucceed to-morrow. This, I fay, muft follow: for if the felf or perfon of to day and that of to-morrow are not the fame, but only like perfons; the perfon of to-day is really no more interefted in what will befal the perfon of to-morrow, than in what will befal any other perfon. It may be thought, perhaps, that this is not a juft reprefentation of the opinion we are fpeaking of; becaufe thofe who maintain it allow that a perfon is the fame as far back as his remembrance reaches: And indeed they do ufe the words *identity* and *fame* perfon; nor will language permit thefe words to be laid afide. But they cannot, confiftently with themfelves, mean that the perfon is really the fame: For it is felf-evident, that the perfonality cannot be really the fame, if, as they exprefsly affert, that in which it confifts is not the fame. And as, confiftently with themfelves, they cannot, fo I think it appears they do not, mean that the perfon is *really* the fame, but only that he is fo in a fictitious fenfe, in fuch a fenfe only as they affert: for this they do affert, that any number of perfons whatever may be the fame perfon. The bare unfolding this notion, and laying it thus naked and open,

§ *Anfwer to Dr Clarke's third Defence of his Letter to Mr Dodwell*, fecond edit. p. 44, 56, &c.

feems the beft confutation of it. However, fince great ftrefs is faid to be put upon it, I add the following things:

256 Overthrow

"*Firft*, This notion is abfolutely contradictory to that certain conviction, which neceffarily and every moment rifes within us, when we turn our thoughts upon ourfelves, when we reflect upon what is paft, and look forward to what is to come. All imagination, of a daily change of that living agent which each man calls himfelf for another, or of any fuch change throughout our whole prefent life, is entirely borne down by our natural fenfe of things. Nor is it poffible for a perfon in his wits to alter his conduct with regard to his health or affairs, from a fufpicion that though he fhould live to-morrow he fhould not however be the fame perfon he is to day.

"*Secondly*, It is not an *idea*, or abftract *notion*, or quality, but a being only which is capable of life and action, of happinefs and mifery. Now all beings confeffedly continue the fame during the whole time of their exiftence. Confider then a living being now exifting, and which has exifted for any time alive: this living being muft have done, and fuffered, and enjoyed, what it has done, and fuffered, and enjoyed, formerly (this living being, I fay, and not another), as really as it does, and fuffers, and enjoys, what it does, and fuffers, and enjoys, this inftant. All thefe fucceffive actions, fufferings, and enjoyments, are actions, enjoyments, and fufferings, of the fame living being; and they are fo prior to all confiderations of its remembering or forgetting, fince remembering or forgetting can make no alteration in the truth of paft matter of fact. And fuppofe this being endued with limited powers of knowledge and memory, there is no more difficulty in conceiving it to have a power of knowing itfelf to be the fame being which it was fome time ago, of remembering fome of its actions, fufferings, and enjoyments, and forgetting others, than in conceiving it to know, or remember, or forget, any thing elfe.

"*Thirdly*, Every perfon is confcious that he is now the fame perfon or felf he was as far back as his remembrance reaches: fince when any one reflects upon a paft action of his own, he is juft as certain of the perfon who did that action, namely himfelf (the perfon who now reflects upon it), as he is certain that the action was at all done. Nay, very often a perfon's affurance of an action having been done, of which he is abfolutely affured, arifes wholly from the confcioufnefs that he himfelf did it: and this he, perfon, or felf, muft either be a fubftance or the property of fome fubftance. If *he*, if perfon, be a fubftance; then confcioufnefs that he is the fame perfon, is confcioufnefs that he is the fame fubftance. If the perfon, or *he*, be the property of a fubftance, ftill confcioufnefs that he is the fame property is as certain a proof that his fubftance remains the fame, as confcioufnefs that he remains the fame fubftance would be; fince the fame property cannot be transferred from one fubftance to another.

"But though we are thus certain that we are the fame agents, living beings, or fubftances, now, which we were as far back as our remembrance reaches; yet it is afked, Whether we may not poffibly be deceived in it? And this queftion may be afked at the end of any demonftration whatever; becaufe it is a queftion con-

concerning the truth of perception by memory: and he who can doubt whether perception by memory can in this case be depended upon, may doubt also whether perception by deduction and reasoning, which also include memory, or indeed whether intuitive perception itself, can be depended upon. Here then we can go no farther: for it is ridiculous to attempt to prove the truth of our faculties, which can no otherwise be proved than by the use or means of those suspected faculties themselves."

7 [Objections fore-stalled &c.]

This reasoning, which we believe will to most men appear unanswerable, Mr Cooper hopes to overturn by the following observations*: "If all imagination of a daily change in us be borne down by our natural sense of things, then (says he) does our natural sense of things positively contradict known fact; for a daily, a momentaneous, change in us, *i. e.* in our bodies, does actually take place." True, a daily change in our bodies does take place, and so likewise does a daily change in our cloaths; but surely no man was ever led by his natural sense of things to suppose, that his limbs or external organs were the seats of sensation and will, any more than that his coat or his shoes were any real parts of his trunk or of his feet. But it is only that which thinks and wills that any man considers, in this case, as himself or his person; and if our natural sense of things, or consciousness, tell us, that what thinks and wills has continued the same from a distance of time as far back as we can remember, it is certain, that, whether it be material or immaterial, it has continued from that period, otherwise we can be certain of nothing. "But (says our philosopher) other known and ascertained facts are frequently borne down by our natural sense of things: for how many thousand years before the days of *Copernicus* was the motion of the earth round the sun entirely borne down by our natural sense of things, which made us give full credit to the motion of the sun round the earth? Do not the generality of mankind believe, upon the evidence of their natural sense of things, that every part of their body remains exactly the same today as it was yesterday?"

8 [...ered.]

To the former of these questions we answer positively, that before the days of *Copernicus* the motion of the earth round the sun was *not* borne down by our *natural sense* of things, but by ill-founded hypotheses and inconclusive reasonings. By the natural sense of things, nothing can be meant, in this place, but the evidence of consciousness or of external sensation; but the *actual motion* either of the sun or of the earth is not perceived either by consciousness or by sensation. Of consciousness nothing is the object but the internal energies and feelings of our own minds; and with regard to the motion of the sun or of the earth, nothing is perceived by the sense of sight but that, after considerable intervals of time, these two great bodies have repeatedly changed their places in the heavens with respect to each other. This is all that on this subject our *natural sense of things* leads us to believe; and is not this infallibly true? Afterwards indeed, by taking for granted the truth of propositions, for which neither sense nor consciousness affords the shadow of evidence; the vulgar now, and all mankind formerly, reasoned themselves into the opinion, that the earth stands still, and that the sun moves round it. In vulgar philosophy it is taken for granted, that in the universe there is not a *relative* but an *absolute upwards* and an *absolute downwards*; that our heads are absolutely upward, and our feet downward; and that were the earth to revolve round its axis, these positions would be reversed, that our heads would be placed beneath our feet, and that we ourselves would fall from the earth into empty space. Upon these false hypotheses the vulgar reason correctly. They know that bodies cannot change their place without motion; they know that in the time of their remembrance the sun and the earth have been perpetually varying their places with respect to each other; they know that they themselves have never fallen, nor had a tendency to fall, into empty space; and hence they infer that it is the sun and not the earth that moves (K). But will any man say that the absurd suppositions from which this conclusion is logically deduced, have the evidence either of sensation or of consciousness, as the permanency of that living agent which each man calls himself has?

To our author's second question we likewise reply with confidence, that the generality of mankind do *not* believe, upon their natural sense of things, that every part of their body remains exactly the same to-day as it was yesterday. It would be strange indeed if they did, after having repeatedly experienced the waste of increased perspiration or sweating; after having witnessed men emaciated by sickness, and again restored to plumpness in health; and after having perhaps lost whole limbs, which certainly their natural sense of things teaches them to consider as parts of their body. In all these cases, the generality of mankind are as sensible of changes having taken place in their bodies as he who has attended ever so closely to physiological inquiries, though not one of them has the least imagination of a change having taken place in the living agent which each man calls himself.

Bishop Butler observes, that if the living agent be perpetually changing, it is a fallacy upon ourselves to charge our present selves with any thing we did, to imagine our present selves interested in any thing which befel us yesterday, or that our present self will be interested in what will befal us to-morrow. To this judicious observation our daring philosopher replies, "that as the man of to-morrow, though not in all points the same with, yet depends for his existence upon, the man of to-day, there is sufficient reason to care about him." Could he have said, that as the man of to-day depends for his existence on the man of to-morrow, there is sufficient reason for the present man to care about the future man; or that as the man of to-morrow depends for his existence on the man of to-day,

(K) This inference too has been so often drawn, that it comes in time to coalesce in the mind with the *sensations*, from which the motion either of the sun or of the earth is deduced with infallible certainty; and hence it is considered as part of that truth which sensation immediately discovers. *See our Chapter of Association.*

Of Perfonal Identity

day, there is to-day fufficient reafon for the future man to care about the prefent man; we fhould in either cafe, if the anachronifm had been kept out of fight, have feen the force of his argument. Every man has fufficient reafon to care about the ox upon which he is to be fed; but we cannot fo clearly perceive what reafon the ox has to care about the man.

Not fatisfied, it would feem, with this reply, our author proceeds to affirm, "that the man of to-morrow, poffeffing a reminifcence of the actions of the man of to-day, and knowing that thefe actions will be referred to him both by himfelf and others (which is certainly knowing that both himfelf and others are moft iniquitous wretches), they cannot be indifferent to the man of to-day, who looks forward to the properties of the man of to-morrow," *i. e.* the reminifcence and knowledge of a future man conftitute all the relation that fubfifts between a prefent man and his actions; a difcovery worthy of an original genius. But as on the fubject of perfonal identity we pretend to no originality, we fhall leave this propofition to the meditation of our readers, and take the liberty to afk our author a queftion or two refpecting this fame reminifcence, which he is gracioufly pleafed to acknowledge for a property.

He defines identity, "the continued exiftence of any being unaltered in fubftance or in properties;" and he repeatedly acknowledges that no identical quality or property can be transferred from one fubject to another. Let us now fuppofe, that a man has a reminifcence of an individual action performed a month ago, and that this reminifcence is accompanied with a confcioufnefs that the action was performed by himfelf. This fuppofition, whether true or falfe, may certainly be made; for it implies nothing more than what every man firmly believes of himfelf in every act of remembrance. Let us again fuppofe, that, at the diftance of ten or twenty years, the man known by the fame name has a reminifcence of the fame action, with a confcioufnefs that he himfelf performed it. Is this reminifcence the fame with the former? or is it a different reminifcence? If it be the fame, either the perfon remembering at the diftance of ten or twenty years is the fame with him who remembered at the diftance of a month, or there is an identical quality transferred from one fubftance to another, which is admitted to be impoffible. If reminifcence be itfelf a real and immediate quality of any fubftance, and not the mere energy of a power, and if the one reminifcence be different from the other, the fubjects in which thefe two different qualities inhere muft likewife be different. Yet the man who has the reminifcence at the diftance of a month, has the evidence of confcioufnefs that the action was performed by him; and the man who has the reminifcence at the diftance of ten or twenty years, has likewife the evidence of confcioufnefs that the fame action was performed by him and not by another. By the confeffion of Hume and of all philofophers, confcioufnefs never deceives; but here is the evidence of one confcioufnefs in direct oppofition to another; and therefore, as two contradictory propofitions cannot both be true, either the one reminifcence is the fame with the other, or reminifcence is no real quality. That one act of reminifcence fhould be numerically the fame with another, which followed it at the diftance of twenty years, is plainly impoffible; whence it fhould feem, that reminifcence itfelf is no real and immediate quality of any fubftance. But if this be fo, what is reminifcence? We anfwer, it is plainly neither more nor lefs than the *energy* of a power, which though dormant between its energies, remains unchanged from the one to the other, and which being itfelf the real and immediate quality of a fubject, that fubject muft likewife remain unchanged. That powers may remain dormant, and yet unchanged, every man muft be convinced; who having ftruck any thing with his hand, knows that he has power to repeat the ftroke, and yet does not actually repeat it. Two blows with the hand immediately following each other are numerically different, fo that the one cannot with truth be faid to be the other; but we have the evidence of external fenfe, that they are both ftruck by the fame member. In like manner, two energies of reminifcence directed to the fame object, and fucceeding each other at any interval of time, cannot poffibly be one and the fame energy; but as the latter energy may include in it the former as well as the object remembered by both, we have the evidence of confcioufnefs that both are energies of the fame power; and we have feen, that to fuppofe them any thing elfe, may be demonftrated to involve the groffeft abfurdities and contradictions.

Mr Cooper has other arguments to obviate the force of Bifhop Butler's demonftration of perfonal identity; fuch as, that a "high degree of *fimilarity* between the two fucceeding men is fufficient to make the one care about the other;" and, that "a good man, knowing that a future being will be punifhed or rewarded as the actions of the prefent man deferve, will have a fufficient motive to do right and to abftain from wrong." But if there be any one of our readers who can fuffer himfelf to be perfuaded by fuch affertions as thefe, that the living agent which he calls himfelf is perpetually changing, and at the fame time that fuch change is confiftent with the expectation of future rewards and punifhments, he would not be reclaimed from his error by any reafoning of ours. We fhall therefore truft fuch trifling with every man's judgment, and proceed to examine our author's *demonftration*, that perfonal identity has no exiftence. But here it is no part of our purpofe to accompany him through his long chemical ramble, or to controvert his arguments for the non-identity of vegetable and animal bodies. The only thing to which, after Bifhop Butler, we have afcribed identity, is that which in man is fentient and confcious; and the non-identity of this thing, whatever it be, Mr Cooper undertakes to demonftrate from the known properties of fenfations and ideas.

25
A pretended demonftration that perfonal identity is impoffible.

This demonftration fets out with a very ominous circumftance. The author, after conducting impreffions *ab extra*, from the extremities of the nerves to the brain, affirms, that *fenfations* and *ideas* are nothing but "motions in the brain perceived;" *i. e.* when a man thinks he is looking at a mountain, not only at reft, but to appearance immoveable, he is grofsly deceived; for he perceives nothing all the while but *motion in his brain!* Were not the defire of advancing novelties and paradoxes invincible in fome minds, we fhould be aftonifhed at finding fuch an affertion as this

this fall from the pen of any man who had paid the slightest attention to the different energies of his own intellect. Motions in the brain, as we have repeatedly observed, are the immediate causes of our sensations; but is it conceivable, is it possible, that any thing should be the cause of itself? The motion of a sword through the heart of a man, is the immediate cause of that man's death; but is the sword or its motion *death* itself, or can they be conceived as being the *sensations* of the *man* in the *agonies* of *dying?* But sensations and ideas, whatever they be, exist in succession; and therefore, argues our demonstrator, no two sensations or ideas can be one and the same sensation or idea. The conclusion is logically inferred; but what purpose can it possibly serve? What purpose, why it seems "sensations and ideas are the only *existences whose existence* we certainly know (a charming phrase, the *existence* of *existences*, and as original as the theory in which it makes its appearance); and, therefore, from the nature of sensations and ideas, there is no such thing as permanent identity." Indeed! what then, we may be permitted to ask, is the import of the word *we* in this sentence? Does it denote a series of sensations and ideas, and does each sensation and each idea certainly know not only itself, but all its ancestors and all its descendants? Unless this be admitted, we are afraid that some other existence besides sensations and ideas must be allowed to be certainly known, and even to have something of a permanent identity. Nay, we think it has been already demonstrated (see chap. of Time), that were there not something permanent, there could be no time, and of course no notion of a first and last, or indeed of succession, whether of sensations or ideas. And therefore, if we have such a notion, which the author here takes for granted, and upon which indeed his demonstration rests, it follows undeniably that there is something permanent, and that we *know* there is something permanent, which observes the succession of sensations and ideas.

All this, indeed, Mr Cooper in effect grants; for he is not much startled at the appearance of contradictions in his theory. "I find (says he), by perpetually repeated impressions which I perceive, that my hands, body, limbs, &c. are connected, are parts of one whole. I find, by perpetually repeated perceptions also, that the sensations excited by them are constantly similar, and constantly different from the sensations excited by others." He has then repeated perceptions: but how can this be possible, if *he* be not different from the perceptions, and if *he* do not *remain unchanged* while the perceptions succeed each other at greater or less intervals of time? A striking object passing with rapidity before the eyes of a number of men placed beside each other in a line of battle, would undoubtedly excite a succession of sensations; but surely that succession would not take place in the mind of *any individual* in the line, nor could any *single man* in this case say with truth that he had *repeated* perceptions of the object. In like manner, were that which is sentient perpetually changing, no man could possibly say or suppose that he had repeated perceptions of any thing; for upon this supposition, the man of to-day would have no more connection with the man who bore his name yesterday, or twenty years ago, than the last man in the line had with the first.

Upon the whole, we cannot help thinking, that Bishop Butler's demonstration of personal identity remains unshaken by the batteries of Mr Cooper.—It rests, indeed, upon the solid basis of consciousness and memory; and if implicit credit be not given to the evidence of these faculties, we cannot proceed a single step in any inquiry whatever, nor be certain of the truth even of a mathematical demonstration.

261 A difficulty removed.

But as we have ourselves supposed, that to sensation, reminiscence, and every actual energy of the mind of man, the instrumentality of some material system is necessary, it may perhaps be thought incumbent on us to show how the perpetual flux of the particles of matter which compose the brain, as well as all the other parts of the body, can consist with the identity of the person who perceives, remembers, and is conscious. If this cannot be done, our hypothesis, ancient and plausible as it is, must be given up; for of personal identity it is impossible to doubt. In this case, however, we perceive no difficulty; for if there be united to the brain an immaterial being, which is the subject of sensation, consciousness, and will, &c. it is obvious, that all the *intellectual powers* which properly constitute the person, must be inherent in that being. The material system, therefore, can be necessary only as an instrument to excite the energies of those powers; and since the powers themselves remain unchanged, why should we suppose that their energies may not be continually exerted by successive instruments of the same kind, as well as by one permanent instrument? The powers of perception and volition are not, in the material system, any more than the sensation of seeing is in the rays of light, or the energy of the blacksmith in the hammer with which he beats the anvil. Let us suppose a man to keep his eye for an hour steadily fixed upon one object. It will not surely be denied, that if this could be done, he would have one uninterrupted and unvaried perception of an hour's duration, as measured by the clock. Yet it is certain, that the rays of light which alone could occasion that perception would be perpetually changing. In like manner, a blacksmith, whilst he continues to beat his anvil, continues to exert the same power whether he uses one hammer all the time, or a different hammer at each stroke. The reason is obvious; the eye, with all its connections of brain and mind in the one case, and the person of the smith in the other, remain unchanged; and in them alone reside the faculty of sensation and the power of beating, though neither the faculty nor the power can be exerted without material instruments. But were it possible that millions of men could in the space of an hour take their turns in rotation with each new ray of light, it is self-evident, that in this case, there would be nothing permanent in sensation; and, therefore, there could not be one uninterrupted and unvaried perception, but millions of perceptions, during the hour, totally distinct from and unconnected with each other. Let us now suppose a man to fix his eye upon an object for the space of a minute, and at the distance of a day or a month to fix it upon the same object

object a second time: He would not indeed, in this case, have one uninterrupted and unvaried perception, but he would be conscious of the energy of the very same faculty the second time as at the first. Whereas, were one man to view an object to-day, and another to view the same object to-morrow, it is obvious, that he who should be last in the succession could know nothing of the energy of that faculty by which the object was perceived the first day, because there would be nothing common to the two perceptions.

Thus then we see, that *personal identity* may with truth be predicated of a compound being, though the material part be in a perpetual flux, provided the immaterial part remain unchanged; and that of such a being only is a resurrection from the dead possible.—For since the motions of the brain do nothing more than excite to energy the permanent powers of the mind, it is of no sort of consequence to that energy, whether these motions be continued by the same numerical atoms, or by a perpetual succession of atoms arranged and combined in the very same manner. We shall, therefore, be the same persons at the resurrection as at present, whether the mind be united to a particular system composed of any of the numberless atoms which have in succession made parts of our present bodies, or to a system composed of totally different atoms, provided that new system be organised in exactly the same manner with the brain or material vehicle, which is at present the immediate instrument of perception. This (we say) is self-evident; but were the immaterial part to change with the changing body, a resurrection of the same persons would be plainly impossible.

Chap. IV. *Of the* Immortality *of the* Soul.

262 The immortality of the soul the general belief in all nations.

Wherever men have been in any degree civilized, and in some nations where they have been in the most savage state, it has been the general persuasion, that the mind or soul subsists after the dissolution of the body. The origin of this persuasion, about which disputes have been raised, no Christian hesitates to attribute to revelation. The Egyptians, from whom the Greeks derived many of their theological and philosophical principles, appear to have taught the immortality of the soul, not as a truth discovered by the exertions of human reason, but as a dogma derived to them from the earliest ages by tradition. This indeed may be confidently inferred from the character and conduct of their first Greek disciples. Those early wise men who fetched their philosophy immediately from Egypt, brought it home as they found it, in detached and independent placits. Afterwards, when schools were formed, and when man began to philosophise by hypothesis and system, it was eagerly inquired upon what foundation in *nature* the belief of the soul's immortality could rest; and this inquiry gave rise to the various disquisitions concerning the *substance* of the soul, which have continued to exercise the ingenuity of the learned to the present day. It was clearly perceived, that if consciousness, thought, and volition, be the result of any particular modification of matter and motion, the living and thinking agent must perish with the dissolution of the system; and it was no less evident, that if the being which perceives, thinks, and wills, be not material, the mind of man *may* subsist after the resolution of the body into its component particles. The discovery of the immateriality of the mind was therefore one *step towards* the proof of its immortality; and in the opinion of many philosophers, whose hopes ought to rest on a surer basis, it was alone a complete proof.—"They who hold sensitive perception in brutes (says a pious writer †) to be an argument for the immateriality of their souls, find themselves under the necessity of allowing those souls to be immortal."

† See Proced. Extent and Limits of Understanding.

26 The philosophers of ancient Greece believed likewise in pre-existence.

The philosophers of ancient Greece, however, felt not themselves under any such necessity. Whatever were their opinions respecting the souls of brutes, they clearly perceived that nothing which had a beginning of existence could be naturally immortal, whether its substance were material or immaterial.—"There never was any of the ancients before Christianity (says the accurate Cudworth), that held the soul's future permanency after death, who did not likewise assert its pre-existence; they clearly perceiving, that if it were once granted that the soul was generated, it could never be proved but that it might be also corrupted. And, therefore, the assertors of the soul's immortality commonly began here, first to prove its pre-existence, proceeding thence to establish its permanency after death. This is the method of proof used in Plato: Ην που ἡμων ἡ ψυχη πριν εν τῳδε τῳ ανθρωπινῳ ειδει γενεσθαι, ὡστε και ταυτῃ αθανατον τι εοικεν ἡ ψυχη ειναι. *Our soul was somewhere before it came to exist in this human form, and thence it appears to be immortal, and as such will subsist after death.*"

26 And also in its eternity.

To give this argument for immortality any strength, it must be taken for granted, not only that the soul existed in a *prior* state, but that it existed from all *eternity*; for it is obvious, that if it had a beginning in any state, it may have an end either in that state or in another. Accordingly, Plato asserts in plain terms its eternity and self-existence, which, as we learn from Cicero, he infers from its being the principle of motion in man. "Quin etiam cæteris, quæ moventur, hic fons, hoc principium est movendi. *Principii autem nulla est origo.* Nam ex principio oriuntur omnia: ipsum autem nulla ex re alia nasci potest: nec enim esset id principium, quod gigneretur aliunde §." This, it must be acknowledged, is very contemptible reasoning; but the opinion which it was intended to prove was held by all the philosophers. They were unanimous in maintaining the *substance* of the soul, though not its *personality*, to be eternal *à parte ante* as well as *ad partem post*; and Cicero, where he tells us that this opinion passed from *Pherecydes, Syrus*, to Pythagoras, and from Pythagoras to *Plato*, expresses his notion of the soul's duration by the word *sempiternus* *, which, in its original and proper sense, is applicable only to that which has neither beginning nor end.

§ Tusc. lib. i. c. 23.

* Tusc. lib. i.

Indeed none of the philosophers of ancient Greece appear to have believed a creation (see Creation) possible: for it was a maxim universally received among them, *De nihilo nihil fit, in nihilum nil posse reverti*; that *nothing can come from nonentity, or go to nonentity.* This maxim, as held by the theistical philosophers, the learned Cudworth labours to interpret in a sense agreeable

able to our notions of the orgin of the world; but the quotations urged by himself must convince every competent reader that on this occasion he labours in vain. For instance, when Aristotle writes of Parmenides and Melissus, that ουδεν ουδε γινεσθαι φασιν ουδε φθειρεσθαι των οντων, *they say that no real entity is either made or destroyed*; what can be his meaning, but that those philosophers taught that nothing could be either created or annihilated? He testifies the same thing of *Xenophanes* and *Xeno*, when he says that it was a fundamental principle of their philosophy—μη ενδεχεσθαι γινεσθαι μηδεν εκ μη οντος—*that it is impossible that any thing should be made out of nothing*. And of Empedocles, when he relates απαντα ταυτα και εκεινος ὁμολογει ὁτι εκ τε μη οντος αμηχανον εστι γινεσθαι το τε ον εξολλυσθαι ανηνυστον και απρηκτον—*That he acknowledges the very same thing with other philosophers, viz that it is impossible that any thing should be made out of nothing, or perish into nothing*. But it is needless to multiply quotations respecting the opinions of single philosophers. Of all the physiologers before himself and Plato, Aristotle says, without exception, περι ταυτης ὁμογνωμονουσι της δοξης οἱ περι φυσεως, ὁτι το γιγνομενον εκ μη οντων γιγνεσθαι αδυνατον ‡—*That they agree in this opinion, that it is impossible that any thing should be made out of nothing*: and he calls this the common principle of naturalists; plainly intimating, that they considered it as the greatest absurdity to suppose that any real entity in nature could either be brought from nothing or reduced to nothing.

The author of the *Intellectual System*, in order, perhaps, to hide the impiety of this principle, endeavours to persuade his readers, that it was urged only against the hypothesis of forms and qualities of bodies considered as real entities, distinct from matter. But how it could be supposed to militate against that particular opinion, and not against the possibility of all creation, is to us perfectly inconceivable. The father of the school which analysed body into matter and form, together with by far the greater part of his followers, taught the eternity of both these principles (L); and therefore maintained, as strenuously as any atomist, the universal maxim, *De nihilo nihil fit*. Even Plato himself, whose doctrine of *ideas* is supposed to wear a more favourable aspect than Aristotle's *forms* to the truths of revealed religion, taught the *eternity* of *matter*; but whether as a self-existing substance, or only as an emanation from the Deity, is a question which has been disputed. That he admitted no proper creation, may be confidently inferred from Plutarch; who writing upon the generation of animals, according to the doctrine laid down in the *Timæus*, has the following passage: Βελτιον ουν, Πλατωνι πειθομενους τον μεν κοσμον υπο θεου γεγονεναι λεγειν και αδειν· ὁ μεν γαρ καλλιστος των γεγονοτων, ὁ δ' αριστος των αιτιων· την δε ΟΥΣΙΑΝ και ΥΛΗΝ εξ ἡς γεγονε, ου γενομενην, αλλα ὑποκειμενην αει τω δημιουργω εις διαθεσιν και ταξιν αυτης, και προς εξομοιωσιν, ὡς δυνατον ην, παρασχειν· ου γαρ εκ του μη οντος ἡ γενεσις, αλλ' εκ του μη καλως, μηδ' ἱκανως εχοντος, ὡς οικιας και ἱματιου, και ανδριαντος †. *It is therefore better for us to follow Plato, and to say and sing that the world was made by God. For as the world is the best of all works, so is God the best of all causes. Nevertheless, the* SUBSTANCE *or* MATTER *out of which the world was made, was* NOT *itself made, but was always ready at hand, and subject to the artificer, to be ordered and disposed by him. For the making of the world was not the production of it out of nothing, but out of an antecedent bad and disorderly state, like the making of a house, garment, or statue.*

Of the Immortality of the Soul.

† Plut. Op. tom. ii. p. 1014.

If, then, this be a fair representation of the sentiments of Plato, and surely the author understood those sentiments better than the most accomplished modern scholar can pretend to do, nothing is more evident, than that the founder of the academy admitted of no proper creation, but only taught that the matter which had existed from eternity in a chaotic state, was in *time* reduced to order by the *Demiurgus*, or supreme Being. And if such were the sentiments of the divine Plato, we cannot hesitate to adopt the opinion of the excellent Mosheim, which the reader will probably be pleased to have in his own words. "Si a Judæis discedas, nescio an ullus antiquorum philosophorum mundum negaverit æternum esse. Omnes mihi æternum professi videntur esse mundum: hoc uno vero disjunguntur, quod nonnulli, ut *Aristoteles, formam* et *materiam* simul hujus orbis, alii vero, quorum princeps facile Plato, *materiam* tantum *æternam*, formam vero, a Deo comparatam, dixerunt †."

† Notes on Cudworth's Intellectual System.

Now it is a fact so generally known, as not to stand in need of being proved by quotations, that there was not among them a single man who believed in the existence of mind as a being more excellent than matter, and essentially different from it, who did not hold the superior of at least equal antiquity with the inferior substance. So true is this, that Synesius, though a Christian, yet having been educated in one of the schools of philosophy, could not by the hopes of a bishopric be induced to dissemble this sentiment: αμελει την ψυχην ουκ αξιωσω ποτε σωματος ὑστερογενη νομιζειν *.—*I shall never be persuaded to think my soul younger than my body*. This man probably believed upon the authority of the scriptures, that the matter of the visible world was created in time; but he certainly held with his philosophic masters, that his own soul was as old as any atom of it, and that it had consequently existed in a prior state before it animated his present body.

Of the Immortality of the Soul.

Thoſe who maintained that the world was uncreated, maintained upon the ſame principle that their ſouls were uncreated likewiſe; and as they conceived all bodies to be formed of one firſt matter, ſo they conceived all ſouls to be either emanations from the one firſt Mind, or diſcerpted parts of it. Ariſtotle, who diſtinguiſhes between the intellectual and ſenſitive ſouls, ſays expreſsly of the former, that "it enters from without, and is DIVINE;" adding this reaſon for his opinion, that "its energy is not blended with that of the body—λειπεται δε τον νουν μονον θυραθεν επεισιεναι, και θειον ειναι μονον· ουδε γαρ αυτου τη ενεργεια κοινωνει σωματικη ενεργεια *. As to the Stoics, *Cleanthes* held (as Stobæus informs us †), that "every thing was made out of one, and would be again reſolved into one." But let Seneca ſpeak for them all: "Quid eſt autem, cur non exiſtimes in eo *divini* aliquid exiſtere, qui DEI PARS eſt? Totum hoc, quo continemur, et unum eſt, et Deus: et ſocii ejus ſumus, et membra||—*Why ſhould you not believe ſomething to be divine in him, who is indeed* PART OF GOD? *That* WHOLE *in which we are contained is* ONE, *and that one is* GOD; *we being his companions and* MEMBERS. Epictetus ſays, *The ſouls of men have the neareſt relation to God, as being* PARTS *or* FRAGMENTS *of him,* DISCERPTED *and* TORN *from his* SUBSTANCE: συναφεις τω θεω, ἅτε αυτου μορια ουσαι και αποσπασματα. Plato writes to the very ſame purpoſe, when, without any ſoftening, he frequently calls the ſoul *God*, and *part of God*. And Plutarch ſays, that "Pythagoras and Plato held the ſoul to be immortal; for that, launching out into the ſoul of the univerſe, it returns to its parent and original—Πυθαγορας, Πλατων, αφθαρτον ειναι την ψυχην· εξιουσαν γαρ εις την του παντος ψυχην, αναχωρειν προς το ομογενες †. Plutarch declares his own opinion to be, that "the ſoul is not ſo much the work and production of God, as a PART of him; nor is it made BY him, but FROM him, and OUT of him: ἡ δε ψυχη ουκ εργον εστι μονον, αλλα και μερος· ουδ' ΥΠ' αυτου, αλλ' ΑΠ' αυτου, και ΕΞ αυτου γεγονεν *. But it is needleſs to multiply quotations. Cicero delivers the common ſentiments of his Greek maſters on this head, when he ſays §, "A natura deorum, ut doctiſſimis ſapientiſſimiſque placuit, HAUSTOS animos et LIBATOS habemus." And again: "Humanus autem animus DECERPTUS EX MENTE DIVINA: cum alio nullo, niſi cum ipſo Deo (ſi hoc fas eſt dictu), comparari poteſt."

265 They ſuppoſed all ſouls to be emanations from the firſt mind;

* Plato Quæſt

§ De Divinatione, lib. i cap. 49.

266 But differed in opinion as to the mode of their ſeparation.

Whilſt the philoſophers were thus unanimous in maintaining the ſoul to be a part of the ſelf-exiſtent Subſtance, they differed in opinion, or at leaſt expreſſed themſelves differently, as to the mode of its ſeparation from its divine parent. Cicero and the Stoics talk as if the Supreme Mind were extended, and as if the human ſoul were a part literally torn from that mind, as a limb can be torn from the body. The Pythagoreans and Platoniſts ſeem to have conſidered all ſouls as emanations from the divine Subſtance rather than as parts torn from it, much in the ſame way as rays of light are emanations from the ſun. Plato, in particular, believed in two ſelf-exiſtent principles, God and matter. The former he conſidered as the ſupreme Intelligence, incorporeal, without beginning, end, or change; and diſtinguiſhed it by the appellation of τo αγαθον, *the Good*. Matter, as ſubſiſting from eternity, he conſidered as without any one *form* or *quality* whatever, and as having a natural tendency to diſorder. Of this chaotic maſs God formed a perfect world, after the eternal pattern in his own mind, and endowed it with a ſoul or emanation from himſelf. In the language of Plato, therefore, the univerſe being animated by a ſoul which proceeds from God, is called the *ſon of God*; and ſeveral parts of nature, particularly the heavenly bodies, are *gods*. The human ſoul, according to him, is derived by emanation from God, through the intervention of this ſoul of the world; and receding farther from the firſt intelligence, it is inferior in perfection to the ſoul of the world, though even that ſoul is debaſed by ſome material admixture. To account more fully for the origin and preſent ſtate of human ſouls, Plato ſuppoſes *, that "when God formed the univerſe, he ſeparated from the ſoul of the world inferior ſouls, equal in number to the ſtars, and aſſigned to each its proper celeſtial abode; but that thoſe ſouls, (by what means, or for what reaſon, does not appear), were ſent down to the earth into human bodies, as into ſepulchres or priſons." He aſcribes to this cauſe the depravity and miſery to which human nature is liable; and maintains, that it "is only by diſengaging itſelf from all animal paſſions, and riſing above ſenſible objects, to the contemplation of the world of intelligence, that the ſoul of man can be prepared to return to its original ſtate." Not inconſiſtently with this doctrine, our philoſopher frequently ſpeaks of the ſoul of man as conſiſting of three parts: or rather he ſeems to have thought that man has three ſouls; the firſt the principle of intelligence, the ſecond of paſſion, and the third of appetite (M); and to each he aſſigns its proper place in the human body. But it was only the intellectual ſoul that he conſidered as immortal.

Ariſtotle

* En[...] Abri[...] of Bru[...] Hiſtor[...] Phil[...]

(M) "Plato tripliceem finxit animam; cujus principatum, id eſt, rationem, in capite, ſicut in arce, poſuit: et duas partes ſeparare voluit, iram et cupiditatem, quas locis diſcluſit; iram in pectore, cupiditatem ſubter precordia locavit." *Ciceronis Tuſc. Quæſt.* lib. i. cap. 10.

This hypotheſis has been adopted by the learned author of Ancient Metaphyſics: but it cannot be proved by argument, and is in direct oppoſition to conſciouſneſs. Were there three diſtinct minds in each man—the principles of intelligence, of paſſion, and of appetite, it is obvious that *each man* would be *three perſons*, and that *none* of theſe perſons could know any thing of the powers and properties of the *other two*. The intelligent perſon could not reaſon about *paſſion* or *appetite*; nor could the perſons who know nothing but paſſion and appetite reaſon about *intelligence*, or indeed about any thing elſe. The very queſtion at iſſue, therefore, furniſhes the moſt complete proof poſſible, that the ſame individual which each man calls himſelf, is the principle of intelligence, of paſſion, and of appetite: for if the Platonic hypotheſis were true, that queſtion could never have been ſtarted, as no one individual of the human race could have underſtood all its terms. It may be juſt worth while to mention, that the author of Ancient Metaphyſics, attributing all motion, Aristotle taught, in terms equally express, that the human soul is a part of God, and of course that its substance is of eternal and necessary existence. Some of his followers, indeed, although they acknowledged *two first principles*, the active and the passive, yet held, with the Stoics, but *one substance* in the universe; and to reconcile these two contradictory propositions, they were obliged to suppose matter to be both active and passive. Their doctrine on this subject is thus delivered by Cicero: "De natura ita dicebant, ut eam dividerent in res duas, ut altera esset efficiens, altera autem quasi huic se præbens, ea quæ efficeretur aliquid. In eo, quod efficeret, vim esse censebant; in eo autem quod efficeretur, materiam quandam; IN UTROQUE TAMEN UTRUMQUE. Neque enim materiam ipsam cohærere potuisse, si nulla vi contineretur, neque VIM SINE ALIQUA MATERIA; nihil est enim, quod non alicubi esse cogatur†." *They divided nature into two things, as the first principles; one whereof is the efficient or artificer, the other that which offers itself to him for things to be made out of it. In the efficient principle, they acknowledged active force; in the passive, a certain matter; but so, that in* EACH BOTH OF THESE WERE TOGETHER: *forasmuch as neither the matter could cohere together unless it were contained by some active force, nor* THE ACTIVE FORCE SUBSIST OF ITSELF WITHOUT MATTER; *because that is nothing which may not be compelled to be somewhere.* Agreeably to this strange doctrine, Arrian, the interpreter of Epictetus, says of himself, ειμι ανθρωπος, μερος των παντων, ὡς ωρα ἡμερας, "I am a man (a part of the το παν or *universe*), as an hour is part of the day.

Aristotle himself is generally supposed to have believed in the eternal existence of two substances, *mind* and *matter*; but treating of the generation of animals, he says, ενδε το παντι θερμοτης ψυχικη, ὡς τροπον τινα παντα ψυχης ειναι πληρη διο συνισταται ταχεως ὁποταν εμπεριληφθη*, *In the universe there is a certain animal heat, so as that after a manner all things are full of mind; wherefore they are quickly completed (or made complete animals) when they have received a portion of that heat.* This *heat*, from which, according to Cicero‡, the Stagyrite derived all souls, has, it must be confessed, a very material appearance; insomuch that the learned Mosheim seems to have been doubtful whether he admitted of any immaterial principle in man; but for this doubt there appears to us to be no solid foundation. Aristotle expressly declares, that *this heat is not fire* nor any *such power, but a spirit which is in the seeds* or *elementary principles of bodies*; τουτο δε ου πυρ, ουδε τοιαυτη δυναμις εστιν, αλλα το εμπεριλαμβανομενον εν τω σπερματι και εν τω αφρωδει πνευμα*. And as the excellent person himself acknowledes (N), that Aristotle taught the existence of two principles, God and matter, not indeed subsisting separately, but eternally linked together by the closest union; we think it follows undeniably, that this heat, from which he derived all souls, must be that mind which he called *God*, and which he considered as the actuating soul of the universe. Of the Immortality of the Soul.

Upon these principles neither Aristotle nor the Stoics could believe with Plato, that in the order of nature there was first an emanation from the supreme mind to animate the universe, and then through this universal soul other emanations to animate mankind. The Stagyrite believed, that the Supreme Mind himself is the soul of the world, and that human souls are immediately derived from him. The genuine Stoics, acknowledging but one substance, of necessity considered both the souls and bodies of men as portions of that substance, which they called το εν; though still they affected to make some unintelligible distinction between body and mind. But however the various schools differed as to those points, they were unanimous as to the soul's being a part of the self-existing Substance; and Cicero gives their whole system from Pacuvianus in words which cannot be misunderstood:

Quicquid est hoc, omnia animat, format, alit, auget, creat,
Sepelit, recipitque in sese omnia, omniumque idem est Pater:
Indidemque eadem, quæ oriuntur de integro, atque eodem occidunt.

267 To these verses he immediately subjoins the following query: "Quid est igitur, cur, cum domus sit omnium una, eaque communis, cumque *animi hominum* SEMPER FUERINT, FUTURIQUE SINT, cur ii, quid ex quoque eveniat, et quid quamque rem significet, perspicere non possint||?" And upon the same principle he elsewhere argues, not merely for the immortality, but for the *eternity* and *necessary existence* of the soul: "Animorum nulla in terris origo invenire potest: His enim in naturis nihil inest, quod vim memoriæ mentis, cogitationis habeat; quod et præterita teneat, et futura provideat, et complecti possit præsentia; quæ sola divina sunt. Nec invenietur unquam, unde ad hominem venire possint, nisi a Deo. Ita quicquid est illud, quod sentit, quod sapit, quod vult, quod viget, cæleste et divinum est: OB EAMQUE REM ÆTERNUM SIT NECESSE EST*." This was indeed securing the future permanency of the soul in the most effectual manner; for it is obvious, that what had not a beginning can never have an end, but must be of eternal and necessary existence. Upon these principles they maintained the necessary existence of the soul;

|| *De Divinatione*, lib. i. cap. 57.

* *Frag. de Consolatione.*

268 But when the ancients attribute a proper eternity to the soul, we must not suppose that they understood it to be eternal in its *distinct* and *personal existence*. They believed that it proceeded or was *discerpted* in *time* from the But not in its distinct and personal capacity.

tion, and even the coherence of the minute particles of body, to the immediate agency of mind, of course furnishes every human body with at least *four minds*. This fourth mind differs not from the *plastic nature* of Cudworth, and is likewise a Platonic notion apparently better founded. That there are in our bodies motions perpetually carried on by the agency of something which is not the principle of either our intelligence, our passions, or our appetites, is a fact which cannot be denied; but if those motions proceed immediately from mind, it must be either from the *supreme* mind, or from some *subordinate* mind, acting under the supreme, but wholly *distinct from and independent* of that which each man calls himself.

(N) "Non cum illis componi prorsus potest ARISTOTELES, qui bina rerum separataque statuunt principia, Deum et materiam. Arctissime enim utrumque hoc initium conjunxit Stagyrita, atque ipsa naturæ necessitate Deum cohærere cum mole hac corporea putavit." *Cudworth's Intellectual System*, Book I. Chap iv. Sect. 6. Note 3.

Of the Immortality of the Soul.

the substance of God, and would *in time* be again *resolved* into that substance. This they explained by a closed vessel filled with sea-water; which swimming a while upon the ocean, does, on the vessel's breaking, flow in again, and mingle with the common mass. They only differed about the time of this reunion; the greater part holding it to be at death; but the Pythagoreans not till after many transmigrations. The Platonists went between these two opinions; and rejoined pure and unpolluted souls immediately to the Universal Spirit; but those which had contracted much defilement, were sent into a succession of other bodies, to be purged and purified, before they returned to their parent substance.‡"

‡ *Warburton's Divine Legation.*

269 A similar doctrine held by the Bramins.

A doctrine similar to this of Plato has been held from time immemorial by the Bramins in India, whose sacred books teach, "That intellect is a PORTION of the GREAT SOUL of the universe, breathed into all creatures, to animate them for a certain time; that after death it animates other bodies, or returns like a *drop* into that *unbounded ocean* from which it first arose; that the souls of men are distinguished from those of other animals, by being endowed with reason and with a consciousness of right and wrong; and that the soul of him who adheres to right as far as his powers extend, is at death ABSORBED INTO THAT DIVINE ESSENCE, never more to reanimate flesh. On the other hand, the souls of those who do evil, are not at death disengaged from all the elements; but are immediately cloathed with a body of fire, air, and *akash* (a kind of celestial element, through which the planets move, and which makes no resistance) in which they are for a time punished in hell. After the season of their grief is over, they reanimate other bodies; and when they arrive through these transmigrations at a state of purity, they are absorbed into God, where all PASSIONS are UTTERLY UNKNOWN, and where CONSCIOUSNESS IS LOST IN BLISS‡."

‡ See *Preliminary Dissertation to Dow's History of Indostan.*

270 This doctrine incompatible with a future state of rewards and punishments, and

Whether the Greeks derived their notions of the divinity and transmigration of souls from the east, or whether both they and the Bramins brought the same doctrines at different periods from Egypt, it is foreign from the purpose of this article to inquire. Certain it is, that the philosopher's of Greece and India argued in the very same manner, and upon the very same principles, for the *natural* immortality of the soul; and that the immortality which they taught was wholly incompatible with God's moral government of the world, and with a future state of rewards and punishments. That this is true of the doctrine of the Bramins, is evident from the last quoted sentence: for if the soul, when absorbed into the Divine essence, loses all consciousness of what it did and suffered in the body, it cannot possibly be rewarded for its virtues practised upon earth. That the philosophers of Greece taught the same cessation of consciousness, might be inferred with the utmost certainty, even though we had not Aristotle's express declaration to that purpose: For as they all believed their souls to have existed before they were infused into their bodies, and as each must have been conscious that he remembered nothing of his former state (o), it was impossible to avoid concluding, that in the future state of his soul as little would be remembered of the present. Accordingly Aristotle teaches, that "the agent intellect only is immortal and eternal, but the passive corruptible",—τουτο μονον αθανατον και αιδιον ὁ δε παθητικος νους φθαρτος.* Cudworth thinks this a very doubtful and obscure passage; but Warburton, whose natural acuteness often discovered the sense of ancient authors when it had escaped the sagacity of abler scholars, has completely proved, that by the *agent intellect* is meant the *substance* of the soul, and by the *passive* its *particular perceptions*. It appears therefore that the Stagyrite, from the common principle of the soul's being a part of the Divine substance, draws a conclusion against a future state of rewards and punishments; which though all the philosophers (except Socrates) embraced, yet all were not so forward to avow.

* De anima, lib. 3. cap.

271 Gross absurdity itself;

That the hypothesis of the soul's being a part of the Divine substance is a gross absurdity, we surely need not spend time in proving. The argument long ago urged against it by St Austin must ere now have occurred to every reader. In the days of that learned father of the church, it was not wholly given up by the philosophers; and in his excellent work of the *City of God*, he thus exposes its *extravagance* and impiety: "Quid infelicius credi potest, quam Dei partem vapulare, cum puer vapulat? Jam vero *partes Dei* fieri *lascivas*, *iniquas*, *impias*, atque omnino *damnabiles*, quis ferre potest nisi qui prorsus insanit?"

272 Yet ... from which ...

But though this hypothesis be in the highest degree absurd and wholly untenible, we apprehend it to be the only principle from which the *natural* or *essential* immortality of the soul can possibly be inferred. If the soul had a *beginning*, it *may* have an *end*; for nothing can be more evident than that the being which had not existence of itself cannot of itself have perpetuity of existence. Human works, indeed, continue in being after the power of the workman is withdrawn from them; but between human works and the Divine there is this immense difference, that the former receive from the artist nothing but their form; whereas the latter receive from the Creator both their form and their substance. Forms are nothing but modifications of substance; and as substances depend upon God and not upon man, human works are continued in being by that fiat of the Creator, which made the substances of which they are composed susceptible of different forms, and of such a nature as to retain for a time whatever form may be impressed upon them. Human works therefore are continued in being by a power different from that by which they are finished; but the works of God depend wholly upon that power by which they were originally brought into existence; and were the Creator to withdraw his supporting energy, the whole creation would sink into nothing.

(o) This is expressly acknowledged by Cicero, though he held with his Greek masters the eternity of the soul. In answer to some very foolish assertions concerning the evil of death, he says, "Ita, qui nondum nati sunt, miseri jam sunt, quia non sunt: et nos ipsi, si post mortem miseri futuri sumus, miseri fuimus antequam nati. Ego autem *non commemini, antequam sum natus, me miserum. Tuscul.* lib. 1. cap. 6.

Self-evident as this truth certainly is, ſome eminent philoſophers *ſeem* to have queſtioned it. "No ſubſtance or being (ſays Mr Baxter *) can have a natural tendency to annihilation, or to become nothing. That a being which once exiſts ſhould ceaſe to exiſt is a real effect, and muſt be produced by a real cauſe: But this cauſe could not be planted in the nature of any ſubſtance or *being* to become a tendency of its nature; *for it could not be a free cauſe*, otherwiſe it muſt be a *being* itſelf, the ſubject of the *attribute freedom*, and therefore not the property of another *being*; *nor a neceſſary cauſe*, for ſuch a cauſe is only the effect of ſomething impoſing that neceſſity, and ſo no cauſe at all."

That the author's meaning in this argument is good, cannot, we think, be controverted; but he has not expreſſed himſelf with his uſual accuracy. He ſeems to confound *cauſes* with the *abſence* of cauſes, and the *effects* of the *former* with the *conſequences* of the *latter*. The viſible world was brought into exiſtence by the actual energy of the power of God; and as the viſible world had nothing of itſelf, it can *remain* in exiſtence only by a *continuance* of the *ſame energy*. This energy therefore is at the preſent moment as *real a cauſe* as it was ſix thouſand years ago, or at any paſt period when it may have been firſt exerted; and the viſible world is its *real and permanent effect*. But would the ceaſing of this energy be likewiſe a *cauſe?* It would certainly be followed with the annihilation of the viſible world, juſt as the withdrawing of the ſun-beams would be followed with darkneſs on the earth. Yet as no one has ever ſuppoſed that darkneſs, a non-entity, is a *poſitive effect* of the ſun or of his beams, but only a mere negative conſequence of their abſence; ſo, we think, no one who believes in creation can conſider that deſtruction which would inevitably follow the withdrawing of the energy by which all things are ſupplied, as the *poſitive effect* of a contrary energy, or as any thing more than a *negative conſequence* of the ceaſing of that volition or energy of power by which God at firſt brought things into exiſtence. For "where the *foundation* of exiſtence lies *wholly* in the power of an infinite Being *producing*, the *ground* of the *continuance* of that exiſtence muſt be wholly in the ſame power *conſerving*; which has, therefore, with as much truth as frequency, been ſtyled a continued creation (P)."

The force of this reaſoning Mr Baxter certainly ſaw when he ſaid, that "a tendency to perſevere in the ſame ſtate of nature, and a tendency to change it, are contradictories, and impoſſible to be planted in the ſame ſubject at once: or, not to urge the contradiction, if the laſt prevailed, the remaining in the ſame ſtate for any given time would be impoſſible. We forget the true cauſe of all theſe tendencies, *the will of God*, which it is abſurd to ſuppoſe contrary to itſelf. The tendency in matter to perſevere in the ſame ſtate of reſt or motion, is nothing but *the will of the Creator*, who preſerves all things in their exiſtence and manner of exiſtence: nor can we have recourſe to any other cauſe for the preſervation of immaterial ſubſtance in its exiſtence. Therefore theſe tendencies are to be aſcribed to the will of God, and it is abſurd to ſuppoſe them contrary."

Immortality of the Soul.

276 Analogical evidence of the immortality of the ſoul, and a moral proof of a future ſtate of rewards and puniſhments.

All this is unqueſtionably true. The exiſtence or non-exiſtence of matter and of created ſpirits depends wholly upon the will of God; and we cannot ſuppoſe him to be willing to-day the reverſe of what he willed yeſterday, becauſe we know that all his volitions are directed by unerring wiſdom. We have likewiſe the evidence of experience, that nothing is ever ſuffered to periſh but particular ſyſtems, which periſh only *as ſyſtems* by a decompoſition of their parts. A being, which like the ſoul has no parts, can ſuffer no decompoſition; and therefore, if it periſh, it muſt periſh by annihilation. But of annihilation there has not hitherto been a ſingle inſtance; nor can we look for a ſingle inſtance without ſuppoſing the volitions of God to partake of that unſteadineſs which is characteriſtic of man. Corporeal ſyſtems, when they have ſerved their purpoſe, are indeed reſolved into their component parts; but the matter of which they were compoſed, ſo far from being *loſt*, becomes the matter of *other ſyſtems* in endleſs ſucceſſion. Analogy, therefore, leads us to conclude, that when the human body is diſſolved, the immaterial principle by which it was animated continues to think and act, either in a ſtate of ſeparation from all body, or in ſome material vehicle to which it is intimately united, and which goes off with it at death; or elſe that it is preſerved by the Father of ſpirits, for the purpoſe of animating a body in ſome future ſtate. When we conſider the different ſtates through which that living and thinking *individual*, which each man calls himſelf, goes, from the moment that it firſt animates an embryo in the womb, to the diſſolution of the man of fourſcore; and when we reflect likewiſe on the wiſdom and *immutability* of God, together with the various diſſolutions of corporeal ſyſtems, in which we know that a ſingle atom of matter has never been loſt; the preſumption is certainly ſtrong, that the ſoul ſhall ſubſiſt after the diſſolution of the body. But when we take into the conſideration the *moral* attributes of God—his juſtice and goodneſs, together with the unequal diſtribution of happineſs and miſery in the preſent world; this preſumption from analogy amounts to a *complete moral proof* that there ſhall be a future ſtate of rewards and puniſhments (Q). (See Moral *Philoſophy* and Religion); and if we eſtimate the duration of the rewards by the benevolence of Him by whom they are to be conferred, we cannot imagine them ſhorter than eternity.

(P) See Stillingfleet's *Origines Sacræ*, where this queſtion is treated in a very maſterly manner by one of the ableſt metaphyſicians of the laſt century. See alſo our article Providence.

(Q) It was by ſuch arguments that Socrates reaſoned himſelf into the belief of a future ſtate of rewards and puniſhments. He was ſingular, as we have already obſerved, in this belief; and he was as ſingular in confining himſelf to the ſtudy of morality. "What could be the cauſe of this belief, but this reſtraint, of which his belief was a natural conſequence? For having confined himſelf to morals, he had nothing to miſlead him; whereas the reſt of the philoſophers, applying themſelves with a kind of fanaticiſm to *phyſics* and *metaphyſics*, had drawn a number of abſurd, though ſubtle, concluſions, which directly oppoſed the conſequences of thoſe moral arguments." *Warburton's Div. Leg.* vol. ii.

Of Necessity and Liberty.

Chap. V. *Of* Necessity *and* Liberty.

277
Freedom of agency implied in accountableness.

In the preceding chapter we have adverted to that great *moral proof* for a future state, and the immortality of the soul, arising from the relation in which man, as a being accountable for his conduct, stands to a God of almighty power, infinite wisdom, and perfect justice. But the circumstance of accountableness implies freedom of agency; for it is contrary to all our notions of right and wrong (see Moral *Philosophy*), that a man should be either rewarded or punished for actions which he was necessitated or compelled to perform.

278
Every man has power to do what he wills:

Human actions are of three kinds: one, where we act by instinct, without any view to consequences; one, where we act by will, in order to obtain some end; and one, where we act against will. It is the second kind of actions only which confers upon the agent merit or demerit. With respect to the first, he acts blindly (see Instinct), without deliberation or choice; and the external act follows from the instinctive impulse, no less necessarily than a stone by its gravity falls to the ground. With respect to the last, he is rather an instrument than an agent; and it is universally allowed, that were a strong man to put a sword into the hand of one who is weaker, and then to force it through the body of a third person, he who held the sword would be as guiltless of the murder as the sword itself. To be intitled to rewards, or liable to punishment, a man must act voluntarily; or in other words, his actions must proceed from that energy of mind which is termed *volition*: and, we believe, it has never been denied, that all men have power to do whatsoever they *will*, both with respect to the operations of their minds and the motions of their bodies, uncontrolled by any foreign principle or cause. "Every man (says Priestley) is at liberty to turn his thoughts to whatever subject he pleases, to consider the reasons for or against any scheme or proposition, and to reflect upon them as long as he shall think proper; as well as to walk wherever he pleases, and to do whatever his hands and other limbs are capable of doing." Without such liberty as this, morality is inconceivable.

279
But different opinions entertained of the freedom of volition.

But though philosophers have in general agreed with respect to the power which a man has to perform such actions as he wills, they have differed widely in opinion respecting the nature of his volitions. That these are the result of motives, has seldom if ever been questioned; but whether that result be necessary, so as that the agent has no self-determining power to decide between different motives, has been warmly disputed by men equally candid, impartial, and intelligent. The principal writers on the side of necessity are, Hobbes, Collins, Hume, Leibnitz, Lord Kames, Hartley, Edwards, Priestley, and perhaps Locke. On the other side are, Clarke, King, Law, Reid, Butler, Price, Bryant, Wollaston, Horsley, Beattie, and Gregory, &c. To give a short view of this celebrated question, is all that our limits will permit; and as we do not think ourselves competent to settle the dispute, it were perhaps a thing desirable to give the opposite reasonings in the words of those eminent authors themseves. It must, however, be obvious to the reader, that the style and manner of so many different writers are extremely various, and that to introduce them all into our abstract, would make the whole a mass of confusion. We shall, therefore, select one writer to plead the cause of necessity, supplying his defects from those who, though inferior to him on the whole, may yet have argued more ably on some particular points which the question involves: and to this combined reasoning we shall subjoin such answers as to us appear most conclusive. Hartley, Hume, and Priestley, are perhaps the most profound reasoners on the side of necessity; but there is so much more perspicuity in the arguments of Lord Kames, that we cannot help preferring them, as being on the whole better calculated to give the ordinary reader a fair view of the subject.

28[0]
Scheme of necessity according to L. Kames.

"Into actions done with a view to an end (says his Lordship §), desire and will enter: desire to accomplish the end goes first; the will to act, in order to accomplish the end, is next; and the external act follows of course. It is the will then, that governs every external act done as a mean to accomplish an end; and it is desire to accomplish the end that puts the will in motion; desire, in this view, being commonly termed the *motive* to act. But what is it that raises desire? The answer is ready: It is the prospect of attaining some agreeable end, or of evading one that is disagreeable. And if it be inquired, what makes an object agreeable or disagreeable? the answer is equally ready: It is our nature that makes it so. Certain visible objects are agreeable, certain sounds, and certain smells: other objects of these senses are disagreeable. But there we must stop; for we are far from being so intimately acquainted with our own nature as to assign the causes.

§ Hist. of the Hist. of Man, Book Sketch part I sect. S

"With respect to instinctive actions, no person, I presume, thinks that there is any freedom. With respect to voluntary actions, done in order to produce some effect, the necessity is the same, though less apparent at first view. The external action is determined by the will; the will is determined by desire; and desire by what is agreeable or disagreeable. Here is a chain of causes and effects, not one link of which is arbitrary, or under command of the agent: he cannot will but according to his desire; he cannot desire, but according to what is agreeable or disagreeable in the objects perceived: nor do these qualities depend on his inclination or fancy; he has no power to make a beautiful woman ugly, nor to make a rotten carcase smell sweetly.

"Many good men, apprehending danger to morality from holding our actions to be necessary, endeavour to break the chain of causes and effects above mentioned; maintaining, that whatever influence desire or motives may have, it is the agent himself who is the cause of every action; that desire may advise, but cannot command; and, therefore, that a man is still free to act in contradiction to desire and to the strongest motives.

"That a being may exist which in every case acts blindly and arbitrarily, without having any end in view, I can make a shift to conceive: but it is difficult for me even to imagine a thinking and rational being, that has affections and passions, that has a desirable end in view, that can easily accomplish this end; and yet after all can fly off or remain at rest, without any cause, reason, or motive, to sway it. If such a

Of Ne-
cessity and
Liberty.

whimſical being can poſſibly exiſt, I am certain that man is not that being. There is not perhaps a perſon above the condition of a changeling, but can ſay *why* he did ſo and ſo, what moved him, what he intended. Nor is a ſingle fact ſtated to make us believe that ever a man acted againſt his own will or deſire, who was not compelled by external force.—On the contrary, conſtant and univerſal experience proves, that human actions are governed by certain inflexible laws; and that a man cannot exert his ſelf-motive power but in purſuance of ſome deſire or motive.

"Had a motive always the ſame influence, actions proceeding from it would appear no leſs neceſſary than the actions of matter. The various degrees of influence that motives have on different men at the ſame time, and on the ſame man at different times, occaſion a doubt, by ſuggeſting a notion of chance. Some motives, however, have ſuch influence as to leave no doubt: a timid female has a phyſical power to throw herſelf into the mouth of a lion roaring for food; but ſhe is with-held by terror no leſs effectually than by cords: if ſhe ſhould ruſh upon a lion, would not every one conclude that ſhe was frantic? A man, though in a deep ſleep, retains a phyſical power to act, but he cannot exert it. A man, though deſperately in love, retains a phyſical power to refuſe the hand of his miſtreſs; but he cannot exert that power in contradiction to his own ardent deſire, more than if he were faſt aſleep. Now, if a ſtrong motive have a neceſſary influence, there is no reaſon for doubting, but that a weak motive muſt alſo have its influence, the ſame in kind, though not in degree. Some actions indeed are ſtrangely irregular; but let the wildeſt actions be ſcrutiniſed, there will always be diſcovered ſome motive or deſire, which, however whimſical or capricious, was what influenced the perſon to act. Of two contending motives, is it not natural to expect that the ſtronger will prevail, however little its exceſs may be? If there be any doubt, it muſt ariſe from a ſuppoſition, that a weak motive may be reſiſted arbitrarily. Where then are we to fix the boundary between a weak and a ſtrong motive? If a weak motive can be reſiſted, why not one a little ſtronger, and why not the ſtrongeſt? Between two motives oppoſing each other, however nearly balanced, a man has not an arbitrary choice, but muſt yield to the ſtronger. The mind, indeed, fluctuates for ſome time, and finds itſelf in a meaſure looſe: at laſt, however, it is determined by the more powerful motive, as a balance is by the greater weight after many vibrations.

"Such, then, are the laws that govern our voluntary actions. A man is abſolutely free to act according to his own will; greater freedom than which is not conceivable. At the ſame time, as man is made accountable for his conduct to his Maker, to his fellow-creatures, and to himſelf, he is not left to act arbitrarily; for at that rate he would be altogether unaccountable: his will is regulated by deſire; and deſire by what pleaſes or diſpleaſes him.—Thus, with regard to human conduct, there is a chain of laws eſtabliſhed by nature; no one link of which is left arbitrary. By that wiſe ſyſtem, man is made accountable; by it he is made a fit ſubject for divine and human government; by it perſons of ſagacity foreſee the conduct of others; and by it the preſcience of the Deity with reſpect to human actions is clearly eſtabliſhed."

Of Ne-
ceſſity and
Liberty.

Of the doctrine of neceſſity, a more perſpicuous or plauſible view than this is not to be found in any work with which we are acquainted. It is indeed defective perhaps, as his Lordſhip only *hints* at the *nature* of that relation which ſubſiſts between motive and action; but from his comparing the fluctuations of the mind between two contending motives, to the vibrations of a balance with different weights in the oppoſite ſcales, there is no room to doubt but that he agreed exactly in opinion with Mr Hume and Dr Prieſtley. Now both theſe writers hold, that the relation of motives to volition and action, is the very ſame with that which ſubſiſts between cauſe and effect in phyſics, as far as they are both known to us. 281
Mr Hume,
and
"It is univerſally allowed (ſays Mr Hume †), that matter, in all its operations, is actuated by a neceſſary force; and that every natural effect is ſo preciſely determined by the energy of its cauſe, that no other effect, in ſuch particular circumſtances, could poſſibly have reſulted from it. The degree and direction of every motion is, by the laws of nature, preſcribed with ſuch exactneſs, that a living creature may as ſoon ariſe from the ſhock of two bodies, as motion in any other degree or direction than what is actually produced by it. Would we, therefore, form a juſt and preciſe idea of *neceſſity*, we muſt conſider whence that idea ariſes, when we apply it to the operation of bodies. But our idea of this kind of neceſſity and cauſation ariſes entirely from the uniformity obſervable in the operations of nature, where ſimilar objects are conſtantly conjoined together, and the mind is determined by cuſtom to infer the one from the appearance of the other. Theſe two circumſtances form the whole of that neceſſity which we aſcribe to matter. Beyond the *conſtant conjunction* of ſimilar objects, and the conſequent *inference* from one to the other, we have no notion of any neceſſity or connection." He then gives a pretty long detail to prove a great uniformity among the actions of men in all nations and ages; and concludes that part of his argument with affirming, "not only that the conjunction between motives and voluntary actions is as regular and uniform as that between the cauſe and effect in any part of nature; but alſo, that this regular conjunction has been univerſally acknowledged among mankind, and has never been the ſubject of diſpute either in philoſophy or common life." He afterwards obſerves, "that men begin at the wrong end of this queſtion concerning liberty and neceſſity, when they enter upon it by examining the faculties of the ſoul, the influence of the underſtanding, and the operations of the will. Let them firſt diſcuſs a more ſimple queſtion, namely, the operations of body, and of brute unintelligent matter; and try whether they can there form any idea of cauſation and neceſſity, except that of a conſtant conjunction of objects and ſubſequent inference of the mind from one to another. If theſe circumſtances form in reality the whole of that neceſſity which we conceive in matter, and if theſe circumſtances be alſo univerſally acknowledged to take place in the operations of the mind, the diſpute is at an end; at leaſt muſt

† *Inquiry concerning Human Underſtanding*, ſect. 8.

Of Necessity and Liberty.

must be owned to be thenceforth merely verbal. When we consider how aptly *natural* and *moral* evidence link together, and form only one chain of argument, we shall make no scruple to allow that they are of the same nature, and derived from the same principles.—Between a connected chain of natural causes and voluntary actions, the mind feels no difference in passing from one link to another; nor is less certain of a future event which depends upon motives and volitions, than if it were connected with the objects present to the memory and senses by a train of causes, cemented together by what we are pleased to call a *physical* necessity. The same experienced union has the same effect on the mind, whether the united objects be motives, volition and action, or figure and motion. We may change the names of things, but their nature and their operation on the understanding never change."

282 Dr Priestley

Dr Priestley, in words a little different, teaches the very same doctrine which was taught by Mr Hume.—"In every determination of the mind (says he *), or in cases where volition and choice are concerned, all the previous circumstances to be considered are the *state of mind* (including *every thing belonging to the will itself*), and the *views of things* presented to it; the latter of which is generally called the *motive*, though under this term some writers comprehend them both. To distinguish the *manner* in which events depending upon *will* and *choice* are produced, from those in which no volition is concerned, the former are said to be produced *voluntarily*, and the latter *mechanically*. But the same general maxims apply to them both. We may not be able to determine *à priori* how a man will act in any particular case; but it is because we are not particularly acquainted with his *disposition of mind*, *precise situation*, and *views of things*. But neither can we tell in which way the wind will blow to-morrow, though the *air* is certainly subject to no other than necessary laws of motion.

* *The Doctrine of philosophical Necessity illustrated.*

"It is universally acknowledged, that there can be no effect without an adequate cause. This is even the foundation on which the only proper argument for the being of a God rests. And the necessarian asserts, that if, in any given state of mind, with respect both to *disposition* and *motives*, two different determinations or volitions be possible, it can be so on no other principle, than that one of them shall come under the description of an *effect without a cause*; just as if the beam of a balance might incline either way, though loaded with equal weights. It is acknowledged, that the mechanism of the balance is of one kind, and that of the mind of another; and, therefore, it may be convenient to denominate them by different words; as, for instance, that of the balance may be termed a *physical*, and that of the mind a *moral* mechanism. But still, if there be a *real mechanism* in both cases, so that there can be only one result from the same previous circumstances, there will be a *real necessity*, enforcing an absolute certainty in the event. For it must be understood, that all that is ever meant by *necessity in a cause*, is that which produces *certainty in the effect*."

Such is the nature of human volitions, according to every necessarian of eminence who has written on the subject since the days of Hobbes: and if this theory be just, if there be a constant and inseparable conjunction of motives and actions similar to that of cause and effect in physics, it is obvious, that in volition the mind is as inert as body is in motion.

283 View of human liberty.

This consequence is indeed avowed and insisted upon by Hume, Priestley, and their adherents; whilst the advocates for human liberty, on the other hand, contend for an absolute exemption of the will from all internal *necessity*, arising from its own frame and constitution, the impulse of superior beings, or the operations of objects, reasons, or motives, &c. By this they do not mean, that between motives and volitions there is no relation whatever, or that a man can ever choose evil as evil, or refuse good as good. Such an assertion would be contrary to consciousness and universal experience. But what they endeavour to prove is, that the conjunction of motive and volition is not inseparable, like that of cause and effect in physics; that a man may in most cases choose according to any one of two or more motives presented to his view; that by choosing any thing, he may make it in some measure agreeable by his own act, or, to speak more properly, may bend his desire to it; that in volition, the mind is not inert; and that, therefore, we are under no *necessity* to act in a particular manner in any given case whatever.

That the conjunction of motive and action is not constant like that of cause and effect in physics, and that by consequence the mind in forming volitions is not inert, has been evinced by Dr Gregory with the force and precision of mathematical demonstration.—Former writers on the side of liberty had often observed, that upon the supposition of the *inertia* of mind, a man, with equal and opposite motives presented at once to his view, would, during their continuance, remain perfectly at rest, like a balance equally loaded in both scales. The observation is admitted to be just by all the advocates for necessity; but they contrive to evade its consequences, by denying that in any given case a man can be at once assailed by two equal and opposite motives. Thus, when it is said that a porter, standing with his face due north, must remain in that position at perfect rest, as long as equal motives shall at once be offered to him for travelling eastward and westward, the necessarians admit the force of the argument; but when it is added that a guinea, offered for every mile that he should travel in each of these opposite directions, ought therefore to fix him at rest till one of the offers be withdrawn, they deny that the desire of gaining the guineas is the *whole* of the motives which operate upon his mind. He may have, say they, some secret reason which we cannot discern for preferring the one direction to the other; and that reason, added to the guinea, will make him go eastward or westward, just as an ounce thrown into either scale of a balance poised by equal weights will make that scale preponderate. Though we think that this solution of the difficulty can satisfy no man who is not already biassed to the necessarian system; and though, even were it to be admitted, it seems to militate against the constant conjunction of motives and actions, unless it can be proved that the porter must travel the road which he has been necessitated to choose with reluctance and a heavy heart; yet as it may admit of endless quibbling upon ambiguous words,

words, the philofophical world is much indebted to Dr Gregory ‡ for an argument which, in our opinion, can neither be overturned nor evaded, and which demonftrates that the conjunction of motive and action cannot be conftant and infeparable, like that of caufe and effect in phyfics.

His reafoning is to this purpofe: Suppofe a porter to be offered a guinea for every mile that he fhall travel directly eaftward. If there be no phyfical caufe or moral motive to keep him at reft, or to induce him to move in another direction, there cannot be a doubt, upon either hypothefis, but he will gladly embrace the propofal, and travel in the direction pointed out to him, till he fhall have gained as much money as to fatisfy his moft avaricious defires. The fame thing would have happened, if a guinea had been offered for every mile that he fhould travel due fouth. In thefe two cafes taken feparately, the relation between the man's motives and his actions would be ftrikingly analogous to that between a fingle impulfe and motion in phyfics. Let us now fuppofe the two offers to be made at the fame inftant, and the man to be affured that if he travel eaftward he can have no part of the reward promifed for his travelling to the fouth, and that if he travel fouthward he can have no part of the reward promifed for his travelling to the eaft. What is he to do in this cafe? If his mind be inert in volition, and if the two motives operate upon him with the fame neceffity that caufes operate in phyfics, it is obvious that the man could travel neither towards the eaft nor towards the fouth, but in a diagonal direction from north-weft to fouth-eaft; and this he muft do *willingly*, although perfectly fatisfied that he could gain nothing by his journey. As this inference is contrary to fact and univerfal experience, the Doctor very juftly concludes that the premifes, from which it is deduced by mathematical reafoning, muft be falfe and abfurd; or, in other words, that the relation between motive and action cannot be that of conftant conjunction, like the relation between caufe and effect in phyfics.

He ufes many arguments of the fame kind, and equally convincing, to prove the abfurdity of fuppofing the inertnefs of mind, and only an occafional conjunction of motives and actions; but we forbear to quote them, both becaufe we wifh his book to be read, and becaufe we think the fingle argument which we have borrowed from him fufficient to demolifh the theory of Prieftley and Hume, which refts wholly upon the hypothefis of the *conftant* conjunction of motive and action.

But is it then not really true, that the external action is determined by the will, the will by defire, and defire by what is agreeable or difagreeable? That the external action is univerfally determined by the will, is certainly true; but that the will is neceffitated and univerfally determined by the defire is as certainly falfe. If Potiphar's wife was handfome, and made her propofal to Jofeph with any degree of female addrefs; and if his conftitution was like that of other young men; there cannot be a doubt but that he felt a *defire* to do what fhe requefted of him: yet we know that he *willed* to do otherwife, and in direct oppofition to his *defire* fled from the room. Perhaps it may be faid, that his volition to flee was the effect of a contrary and ftronger *defire* not to fin againft God; but this is confounding the reader, by calling two energies of mind, between which there is little or no fimilarity, by the fame name. He perceived, or knew, that to comply with his miftrefs's requeft would be to fin againft God; he knew that he ought not to fin againft God, and therefore he chofe or determined himfelf not to do it. We can eafily conceive how the prefence, attitudes, and addrefs, of the lady might be agreeable to him, and excite defire. There may very poffibly be more than one of our readers, who, during the courfe of their lives, have experienced fomething of the fame kind: but could abftract truth be in the fame way agreeable, fo as to excite in his mind a *defire* of virtue fufficient to annihilate or banifh the *defire* of the woman? As well may it be faid that one fenfation can annihilate another, that the beautiful colours of the rainbow can remove the fenfation of ftench from the mind of him who is plunged into the midft of a dunghill, or that the fmell of a rofe can make a man infenfible to the pain of a ftroke inflicted by a bludgeon. Senfitive defire, and the perception of duty, are things fo totally different, that to confider them as operating againft each other, like different weights in the oppofite fcales of a balance, is as abfurd as to fuppofe that found can operate againft colour, or colour againft fmell. A man may prefer found to colour, or colour to fmell, and act accordingly; but the determination muft be wholly his own, unlefs thefe two fenfations be themfelves either agents or phyfical caufes of the *fame kind*, like the weights in the oppofite fcales of the balance.

Of Neceffity and Liberty.

285 Men do not always determine themfelves by the ftrongeft motive.

The advocates for liberty do not pretend, that in matters of importance a man ever acts without fome motive or reafon for his conduct. All that they infift upon is, that between two or more motives of different kinds he has a liberty of choice, and that he does not always determine himfelf by that which he knows to be the greateft. Without fuch freedom, they think men might be often brought into fituations where they could not act at all, and where inaction would at the fame time be in the higheft degree abfurd. Thus, were two bags of gold, containing each a thoufand or ten thoufand guineas, to be placed on the fame table, before a man whofe family is perifhing for want, and were the man to be told that he might take either of them, but not both, is it conceivable that he would be held in perpetual fufpence between the two? No; he would inftantly and with alacrity take up one of them, without feeling the leaft regret for the want of the other. This action would, indeed, be the confequence of a very powerful motive, the defire to obtain honeftly that wealth of which he and his family ftood fo much in need. That motive, however, being general, would draw him equally to both bags; and it remains with the neceffarians to fay by what elfe than a felf determining power he could take either the one or the other. When it is affirmed, that fuch felf determination would be an effect without a caufe, the advocates for liberty cannot help thinking that their antagonifts are guilty of advancing as an argument a *petitio principii*; for the affirmation is true, only if the mind in volition be inert, and the *inertia* of the mind is the fole queftion at iffue. If the mind be not inert, it is plain, that in confequence of a man's felf-determination, no effect would be produced without

Of Necessity and Liberty.

a sufficient cause. At any rate, motives cannot be causes. In the proper sense of the word, a cause is that which produces an effect; but the production of an effect requires active power; and power being a quality must be the quality of some being by whom it may be exerted. Power may be dormant, and therefore power without will produces no effect. Are motives, then, real beings, endowed with power and will? No; they are only views of things or mental conceptions, which in the strictest sense of the word are passive; and between two motives the mind determines itself, without receiving an impulse from either.

Nor is it only between motives of equal force that men have the power of determining themselves. Whoever believes in a future state of rewards and punishments, and yet acts in a manner which he knows to be offensive to Him who is to be the future and final judge, unquestionably prefers to the strongest of all motives, another which even to himself appears to have comparatively but very little strength. Whether there be men who occasionally act in this manner, is a question which can be decided only by an appeal to every one's consciousness. That there are, we can have no doubt; for we never met with a single individual, not biassed by system, who was not ready to acknowledge, that during the course of his life he had done many things, which at the time of action he clearly perceived to be contrary to his true interest. Without a self-determining power in the mind, this could never be the case. Did motives operate with the necessity of physical causes, it is obvious that in every possible situation the strongest must constantly prevail; and that he who in certain circumstances had in time past done any particular thing, would on a return of the same circumstances do the very same thing in every time future. Dr Priestley, indeed, wishes to persuade his readers that this is actually the case. "In every determination of the mind (says he), or in cases where volition and choice are concerned, all the previous circumstances to be considered are the *state of mind* (including *every thing belonging to the will itself*), and the various views of things presented to it;" and he affirms, that "whenever the same precise circumstances occur twice, the very same determination or choice will certainly be made the second time that was made the first." This is an assertion of which no man can controvert the truth; for it is an identical proposition. If in the circumstances previous to the determination of the mind, *every thing* belonging to the *will itself* must be included, it is self-evident that he who in any given circumstances has acted a particular part, will on a return of these circumstances act the same part a second time; for this is only saying, that he who on two different occasions shall exert volitions of the same tendency, will not on these occasions exert volitions of which the tendencies are different. But the question to be decided is, Whether a man, in the same general state of mind, possessed of the same degree of health, and conscious of the same appetites, must, in external circumstances perfectly alike, necessarily exert at all times the same volitions. That the human mind is under no such necessity, we think every man's consciousness and experience may abundantly satisfy him; for there are, perhaps, but very few who have not at one time resisted temptations, to which at another they have chosen to yield.

That there is a relation between motives and actions, must be confessed; but that relation is neither *necessity*, nor constant conjunction. If it were, all actions would be perfectly rational; and folly, as well as merit and demerit, would be banished from the conduct of men. What is the particular nature of that relation which subsists between the voluntary actions of men, and the motives from which they proceed, can be known to every individual only by an attentive and unbiassed reflection on the operations of his own mind. Without this reflection, no man can be made to understand it by the reasonings of philosophers, and with it no man can need the aid of those reasonings. That a self-determining power, such as that for which we plead, contributes to the sum of human happiness, has been shown by Archbishop King and his ingenious translator; who have proved, with the force of demonstration, that the mind can take pleasure in the object of its choice, though that object be in itself neither agreeable nor disagreeable to our natural appetites; and that if it could not, it would be vain in such a world as ours to hope for any portion of felicity. Into that detail our limits will not permit us to enter: but to the reader who wishes for further information, we beg leave to recommend the last edition of King's Origin of Evil, by Dr Law late bishop of Carlisle; without, however, vouching for the truth of all the opinions advanced by either of those learned writers.

28
If it were, folly as well as merit and demerit would be banished from the world.

Before we conclude this chapter, it may be proper to observe, that it is only in volition that we are conscious of any original active power in ourselves, and that without such consciousness we could never have acquired the *notion* of active power. In our desires and appetites, we neither are active nor suppose ourselves active. Lord Kames, and most necessarians, confound desire with volition; but that they are perfectly distinct is plain from this circumstance, that we daily *desire* many things which we know to be wholly *out* of our own power *, whereas no man ever *willed* what he did not believe to be *in* his own power. We all *desire* or wish that our children may be virtuous, wise, and happy; and though we are conscious that it is not in our power to make them so, we cannot banish the desire from our breasts. But madmen only have ever *willed* virtue, wisdom, and happiness, to any person; and if there was ever a man so extravagantly mad as to exert such a volition as this, he has at the time fancied himself a divinity, and therefore believed that the object of his volition depended upon himself. When the astronomer, whose character is so admirably drawn by our great master of moral wisdom †, fancied himself the regulator of the weather and the distributor of the seasons, he might *will* either *rain* or *sunshine* as he thought proper, because he considered the object of his volition as depending upon a power imparted to him from heaven; but though he might *desire*, he could not *will*, the rising or the falling of *winds*, for these he confessed were not subjected to his authority. In a word, without freedom in volition, power is inconceivable; and therefore it is as certain that we are free agents, as that we have any notion of active powers.

CHAP.

Chap. VI. *Of the* Being *and* Attributes *of* God.

It has been already observed, that as of bodies there are various kinds, endowed with various properties; so the probability is, that of minds endowed with different powers, or different degrees of power, the variety may be as great, or perhaps greater. The existence and powers of our own minds are made known to us by consciousness and reflection; and from our dependent state, and the mutability of the objects around us, we are necessarily led to infer the existence of another mind, which is independent, unchangeable, eternal, and the cause of all things which have a beginning of existence. Between that mind and our own, we can hardly avoid believing that there are many orders of "thrones, dominations, princedoms, virtues, powers;" but as we have no intuitive knowledge of such intermediate beings, and cannot form any thing which we perceive discern the *necessity* of their existence, they are not properly the objects of science. The existence, however, and many of the attributes of One First Cause, are capable of the strictest demonstration; "for the invisible things of Him from the creation of the world are clearly seen, being understood by the things which are made."

Of this great truth, the most important by far which can occupy the mind of man, many demonstrations have been given both by divines and by philosophers. We shall lay before our readers such a one as to us appears perfectly conclusive, being founded on the intuitive knowledge which we have of our own existence, and therefore independent of all theories about the nature and reality of the material world.

Every man, whether he adopt the common theory or that of Berkeley respecting matter, is conscious that he *himself* exists, and must therefore grant that *something now* exists. But if any thing exist *now* *, then must something have *always* existed; otherwise that thing which *now* exists, must either have been created by *nothing*, i. e. have been *caused by no cause*, or else it must have *created itself*, acting before it existed. Both these suppositions are so palpably absurd, that no atheist has avowed them, either among the ancients or the moderns. We must therefore admit, either that there is some one *independent* being, which now exists, and always has existed; or that the things which we know to exist at present (every man's *self* for instance), were produced by *something* which had its *existence* from *something else*, which also depended upon *some other cause*, and so on in an *infinite series of caused* or *successive beings*. But this last supposition, though it has been often made, is as grossly absurd as either of the two former. For of this infinite series, either *some one* part has *not* been successive to any other, or else *all* the several parts of it have been successive. If some one part of it was *not successive*, then it had a *first part*; which destroys the supposition of its infinity (R). If *all* the several parts of it have been successive, then have they all once been *future*; but if they have *all* been future, a time may be conceived when none of them had existence: and if so, then it follows, either that all the *parts*, and consequently the *whole* of this infinite series, must have arisen from *nothing*, which is absurd; or else that there must be something in the *whole* besides what is contained in *all the parts*, which is also absurd.

Of the Being and Attributes of God.

As the possibility or impossibility of an infinite series of dependent beings is the main question at issue between the atheists and us, we shall state the preceding reasoning in a manner somewhat different. For this purpose, let us suppose some one to affirm, that the course of generation has had no beginning, and consequently that the number of successive births has been infinite. We would ask such a person, Whether before the birth of Abraham, for example §, there had past an infinite series of generations or not? If not, the course of generation must have had a beginning, which is the conclusion for which we contend. But if the series past was infinite, then at the birth of Joseph the great-grandson of Abraham, it is evident, that more generations were past, and that the number then was greater than that which was supposed to be infinite; so that upon this supposition we have a number that is both infinite and not infinite, which is a manifest contradiction. Should it be said that the number of generations was infinite, as well at the birth of Abraham as at the birth of Joseph; it will then follow, that one infinite may be greater than another of the very same kind; and consequently that an infinite may be bounded, *i. e.* be finite. But should it be alleged, that the number of births at Abraham's was finite, and became infinite when it reached to Joseph's, it will then follow, that one finite number added to another may make an infinite number, which is directly contrary to every possible notion of infinity. We might argue in the same manner against an infinite series of every kind, the very supposition of which involves the most palpable contradictions. See Chap. *Of* Infinity *and* Eternity.

§ See an *Essay towards an Eviction of the Being and Attributes of God, by Seth Ward*—Printed at Oxford, 1655.

289
Whose duration is not commensurate with succession, and

From the impossibility of an infinite series it necessarily follows, that there exists, and must have existed from eternity, some one independent being, whose duration cannot be commensurate with succession, and to whom the relation of time is not applicable. Here will some atheists presently imagine, that by the same mode of reasoning they may disprove the existence of God: for do not they who thus destroy the eternity of the world, destroy at the same time the eternity of the Creator? If time itself be not eternal, how can the Deity or any thing else be so?

In urging these questions, it must be taken for granted that time is essential to all existence, and that God cannot be eternal otherwise than by a successive flux of infinite time. But it has been already shown (n° 225), that successive duration is not essential to existence; that we can even *conceive* existence without succession; and it may here be added, that if we suppose a perfect being alone in nature, we shall find it impossible to imagine any *succession of ideas*, any *flux of moments*, or any *alteration* or *increase* whatever in his knowledge and essence.

(R) Των απειρων ουκ εϛιν ουδεν πρωτον. *Arist. Phys.* lib. viii. cap. 5. sect. 4.

Of the Being and Attributes of God.

eſſence. Such duration as we are acquainted with can have no relation to an immutable Being, while ſuppoſed to exiſt alone; but as ſoon as he determined to exerciſe his ſeveral attributes in the production of ſomething diſtinct from himſelf, then, and not till then, have we reaſon to think that *time, ſucceſſion*, and *increaſe*, began. Theſe atheiſtical queſtions, therefore, inſtead of containing an objection to the exiſtence of a Deity, afford a plain demonſtration of it: for ſince it is not more evident that ſomething now exiſts than that ſomething muſt have exiſted from eternity; and ſince it has been ſhown, that neither the world in its preſent ſtate, nor time, nor any thing capable of change or ſucceſſion, can poſſibly be eternal; it follows, that there muſt neceſſarily be ſome Being who, in the order of nature, is before time, and who, in the ſtability and immutable perfection of his own intelligence, comprehends at once his *yeſterday, to-day*, and *for ever*. "The atheiſts (ſays the excellent Cudworth*) can here only ſmile, or make wry faces, and ſhow their little wit in quibbling upon *nunc-ſtans*, or a *ſtanding now of eternity*; as if that *ſtanding eternity* of the *Deity* (which with ſo much reaſon hath been contended for by the ancient *genuine theiſts*) were nothing but a *pitiful ſmall moment of time ſtanding ſtill*, and as if the duration of all beings whatſoever muſt needs be like our own: whereas the duration of every thing muſt of neceſſity be agreeable to its nature; and therefore, as that whoſe *imperfect nature* is ever *flowing* like a river, and conſiſts in *continual motion* and *changes* one after another, muſt needs have accordingly a *ſucceſſive* and *flowing duration*, ſliding perpetually from *preſent* into *paſt*, and always haſting on towards the *future*, expecting ſomething of itſelf which is not yet in being; ſo muſt that whoſe perfect nature is *eſſentially immutable* have *permanent and unchanging duration*, never loſing any thing of itſelf once preſent, nor yet running forward to meet ſomething of itſelf which is not yet in being."

* *Intellectual Syſtem*, Book i. chap. 5.

290 who is ſelf-exiſtent, and

From the eternity of the ſupreme Being we neceſſarily infer his independence or ſelf-exiſtence; for that which never had a *beginning* of exiſtence cannot poſſibly have any cauſe of that exiſtence, or in any manner depend upon any other being, but muſt exiſt of itſelf, or be *ſelf-exiſtent*.

291 cannot ceaſe to be.

Eternity *ad partem poſt*, or *neceſſary exiſtence*, or the impoſſibility of ever ceaſing to be, follows from independence: For to the nature of that which exiſts without any cauſe, exiſtence muſt be eſſential. But a being whoſe exiſtence is of itſelf and eſſential to its nature, cannot be *indifferent* to exiſtence or non-exiſtence, but muſt exiſt *neceſſarily*. And here it may be proper to obſerve, that the word *neceſſity*, when applied to exiſtence, may be taken in two acceptations very different from each other §; either as it ariſes from the relation which the exiſtence of that thing, of which it is affirmed, has to the exiſtence of *other things*; or from the relation which the *actual* exiſtence of that thing has to the *manner* of its *own* exiſtence.

§ *Notes to King on Evil*, and *Law's Inquiry into the Ideas of Space*, &c.

292 What is meant by neceſſary exiſtence.

In the former ſenſe, when neceſſity of exiſtence has relation to the exiſtence of other things, it denotes that the ſuppoſition of the *non*-exiſtence of that thing of which neceſſity is affirmed, implies the non-exiſtence of things which we *know to exiſt*. Thus, ſome independent being does *neceſſarily exiſt*: becauſe, to ſuppoſe *no independent* being, implies that there are *no dependent beings*; the contrary of which we know to be true.

Of the Being and Attributes of God.

In the ſecond ſenſe, when the neceſſity of exiſtence ariſes from the relation which the actual exiſtence of any thing has to the *manner* of its own exiſtence, neceſſity means, that the thing, of which it is affirmed, exiſts after ſuch a manner as that it never could in *time paſt* have *been non-exiſtent*, or can in *time future ceaſe to be*. Thus, *every independent being*, as it exiſts without a cauſe, is *neceſſarily* exiſting; becauſe exiſtence is *eſſential* to ſuch a being; ſo that it never could *begin* to exiſt, and never can *ceaſe to be*: For to ſuppoſe a being to begin to exiſt, or to loſe its exiſtence, is to ſuppoſe a *change* from non-entity to entity, or *vice verſa*; and to ſuppoſe ſuch a change is to ſuppoſe a cauſe upon which that being depends. Every being, therefore, which is independent, *i. e.* which had no cauſe of it exiſtence, muſt exiſt *neceſſarily*, and cannot poſſibly have begun to exiſt in time paſt, or ceaſe to be in time future.

29[3] Only one neceſſ[arily] exiſtent [be]ing in [the] former ſenſe; and

Theſe two kinds of neceſſity as applied to exiſtence, though they have been often confounded, are in themſelves perfectly diſtinct: For though a being cannot be neceſſarily exiſtent in the *former* ſenſe without being ſo in the latter alſo; yet may it be neceſſarily exiſtent in the latter ſenſe without being ſo in the former. For any thing that we know to the contrary, there may be two or more beings exiſting *neceſſarily* in the latter ſenſe of the word *neceſſity*, i. e. with regard to *independence* and the *manner* of their own exiſtence: but in the former ſenſe of the word, *i. e.* in relation to *this ſyſtem*, there can be but *one neceſſarily* exiſtent being; for it is obvious that no more are neceſſary to account for the production of the *dependent* beings which we know to exiſt. To ſuppoſe the non-exiſtence of *all independent* beings, implies the non-exiſtence of all dependent beings, ourſelves and every thing elſe; but to ſuppoſe the non-exiſtence of all independent beings except *one*, involves in the ſuppoſition no ſuch abſurdity.

[2]9[4] though there be mo[re] than o[ne] in the [lat]ter, th[ey] would no go[ds t]o us.

Thus the phenomena of nature leads us, by the ſtricteſt reaſoning, to one firſt cauſe, which is ſufficient for their production; and therefore none but *one* firſt cauſe can in this ſenſe of the word be *neceſſary*: And though ſeveral mere *independent* beings might poſſibly exiſt, yet they would be no gods to us: they would have no relation to us demonſtrable by reaſon, nor we any thing to do with them. For if the ſuppoſition of their exiſtence were not requiſite to the production of this ſyſtem, which it obviouſly would not be, we could *perceive* no neceſſity for it at all; we could never diſcover it by our own faculties, and therefore it could be nothing to us. And tho' two or three ſuch beings ſhould exiſt, and act in the formation and government of their *reſpective* ſyſtems, or *agree in one*; yet till their exiſtence and operations were made known to us, and a natural relation diſcovered, nothing would be due from us to them. They would have no *religious* or *moral* relations to us; and we ſhould have no reaſon to call more than one of them *our* creator, preſerver, and governor, which is the proper ſenſe of the word *God*.

To ſhow in this manner that there is only *one* eternal ſelf-exiſtent Being which bears the relation of *God to us*, ſeems to be going as far as is neceſſary, or as natural

tural light will lead us. Thoſe who endeavour to *demonſtrate* that there *cannot poſſibly* be *more than one* ſelf-exiſtent Being, either reaſon in a circle, or proceed upon principles which their antagoniſts cannot be compelled to grant. When they deduce the Divine unity from independence or omnipotence, they evidently preſuppoſe it in their definition of theſe attributes: and when they infer it from the nature of ſpace and duration, which they conſider as modes of the ſelf-exiſtent Being, they take it for granted, that ſpace and duration have a real exiſtence, independent of us and our thoughts; and that the one is infinite and the other eternal, contrary to what has been already proved, we think, with the force of demonſtration. The celebrated Dr Clarke made much uſe of ſpace and duration in his attempt to demonſtrate that there can be but one ſelf-exiſtent Being; but he argues for the ſame thing from the nature of neceſſity as applied to exiſtence.

"Neceſſity (ſays he *), abſolute in itſelf, is *ſimple* and *uniform* and *univerſal*, without any poſſible *difference*, *difformity*, or *variety*, whatſoever: and all *variety* or *difference* of *exiſtence* muſt needs ariſe from ſome *external* cauſe, and be *dependent upon it*, and *proportionable* to the efficiency of that *cauſe*, whatſoever it be. *Abſolute neceſſity*, in which there can be *no variation* in *any kind* or *degree*, cannot be the *ground* of exiſtence of a *number* of Beings, however *ſimilar* and *agreeing*: becauſe, without any *other difference*, even *number* is itſelf a manifeſt *difformity* or *inequality* (if I may ſo ſpeak) of *efficiency* or *cauſality*."

Such is this great man's firſt argument from neceſſity, to prove that there cannot be more than one ſelf-exiſtent Being. But what is this *neceſſity* which proves ſo much? It is the ground of exiſtence (he ſays) of that which exiſts of itſelf; and if ſo, it muſt, in the order of nature, and in our conceptions, be antecedent to that being of whoſe exiſtence it is the ground. Concerning ſuch *a* principle, there are but three ſuppoſitions which can poſſibly be made; and all of them may be ſhown to be abſurd and contradictory. We may ſuppoſe either the *ſubſtance* itſelf, ſome *property* of that ſubſtance, or ſomething *extrinſic* to both, to be this *antecedent ground* of exiſtence prior in the order of nature to *the firſt cauſe*.

One would think, from the turn of the argument which here repreſents this antecedent neceſſity as *efficient* and *cauſal*, that it were conſidered as ſomething *extrinſic* to the firſt cauſe *. Indeed if the words have any meaning in them at all, or any *force* of argument, they muſt be ſo underſtood, juſt as we underſtand them of any external cauſe producing its effect. But as an *extrinſic* principle is abſurd in itſelf, and is beſides rejected by Dr Clarke, who ſays expreſsly, that "of the thing which derives not its being from any other thing, this *neceſſity* or ground of exiſtence muſt be *in* the thing itſelf," we need not ſay a word more of the laſt of theſe ſuppoſitions.

Let us then conſider the firſt; let us take the *ſubſtance* itſelf, and try whether *it* can be conceived as *prior* or *antecedent* to itſelf in our conceptions or in the order of nature. Surely we need not obſerve that nothing can be more abſurd or contradictory than ſuch a ſuppoſition. Dr Clarke himſelf repeatedly affirms, and it would be ſtrange indeed if he did not affirm, that no *being*, no *thing* whatever, can be conceived as in any reſpect prior to the firſt cauſe.

The only remaining ſuppoſition is, that ſome *attribute* or *property* of the ſelf-exiſtent Being may be conceived as in the order of nature *antecedent* to that being. But this, if poſſible, is more abſurd than either of the two preceding ſuppoſitions. An *attribute* is *attributed* to its *ſubject* as its ground or ſupport, and *not* the *ſubject* to its *attribute*. A *property*, in the very notion of it, is *proper* to the ſubſtance to which it belongs, and *ſubſequent* to it both in our conceptions and in the order of nature. An *antecedent* attribute, or *antecedent* property, is a ſoleciſm as great, and a contradiction as flat, as an *antecedent ſubſequent* or *ſubſequent antecedent*, underſtood in the ſame ſenſe and in the ſame ſyllogiſm. Every property or attribute, as ſuch, preſuppoſes its ſubject; and cannot otherwiſe be underſtood. This is a truth ſo obvious and ſo forcible, that it ſometimes extorts the aſſent even of thoſe who upon other occaſions labour to obſcure it. It is confeſſed by Dr Clarke ‡, that "the ſcholaſtic way of proving the *exiſtence* of the ſelf-exiſtent Being from the abſolute perfection of his nature, is ὕστερον πρότερον. For all or any perfections (ſays he) preſuppoſe exiſtence; which is a *petitio principii*." If therefore properties, modes, or attributes in God, be conſidered as perfections (and it is impoſſible to conſider them as any thing elſe), then, by this confeſſion of the great author himſelf, they muſt all or any of them *preſuppoſe* exiſtence. It is indeed immediately added in the ſame place, "that bare neceſſity of exiſtence does not preſuppoſe, but infer exiſtence;" which is true only if ſuch neceſſity be ſuppoſed to be a principle *extrinſic*, the abſurdity of which has been already ſhown, and is indeed univerſally confeſſed. If it be a *mode* or *property*, it muſt *preſuppoſe* the exiſtence of its ſubject, as certainly and as evidently as it is a *mode* or a *property*. It might perhaps *à poſteriori* infer the exiſtence of its ſubject, as effects may infer a cauſe; but that it ſhould infer in the other way *à priori* is altogether as impoſſible as that a *triangle* ſhould be a *ſquare*, or a *globe* a *parallelogram*.

Of the Being and Attributes of God.

‡ Anſwer to the Sixth Letter.

298
A ſecond demonſtration of the ſame author.

Doubtful, as it would ſeem, of the force of his firſt argument, which even thoſe who pretend to be convinced by it acknowledge to be obſcure, the Doctor gives a ſecond, which we muſt confeſs appears to us to be ſtill more obſcure, and if poſſible leſs concluſive. "To ſuppoſe two or more *diſtinct beings* exiſting *of themſelves* neceſſarily and *independent* of each other, implies (he ſays) this *contradiction*, that *each* of them being independent from the other, they may either of them be ſuppoſed to exiſt *alone*; ſo that it will be no contradiction to ſuppoſe the other not to exiſt; and conſequently *neither of them* will be neceſſarily exiſting. Whatſoever therefore exiſts neceſſarily is the one ſimple eſſence of the ſelf-exiſtent Being; and whatſoever differs from that is not neceſſarily exiſting, becauſe in abſolute neceſſity there can be no *difference* or *diverſity* of exiſtence.

"Neceſſity is uſed here in two different ſenſes ‡, both as *abſolute* and *relative*. In the former, neither of the two beings can exiſt without the other, *i. e.* without our ſuppoſing the other to exiſt alſo, ſince that is equally neceſſary. In the latter, either of them may exiſt

‡ Law's Inquiry into the Ideas of Space, &c. chap. 6.

exist alone, *i. e.* without the help of the other, or without the supposition of the other as requisite to its own existence. The consequence therefore that either of them may exist alone, and so neither of them is necessary, is a mere *equivocation* on *necessity*, using it both in an absolute and relative sense at the same time." But as this is a question of the highest importance, and as the author was a man of great worth, we shall consider his argument upon the supposition that the word *necessity* has from the beginning to the end of it the same invariable meaning.

299 examined, and shown to be equally inconclusive.

It has been already observed, that there are only two senses in which that word can be applied to the existence of any being; and whether it be here used in the one or the other of these senses, the reasoning, if resolved into a syllogism, will appear to be inconclusive. If the word be taken in that sense of necessity which arises from the relation that dependent beings which we know to exist bear to some one independent Being, the argument will stand thus:

> From a known effect no more causes can be *necessarily* inferred than what are sufficient to account for that effect: but
>
> *One* self-existent and independent Being is sufficient to account for all the phenomena of nature; therefore, from the phenomena, &c.
>
> *No more* than *one* such Being can be *necessarily* inferred to exist.

But though no more than *one* independent being can in this sense of the word *necessarily* exist, it by no means follows from this syllogism, that two or more such beings may not *possibly* exist. It is, indeed, a plain contradiction to say, that two or more self-existent beings are in this sense *necessary;* but surely there is no contradiction in saying, that two or twenty such beings are *possible.* We could not, therefore, by this argument, convict a person of absurdity, who should affirm that two or more independent beings *actually* exist. We might, indeed, deny the existence of them all but *one*, because one is sufficient to account for those phenomena, from which alone we know that *any* independent being exists; but because one of them might be supposed to exist *alone*, so that it would be no contradiction to suppose the other not to exist; we know not how the Doctor came to affirm, in direct opposition to his own demonstration, that *not one* of them would be necessarily-existing.

Necessity, as applied to existence, in the other sense of the word, arises, as we have seen, from the relation which the *actual* existence of the being, of which it may be affirmed, has to the *manner* of that being's existence. It is the same necessity, we are told *, with that which is the *cause* of the unalterable proportion between two and four; and it is considered as the *formal* cause or *ground* of the existence of an independent being. Were it not for the strange expressions *formal cause* and *ground* of *existence*, we should have no objection to this account of that *necessity* by which a being independent undoubtedly exists: but this kind of necessity is a principle which will not support the superstructure which the learned author labours to raise upon it The same *necessity* which is the cause of the unalterable proportion between *two* and *four*, is likewise the cause of the unalterable proportion between *three* and *six*, between *four* and *eight*, and between *five* and *ten*, &c. But if it can be the cause of so many different proportions of the same kind, why may it not be the *formal cause* or *ground* of existence to as *many independent beings* of the same kind as well as to *one?* The following syllogism, we apprehend, to be legitimate both in mode and figure, and its conclusion is directly contrary to the proposition which the Doctor deduces from the same notion of necessity.

* *Answer to the Sixth Letter*, from a Gentleman in Gloucestershire.

> If necessity, considered as a *formal cause* or *ground* of *existence*, be in *one instance* of its causality the formal cause or ground of existence to *many things* of the same kind, it *may* likewise in *every other instance* of its causality, be the formal cause or ground of existence to many things of the same kind.
>
> But such necessity, in that instance of its causality where it is the formal cause or ground of existence to the unalterable proportion between two and four, *is* the formal cause or ground of existence to *many proportions* of the same kind.
>
> Therefore, the same necessity in that other instance of its casuality, where it is said to be the formal cause or ground of existence to *one* independent being, undoubtedly *may be* the formal cause or ground of existence to *many independent beings* of the same kind.

300 Necessity a dangerous principle.

Thus it appears, that *necessity*, in any sense in which it can be properly affirmed of existence, cannot be the foundation of any argument to prove the impossibility of more than one self-existent being. It is indeed a principle from which we apprehend that no positive conclusion whatever can be deduced by reasoning *à priori.* That necessity of existence may be predicated of a being which is independent and uncreated, is self-evident; because to the *nature* of such a being existence is essential. But whilst *that nature* itself remains wholly *incomprehensible* by us, it is impossible that we should discover, by our own unassisted reason, whether it can be the nature of *only one* or of *more than one* independent being. To argue from necessity, as if it were the cause or ground of existence to such a being, is certainly absurd, if it be not impious; for if that to which existence is essential, does not exist without any cause efficient or formal, we shall be obliged to inquire after a cause or ground of this cause, and thus be involved in all the absurdities and contradictions of an infinite series. We have insisted the longer on this point, because *necessity*, as the foundation of the argument *à priori*, has sometimes been employed to very bad purposes. Attempts have been made from the notion of *necessary* existence, to prove that the Supreme Being cannot be a free agent, and to set the first principles of the religion of nature at variance with those which are revealed in the scriptures.

301 The unity of God highly probable.

But though we are firmly persuaded that the divine unity cannot be *demonstrated à priori*, we are far from thinking it incapable of any *proof.* On the contrary, the common arguments *à posteriori* drawn from the *order* and *harmony* of the world, have always satisfied us, and in our opinion must satisfy every person capable of proportioning his assent to evidence, that the Creator and Preserver of such a system has but *one will* and *one intelligence*, and therefore is himself but *one being*. But *proof* is one thing; and *demonstration* is, in the proper sense of the word, another.

ther (G). And if we cannot arrive at *absolute* certainty concerning this important truth by the light of nature, we ought to be the more thankful for that revelation, which has put the unity of God past disputes to all who believe the holy scriptures.

The being which is self-existent and independent must be also *omnipotent*. That such a being has *active power in some degree*, is shown at the same time and by the same medium that we prove his existence; and since he depends upon no cause for his existence or his power, he cannot depend upon any for the exertion of that power, and consequently no *limits* can be applied to it. Limitation is an *effect* of some *superior cause*, which in the present instance there cannot be: consequently to suppose *limits* where there can be no *limiter*, is to suppose an *effect* without a *cause*. For a being to be *limited* or *deficient* in any respect †, is to be *dependent* in that respect on some *other* being which gave it just so much and no more; consequently that being which in *no respect* depends upon any other is in *no respect* limited or deficient. In all beings capable of increase or diminution, and consequently incapable of *perfection* or *absolute infinity*, *limitation* or *defect* is indeed a necessary consequence of existence, and is only a *negation* of that perfection which is wholly incompatible with their nature; and therefore in these beings it requires no further cause. But in a being *naturally capable* of *perfection* or absolute *infinity*, all *imperfection* or *finiteness*, as it cannot flow from the *nature* of that being, seems to require some *ground* or *reason*; which reason, as it is foreign from the being itself, must be the effect of some other external cause, and consequently cannot have place in the *first cause*. That the self-existent being is *capable* of perfection or absolute infinity must be granted, because he is manifestly the subject of one infinite or perfect attribute, viz. *eternity*, or absolute invariable existence. In this respect his existence has been shown to be perfect, and therefore it *may* be perfect in every other respect also. Now that which is the subject of one infinite attribute or perfection, must have all its attributes infinitely or in perfection; since to have any perfections in a finite limited manner, when the subject and these perfections are both *capable* of strict *infinity*, would be the forementioned absurdity of positive limitation without a cause. To suppose this eternal and independent being limited *in* or *by* its own *nature*, is to suppose some *antecedent nature* or *limiting quality* superior to that being, to the existence of which no *thing*, no *quality*, is in any respect *antecedent* or *superior*. And to suppose that there is no such thing as *active power* in a being which is evidently the fountain of all power, is the grossest of all absurdities. The same method of reasoning will prove knowledge and every other perfection to be *infinite* in the Deity, when once we have proved that perfection to belong to him at all; at least it will show, that to suppose it limited is unreasonable, since we can find no manner of *ground* for limitation in any respect; and this is as far as we need go, or perhaps as natural light will lead us.

Of the Being and Attributes of God.

373

Omnipotence can do every thing which does not imply a contradiction.

Of the omnipotence of the supreme Being some philosophers, as well theists as atheists, have talked very absurdly. *Hobbes* ‖, with a view to make this attribute appear impossible and ridiculous, affirms "that God by his omnipotence or infinite power could turn a tree into a syllogism." And *Des Cartes* *, though certainly no atheist, childishly asserts, that all things whatever, even abstract truth and falsehood, do so depend upon the arbitrary will and power of God, as that if he had pleased "twice two should not have been four, nor the three angles of a plain triangle equal to two right ones." But the true notion of Omnipotence, so far from implying a power to turn a tree into a syllogism, or to make twice two not equal to four, implies only that the being possessed of it can actually perform whatever can be conceived by the most perfect understanding; conception in this case being the measure of possibility. Now every thing may be conceived by a mind sufficiently enlarged which does not involve in it a direct contradiction; but what we clearly discern to imply a contradiction, such as that a thing may be and not be at the same instant, cannot be conceived by any intellect, or made to exist by any power. And thus has this attribute of the Divinity been always stated, not only by the wiser Christians, but also by most of the ancient philosophers themselves, who expressly admit that "nothing is exempted from the divine power, but only to make that which hath been done to be undone." (H)

Of the Being and Attributes of God.

the proper ſenſe of the word (ſee CREATION), be within the compaſs of infinite power. All the ancient philoſophers, who were unenlightened by the rays of divine revelation, held that it is not †; grounding their opinion upon this maxim, *Ex nihilo nihil fit*. But the maxim will ſupport no ſuch concluſion.—The ancients, or at leaſt the Peripatetic ſchool, with the metaphyſics of which we are beſt acquainted, conſidered four kinds of cauſes, the *efficient*, the *material*, the *formal*, and the *final*; and though they extended the maxim to the firſt *two*, if not to all theſe cauſes, it is a ſelf-evident truth only when applied to the *efficient cauſe*. Without the actual exertion of *power*, it is indeed moſt certain that nothing could be brought into exiſtence; but it is ſo far from being clear that pre-exiſtent matter, or, as Ariſtotle choſe to expreſs himſelf, a *material cauſe*, muſt be ſuppoſed for infinite power to operate upon, that, we think, every man may find complete evidence of the contrary in himſelf. That ſenſation, intelligence, conſciouſneſs, and volition, are not the reſult of any modifications of figure and motion, is a truth as evident as that conſciouſneſs is not ſwift, nor volition ſquare. If then theſe be the powers or properties of a being diſtinct from matter, which we think capable of the completeſt proof, every man who does not believe that his mind has exiſted and been conſcious from eternity, muſt be convinced that the power of creation has been exerted in himſelf. If it be denied that there is any immaterial *ſubſtance* in man, ſtill it muſt be confeſſed, that, as matter is not eſſentially conſcious, and cannot be made ſo by any particular organization, there is ſome real *thing* or *entity*, call it what you pleaſe, which has either exiſted and been conſcious from eternity, or been in time brought from non-entity into exiſtence by an exertion of infinite power.

304 Creation poſſible to Omnipotence.

† See *Moſheim's Diſſertation on this Subject, in his Edition on Cudworth's Intellectual Syſtem.*

To this perhaps ſome one may object, that upon our own ſuppoſition of the inability of the human mind to exert its faculties but in union with ſome material and organiſed ſyſtem, the mind of every man may have exiſted from eternity without being conſcious of its own exiſtence; and that, therefore, we have in ourſelves no evidence of *creation*, but only of the union of two ſelf-exiſtent ſubſtances, which in their prior ſtate had been diſtinct and ſeparate from each other. But ſuch an objection as this, we beg leave to reply, can ariſe from nothing but miſapprehenſion of our hypotheſis, and of the reaſons by which we think it ſupported. We ſuppoſe, that to the exertion of the human faculties, a body of ſome kind or other may be neceſſary as an inſtrument, not merely from what we obſerve of the dependence of perception and memory on the ſtate of the brain, but becauſe we cannot conceive a Creator of infinite wiſdom and goodneſs to immerſe in ſyſtems of matter, minds to which he knows that ſuch ſyſtems muſt be always uſeleſs and often hurtful. We believe, therefore, that our ſouls and bodies were created and formed for each other; but as our preſent adverſaries admit not of a Creator, we muſt aſk them, How their ſelf-exiſtent ſouls have been diſpoſed of from eternity, and by what power they have all in due ſucceſſion been united each to its proper body? As before the union they were not conſcious, they could not unite themſelves; and to ſuppoſe them united by ſome ſuperior intelligence, is to ſuppoſe them in ſome reſpects dependent on that intelligence, which ſeems not to accord with their ſelf-exiſtence. Whatever is ſelf-exiſtent and eternal muſt be independent; and if poſſeſſed of any power, cannot be conceived to have that power limited.—We repeat, therefore, that every man has in himſelf ſufficient evidence that creation is poſſible; for if infinite power can create an immaterial and percipient being, it may ſurely be ſuppoſed capable of creating dead and unintelligent matter.

But the creation of the material ſyſtem may be ſhown to be in the higheſt degree probable by other arguments. The ſame reaſoning which proves the impoſſibility of an infinite ſeries and of eternal time, proves that the univerſe cannot have exiſted from eternity in its preſent ſtate. But if it has not exiſted from eternity in its preſent ſtate, it belongs to the opponents of creation to ſay what was its former. We talk indeed of *chaos*; but ſuch language, when a Creator is not admitted, is moſt unphiloſophical trifling. It appears from the moſt accurate inquiries that have been made into the ſubſtance and eſſence of body ‡, that the atoms of which each maſs is compoſed are held together by a foreign force. If by chaos be meant matter, when this force is ſuppoſed to be removed, we muſt beg leave to ſay, that of ſuch a ſubſtance we have neither idea nor notion, and cannot diſtinguiſh it from non-entity. The original atoms of matter, we believe indeed to require no other agency to keep each entire than that *fiat* by which it was created; but ſtill, as thoſe atoms are conceived to be ſolid and extended, they muſt be capable of diviſion by infinite power; and if that *fiat* or influence which makes them ſolid and extended were removed, they would loſe ſolidity and extenſion, and of courſe become nothing. So far is it, therefore, from being true, that the creation of matter appears to be impoſſible, that we are compelled by every thing that we know of it to believe that matter cannot poſſibly be ſelf-exiſtent.

‡ Baxter's *Inquiry into the Nature of the Human Soul*.

"Becauſe it is undeniably certain, concerning ourſelves (ſays Cudworth †), and all imperfect beings, that none of theſe can create any *new ſubſtance*, men are apt to meaſure all things by their own ſcantling, and to ſuppoſe it univerſally impoſſible for any power whatever thus to create. But ſince it is certain, that imperfect beings can themſelves produce *ſome things* out of nothing pre-exiſting, as *new cogitations*, *new local motion*, and *new modifications* of things corporeal, it is ſurely reaſonable to think that an abſolutely perfect Being can do *ſomething more*, *i.e.* create *new ſubſtances*, or give them their whole being. And it may well be thought as eaſy for God or an Omnipotent Being, to make a whole world, matter and all, ἐξ οὐκ ὄντων, as it is for us to create *a thought* or to move a finger, or for the ſun to ſend out rays, or a candle light; or laſtly, for an opaque body to produce an image of itſelf in a glaſs or water, or to project a ſhadow: all theſe imperfect things being but the *energies*, *rays*, *images*, or *ſhadows*, of the Deity. For a ſubſtance to be made out of nothing by *God*, or a *Being infinitely perfect*, is not for it to be made out of nothing in the impoſſible ſenſe, becauſe it comes from him who is *all*. Nor can it be ſaid to be impoſſible for any thing whatever to be made by that which hath.

† *Intellectual Syſtem*, Book … Chap. …

hath not only *infinitely greater perfection*, but also *infinite active power*. It is indeed true, that infinite power itself cannot do things in their own nature impossible; and, therefore, those who deny creation, ought to prove, that it is absolutely impossible for a *substance*, though not for an *accident* or *modification*, to be brought from non-existence into *being*. But nothing is in itself impossible, which does not imply a contradiction: and though it be a contradiction for a thing to be and not to be at the same time, there is surely no contradiction in conceiving an imperfect being, which before was not, afterwards to be." To call in question the possibility of creation, because we have no *adequate conception* how a thing can be brought into existence, would be in the highest degree absurd; for it may be doubted, whether we have *adequate* conceptions of any thing except our own ideas and their various relations (1).

305 The Being which is self-existent, omnipotent, and omniscient, is not a *necessary*, but a *free* agent; for *active power* implies *freedom*, and *infinite* power *infinite* freedom. What, therefore, hath no bounds set to its power, what can have no opposition made to its will, nor restraint laid on its actions, must both will and act freely. "If the supreme cause were not a being endowed with liberty and choice, but a mere necessary agent, then would it follow, as Dr Clarke well observes †, that nothing which is not, could *possibly* have been; and that nothing which is, could *possibly* not have been; and that no mode or circumstance of the existence of any thing could *possibly* have been in any respect otherwise than it now actually is. All which being evidently most false and absurd; it follows, on the contrary, that the supreme cause is not a mere necessary agent, but a Being endued with liberty and choice."

To this reasoning it has been lately replied †, that "Clarke must have known, that all those who contend against the free agency of the Deity, do of course acknowledge, that nothing could have happened, or does happen, or will happen, but what actually has happened, or doth happen, or will happen; and that it is most false and absurd to deny it." It is, therefore, according to the necessarians, absolutely impossible, that at present there could exist upon this earth more or fewer persons than are now actually alive; that the earth could move in any other direction than from west to east; or that there could be more or fewer planets in the solar system. Yet is it most certain, that there *have been fewer persons* on the earth than there are now; that there is not a cultivated country in Europe which could not contain *more* people than now inhabit it; that the comets move in very different directions from that of west to east; and that as, till very lately, we *conceived* only six primary planets in the system, it is evidently *possible* that the system *might contain* no more. Upon the supposition, therefore, that the Supreme Being acts under a physical necessity, the same things are possible and not possible at the same time, which is the grossest of all absurdities. It might have been objected with much more plausibility, that the first cause cannot possibly be free, because he must needs do always what is best in the whole; but it will be seen by and by, that among different created systems, there is no reason for supposing any one absolutely *best*.

306 But though this Being is *free*, and as such the author of *change* in other beings, yet he must himself be *unchangeable*; for all changes have a beginning, and consequently are effects of some *prior causes*. But there can be nothing prior to the existence of this Being, as he is *eternal*; neither any *cause* of it, as he is *independent*; nor consequently any *change* in it, except we could suppose him to *change himself*, which is the same absurdity as to *produce* himself, *i. e.* to be at *the same time both effect* and *cause*.

307 Omniscience, as well as some of the foregoing attributes of the Supreme Being, may perhaps be more easily deduced thus §. We find in ourselves such qualities as *thought* and *intelligence*, *power* and *freedom*, &c. for which we have the evidence of consciousness as much as for our own existence. Indeed, it is only by our consciousness of these that our existence is known to ourselves. We know likewise that these are *perfections*, and that to have them is better than to be without them. We find also that they have not been in us from eternity. They must, therefore, have had a *beginning*, and consequently some *cause*, for the very same reason that a *being* beginning to exist in time requires a cause. Now this cause, as it must be *superior* to its *effect*, must have those perfections in a *superior* degree; and if it be the *first cause*, it must have them in an *infinite* or *unlimited* degree, since *bounds*, or *limitation* without a limiter, would, as we have already shown, be an *effect* without a *cause*.

It is indeed obvious, that the *omniscience* of the Supreme Being is implied in his very existence. "For all things being not only present to him, but also entirely

Of the Being and Attributes of God.

Himself unchangeable.

Omniscience, &c. proved in a different manner.

§ *Notes to King on Evil.*

---

(1) "Ridicula foret et inepta ejus temeritas, qui corporum ideo creationem sibi duceret negandum esse, quod ejus creationis *clarem et perspicuam notionem* effingere cogitatione nobis haud licet. Infinita enim est rerum copia, quarum perspicuis et apertis caremus notionibus. Et si omnia neganda continuo nobis essent, quorum confusam tantum et imperfectam consequi possumus notionem, omnia fere nobis essent neganda, exceptis *relationibus*, quas inter notiones quasdam abstractas esse intelligimus. Quis interiorem sibi naturam rerum, tam corporum, quam spirituum, cognitam esse dixerit? Et esse tamen has naturas, omni plane dubitatione vacat. Quis quemadmodum altera harum naturarum agat in alteram, sese scire, affirmet? Quis causas sibi patere, propter quas hi vel illi effectus, quos videmus quotidie contingere, a certis veniant corporibus, jure glorietur? Nec tamen quisquam est, qui vel illam animæ in corpus operationem, vel hos effectus in dubium revocare ausit. Teneamus igitur ea, quæ certo novimus, nec idcirco nos ab illis dimoveri patiamur, quod multa rursus sunt, quorum naturam ignoramus; contra multa nos fugere et cognitionem nostram superare, æquo et tranquillo feramus animo. *Joannis Clerici contra eos qui negant, ex nihilo ulla ratione fieri posse aliquid, observationes; in Moshemii edit. Intellec. Syst.*

Of the Being and Attributes of God.

tirely *depending* upon him, and having *received* both their *being* itſelf and all their powers and faculties *from him*, it is manifeſt that as he knows all things that are, and penetrates every part of their ſubſtance with his all-ſeeing eye, ſo muſt he likewiſe know *all poſſibilities* of things, that is, all effects that *can be*. For, being alone ſelf-exiſtent, and having alone given to all things all the powers and faculties with which they are endued, it is evident that he muſt of neceſſity know perfectly what all and each of theſe powers and faculties, *which are derived wholly from himſelf*, can poſſibly produce. And ſeeing at one boundleſs view, or more properly in his own ideas, all the poſſible compoſitions and diviſions, variations and changes, circumſtances and dependencies of things, all their poſſible relations one to another, and their diſpoſitions or fitneſſes to certain and reſpective ends, he muſt without poſſibility of error know exactly what is beſt and propereſt in every one of the numberleſs poſſible caſes, or methods of diſpoſing things; and underſtand perfectly how to order and direct the reſpective means to bring about what he ſo knows to be in its kind, or on the whole, the beſt and fitteſt in the end. This is what is meant by infinite wiſdom, or omniſcience †;" and it has been readily admitted by every man who has believed in the exiſtence of a God as the creator and preſerver of all things.

† *Clarke's Demonſtration, &c.*

308 God foreknows the actions of free agents.

Doubts, however, have been entertained by theiſts, and pious theiſts, whether omniſcience itſelf can certainly foreknow what are called contingent events, ſuch as the actions of free agents; and ſome few there are profeſſing to be even Chriſtians, who have boldly pronounced ſuch knowledge to be impoſſible. That we have no adequate notion *how* events, which are called contingent, can be certainly foreknown, muſt indeed be granted; but we are not, therefore, authoriſed to ſay that ſuch knowledge is impoſſible, unleſs it can be clearly ſhown to imply a contradiction. They who ſuppoſe that it implies a contradiction, muſt likewiſe ſuppoſe, that, where there is not a chain of neceſſary cauſes, there can be no certainty of any future event; but this is evidently a miſtake. "For let us ſuppoſe that there is in man a power of beginning motion, and of acting with what has of late been called *philoſophical* freedom; and let us ſuppoſe farther that the actions of ſuch a man cannot poſſibly be foreknown; will there not yet be in the nature of things, notwithſtanding this ſuppoſition, the ſame *certainty of event* in every one of the man's actions, as if they were ever ſo fatal and neceſſary? For inſtance, ſuppoſe the man, by an internal principle of motion, and an abſolute freedom of mind, to do ſome particular action *to-day*, and ſuppoſe it was not poſſible that this action ſhould have been foreſeen *yeſterday*, was there not nevertheleſs the ſame *certainty of event* as if it had been foreſeen, and abſolutely neceſſary? That is, would it not have been as *certain a truth* yeſterday, and from eternity, that this action was in event *to be performed to-day*, notwithſtanding the ſuppoſed freedom, as it is now a *certain and infallible truth* that it is performed? Mere *certainty of event*, therefore, does not in any meaſure imply *neceſſity* †." And ſurely it implies no contradiction to ſuppoſe, that every future event which in the nature of things is *now certain*, may *now be certainly known* by that intelligence which is omniſcient. The *manner* how God can foreknow future events, without a *chain of neceſſary cauſes*, it is indeed impoſſible for us to explain: yet ſome ſort of *general notion* of it we may conceive. "For, as a man who has no influence over another perſon's actions, can yet often perceive beforehand what that other will do; and a wiſer and more experienced man, with ſtill *greater probability* will foreſee what another, with whoſe diſpoſition he is perfectly acquainted, will in certain circumſtances do; and an angel, with ſtill *leſs degrees of error*, may have a further proſpect into mens future actions: ſo it is very reaſonable to conceive, that God, without influencing mens wills by his power, or ſubjecting them to a chain of neceſſary cauſes, cannot but have a knowledge of future free events, as much *more certain* than men or angels can poſſibly have, as the *perfection* of *his* nature is greater than that of *theirs*. *The diſtinct manner how* he foreſees theſe things we cannot, indeed, explain; but neither can we explain the *manner* of numberleſs other things, of the reality of which, however, no man entertains a doubt †." We muſt therefore admit, ſo long as we perceive no contradiction in it, that God always knows all the free actions of men, and all other beings endued with liberty; otherwiſe he would know many things now of which he was once ignorant, and conſequently his *omniſcience* would receive addition from events, which has been already ſhown to be contrary to the true notion of infinity.—In a being incapable of change, knowledge has nothing to do with *before* or *after*. To every purpoſe of knowledge and power, all things are to him equally preſent. He knows perfectly every thing that is, and what to us is future he knows in the very ſame manner as he knows what to us is preſent.

† *Clarke's Demonſtration, &c.*

309 God infinitely perfect, all-ſufficient and omnipreſent.

Thus have we demonſtrated the neceſſary exiſtence of a being who is *eternal, independent, unchangeable, omnipotent, free in his actions*, and *omniſcient*; and this is the being whom we worſhip as God. *Eternity, independence, immutability, omnipotence, liberty*, and *omniſcience*, which ſeem to be all the *natural* attributes which we can diſcover in the divine nature, as they are conceived to be differently combined, make us ſpeak of him in different terms. His enjoying in an abſolute manner every conceiveable power or perfection, makes us call him a Being *infinitely perfect*. His being capable of no want, defect, or unhappineſs of any kind, denotes him to be *all-ſufficient in himſelf*; and the unlimited exerciſe of his knowledge and power, demonſtrates him to be *omnipreſent*. That ſuch a Being muſt be incomprehenſible by us, and by every creature, is a truth ſelf-evident; and yet in all ages men of the beſt intentions have been vainly attempting this impoſſibility. The manner of his omniſcience, for inſtance, has been the ſubject of much diſputation among thoſe who ought to have reflected that they knew not how their own minds were preſent to their own bodies.—The celebrated Dr Clarke and his adherents, who conſidered ſpace as the *ſine qua non* of all other things, inſiſted, that God muſt be infinitely extended; and that, as wherever his ſubſtance is, there his attributes muſt be, it is thus that his knowledge and power are preſent with every creature. But this notion labours under inſuperable difficulties.

For "if the Divine ſubſtance be infinitely extended, then will there be part of it in this place and part in in that. It muſt be commenſurate with all particular beings, ſo that ſome will occupy more and ſome leſs of its dimenſions. By this account it will be very proper and philoſophical to ſay, that God is not in *heaven*, but only a *part* of him; and that an *elephant* or a *mountain*, a *whale* or a wicked *giant*, have more of the eſſence or preſence of God with them than the *holieſt* or *beſt* man in the world, unleſs he be of equal ſize: all which, as has been well obſerved †, are at leaſt harſh and grating expreſſions. As the attributes of the Divine Being muſt be conſidered in the ſame manner with his ſubſtance, we ſhall likewiſe, upon this notion of omnipreſence, have a part of his knowledge and power in this place, and a part of them in that; and of theſe parts the one muſt be greater or leſs than the other according to the dimenſions of the place with which it is commenſurate; which is a ſuppoſition that appears to us harſher, if poſſible, than even the former.

"Should it be ſaid that the Divine attributes are not to be conſidered as having parts (though we ſee not how they can be conſidered otherwiſe than as their ſubject), they muſt then exiſt *completely* in every point of this immenſe expanſion. Be it ſo; and what follows? Why, every point of this infinitely expanded being will be omniſcient and omnipotent by itſelf; an inch of it will have as much wiſdom and power as a yard, a mile, or the whole; and, inſtead of one infinite wiſdom and power, we ſhall have millions: For as theſe parts of the ſubſtance are conceived *diſtinctly*, and one individual part is not another, ſo muſt the attributes be likewiſe conceived, and the individual power and knowledge of one part be diſtinct from that of another." And if ſo, it follows, that one point of this expanded being has equal power and intelligence with the whole; ſo that the notion of extenſion being *neceſſary* to God's preſence with every creature, involves in it the moſt palpable contradiction. That God is at all times and in all places ſo preſent with every creature as to have an abſolute knowledge of and power over it, is indeed capable of the ſtricteſt demonſtration; but we think it great preſumption to aſſign the particular *mode* of his preſence, eſpecially ſuch a one as is neither agreeable to the nature of an abſolutely perfect Being, nor in the leaſt neceſſary to the exerciſe of any one perfection which he can be proved to poſſeſs. Philoſophers and divines have offered ſeveral names for the manner in which God is preſent with his works; but we chooſe rather to confeſs, that the *manner* of his preſence is to us, and probably to every creature, wholly incomprehenſible. Nor need we be ſurpriſed or ſtaggered at this, when we reflect that the manner in which our own minds are preſent with our bodies is to us as incomprehenſible as the manner in which the ſupreme Mind is preſent with every thing in the univerſe. That our minds have a power over our limbs, we know by experience: but that they are not extended or ſubſtantially diffuſed through them, is certain; becauſe men daily loſe arms and legs without loſing any part of their underſtanding, or feeling their energies of volition in the ſmalleſt degree weakened. But we need purſue this ſubject no farther. It has been confeſſed by one of the moſt ſtrenuous advocates ‡ for the extenſion of the Deity and all minds, that "there is an incomprehenſibleneſs in the *manner* of every thing, about which no controverſy can or ought to be concerned."

The moral attributes of God may be deduced from his natural ones, and are immediate conſequences of them when exerciſed on other beings. They may be termed his *ſecondary relative* attributes, as they ſeem to be the perfection of his *external acts* rather than any *new internal* perfections. And though the exiſtence of any moral quality or action is not capable of ſtrict *demonſtration*, becauſe every moral action or quality, as ſuch, depends upon the *will* of the agent, which muſt be abſolutely free; yet we have as great aſſurance that there are moral qualities in God, and that he will always act according to theſe qualities, as the nature of the thing admits; and may be as well ſatisfied of it, as if it were capable of the moſt rigid demonſtration. This important point, however, cannot be ſo clearly or ſo firmly eſtabliſhed by abſtract reaſoning as by taking a ſcientific view of the works of creation, which evince the goodneſs, holineſs, and juſtice, of their Author, as well as his perfect wiſdom and infinite power. The conſideration, therefore, of the moral attributes of God, together with his providence, and the duties thence incumbent on man, is the proper buſineſs of other articles (ſee RELIGION, THEOLOGY, and MORAL *Philoſophy*.)

Of the Being and Attributes of God.

311 God's moral attributes reſult from his natural perfections.

At preſent we ſhall only obſerve, that by reaſoning *à priori* from his exiſtence and his natural perfections, we muſt neceſſarily infer that his actions are the reſult of unmixed benevolence. Every wiſe agent has ſome end in view in all his actions; it being the very eſſence of folly to act for no end: but there cannot be an end of action which is not either ſelfiſh or benevolent. Selfiſhneſs is the offspring of want and imperfection, and is therefore the ſource of moſt *human* actions; becauſe men are weak and imperfect beings, capable of daily additions to their happineſs. When the thief plunders a houſe at midnight, when the highwayman robs a traveller on the road, and even when the aſſaſſin murders the man who never injured him; it will be found that their actions ſpring not from an innate deſire to inflict miſery upon others, but from a proſpect of reaping advantage to themſelves. The object of the thief and the robber is obvious: it is to gain money, which is the mean of procuring the comforts of life. Even the aſſaſſin has always the ſame ſelfiſh end in view: either he is *bribed* to commit the murder, or he fancies that his horrid deed will remove an *obſtacle* from the way to his own happineſs. But they are not vicious men *only* who act from ſelfiſh conſiderations: much of human *virtue*, when traced to its ſource, will be found to have its origin in the deſire of happineſs. When a man gives his money to feed the hungry and to clothe the naked, he believes that he is acting agreeably to the will of Him to whom he and the poor ſtand in the ſame relation; and he looks for a future and eternal reward. By continuing the practice, he ſoon acquires the habit of benevolence; after which, indeed, he looks for no further reward, when performing particular actions, than the immediate pleaſure of doing good. This ſelfiſhneſs of man is the neceſſary conſequence of his progreſſive ſtate. But the Being who is independent, omnipotent, omniſcient, and, in a word, poſſeſſed of every poſſible

312 How they ought to be conceived.

per-

Of the Being and Attributes of God.

perfection, is incapable of progreſſion, or of having any acceſſion whatever made to his happineſs. He is immutable; and muſt of neceſſity have been as happy from eternity, when exiſting alone, as after the creation of ten thouſand worlds. When, therefore, he willed the exiſtence of other beings, he could have nothing in view but to communicate ſome reſemblance of his own perfections and happineſs. That he had *ſome* end in view, follows undeniably from his infinite wiſdom. That he could not have a *ſelfiſh* end, follows with equal certainty from his own infinite perfections; and as there is no medium, in the actions of a wiſe Being, between ſelfiſhneſs and benevolence, we muſt neceſſarily conclude, that the creation was the reſult of unmixed benevolence or perfect goodneſs. The other moral attributes of the Deity, his juſtice, mercy, and truth, ought therefore to be conſidered only as ſo many different views of the ſame *goodneſs* in the *Creator*, and various ſources of *happineſs* to the *creature*. Theſe are always *ſubordinate* to and *regulated* by this one principal perfection and brighteſt ray of the Divinity.

"Thus we conceive his *juſtice* to be exerted on any being no farther than his goodneſs neceſſarily requires, in order to make that being, or others, *ſenſible* of the *heinous nature* and *pernicious effects of ſin* §, and thereby to bring them to as great a degree of happineſs as their ſeveral natures are capable of. His *holineſs* hates and abhors all wickedneſs, only as its neceſſary conſequences are abſolute and unavoidable miſery; and his veracity or faithfulneſs ſeems to be concerned for truth, only becauſe it is connected with and productive of the happineſs of all rational beings; to provide the propereſt means for attaining which great end, is the exerciſe of his *wiſdom*." Such is the view of God's moral attributes, which the abſtract contemplation of his natural perfections neceſſarily gives; and whether this way of conceiving them be not attended with leſs difficulty than the common manner of treating them under the notion of two infinites *diametrically oppoſite*, muſt be left to the judgment of the reader.

§ *Notes to King on Evil.*

313 The origin of evil.

But if the Creator and ſupreme Governor of all things be a Being of infinite power, perfect wiſdom, and pure benevolence, how came evil into the works of creation? This is a queſtion which has employed the ſpeculative mind from the firſt dawning of philoſophy, and will continue to employ it till our faculties be enlarged in a future ſtate, when philoſophy ſhall give place to more perfect knowledge. To theſe meditations, as has been well obſerved ‡, humanity is not equal. Volumes have been written on the ſubject; but we believe that the following extract from Dr Clarke contains all that can be advanced with certainty, and all that is neceſſary to vindicate the ways of God to man.

‡ *Johnſon's Review of a free Inquiry into the Origin of Evil.*

"All that we call evil (ſays that able reaſoner †), is either an *evil of imperfection*, as the want of certain faculties and excellencies which other creatures have; or *natural evil*, as pain, death, and the like; or *moral evil*, as all kinds of vice. The *firſt* of theſe is not properly an evil: for every power, faculty, or perfection, which any creature enjoys, being the free gift of God, which he was no more obliged to beſtow than he was to confer being or exiſtence itſelf, it is plain, that the want of any certain faculty or perfection, in any kind of creatures, which never belonged to their nature, is no more an evil to them, than their never having been created or brought into being at all could properly be called an evil." To this we may add, that as no created being can be ſelf-exiſtent and independent, imperfection is unavoidable in the creation, ſo that the evil of defect (as it is moſt abſurdly called) muſt have been admitted, or nothing could ever have exiſted but God. "The *ſecond* kind of evil, which we call *natural* evil, is either a neceſſary conſequence of the former, as *death* to a creature on whoſe nature immortality was never conferred; and then it is no more properly an evil than the former: Or elſe it is counterpoiſed in the whole with as great or greater good, as the *afflictions and ſufferings of good men*; and then alſo it is properly no evil: Or elſe it is a *puniſhment*; and then it is a neceſſary conſequence of the *third* and laſt ſort of evil, viz. *moral evil*. And *this* ariſes wholly from the abuſe of *liberty*, which God gave to his creatures for other purpoſes, and which it was reaſonable and fit to give them for the perfection and order of the whole creation: only they, contrary to God's intention and command, have abuſed what was neceſſary for the perfection of the whole, to the corruption and depravation of themſelves. And thus have all ſorts of evils entered into the world without any diminution to the infinite goodneſs of its Creator and Governor."

† *Demonſtration of the Being and Attributes of God.*

31[4] Whether the present syſtem be the beſt poſſible.

But though evil could not be totally excluded from the univerſe, are we not authoriſed to infer, from the infinite power, wiſdom, and goodneſs of the Creator, that the preſent ſyſtem is upon the whole the very beſt ſyſtem poſſible? Undoubtedly we are, if of poſſible ſyſtems there *can be a beſt*; but this is ſo far from being evident, that we think it implies a contradiction. A beſt of beings there is, *viz.* God, who is poſſeſſed of infinite perfections; but there cannot be a beſt of creatures or of created ſyſtems. To prove this, we need only reflect, that wherever creation ſtops, it muſt ſtop infinitely ſhort of infinity; and that how perfect ſoever we conceive any creature or ſyſtem of creatures to be, yet the diſtance between that and God is not leſſened, but continues infinite. Hence it follows, that the nature of God and his omnipotence is ſuch, that whatever number of creatures he has made, he may ſtill add to that number; and that however good or perfect the ſyſtem may be on the whole, he might ſtill make others equally good and perfect.

31[5] Origin of that opinion.

The diſpute, whether a being of infinite power, wiſdom, and benevolence, muſt be ſuppoſed to have created the *beſt poſſible ſyſtem*, and the embarraſſment of mens underſtandings about it, ſeem to have ariſen from their taking the words *good*, *better*, and *beſt*, for abſolute qualities inherent in the nature of things, whereas in truth they are only relations ariſing from certain appetites. They have indeed a foundation, as all relations have, in ſomething abſolute, and denote the thing in which they are founded; but yet they themſelves imply nothing more than a relation of congruity between ſome appetite and its objects. This is evident; becauſe the ſame object when applied to an appetite to which it has a congruity, is good; and bad, when applied to an appetite to which it has no congruity. Thus, the earth and air to terreſtrial animals are good elements, and neceſſary to their preſervation: to thoſe animals the water is bad, which yet affords

affords the beſt receptacle to fiſhes. *Good*, therefore, being relative to appetite, that muſt be reckoned the beſt creature by us which has the ſtrongeſt appetites, and the ſureſt means of ſatisfying them all, and ſecuring its own permanent happineſs. And though the *ſubſtance* of creatures is chiefly to be regarded as contributing to their perfection, yet we have no way of meaſuring the perfection of different ſubſtances but by their qualities, *i. e.* by their appetites by which they are ſenſible of good and evil, and by their powers to procure thoſe objects from which they receive that ſenſe of things which makes them happy.

It is plain, therefore, that whatever ſyſtem we ſuppoſe in nature, God might have made another equal to it; his infinite wiſdom and power being able to make other creatures equal in every reſpect to any that we know or can conceive, and to give them equal or ſtronger appetites, and as certain or more certain ways of ſatisfying them. We ſee in many caſes, that very different means will anſwer the ſame end. A certain number of regular pyramids will fill a ſpace; and yet irregular ones will do it as well, if what we take from the one be added to another; and the ſame thing may be done by bodies of the moſt irregular and different figures in the ſame manner: and therefore we may very well conceive, that the anſwering of appetites, which is all the *natural good* that is in the world, may as well be obtained in another ſyſtem as in this; provided we ſuppoſe, that where the appetites of the ſentient beings are changed, the objects are alſo ſuited to them, and an equal congruity among the parts of the whole introduced. This is ſo eaſily conceived, that in an indefinite number of poſſible worlds, we do not ſee why it may not be done in numberleſs ways by infinite power and wiſdom.

If then it be plain, that there might have been many other worlds, or even but one, equal to this in all reſpects as to goodneſs, there could be no neceſſity, either phyſical or moral, that God ſhould create the one rather than the other; becauſe nothing could make the one better, or to him more agreeable, than the other, but his own free choice. Either, therefore, God muſt be poſſeſſed of abſolute freedom, or, among a number of poſſibilities equally perfect, he could not have made a choice, and ſo nothing would ever have been created. It is not, then, as Leibnitz and others argue, the natural and neceſſary goodneſs of ſome particular things, *repreſented by the divine ideas*, which determines God to prefer them to all others, if underſtood of his *firſt* act of producing them; but it is his own free choice, which among many equal *potential* goods, makes ſome things *actually* good, and determines them into exiſtence. When thoſe are once ſuppoſed to exiſt, every thing or action becomes good which tends to their happineſs and preſervation; and to ſuppoſe their all-perfect Author to have any other end in view than their preſervation and happineſs, is the ſame abſurdity as to ſuppoſe that knowledge may produce ignorance; power, weakneſs; or wiſdom folly.

Of the Being and Attributes of God.

317 God not neceſſitated by his goodneſs to create the preſent in preference to all other worlds.

We have now finiſhed what we propoſed under the article Metaphyſics. It has ſwelled in our hands to a large extent; and yet it can be conſidered as little more than an introduction to that ſcience, which comprehends within its wide graſp every thing exiſting. The reader who wiſhes to purſue theſe intereſting ſpeculations, ſhould ſtudy diligently the authors whom we have conſulted, and to whom we have been careful to refer in the margin. Were we to make a ſelection, we ſhould without heſitation recommend Ariſtotle and Plato among the ancients; and Cudworth, Locke, Hartley, and Reid, among the moderns. Theſe philoſophers, indeed, on many points, differ exceedingly from one another; but he who wiſhes not to adopt opinions at random, ſhould know what can be ſaid on both ſides of every queſtion.

METAPLASMUS, in grammar, a tranſmutation or change made in a word, by adding, retrenching, or altering a ſyllable or letter thereof.

METAPONTUM, or METAPONTIUM, (anc. geog.), a town of Lucania, on the Sinus Tarentinus, to the weſt of Tarentum; built by the Pylians, who returned from Troy, (Mela). Where Pythagoras is ſaid to have taught in the time of Servius Tullius, (Livy). *Metapontini*, the people; who pretended to ſhow, in a temple of Minerva, the tools with which Epeus built the wooden horſe, (Juſtin). Now a tower, called *Torre di Mare*, in the Baſilicata of Naples, (Baudrand.)

METASTASIO (l' abbe Pierre Bonaventure), whoſe real name was *Trapaſſi*, was born at Aſſiſe, on January 3d, 1698. His talent for poetry was firſt unfolded by the reading of Taſſo; and he began to compoſe verſes at ten years of age. "A prodigy of this nature (ſays Metaſtaſio) made ſuch an impreſſion on my maſter, the celebrated Gravina, that he thenceforth conſidered me as a plant worthy of being cultivated by his own hands." Metaſtaſio was only fourteen years of age when he compoſed his tragedy entitled *Il Giuſtino*; in which he appears too cloſe and ſcrupulous an imitator of the Grecian drama. Our young poet unfortunately loſt his patron in 1717; who left him his heir, "as being a young man of the moſt promiſing abilities." Metaſtaſio, at the age of nineteen, being, in conſequence of this inheritance, ſuperior to thoſe wants which repreſs the exertions of genius, and to which men of abilities are too often ſubject, gave full ſcope to his inclination for poetry. He began his dramatic career with the *Didonne Abandonnata*, which was acted at Naples in 1724: the muſic was compoſed by Sarro. He ſoon acquired ſuch celebrity, that in 1729 he was invited to Vienna by the emperor Charles VI.; who appointed him imperial poet, and granted him a penſion of 4000 florins. From that time ſome of his works were preſented at every court-feſtival; and notwithſtanding the extreme magni-

Metaſtaſio.

magnificence of theſe entertainments, they would now be forgotten were it not for the verſes which he compoſed upon the occaſion. The courts of Vienna and Madrid vied with each other in the preſents which they conferred upon him. From Maria Thereſa he received a ſnuff-box and a port-folio ſet with diamonds, and a golden candleſtick with a ſcreen. Ferdinand VI. king of Spain, informed of the great merit of Metaſtaſio by Farinelli, of whom he was a paſſionate admirer, ſent him a preſent of a caſket mounted with gold, and furniſhed with the different implements of writing. This favourite of kings and of the muſes was of a cheerful temper, and was exceedingly temperate: to this he was probably indebted for the uninterrupted health which he enjoyed, and for the entire poſſeſſion of his ſenſes and faculties to the moſt advanced period of old-age. He took his meals, aroſe, and went to bed, always at ſtated hours. This exactneſs and order were ſcrupulouſly obſerved even in the moſt trifling actions of his life. He uſed to ſay in jeſt, that he dreaded hell for no other reaſon but becauſe it was a place *ubi nullus ordo, ſed ſempiternus horror inhabitat*. He had even his ſtated hours for making verſes; to which he ſcrupulouſly adhered, without waiting for the moment of poetical enthuſiaſm. He was equally regular in the duties of the Chriſtian as in the labours of the ſcholar. His behaviour was that of a true philoſopher: his ambition extended no farther than the attainment of literary fame; and he deſpiſed every civil mark of diſtinction. When Charles VI. offered him the titles of *Count* or of *Baron*, which add no real worth or dignity to the poſſeſſor, but frequently make him appear in a more ridiculous light, he inſtantly begged the favour that he would allow him ſtill to continue *Metaſtaſio*. The empreſs Maria Thereſa afterwards wiſhed to beſtow upon him the ſmall croſs of St Stephen; but he excuſed himſelf on account of his age, which would prevent him from aſſiſting at the feſtivals of the order. He was attacked by a fever on the 2d of April 1782; and he died on the 12th of the ſame month, at the age of 84. Before his death he received the ſacrament according to the form of the Romiſh church; and Pius VI. who was then at Vienna, ſent him his apoſtolical benediction *in articulo mortis*, He left about 150,000 florins. He compoſed a great number of tragic operas, and ſeveral ſmall dramatic pieces which have been ſent to muſic. We have different editions of them in 4to, 8vo, and 12mo; and M. Richelet has publiſhed a tranſlation of them into French, in 12 vols, ſmall 12mo.

The greateſt part of Metaſtaſio's writings will confer immortality on their author. His dialogue is natural, ſimple, and eaſy; his ſtyle is always pure and elegant, and ſometimes ſublime and pathetic. His ſubjects are noble, intereſting, and excellently adapted for repreſentation. He was perfectly acquainted with the reſources of his art, and has ſubjected the opera to rules. He ſtripped it of its machinery, and of the marvellous, which was fitted to excite the gaze of aſtoniſhment, but which gave no inſtruction to the underſtanding, and made no impreſſion on the heart. His deſcriptions are copied from nature; the ſituations of his characters never fail to raiſe an intereſt in the reader, and often excite the tear of pity. His fables are celebrated; his characters are noble and well ſupported; his plots are excellently conducted, and happily unravelled. "There are ſcenes (ſays Voltaire) worthy of Corneille when he does not declaim, and of Racine when he is not feeble." His operas, in point of the pathetic, may be compared with our fineſt tragedies; and may be read with great pleaſure, independent of the charms of the muſic. We muſt not, however, expect to find in Metaſtaſio that exact regularity, and that fertile ſimplicity, which conſtitutes the excellence of ſome of our tragic poets: But though he ſometimes tranſgreſſes the unities of time and place, he always preſerves the unity of intereſt. Notwithſtanding all theſe advantages, ſome critics will not allow him the merit of invention, which is the firſt qualification of a poet. They conſider him only as a ſucceſsful imitator of the French tragic writers, from whom a great part of his beauties are borrowed, and place him at the head of the fineſt wits of Italy, but deny that he poſſeſſed genius. He was a fond admirer of the ancients; and this admiration, increaſing with the ſolidity of his underſtanding, continued to the laſt period of his life. He recommended reading them, as he himſelf had done, in a chronological order. His memory was excellent, and continued unimpaired even in old age. Horace was his favourite author, and he could repeat almoſt the whole of him. Metaſtaſio, who, as we have obſerved, was the pupil of the celebrated Gravina, added a gentleneſs of character peculiar to himſelf to the accuracy of thinking and great erudition of his maſter. His abilities and fame were reſpected by the critics in general; and whereas the life of moſt men of letters is one continued warfare, his days happily glided away in tranquillity and peace. The circumſtance which occaſioned the change of his name is thus related in a late anecdote: "Gravina's barber, who, like moſt of his profeſſion, was a great talker, one day informed him, that in the *Place de la Valicella*, where he had his ſhop, a young boy came every evening, and ſung extempore verſes of his own compoſition, ſo harmonious and elegant that all the paſſengers ſtopped to liſten to them. Gravina, upon this information, added one to the number of the young poet's audience, and found the verſes ſo ſuperior to the idea which he had formed of them from the account of the barber, and ſo much above the capacity of a child of ten or eleven years of age, that he inſtantly determined to undertake the cultivation of ſo promiſing a plant. His firſt care was to put the young *Trapaſſi* (which was the boy's name) to ſchool; but apprehending that the ordinary methods of education might check the progreſs of ſo uncommon talents, he took him home to his own houſe, and changed his name into *Metaſtaſio*, which ſignifies the ſame thing in Greek. In ſhort, by a plan of education and by inſtructions ſuited to his genius, Gravina laid the foundation of that reputation which he predicted, and which Metaſtaſio now enjoys." *Vies des Hommes Illuſtres d'Italie, Tom.* I. *p.* 187.

METASTASIS, in medicine, a tranſpoſition or ſettlement of ſome humour or diſeaſe in ſome other part; and ſometimes it ſignifies ſuch an alteration of a diſeaſe as is ſucceeded by a ſolution.

METATARSUS (μετα *beyond*, and ταρσος *the tarſus*), in anatomy, that part of the human ſkeleton containing

 containing the middle of the foot. See ANATOMY, n° 70

METATHESIS, in grammar, a ſpecies of the metaplaſmus; being a figure whereby the letters or ſyllables of a word are tranſpoſed, or ſhifted out of their uſual ſituations, as *piſtris* for *priſtis*, *Lybia* for *Libya*, &c.

This word is, by phyſicians, uſed with reſpect to morbific cauſes, which, when they cannot be evacuated, are removed to places where they are leſs injurious.

METELIN, the modern name of the iſland of Leſbos. See LESBOS and MITYLENE.

In the Iriſh Philoſophical Tranſactions for 1789, we have a deſcription of this iſland by the earl of Charlemont, in which he ſpeaks with raptures of its beauties. "The mountains, whoſe rugged tops exhibit a pleaſing interſperſion of rocks and fine groves, have their green ſides, for many miles along the coaſt, covered with olives, whoſe leſs agreeable verdure is corrected, embelliſhed, and brightened by a lively mixture of bays and laurels aſpiring to the height of foreſt-trees, of myrtles and pomegranates, of arbutes rich at once in bloſſom and in berry, of mulberries growing wild and laden with fruit, &c. Winter is here unknown, the verdure is perpetual, and the frequency of evergreens gives to December the colour of June. The parching heat of ſummer is never felt; the thick ſhade of trees, and thouſands of cryſtal ſprings which every where ariſe and form themſelves into unnumbered rivulets, joined to the refreſhing ſea-breeze the conſtant corrective and companion of noon tide heat, qualify the burning air and render the year a never-ending May. The houſes are conſtructed in ſuch a manner as to have the beſt view of theſe natural beauties. Each is a ſquare tower neatly built of hewn ſtone, ſo high as to overtop the trees, and to command a view of the ſea and neighbouring iſlands. The lower ſtories are granaries and ſtorehouſes; and the habitable apartments are all at the top, to which you aſcend by a ſtone ſtair, built for the moſt part on the outſide, and ſurrounding the tower; ſo that from the apartment the trees are overlooked, and the whole country is ſeen, while the habitations themſelves, which are very numerous, pearing above the groves, add life and variety to the enchanting proſpect, and give an air of human population to theſe woodlands, which might otherwiſe be ſuppoſed the region of Dryads, of Naiads, and of Satyrs."

The moſt remarkable thing, however, in this iſland is a cuſtom by which the women have here openly uſurped thoſe rights of ſovereignty which in other countries are ſuppoſed to belong eſſentially to the men. "Contrary (ſays his lordſhip) to the uſage of all other countries, the eldeſt daughter here inherits; and the ſons, like daughters every where elſe, are portioned off with ſmall dowers, or, which is ſtill worſe, turned out pennyleſs to ſeek their fortune. If a man has two daughters, the eldeſt, at her marriage, is intitled to all her mother's poſſeſſions, which are by far the greater part of the family eſtate, as the mother, keeping up her prerogative, never parts with the power over any portion of what ſhe has brought into the family, until ſhe is forced into it by the marriage of her daughter; and the father alſo is compelled to ruin himſelf by adding whatever he may have ſcraped together by his induſtry. The ſecond daughter inherits nothing, and is condemned to perpetual celibacy. She is ſtyled a *calogria*, which ſignifies properly a religious woman or nun, and is in effect a menial ſervant to her ſiſter, being employed by her in any office ſhe may think fit to impoſe, frequently ſerving her as waiting-maid, as cook, and often in employments ſtill more degrading. She wears a habit peculiar to her ſituation, which ſhe can never change; a ſort of monaſtick dreſs, coarſe, and of a dark brown. One advantage, however, ſhe enjoys over her ſiſter, that whereas the elder, before marriage, is never allowed to go abroad, or to ſee any man, her neareſt relations only excepted, the calogria, except when employed in domeſtic toil, is in this reſpect at perfect liberty. But when the ſiſter is married, the ſituation of the poor calogria becomes deſperate indeed, and is rendered ſtill more humiliating by the compariſon between her condition and that of her happy miſtreſs. The married ſiſter enjoys every ſort of liberty; the whole family fortune is hers, and ſhe ſpends it as ſhe pleaſes; her huſband is her obſequious ſervant; her father and mother are dependent upon her, ſhe dreſſes in a moſt magnificent manner, covered all over, according to the faſhion of the iſland, with pearls and with pieces of gold, which are commonly ſequins; thus continually carrying about her the enviable marks of affluence and ſuperiority, while the wretched calogria follows her as a ſervant, arrayed in ſimple homeſpun brown, and without the moſt diſtant hope of ever changing her condition. Such a diſparity may ſeem intolerable, but what will not cuſtom reconcile? Neither are the misfortunes of the family yet at an end. The father and mother, with what little is left them, contrive by their induſtry to accumulate a ſecond little fortune; and this, if they ſhould have a third daughter, they are obliged to give to her upon her marriage; and the fourth, if there ſhould be one, becomes her calogria; and ſo on through all the daughters alternately. Whenever the daughter is marriageable, ſhe can by cuſtom compel the father to procure her a huſband; and the mother, ſuch is the power of habit, is fooliſh enough to join her in teaſing him into an immediate compliance, though its conſequences muſt be equally fatal and ruinous to both of them. From hence it happens, that nothing is more common than to ſee the old father and mother reduced to the utmoſt indigence, and even begging about the ſtreets, while their unnatural daughters are in affluence; and we ourſelves have frequently been ſhown the eldeſt daughter parading it through the town in the greateſt ſplendor, while her mother and ſiſter followed her as ſervants, and made a melancholy part of her attendant train.

"The ſons, as ſoon as they are of an age to gain a livelihood, are turned out of the family, ſometimes with a ſmall preſent or portion, but more frequently without any thing to ſupport them; and thus reduced, they either endeavour to live by their labour, or, which is more uſual, go on board ſome trading veſſel as ſailors or as ſervants, remaining abroad till they have got together ſome competency, and then return home to marry and to be henpecked Some few there are who, taking advantage of the Turkiſh law, break through this whimſical cuſtom, who marry their calogrias, and

Metelin. retain to themſelves a competent proviſion: but theſe are accounted men of a ſingular and even criminal diſpoſition, and are hated and deſpiſed as conformiſts to Turkiſh manners, and deſerters of their native cuſtoms; ſo that we may ſuppoſe they are few indeed who have the boldneſs to depart from the manners of their country, to adopt the cuſtoms of their deteſted maſters, and to brave the contempt, the deriſion, and the hatred, of their neighbours and fellow-citizens.

"Of all theſe extraordinary particulars I was informed by the French conſul, a man of ſenſe and of indiſputable veracity, who had reſided in this iſland for ſeveral years, and who ſolemnly aſſured me that every circumſtance was true: but indeed our own obſervation left us without the leaſt room for doubt, and the ſingular appearance and deportment of the ladies fully evinced the truth of our friend's relation. In walking through the town, it is eaſy to perceive, from the whimſical manners of the female paſſengers, that the women, according to the vulgar phraſe, *wear the breeches*. They frequently ſtopped us in the ſtreets, examined our dreſs, interrogated us with a bold and manly air, laughed at our foreign garb and appearance; and ſhowed ſo little attention to that decent modeſty which is or ought to be the true characteriſtic of the ſex, that there is every reaſon to ſuppoſe they would, in ſpite of their haughtineſs, be the kindeſt ladies upon earth, if they were not ſtrictly watched by the Turks, who are here very numerous, and would be ready to puniſh any tranſgreſſion of their ungallant laws with arbitrary fines. But nature and native manners will often baffle the efforts even of tyranny. In all their cuſtoms theſe manly ladies ſeem to have changed ſexes with the men. The woman rides aſtride, the man ſits ſideways upon the horſe; nay, I have been aſſured that the huſband's diſtinguiſhing appellation is his wife's family name. The women have town and country houſes, in the management of which the huſband never dares interfere. Their gardens, their ſervants, are all their own; and the huſband, from every circumſtance of his behaviour, appears to be no other than his wife's firſt domeſtic, perpetually bound to her ſervice, and ſlave to her caprice. Hence it is that a tradition obtains in the country, that this iſland was formerly inhabited by Amazons; a tradition, however, founded upon no ancient hiſtory that I know of. Sappho indeed, the moſt renowned female that this iſland has ever produced, is ſaid to have had manly inclinations; in which, as Lucian informs us, ſhe did but conform with the ſingular manners of her countrywomen: but I do not find that the mode in which ſhe choſe to ſhow theſe inclinations is imitated by the preſent female inhabitants, who ſeem perfectly content with the dear prerogative of abſolute ſway, without endeavouring in any other particular to change the courſe of nature; yet will this circumſtance ſerve to ſhow, that the women of Leſbos had always ſomething peculiar, and even peculiarly maſculine, in their manners and propenſities. But be this as it may, it is certain that no country whatſoever can afford a more perfect idea of an Amazonian commonwealth, or better ſerve to render probable thoſe ancient relations which our manners would induce us to eſteem incredible, than this iſland of Metelin. Theſe lordly ladies are for the moſt part very handſome in ſpite of their dreſs, which is ſingular and diſadvantageous. Down to the girdle, which as in the old Grecian garb is raiſed far above what we uſually call the waiſt, they wear nothing but a ſhift of thin and tranſparent gauze, red, green, or brown, through which every thing is viſible, their breaſts only excepted, which they cover with a ſort of handkerchief; and this, as we were informed, the Turks have obliged them to wear, while they look upon it as an encumbrance, and as no inconſiderable portion of Turkiſh tyranny. Long ſleeves of the ſame thin material perfectly ſhow their arms even to the ſhoulder. Their principal ornaments are chains of pearl, to which they hang ſmall pieces of gold coin. Their eyes are large and fine; and the noſe, which we term Grecian, uſually prevails among them, as it does indeed among the women of all theſe iſlands. Their complexions are naturally fine; but they ſpoil them by paint, of which they make abundant uſe; and they disfigure their pretty faces by ſhaving the hinder part of the eyebrow, and replacing it with a ſtraight line of hair neatly applied with ſome ſort of gum, the brow being thus continued in a ſtraight and narrow line till it joins the hair on each ſide of their face. They are well made, of the middle ſize, and for the moſt part plump; but they are diſtinguiſhed by nothing ſo much and ſo univerſally as by a haughty, diſdainful, and ſupercilious air, with which they ſeem to look down upon all mankind as creatures of an inferior nature, born for their ſervice, and doomed to be their ſlaves; neither does this peculiarity of countenance in any degree diminiſh their natural beauty, but rather adds to it that ſort of bewitching attraction which the French call *piquant*."

His lordſhip has been at great pains to inveſtigate the origin of ſuch a ſingular cuſtom; but is unable to find any other example in hiſtory than that of the Lycians, who called themſelves by the names of their mothers, and not of their fathers. When aſked by their neighbours who they were? they deſcribed themſelves by their maternal genealogy. If a gentlewoman ſhould marry a ſlave, the children by that marriage were accounted noble; but ſhould the firſt man among them marry a foreign woman, the children would be accounted ignoble. This cuſtom is mentioned by ſeveral ancient authors. A difficulty of no little magnitude occurs, however, in accounting for the derivation of the inhabitants of Leſbos from the Lycians. This is ſolved in the following manner: In times of the moſt remote antiquity, the iſland of Leſbos was peopled by the Pelaſgi, who, under their leader Xanthus, the ſon of Triopas king of Argos, firſt inhabitated Leſbos: previous to that time they had dwelt in a certain part of Lycia which they had conquered; and in this country we may ſuppoſe they had learned the cuſtom in queſtion. But though this might readily be granted, as we know ſo little of the origin of ancient nations, yet the queſtion ſtill recurs, Whence did it originate among the Lycians? Here we are ſtill more difficulted than before; and the only thing we have to help us out is an obſcure tradition concerning Bellerophon, *viz.* that the hero having deſtroyed a boar which waſted the territory of Xanthus a city of Lycia, the inhabitants were ſo ungrateful as to return him no thanks for ſo great a favour; upon which, by his prayers, he cauſed the curſe of barrenneſs to fall upon them, but was at length

length prevailed upon, by the intreaties of the women, to intercede with his patron Neptune to pardon them. On this account it was decreed, that the people of Xanthus should be called by the names of their mothers and not of their fathers. Plutarch relates also, that Bellerophon not only freed the Lycians from an invasion of pirates, but from the Amazons also, whom he drove out of their country; "so that there may be some reason (says his Lordship) to suppose, that the Lycian women, by an intercourse with the Amazons, who had, it should seem, dwelt among them, were already previously prepared for the introduction of those customs, which were finally established in consequence of their patriotic merit in deprecating the wrath of Bellerophon, and in averting its fatal consequences."

This is the substance of what his Lordship advances to the origin of this extraordinary custom. He owns, that the traces are very obscure; and though he is conscious that such a speculation may be liable to ridicule, and he is aware "of some objections not easy to be answered, the coincidence will notwithstanding be allowed to be curious and very remarkable. The well known pertinacious adherence to ancient manners among the eastern nations, may in some measure excuse our credulity; and we may still add to our authority, by supposing that this same Xanthus may probably have given his name to the Lycian city of that denomination; and consequently must have inhabited that very part of Lycia where, according to Plutarch, he is supposed more immediately to have flourished."

METELLUS, the surname of the family of the Cæcilii at Rome, the most known of whom were ——A general who defeated the Achæans, took Thebes, and invaded Macedonia, &c.—Q. Cæcilius, who rendered himself illustrious by his successes against Jugurtha the Numidian king, from which he was surnamed *Numidicus*.—Another who saved from the flames the palladium, when Vesta's temple was on fire. He was then high priest. He lost his sight and one of his arms in the action; and the senate, to reward his zeal and piety, permitted him always to be drawn to the senate-house in a chariot, an honour which no one had ever before enjoyed. He also gained a great victory over the Carthaginians, &c.—Q. Cæcilius Celer, another who distinguished himself by his spirited exertions against Catiline. He married the sister of Clodius, who disgraced him by her incontinence and lasciviousness. He died 57 years before Christ. He was greatly lamented by Cicero, who shed tears at the loss of one of his most faithful and valuable friends.—L. Cæcilius, a tribune in the civil wars of J. Cæsar and Pompey. He favoured the cause of Pompey, and opposed Cæsar when he entered Rome with a victorious army. He refused to open the gates of Saturn's temple, in which were deposited great treasures; upon which they were broke open by Cæsar, and Metellus retired when threatened with death.—Q. Cæcilius, a warlike general who conquered Crete and Macedonia, and was surnamed *Macedonicus*. He had four sons, of which three were consuls, and the other obtained a triumph, all during their father's lifetime.—A general of the Roman armies against the Sicilians and Carthaginians. Before he marched, he offered sacrifices to all the gods except Vesta; for which neglect the goddess was so incensed, that she demanded the blood of his daughter Metella. When Metella was going to be immolated, the goddess placed a heifer in her place, and carried her to a temple at Lanuvium, of which she became the priestess.—Another, surnamed *Dalmaticus* from his conquest over Dalmatia, A. U. C. 634.—Cimber, one of the conspirators against J. Cæsar. It was he who gave the signal to attack and murder the dictator in the senate-house. —Pius, a general in Spain, against Sertorius, on whose head he set a price of 100 talents and 20,000 acres of land.

METEMPSYCHOSIS, (formed of μετα "beyond," and ἐμψυχω "I animate or enliven"), in the ancient philosophy, the passage or transmigration of the soul of a man, after death, into the body of some other animal.

Pythagoras and his followers held, that after death mens souls passed into other bodies, of this or that kind, according to the manner of life they had led. If they had been vicious, they were imprisoned in the bodies of miserable beasts, there to do penance for several ages; at the expiration whereof, they returned afresh to animate men. But, if they lived virtuously, some happier brute, or even a human creature, was to be their lot.

What led Pythagoras into this opinion was, the persuasion he had that the soul was not of a perishable nature: whence he concluded that it must remove into some other body upon its abandoning this. Lucan treats this doctrine as a kind of officious lie, contrived to mitigate the apprehension of death, by persuading men that they only changed their lodging, and only ceased to live to begin a new life.

Reuchlin denies this doctrine; and maintains that the metempsychosis of Pythagoras implied nothing more than a similitude of manners, desires, and studies, formerly existing in some person deceased, and now revived in another alive. Thus when it was said that Euphorbus was revived in Pythagoras, no more was meant than that the martial virtue which had shone in Euphorbus at the time of the Trojan war, was now, in some measure, revived in Pythagoras, by reason of the great respect he bore the *athletæ*. For those people wondering how a philosopher should be so much taken with men of the sword, he palliated the matter, by saying, that the soul of Euphorbus, *i. e.* his genius, disposition, and inclinations, were revived in him. And this gave occasion to the report, that Euphorbus's soul, who perished in the Trojan war, had transmigrated into Pythagoras.

Ficinus asserts, that what Plato speaks of the migration of a human soul into a brute, is intended allegorically, and is to be understood only of the manners, affections, and habits, degenerated into a beastly nature by vice. Serranus, though he allows some force to this interpretation, yet inclines rather to understand the metempsychosis of a resurrection.

Pythagoras is said to have borrowed the notion of a metempsychosis from the Egyptians; others say, from the ancient Brachmans. It is still retained among the Banians and other idolaters of India and China; and makes the principal foundation of their religion. So extremely are they bigotted to it, that they not only

Metemptosis. forbear eating any thing that has life, but many of them even refuse to defend themselves from wild beasts. They burn no wood, lest some little animalcule should be in it; and are so very charitable, that they will redeem from the hands of strangers any animals that they find ready to be killed. See PYTHAGOREANS.

METEMPTOSIS (from μετα "post," and πιπτω *cado* "I fall,") a term in chronology, expressing the solar equation, necessary to prevent the new moon from happening a day too late. By which it stands contradistinguished from *proemptosis*, which signifies the lunar equation, necessary to prevent the new moon from happening a day too soon.

The new moons running a little backwards, that is, coming a day too soon at the end of 312 years and a half; by the proemptosis, a day is added every 300 years, and another every 2400 years: on the other hand, by the metemptosis, a bissextile is suppressed each 134 years; that is, three times in 400 years. These alterations are never made but at the end of each century; that period being very remarkable, and rendering the practice of the calendar easy.

There are three rules for making this addition or suppression of the bissextile-day, and, by consequence, for changing the index of the epacts. 1. When there is a metemptosis without a proemptosis, the next following, or lower index, must be taken. 2. When there is a proemptosis without a metemptosis, the next preceding or superior index is to be taken. 3. When there are both a metemptosis and a proemptosis, or when there is neither the one nor the other, the same index is preserved. Thus, in 1600, we had D: in 1700, by reason of the metemptosis, C was taken: in 1800, there will be both a proemptosis and a metemptosis; so the same index will be retained. In 1900, there will be a metemptosis again, when B will be taken; which will be preserved in 2000, because there will then be neither the one nor the other. This is as far as we need compute for it: but Clavius has calculated a cycle of 301800 years; at the end of which period, the same indices return in the same order. See EPACT.

Meteorology. METEOR, (by the Greeks called μετεωρα, q. d. *sublima* or "high raised;" by the Latins *impressiones*, as making signs or impressions in the air), commonly denotes any bodies in the air that are of a flux or transitory nature. Hence it is extended to the phenomena of hail, rain, snow, thunder, &c.; but is most commonly confined to those unusual and fiery appearances named *falling-stars*, *ignes fatui*, *auroræ boreales*, &c. whether they appear at a great distance from the earth or not. See METEOROLOGY.

METEOROLOGICAL, something belonging to meteors.

METEOROLOGICAL Journal, is a table recording the daily state of the air, exhibited by the barometer, thermometer, hygrometer, anemometer, and other meteorological instruments. We have many journals of this kind, kept at the house of the Royal Society, and by different observers in other places, in the Philosophical Transactions, the Memoirs of the Academy of Sciences, and similar publications.

METEOROLOGY;

THAT science which investigates the phenomena of our atmosphere * (commonly called *meteors*), giving an account of the circumstances attending each, and explaining the causes from whence they arise.

* See *Atmosphere.*

1 Meteors, how divided. In considering this science, we find the objects of it naturally divided into two classes, *viz.* those which rise high in the heavens, seemingly without any connection with this earth; and others which are more particularly connected with the earth, or are perceptible only in the lower regions of the atmosphere. The former, which may properly be called *celestial meteors*, are only three in number, *viz.* the large fire-balls, falling stars, and aurora borealis. The second class is much more numerous; including the phenomena of the ordinary winds, rain, hail, snow, clouds and vapours of all kinds, thunder and lightning, hurricanes, whirlwinds, water-spouts, ignes fatui, and other wandering luminous appearances; not excepting the various changes of the atmosphere itself, with regard to its specific gravity, rarefaction, heat, and moisture, as indicated by the barometer, thermometer, and hygrometer.

2 Difficulties attending the subject. To treat of all these in a satisfactory manner, it is plain that we ought to have an intimate acquaintance with the constitution of the atmosphere; with the nature of those powerful agents by which it appears to be principally influenced, *viz.* fire, light, and electric fluid; and with their peculiar modes of operation and action upon one another and upon the atmosphere, and this in every possible variety of circumstances. Nor is even all this sufficient: The various phenomena of rain, wind, snow, thunder, heat, cold, &c. are known to depend very much upon the situation of different places on the surface of the earth; and their occasional variations are with great reason *suspected* to proceed, partly at least, from changes which take place in the bowels of the earth *: whence a meteorologist ought not only to be perfectly well acquainted with geography, but with mineralogy also; and that to an extent at which human knowledge will probably never arrive.

* See *Earth*.

In a science so very difficult, it is not to be supposed that any thing like a certain and established theory can be laid down: our utmost knowledge in this respect goes no farther as yet than to the establishment of a few facts; and in reasoning even from these, we are involved every moment in questions which seem scarcely within the compass of human wisdom to resolve.

3 Causes probably concerned. In considering the subject of meteorology, it will readily be admitted, that the whole atmospherical phenomena depend some how or other upon the action of the sun upon the earth, and the annual and diurnal revolutions of the latter. As these causes, however, are always invariably the same, why do we not find the same regularity in meteors that we do in other phenomena of nature? The eclipses of the sun and moon, for instance, which depend on the different po-

ſitions of the earth and moon with regard to the great luminary, are found to follow a certain and regular courſe; ſo that the very ſame eclipſes, both as to quantity and duration, which happened before will happen again. But with meteors the caſe is quite different. Moſt of the atmoſpherical phenomena are ſo various and uncertain, that no perſon can pretend to reduce them to any kind of rule. Every ſucceeding year, for inſtance, differs in a vaſt number of particulars from that which preceded it, even in ſuch as are the moſt ſimilar to one another. Sometimes we find a number of years ſucceſſively ſimilar to one another, and another ſet quite different taking place immediately after them; and ſome have even fancied that this ſucceſſion took place every 19 years, nearly the time of the revolution of the moon's nodes, though the obſervations on which this opinion is built are far from being ſufficient to eſtabliſh it: at any rate, the diſſimilarity between the phenomena of different years may ſufficiently warrant us to conclude, that other cauſes beſides the regular action of the ſun and revolution of the earth are concerned. Some of theſe cauſes may be ſuppoſed to be fermentations and other commotions within the bowels of the earth itſelf; but as all fermentation is a regular proceſs, and takes place only in certain circumſtances, of which heat is a very conſiderable one, why is there not annually a certain quantity of this fermentation excited, and why are not regular effects obſerved in proportion? It does not indeed appear, that the immenſe variety which occurs in meteorological appearances can by any means be accounted for but by the interference of ſome cauſes in their own nature *irregular*; that is, capable of ſuch endleſs variety, that no aſſignable ſpace of time is ſufficient to exhauſt it. Theſe cauſes, as they cannot be proved to exiſt either on the ſurface of the earth or in its internal parts, muſt be ſought for in the celeſtial expanſe itſelf. Sir Iſaac Newton ſuppoſed the planets to be influenced by the comets, and that from the tails of the latter ſome of the finer parts of our atmoſphere were produced. He even ſuppoſed, that from theſe bodies a quantity of water, imagined to be waſted in the various operations of nature, might be ſupplied. But if it is not unreaſonable to ſuppoſe that *comets* anſwer ſome ſuch purpoſes in nature, it is as little unreaſonable to think that the *planets* may influence the atmoſpheres of one another. That this muſt be the caſe indeed is very probable, not only on account of the light they reflect upon one another, but alſo by reaſon of their ſpheres of mutual attraction, which extend an immenſe way, and are ſo powerful in the planets Jupiter and Saturn, that they diſturb the motions of each others ſatellites as they paſs. But beſides even theſe cauſes, if we allow them to be ſuch, there are others which take place in the immenſe void betwixt the celeſtial bodies, and which has with great impropriety been determined an abſolute vacuum. That changes do take place in this ſpace, is evident from what is related of the temporary diſappearance of ſome of the ſatellites of Saturn, and their ſudden re-appearance, without any perceptible change in our atmoſphere ſo as to affect our view of other celeſtial objects. It may appear ridiculous to think, that a change in ſuch diſtant regions ſhould have any influence upon the atmoſphere of the earth; but we muſt remember, that if the univerſe is connected together as one vaſt ſyſtem, which we have every reaſon to believe, it is as impoſſible that a change can take place in any part without affecting the whole in ſome degree, as it is impoſſible to change any part of a clock or watch without in ſome meaſure affecting the whole movement.

5
Or in the ſun.

But of all the changes which take place in the celeſtial regions, thoſe which affect the ſun ſeem moſt likely to produce changes in our atmoſphere, and to be the hidden cauſe of many meteorological phenomena. That the ſun is not exempt from thoſe changes, is evident from the ſpots which are always or for the moſt part to be ſeen on his diſk when viewed through a teleſcope. It has been obſerved in ſome years, that the ſun has ſeemed to loſe his influence, and even to the naked eye appeared much dimmer than uſual. In ſuch caſes it is impoſſible but our atmoſphere, and even the whole ſolar ſyſtem, muſt have been affected; and not only muſt the ſeaſons for the preſent time have felt the malign influence of thoſe ſpots, but the atmoſphere itſelf may have acquired ſuch a diſpoſition as to produce ſeaſons of a peculiar nature for a number of years afterwards. If it be true, according to the hypotheſis of ſome, that the ſun is ſupplied with fuel by comets falling into his body, it is plain that every new acceſſion of this kind muſt have a proportionable effect upon all the bodies expoſed to his light. If the comets do not perform any ſuch office, ſtill it is very probable that they anſwer ſome purpoſes to the planets, becauſe they are never ſeen without the planetary regions: and though their influence be not immediately perceptible, it is impoſſible to prove that they have none, nor indeed is it probable that they have not; for we are very certain, that the influence of any object extends as far as its light, and how much farther we cannot tell. Conſidering the matter in this view, therefore, there is not a ſpot which can obſcure the ſun, a comet that can appear in the celeſtial regions, a planet that can approach the earth, nor perhaps a belt or ſpot which can take place on Mars, Jupiter, or Saturn, which may not be productive of important changes in our atmoſphere, and affect the meteors produced by it in many different ways.

6
Action of the ſun, moon, and planets, concerned.

It would no doubt be an error to have recourſe to ſo many obſcure cauſes, were there any plain and obvious ones from whence the phenomena could be deduced. But the endleſs variety of meteors which occur throughout every part of the globe, plainly ſhow that the cauſes, whatever they are, muſt be infinitely varied alſo. The principal one is no doubt the action of the ſun upon the earth and atmoſphere in its various poſitions: but this is regular; and, did nothing elſe interfere, would produce regular effects. Secondary cauſes probably are the action of the moon and planets: but theſe alſo are regular, though much more diverſified than the former: ſo that we are at laſt obliged to have recourſe to cauſes ſtill more obſcure and remote, as comets, ſpots on the ſun, and changes taking place in the etherial fluid which pervades the whole celeſtial expanſe. Theſe we muſt either aſſign as the remote cauſes of the phenomena of our atmoſphere,

ſphere, or admit others equally obſcure; or we muſt be contented to own our ignorance, as indeed muſt at all events be frequently the caſe.

But though, to ſatisfy ourſelves, ſuch conjectures may occaſionally be indulged, it is not from them that we are to derive any of the regular phenomena of nature; for theſe are evidently owing to the ſettled and eſtabliſhed action of heat, light, and electric matter, which have already been enumerated as the great powers influencing, and indeed in a great meaſure forming, the ſubſtance of our atmoſphere. The moſt remarkable effects of theſe are,

7 Evaporation a principal cauſe of meteors.

I. *Evaporation.* This, which is the principal cauſe of almoſt all the meteors of our atmoſphere, may be reckoned in a more particular manner the effect of heat. Upon this principle it is explained under the article CHEMISTRY, where vapour is ſhown to be a compound of water and fire; and ſuch it is ſuppoſed to be by M. de Luc, in his Treatiſe on Meteorology, as well as by other philoſophers of the higheſt rank.

8 Natural evaporation different from artificial.
