PHOSPHORUS, a name given to certain ſubſtances which ſhine in the dark without emitting heat. By this circumſtance they are diſtinguiſhed from the *pyrophori*, which though they take fire on being expoſed to the air, are yet entirely deſtitute of light before this expoſure.

2 Divided into various kinds.

Phoſphori are divided into ſeveral kinds, known by the names of *Bolognian phoſphorus*, *Mr Canton's phoſphorus*, *Baldwin's phoſphorus*, *phoſphorus of urine*, &c. of which the laſt is by far the moſt remarkable both with reſpect to the quantity of light which it emits, and its property of taking fire and burning very fiercely upon being ſlightly heated or rubbed. For the method of preparing theſe, ſee *CHEMISTRY-Index*.

Beſides theſe, however, it has been found that almoſt all terreſtrial bodies, upon being expoſed to the light, will appear luminous for a little time in the dark, metals only excepted. This points out a general diviſion of the phoſphori into two claſſes; namely, ſuch as require to be expoſed to the light either of the ſun or of ſome artificial fire, before they become luminous; and ſuch as do not. Of the former kind are the Bolognian phoſphorus, Mr Canton's phoſphorus, the phoſphori from earths, &c. Of the latter kind are rotten wood, the ſkins of fiſhes, and the phoſphorus of urine. To theſe we may add ſome other ſubſtances which become luminous in another way; *viz.* the maſs which remains after the diſtillation of volatile ſal ammoniac with chalk, loaf-ſugar, and the phoſphorus of urine diſſolved in ſpirit of wine. The firſt, which is a compoſition of the marine acid of the ſal ammoniac with the chalk, after being fuſed in a crucible, becomes luminous when

3 Divided into two claſſes.

ſtruck with any hard body; white ſugar is luminous when grated or ſcraped in the dark; and the ſolution of phoſphorus in ſpirit of wine is luminous only when dropped into water; and even then the light is only perceived where the drops fall into the liquid. One part of phoſphorus communicates this property to 600,000 parts of ſpirit of wine. Phoſphorus

4 Remarkable difference between the phoſphoric bodies.

There is a remarkable difference between the light of rotten wood, fiſhes, and that of phoſphorus of urine, even when it is not in an ignited ſtate; for this laſt does not ceaſe to be luminous even when included within an exhauſted receiver; the contrary of which happens to rotten wood and fiſhes. If air is ſtrongly blown upon this phoſphorus from a pair of bellows, it will extinguiſh its light for ſome time, which is not the caſe with the other kinds. When kept in water, and placed in a warm air, the phoſphorus of urine diſcharges ſuch large and bright flaſhes into the air above it, as are apt to ſurpriſe and even frighten thoſe who are unacquainted with it. Theſe coruſcations are contracted in their paſſage through the water, but expand as ſoon as they get above it; however, the experiment can only be tried to advantage in warm weather, and in a cylindrical glaſs not above three quarters filled with water.

5 Phenomena of earthy phoſphori.

The phenomena exhibited by the earthy phoſphori are very curious; both on account of the ſingular circumſtances in which they exhibit their light, and the varieties obſerved in the light itſelf. All theſe, as has been already mentioned, emit no light till they have been firſt expoſed to the light of the ſun, or ſome other luminous body. After that, they are luminous in the dark for a conſiderable time; but by degrees their light dies away, and they emit no more till after another expoſure to the ſun. But if this happens to be too long continued, they are then irrecoverably ſpoiled. The ſame thing will happen from being too much heated without any expoſure to light. Indeed, if a phoſphorus, which has juſt ceaſed to be luminous, be heated, it will again emit light without any expoſure to the ſun; but by this its phoſphoric quality is weakened, and will at laſt be deſtroyed. Indeed theſe phoſphori are ſo tender, and impatient either of light or heat, that the beſt method of rendering them luminous occaſionally is by diſcharging an electric bottle near them. The light of the flaſh immediately kindles the phoſphorus, and it continues luminous for a conſiderable time, after which it may again be revived by another flaſh, and ſo on. However, with all the care that can be taken, theſe phoſphori are very far from being perpetual; nor has any method been yet fallen upon to render them ſo.

The ſingularities in the light of the phoſphori above-mentioned are, that they emit light of many different and moſt beautiful colours. This difference of colours ſeems to be natural to them; for ſome will at firſt emit a green, others a red, others a violet, &c. at their formation. However, the beſt kinds agree in this ſtrange property, that if they are expoſed to a red light, they emit a red light in the dark; and the ſame of other colours. But this muſt not be underſtood without limitation; nor is the phoſphoreal light at any time ſo bright as the luminous body, whatever it was, by which it was kindled. Neither are we to imagine, that any particular phoſphorus has a particu-

Phofphorus. lar kind of light appropriated to it; for the ſame phoſphorus which at one time emits a purple light, will at another perhaps emit a green, or a light of ſome other colour.

6 The nature of the ſpecific phenomena explained.

The explanation of the principal phenomena of phoſphorus is deducible from what has been ſhown concerning the nature of fire, compared with what is mentioned under the article QUICKLIME. Under this laſt article it is ſhown, that, when calcareous earths are deprived of their fixed air, a proportionable quantity of active fire is abſorbed by them; that is, the etherial fluid which pervades all bodies, has a violent tendency to expand itſelf, or to act all around every particle of the calcined earth, as from a centre. Of conſequence, if this tendency was not counteracted by ſome other power, theſe ſubſtances would emit a perpetual flame. This power, however, is found in our atmoſphere; which has already been ſhown either to be the poſitive principle of cold, or to contain it†. Hence, the latent fire in theſe ſubſtances is checked, and cannot act, excepting within the very ſubſtance itſelf. But if any other body comes in contact with the calcined earth, in which the principle of cold is leſs vigorous than in the atmoſphere, the active fire in the quicklime immediately ſhows itſelf, and the body either becomes hot, or is conſumed as if by fire. Hence it will follow, that if a very inflammable body is touched by quicklime, it ought to be ſet on fire. But of this we have no inſtance, becauſe it is impoſſible for the quicklime to part with any of its fire, unleſs it receives ſomething in exchange. This indeed it might receive from the atmoſphere; which could ſupply it either with more fire, if it was in a ſtate of ignition; or with fixed air, if any ſubſtance was at hand to receive the fire. But the atmoſphere refuſes to part with the fire which it contains, becauſe the effort of the fire in the quicklime is not ſufficiently ſtrong to overcome the oppoſition it meets with in other bodies; and, on the other hand, the effort of the fire in the quicklime is ſufficient to keep the earth from attracting fixed air out of the atmoſphere. But when water, for inſtance, is poured on the quicklime, the dry earth abſorbs it very greedily, and parts with a proportionable quantity of its latent fire, which the water alſo abſorbs much more readily than the atmoſphere. Hence the mixture becomes ſo exceedingly hot as ſometimes to fire combuſtible bodies. Now if, inſtead of water, we ſuppoſe the lime to be mixed with oil, this alſo will abſorb the fire, but not with ſuch force as the water; neither is the heat by any means ſo conſiderable; becauſe oil is capable of detaining a vaſt quantity of heat in a latent ſtate, the only conſequence of which is an increaſe of its fluidity, without any very perceptible change of temperature. At the ſame time, however, we muſt remember, that if the oil is in very ſmall quantity, and intimately combined with the quicklime in that peculiar ſtate which was formerly called *phlogiſton*, it is eaſy to conceive, that it may be ſo much ſaturated with fire, as to be unable to contain any more without being ignited. In this caſe, if more fire is forced into the compound, a quantity of the phlogiſtic matter which it contains will be decompounded; and of conſequence, the fire which it has imbibed will be thrown out, as in the common ignition of vapour; and in proportion to the degree of heat thus communicated, will the degree of ignition and the continuance of it be. If the quantity of heat is very great, the phlogiſton will be diſſipated all at once; but if otherwiſe, the ignition will continue for a much greater length of time, as is the caſe with a common fire.

† See the article GOLD.

Phoſphorus.

7 The compoſition of different phoſphori.

To apply this to the accenſion of phoſphori, we muſt conſider that theſe ſubſtances are all formed by calcining calcareous ſubſtances, and combining them with ſome portion of phlogiſtic matter. Baldwin's phoſphorus is made by diſſolving chalk in the nitrous acid, afterwards evaporating the ſolution, and driving off moſt of the acid. The conſequence of this is, that the earth is left in an exceedingly cauſtic ſtate, as the acid expels the fixed air more completely than could be done almoſt by any calcination whatever; at the ſame time that any phlogiſtic matter which might have been contained in the mixture is moſt accurately diffuſed through it, and combined with it. The Bolognian phoſphorus is compoſed of a gypſeous earth, which contains a quantity of vitriolic acid; and as no mineral is to be found perfectly free from phlogiſtic matter, the vitriolic acid unites with it during the calcinaton into an exceedingly inflammable ſulphur; for the greater the quantity of acid there is in proportion to the phlogiſton, the more inflammable is the compound *. Thus the Bolognian, as well as Baldwin's phoſphorus, is a compound of quicklime and inflammable matter; and the caſe is ſtill more plain with regard to Mr Canton's, where the quicklime is mixed with ſulphur, and both calcined together.—Neither are the phoſpheri made by calcining oyſter-ſhells without addition to be accounted any way different from thoſe already mentioned; ſince the ſhells always contain ſome portion of inflammable matter, which, being reduced to a coal by the action of the fire, furniſhes a quantity of phlogiſton, and imparts it to the whole of the calcareous matter.

* See the article SULPHUR.

8 State of the phlogiſton

Having thus ſeen that the phoſphori of which we now ſpeak are all compoſed of pure calcareous earth and phlogiſton, we are next to conſider, that the phlogiſton muſt be in ſuch a ſtate as it is when ſaturated with fire and ready to inflame. It is not indeed in the ſtate of vapour, becauſe this would require a quantity of fire detached from any other ſubſtance, and interpoſed between the particles of the vapour, in order to keep them at a diſtance, or to give it elaſticity. But the fire which ought to do this is confined by the calcareous earth, which alſo detains the phlogiſton itſelf. As long therefore as the balance is thus preſerved, the phoſphorus cannot ſhine; but as ſoon as a freſh quantity of light is diſcharged upon it, then more light or fire (for they are the very ſame in this caſe) enters the quicklime than it can contain. The conſequence of this is, that the quantity which cannot be retained by the earth, exerts its force upon the phlogiſton; which having already as much as it can hold, not only the ſuperfluous quantity is diſcharged, but alſo part of that which the phlogiſton had abſorbed before. The burning indeed is very ſlow and weak, becauſe the phlogiſton is obſtinately retained by the earth, which both impedes the ignition, and prevents the diſſipation of the phlogiſton in vapour. However, as ſoon as the lime has by its action impeded the farther extrication of the phlogiſton, the balance is reſtored, the fire goes out, and the phoſphorus ceaſes to be luminous. Heat

will kindle it again; but thus a larger quantity of phlogiſtic matter is diſſipated, and the phoſphorus is ſoon deſtroyed. Light does the ſame, but in a much more moderate degree; and therefore the phoſphorus may be frequently rekindled by means of light, and will continue its ſplendor for a long time. But if the light is too long continued, or too violent, it will produce the ſame conſequence whether it is attended with perceptible heat or not.

With regard to the phoſphorus of urine, the caſe is the ſame; only, inſtead of the calcareous earth, we have here an acid joined with phlogiſton. The latter is in exceeding ſmall quantity, and of conſequence ſo loaded with fire that the leaſt additional heat, rubbing, or alteration in the weather, forces more fire upon it than it can bear, and therefore part of it is continually flaſhing off in thoſe coruſcations formerly mentioned. The reaſon why this phoſphorus flaſhes like lightning, and the others give only a ſteady light like coals, is, that the compound is very volatile. It requires indeed a violent fire to diſtil it at firſt; but in the diſtillation ſo much fire is imbibed, that it ſeems ever afterwards ready to evaporate ſpontaneouſly; and therefore phoſphorus, when once made, is eaſily redi-ſtilled in cloſe veſſels.

It now remains only to ſhow the reaſon why the phoſphorus of urine and ſome others will ſhine under water, or in an exhauſted receiver, while rotten wood, &c. will not. This ſeems to ariſe from the quantity of fire which they have *internally*, and which requires no ſupply from the external air, as in the caſe of common fire: and hence the phoſphorus of urine ſhines more briſkly *in vacuo* than in the air; becauſe the preſſure of the atmoſphere is then taken off, and the evaporation of the phlogiſtic matter promoted. The light of fiſhes and rotten wood ſeems to be of an electric nature; and therefore ceaſes when the air is exhauſted, as on this fluid all the phenomena of electricity are found to depend.

With regard to the various colours of phoſphoric light, ſome have imagined that the earthy ſubſtance was capable of imbibing a certain quantity of light, and emitting it afterwards in the very ſame ſtate, and having the ſame colour which it had before. But this is now known to be a miſtake, and the light of the phoſphori is found to be owing to a true acenſion, though weak, as in other burning bodies. Hence it is very probable that the colour of the light depends upon the degree of accenſion; for we ſee that even in common fires the colour depends in a great meaſure on the ſtrength of the flame. Thus the flame of a candle, where it is not well kindled at bottom, always appears blue. The flame of a ſmall quantity of ſulphur, or of ſpirit of wine, is blue; but if a large quantity of either of theſe ſubſtances be ſet on fire, the flame will in many places appear white. A ſtrong flame mixed with much ſmoke appears red; a weak one in ſimilar circumſtances appears brown, &c.—Hence if the phoſphoric is weakly kindled it will emit a brown, violet, blue, or green flame; if ſtrongly, a red or white one.

It has already been mentioned, that almoſt all terreſtrial bodies have a phoſphoric quality: however this, in moſt of them, is extremely weak, and continues only for a very ſhort time. Signor Beccaria, who diſcovered this property, in order to find out what ſubſtances were phoſphoric and what were not, had a machine contrived like a dark lanthorn, in which he included himſelf, in order to perceive with the greater facility any ſmall quantity of light which might be emitted by the ſubſtances which he deſigned to examine. In the ſide of the machine was a cylinder capable of being turned about without admitting any light. Upon this were paſted the ſubſtances he deſigned to examine, and by turning the cylinder he immediately brought them from the light of the ſun into intenſe darkneſs; in which ſituation there were but few ſubſtances which did not afford a ſufficient quantity of light to render themſelves viſible. This phenomenon, however, is evidently ſimilar to an optical illuſion by which we are made to ſee what is not preſent before us; for if we look very intenſely upon any thing for ſome time, ſuffering no more light to enter our eyes than what is reflected from that object, we will imagine that we ſtill ſee it, though we remove into the dark or ſhut our eyes. The reaſon of this is, that the nervous fluid being once put in motion after a certain manner, continues that motion for a ſhort ſpace of time after the moving cauſe is removed. In like manner, as the light is partly reflected from bodies, and partly penetrates them, when any body is expoſed to the light, and then is ſuddenly brought into a dark place, the etherial fluid within its ſubſtance being once put into motion does not ceaſe to move immediately, but for a time produces that vibration which we call *light*; for the ſubſtance of light is preſent in the moſt intenſe darkneſs as well as in ſunſhine. Hence almoſt all ſubſtances are capable of emitting light in the dark, after being expoſed to a vigorous ſunſhine; though the reaſon of their doing ſo may be very different from that by which the phoſphori become luminous.

Many entertaining experiments may be made with the various kinds of phoſphori, eſpecially with that of urine. This laſt, however, is ſometimes dangerous on account of the violence with which it burns. If diſſolved in oil of cloves, it loſes this property, but continues to be as luminous as before; ſo that this mixture, called *liquid phoſphorus*, may be uſed with ſafety. As on ſome occaſions it may be wiſhed to have it in powder, it is proper to obſerve that this may be done with ſafety by pouring ſome hot water upon the phoſphorus in a glaſs mortar. The compound melts, and while in a ſoft ſtate is eaſily reducible to powder of any degree of fineneſs.

Mr Margraff endeavoured to combine phoſphorus with metals by diſtillation; but zinc and copper were the only two metals that ſhowed any ſigns of combination (See CHEMISTRY, n° 1413.) The great analogy, however, that has been obſerved between the properties of phoſphorus and thoſe of ſulphur and arſenic, induced M. Pelletier long ago to ſuſpect, that phoſphorus would really combine with metals, and that the eſſential point was to retain the phoſphorus in contact with the metal in a ſtate of fuſion. This happy idea led him to a method from which he has obtained all the ſucceſs that could be deſired. Of this we have already given a very contracted account after the word *Phoſ-*

Phoſphorus. *phorus* in the *Index* to our article CHEMISTRY; we ſhall now extend that account, by giving that in the firſt volume of *Annals of Chemiſtry*.

"Each of the combinations which are now to be deſcribed, M. Pelletier has termed *phoſphorated metal*.

15 Phoſphoret of gold. "M. Pelletier mixed half an ounce of gold of parting, in powder, with an ounce of phoſphoric glaſs and about a dram of powdered charcoal; he put this mixture into a crucible, covering it with a ſmall quantity of charcoal powder; and then applied a degree of heat ſufficient to melt the gold. During the operation, a conſiderable quantity of vapours of phoſphorus was diſengaged, but all the phoſphorus which was produced was not diſſipated; a ſmall quantity united with the gold, which was whiter than in its natural ſtate, broke under the hammer, and had alſo a cryſtallized appearance.

"Twenty-four grains of this phoſphoret of gold, placed on a cupel in a heated muffle, loſt only one grain, and the button of gold that remained had the peculiar colour of that metal.

16 Of Platina. "A mixture, conſiſting of an ounce of platina, an ounce of phoſphoric glaſs, and a dram of powdered charcoal, being put into a crucible, and covered with a little charcoal powder, M. Pelletier gave it a degree of heat nearly equal to what would have fuſed gold: this he continued for an hour. Having broken the crucible, he found underneath a blackiſh glaſs a ſmall button of a ſilver white, weighing more than an ounce. On the inferior part of the button were well defined cryſtals of the ſame ſubſtance, the figure of which was a perfect cube. The ſame experiment, frequently repeated, conſtantly afforded the ſame reſult.

"The phoſphoret of platina is very brittle, pretty hard, and ſtrikes fire with ſteel: it is not acted upon by the magnet, and when it is expoſed naked to a fire capable of fuſing it, the phoſphorus is diſengaged, and burns on its ſurface. Expoſed to the fire in a cupelling furnace on porcelain teſts, the phoſphoret of platina leaves a black glaſs, which ſurrounds the metallic ſubſtance. The colour of the glaſs is owing to iron contained in the platina; and if it continue expoſed to the ſame heat in freſh teſts, the portions of glaſs that form latterly have not ſo deep a colour, are more or leſs greeniſh, have ſometimes a bluiſh tinge, and become at laſt of a tranſparent white. This obſervation led M. Pelletier to imagine, that phoſphorus was well adapted for ſeparating iron from platina, and that it was one of the beſt means of ſeparating it entirely from that metal. But the glaſs which reſults from the combuſtion of the phoſphorus and its combination with the *oxyd* (calx) of iron, forms a cruſt which obſtructs the combuſtion of the phoſphorus that ſtill remains combined with the platina. To overcome this obſtacle, M. Pelletier thought of expoſing the phoſphoret of platina to the fire, in cupels made of calcined bones, which, as they eaſily abſorb the glaſs of lead, ought alſo to have the property of abſorbing the phoſphoric glaſs. He repeated the operation, therefore, ſeveral times ſucceſſively, changing the cupel. A button of platina, which had been thus operated on four times, he preſented to the academy: in this ſtate it was capable of being reduced into plates, but was brittle when heated.

"Since the reading of his memoir, M. Pelletier has purſued his proceſs, and has advanced ſo far as to be able totally to free the platina from the phoſphorus, ſo that it may be worked when heated: thus he has procured us a method of purifying this metal more advantageous probably than any hitherto attempted. The phoſphoret of platina detonates ſtrongly when it is thrown on nitre in fuſion. A mixture of phoſphoret of platina, and oxygenated muriat of potaſh (*dephlogiſticated digeſtive ſalt*), thrown into a red hot crucible, produces a briſk detonation, and the platina remains pure in the crucible. Phoſphorus.

17 Of ſilver. "Half an ounce of ſilver, treated with an ounce of phoſphoric glaſs and two drams of charcoal, acquired an increaſe of weight of one dram. The phoſphoret formed was white: it appeared granulated, and as it were cryſtallized: it broke under the hammer, but was capable of being cut with a knife. Placed in a cupel in a heated muffle, the phoſphorus was diſengaged, and the ſilver remained quite pure.

18 Of copper. "In preparing phoſphorus in the large way, M. Pelletier obſerved, that the phoſphoric acid attacked in ſome degree the copper baſons, which are in other reſpects very convenient for this operation; and in the retorts which he made uſe of for the diſtillation, he found phoſphoret of copper, ſometimes in ſmall diſtinct grains, at others in large maſſes, according as the degree of heat which finiſhed the operation was more or leſs intenſe. This phoſphoret he exhibited to the academy, and thence it was mentioned in the chemical nomenclature. The phoſphoret of copper is alſo obtainable by a proceſs ſimilar to that which we have deſcribed for obtaining that of gold, ſilver, and platina. The proportions which M. Pelletier employed were an ounce of ſhreds of copper, an ounce of phoſphoric glaſs, and a dram of powdered charcoal. This phoſphoret appears whitiſh, is ſometimes variegated with the different colours of the rainbow; changes on expoſure to the air like pyrites, loſes its luſtre, and aſſumes a blackiſh hue.

"Margraff had formed phoſphoret of copper by diſtilling the oxyd of copper, called *crocus veneris*, with phoſphorus; and M. Pelletier alſo obtained it by the ſame proceſs: but he did not obſerve the property attributed to it by Margraff, of running when applied to a candle. Having placed the phoſphoret in a cupel in a heated muffle, it was fuſed, the phoſphorus inflamed on its ſurface; a blackiſh ſubſtance reſembling ſcoriæ remained in the cupel, which was penetrated with a glaſs that gave it a blue colour.

"The phoſphoret of iron produced by the fuſion of an ounce of phoſphoric glaſs, and an ounce of ſhreds of iron, mixed with half a dram of powdered charcoal, was very brittle, and broke white, with a ſtriated and granulated appearance: in one cavity it was cryſtallized in rhomboidal priſms. It is the ſame ſubſtance which Bergman conceived to be a peculiar metal.

"This phoſphoret, placed in a cupel in a heated muffle, ſoon entered into a ſtate of fuſion; in the cupel remained a brittle ſubſtance, which is an oxyd of iron, and the cupel was penetrated with a matter ſimilar to that which M. Pelletier had obſerved on treating in the ſame manner phoſphoret of platina, obtained from platina not purified.

"The

Phoſphoret

"The phoſphoret of lead, obtained by the proceſs already deſcribed, appears little different from common lead. It is malleable, and eaſily cut with a knife, but it loſes its luſtre ſooner than lead, and when melted on charcoal by the blow-pipe, the phoſphorus burns, leaving the lead behind.

19 Of lead.

20 Of tin.

"The phoſphoret of tin, which M. Pelletier obtained by his proceſs, was divided into ſeveral grains, becauſe he had not given a ſufficient degree of fire to unite them. Theſe grains did not appear different from the metal itſelf; but being melted with the blow-pipe, the phoſphorus burnt on the ſurface of the metal, as in the ſimilar experiment with lead.

"In fuſing tin or lead with the charcoal powder and phoſphoric glaſs, care muſt be taken not to urge the fire, as the phoſphorus eaſily flies off from either of thoſe metals.

"From the experiments of M. Pelletier, it appears that phoſphorus may be combined with gold, platina, ſilver, copper, iron, tin, and lead; and that it deprives the five former metals of their ductility. M. Pelletier propoſes to make further experiments, to aſcertain whether it be poſſible or not to combine a greater quantity of phoſphorus with the two latter, and whether they will retain their malleability in that caſe. In another memoir he will examine the action of phoſphorus on ſemimetals: he propoſes alſo to aſcertain the order of its affinity with the metals and ſemimetals.

"It is much to be wiſhed that M. Pelletier may carry to perfection a work which will enrich chemiſtry with a ſpecies of combination hitherto almoſt entirely unknown, and which he has diſcovered means of effecting by a proceſs equally ſimple and ingenious."

In the 10th volume of the ſame Annals we find an account of the action of lime, and of ſome metallic oxyds on phoſphorus, by Dr Raymond.

21 M. Gengembre's diſcovery of a peculiar kind of gas.

M. Gengembre diſcovered, that by boiling phoſphorus in a ſolution of potaſh, a peculiar kind of gas was produced, which had the ſingular property of taking fire on coming into contact with the atmoſphere, and to which the French chemiſts have given the appellation of *phoſphorized hydrogen gas*. Dr Raymond thought of varying the proceſs, in order to diſcover whether this gas might not be produced in ſome other way. He took two ounces of lime ſlaked in the air, a dram of phoſphorus cut ſmall, with half an ounce of water, which he mixed up into a ſoft paſte, and put into a ſtone retort; to this retort a tube was fitted, the internal diameter of which, he ſays, ought not to exceed a line and a half, communicating with a receiver full of water. As ſoon as the retort was well heated, the phoſphorized hydrogen gas was generated ſo abundantly, that, from the quantity of ingredients here mentioned, no leſs than three quarts of it were obtained. The reſiduum was found to have all the characters of the native phoſphat of lime. Hence the Doctor ſuppoſes, that the water was decompoſed during the proceſs, and that its oxygen ſerved to acidify the phoſphorus; which, in this ſtate, was combined with the lime, and formed the phoſphat; while its hydrogen, aſſuming a gaſeous ſtate, carried with it a part of the phoſphorus, to which the property of taking fire by contact with the air muſt be aſcribed. The gas ſoon loſes this property, and the phoſphorus is condenſed on the ſides of the receiver: great caution, however, is neceſſary; for though a part of the gas may ſeem to have depoſited its phoſphorus, and to be reduced to pure hydrogen, yet another part, in the ſame receiver, may retain enough to cauſe a formidable exploſion, when in contact with air.

22 The proceſs varied.

The facility with which water was thus decompoſed led the author to ſuſpect that a ſimilar effect might be produced by the ſame mixture in the mean temperature of the atmoſphere. Accordingly he found that in ten days time a ſmall quantity of hydrogen gas was generated in the vials, in which the ingredients were placed: this, however, was not phoſphorized, the heat not being ſufficient to volatiliize the phoſphorus.

23 Another variation.

Animated by this ſucceſs, Dr Raymond reſolved to try what could be effected by metallic oxyds. He made two mixtures like the former: but inſtead of lime, he ſubſtituted in the one the white oxyd of zinc, and in the other the black oxyd of iron. After long diſtillation with great heat, he obtained from both phoſphoriſed hydrogen gas: but it was produced in much leſs time, and in greater quantity, from the oxyd of zinc than from that of iron; which he aſcribed to the cloſe affinity of the former to the phoſphoric acid.

24 Proceſs for making Kunkel's Phoſphorus from urine.

In the 12th volume of the ſame valuable work, we have an account of a proceſs for making Kunkel's phoſphorus from urine, which is ſhorter and more economical than that by which Meſſrs Scheele and Gahn extract it from the bones of animals, by M. Giobert. This method is founded on the property of the metallic ſalts to ſeparate the phoſphoric acid from urine, which Margraff, we believe, firſt diſcovered: but M. Giobert has greatly improved on the proceſs directed by the German chemiſt, as he avoids the tedious and diſguſting operations of evaporating the urine, and expoſing it to putrefaction. He tells us, that it is indifferent whether the urine be that of healthy or diſeaſed perſons; and that of horſes is nearly as good for this purpoſe as that which is human. He gradually pours into it a ſolution of lead in the nitric acid, till the precipitation ceaſes which this had occaſioned; the whole is then diluted with a conſiderable quantity of water, and afterward filtrated through a linen cloth. The precipitate, which is phoſphat of lead, muſt be made up into a paſte with powder of charcoal, and well dried in an iron or copper pan: it muſt afterward be diſtilled; when it will yield, firſt, an ammoniacal, and then an empyreumatic, oil; theſe oils proceed from the urine, from which it is difficult to purify the phoſphat. As ſoon as the oil ceaſes to come over, a clean receiver muſt be applied, and the fire be greatly increaſed. The phoſphorus generally appears in about half an hour; and, within eight hours, twelve or fourteen ounces of it may thus be obtained. If the proceſs be conducted with care, M. Giobert thinks that a hundred parts of phoſphat of lead will yield between fourteen and eighteen of phoſphorus.

If on the phoſphat of lead thus precipitated from urine, a ſolution of ſulphat of ammoniac be poured, and this, after digeſting during twelve hours, be filtrated and evaporated, phoſphat of ammoniac will be obtained; and if ſulphat of ſoda be uſed, the reſult will be phoſphat of ſoda.

Acid of Phosphorus. This acid, called alſo the *microcoſmic*

Phosphorus

crocosmic acid, has already been described. See CHEMISTRY-*Index* at *Phosphoric Acid* (A). It has been discovered by Mr Scheele, that an acid capable of making phosphorus is producible from calcined bones or hartshorn and the vitriolic acid. The process for procuring this acid recommended by that gentleman was to dissolve the bones in nitrous acid; afterward to precipitate the earth by means of the vitriolic acid; to filter and evaporate the liquor to dryness; and, after driving off the nitrous acid, the phosphoric acid remains. This process, however, is expensive on account of the waste of nitrous acid; and is likewise very inconvenient, because a great deal of the earthy matter continues dissolved even after the vitriolic acid is poured in; and therefore the phosphoric acid is never to be obtained pure: for which reason the following process is preferable.

Take of calcined bones or hartshorn, one pound; oil of vitriol, 14 ounces. Let the bones be reduced to fine powder; then pour on the acid undiluted, and rub both together till they are as accurately mixed as possible. Having let them remain for some hours in this situation, pour on as much water, stirring and dissolving the lumps, into which the mass will now be concreted, till it is all equally distributed through the liquid, and has the consistence of thick gruel. Let it remain 24 hours, and then pour it into a canvas cloth in order to let the liquid drain from it. This is a very tedious operation, as fresh water must continually be pouring on till all the saline matter is washed off. When this is done, pour into the liquid a quantity of caustic volatile alkali, which will occasion a copious precipitation; for the earth of bones is much less strongly attracted by acids than even the caustic volatile alkali. The liquid being now filtered a second time, which will be done with sufficient ease, and afterwards evaporated, there remains a mass composed of phosphoric acid and vitriolic sal ammoniac. By increasing the fire, the latter is dissipated in vapour; and if the process has been successful, four ounces or more of pure phosphoric acid will remain.

With regard to the properties of this acid, it is not yet ascertained whether they are exactly the same with the microcosmic acid or not. Indeed, as far as yet appears, they seem to be different; and there are very strong reasons for supposing that the phosphoric acid thus produced is no other than the vitriolic altered by its combination with the earth of bones. See the article BONES.

Liquor of PHOSPHORUS. See CHEMISTRY, n° 2d 957. 1521.

PHOTINIANS, in ecclesiastical history, were a sect of heretics in the fourth century who denied the divinity of our Lord. They derive their name from *Photinus* their founder, who was bishop of Sirmium, and a disciple of Marcellus. Photinus published in the year 343 his notions respecting the Deity, which were repugnant both to the orthodox and Arian systems. He asserted, that Jesus Christ was born of the Holy Ghost and the Virgin Mary; that a certain divine emanation, which he called the *Word*, descended upon Him; and that because of the union of the divine word with his human nature, He was called the son of God, and even God himself; and that the Holy Ghost was not a person, but merely a celestial virtue proceeding from the Deity. Both parties condemned the bishop in the councils of Antioch and Milan, held in the years 345 and 347. He was condemned also by the council at Sirmium in 351, and was afterwards degraded from the episcopal dignity, and at last died in exile in the year 372 or 375. His opinions were afterwards revived by Socinus. Photinians, Photius

PHOTIUS, patriarch of Constantinople, was one of the finest geniuses of his time, and his merit raised him to the patriarchate; for Bardas having driven Ignatius from the see, Photius was consecrated by Asbestus in 859. He condemned Ignatius in a synod, whereupon the pope excommunicated him, and he, to balance the account, anathematized the pope. Basilius of Macedon, the emperor whom Photius had reproved for the murder of Michael the late emperor, expelled him, and restored Ignatius; but afterwards re-established Photius, upon Ignatius's death, in 878. At last, being wrongfully accused of a conspiracy against the person of Leo the philosopher, son and successor to Basilius, he was expelled by him in 886, and is supposed to have died soon after. He wrote a *Bibliotheca*, which contains an examen of 280 authors: we have also 253 epistles of his; the *Nomacanon* under 14 titles; an abridgment of the acts of several councils, &c. This great man was born in Constantinople, and was descended from a very illustrious and noble family. His natural abilities were very great, and he cultivated them with the greatest assiduity. There was no branch of literature, whether sacred or profane, and scarcely any art or science, in which he was not deeply versed. Indeed he appears to have been by far the greatest man of the age in which he lived; and was so intimately concerned in the chief transactions of it, that ecclesiastical writers have on that account called it *Seculum Photianum*. He was first raised to the chief dignities of the empire, being made principal secretary of state, captain

(A) See particularly n° 904. In addition to what has been already said on the acid of phosphorus, we may just observe, that M. Pelletier has a memoir on this subject in the 14th volume of the Chemical Annals. This philosopher's method of preparing the phosphorous acid differs little from that which was some years ago proposed by M. Sage, and which, we believe, is now pretty generally known. The principal alterations made by the author of the present memoir consist in his putting each stick of phosphorus into a glass pipe, the lower part of which is shaped like a funnel, terminating in a very small opening; and in covering the apparatus with a tubulated receiver, which he can open at pleasure. By these means he can dissolve a greater quantity of phosphorus without danger of an explosion. His method of converting the phosphorus into the phosphoric acid, by the nitric or the oxygenated muriatic acid, is the same with that discovered by M. Lavoisier, which is described in his Elements of Chemistry.

Phraates || Phreatis.

captain of the guards, and a senator. In all these stations he acquitted himself with a distinction suitable to his great abilities; for he was a refined statesman, as well as a profound scholar. His rise to the patriarchate was very quick; for when he was chosen to that office he was only a layman: but that he might be as it were gradually raised to that dignity, he was made monk the first day, reader the next, and the following days sub-deacon, deacon, and priest. So that in the space of six days he attained to the highest office in the church. On the whole, however, his ardent love of glory and unbounded ambition made him commit excesses which rendered him a scourge to those about him.

Fabricius calls this *Bibliotheca* or library, *non liber, sed insignis thesaurus*, "not a book, but an illustrious treasure," in which are contained many curious things relating to authors, and many fragments of works which are no where else to be found. It was brought to light by Andreas Schottus, and communicated by him to David Hoeschelius, who caused it to be printed in 1601. Schottus, considering the great utility of this work, translated it into Latin, and printed his translation alone in 1606. The Greek text, together with the translation, were afterwards printed at Geneva in 1611. The last edition of this work, the largest, and the fairest, was printed at Rouen in 1653, folio.

PHRAATES, or PHRAHATES. There were four kings of this name in Parthia. See PARTHIA.

PHRASE, in grammar, an elegant turn or manner of speech, peculiarly belonging to this or that occasion, this or that art, or this or that language. Thus we say, an Italian *phrase*, an eastern *phrase*, a poetical *phrase*, a rhetorical *phrase*.

PHRASE is sometimes also used for a short sentence or small set or circuit of words constructed together. In this sense, Father Buffier divides phrases into complete and incomplete.

Phrases are *complete* where there is a noun and a verb, each in its proper function; *i. e.* where the noun expresses a subject, and the verb the thing affirmed of it.

Incomplete phrases are those where the noun and the verb together only do the office of a noun; consisting of several words without affirming any thing, and which might be expressed in a single word. Thus, *that which is true*, is an incomplete phrase, which might be expressed in one word, *truth*; as, *that which is true satisfies the mind*, i. e. *truth satisfies the mind*.

PHRASEOLOGY, a collection of the phrases or elegant expressions in any language. See PHRASE.

PHREATIS, or PHREATTIUM, in Grecian antiquity, was a court belonging to the civil government of Athens, situated upon the sea-shore, in the Piræus. The name is derived from ἀπὸ τῶν φρεάτων, because it stood in a *pit*; or, as others suppose, from the hero *Phreatus*. This court heard such causes as concerned persons who had fled out of their own country for murder, or those that fled for involuntary murder, and who had afterwards committed a deliberate and wilful murder. The first who was tried in this place was Teucer, on a groundless suspicion that he had been accessory to the death of Ajax. The accused was not allowed to come to land, or so much as to cast anchor, but pleaded his cause in his bark; and if found guilty, was committed to the mercy of the winds and waves, or, as some say, suffered there condign punishment; if innocent, he was only cleared of the second fact, and, according to custom, underwent a twelvemonth's banishment for the former. See Potter's *Gr. Antiq.* vol. i. p. 111.

Phrenetic || Phryganea.

PHRENETIC, a term used to denote those who, without being absolutely mad, are subject to such strong sallies of imagination as in some measure pervert their judgment, and cause them to act in a way different from the more rational part of mankind.

PHRENITIS, the same with PHRENSY; an inflammation of the meninges of the brain, attended with an acute fever and delirium. See MEDICINE, n° 176; also an account of a strange degree of phrenzy which attacked Charles VI of France in the article FRANCE, n° 88, 90.

PHRYGANEA is a genus of insects, of which Barbut gives the following characters. "The mouth is without teeth, but furnished with four palpi: the stemmata are three in number: the antennæ are filiform, and longer than the thorax. The wings are incumbent; the under ones are folded."

The same author informs us, that the genus is divided into two sections: the first of which is characterized, by having two truncated setæ at the extremity of the abdomen, resembling the beard of an ear of corn; while the second has the abdomen simple, or without appendices. The tarsi of the feet of the first family consist of three articulations; those of the second are composed of five. The wings of this section decline from the inner margin towards the sides, so as to resemble the ridge of a house, and are curved, or turn upwards at their extremity. "This insect (says Mr Barbut), before it becomes an inhabitant of the air, has lived under-water, lodged in a kind of tube or sheath, the inward texture of which is silk; outwardly covered with sand, straws, bits of wood, shells, &c. When the hexapod worm is about to change to a chrysalis, he stops up the opening of his tube with threads of a loose texture, through which the water makes its way, but prevents the approach of voracious insects. The chrysalis is covered with a thin gauze, through which the new form of the insect is easily discerned. The phryganea, on the point of changing its element, rises to the surface of the water, leaves its tube, rises into the air, and enjoys the sweets of the country, flutters upon flowers and trees, but is soon called away to the water-side to deposite its eggs; whence proceeds its posterity. These aquatic larvæ are often found in stagnating waters, where they wrap themselves up in the water-lentil, cut out into regular squares, and fitted one to another. Trouts are very greedy of these larvæ; which is the reason, that in some countries, after stripping them of their coats, they make use of them for fishing-baits."

There are a variety of different species of the phryganea; but except the phryganea bicauda and striata, they do not materially differ from one another, except in size and colour. The bicauda is of a deep dark-brown colour; having a single yellow longitudinal band running across the head and thorax. The legs are of a brown colour, as are the antennæ; which are also long and filiform. Two brown threads, almost as

long

Phrygia. long as the antennæ, terminate the abdomen. The wings, which are about a third longer than the body, are veined with brown fibres, are narrow at the top, broad below, and are as it were ſtuck upon the body; which they infold, croſſing one over the other. This inſect, which is met with on the banks of rivers and ſtanding-waters, carries its eggs in a cluſter at its abdomen, like ſome ſpiders.

The ſtriata is a large ſpecies, of a dun colour, except the eyes, which are black, and has a conſiderable reſemblance to the phalena in the carriage of its wings. The antennæ are as long as the body, and are borne ſtraight forward. The wings are a third larger than the body, having veins of a colour rather deeper than the reſt. The feet are large, long, and ſomewhat finny. Mr Yeats tells us, that the perlæ of Geoffroy, and phryganeæ of Linnæus, do not differ generically. It appears, however, from Yeats's experiments, that the phryganeæ remain longer in the chryſalis than the perlæ.

The leſſer phryganeæ very much reſemble the tineæ; but, upon examining them with a glaſs, the former will be found to be covered with ſmall hairs inſtead of the ſcales which adorn the wings of the latter.

PHRYGIA, a country in Aſia. From whence it derived its name is not certain: ſome ſay it was from the river Phryx (now Sarabat), which divides Phrygia from Caria, and empties itſelf into the Hermus; others from Phrygia, the daughter of Aſopus and Europa. The Greek writers tell us, that the country took its name from the inhabitants, and theſe from the town of Brygium in Macedonia, from whence they firſt paſſed into Aſia, and gave the name of *Phrygia* or *Brygia* to the country where they ſettled. Bochart is of opinion that this tract was called Phrygia from the Greek verb φρυγω "to burn or parch;" which, according to him, is a tranſlation of its Hebrew name, derived from a verb of the ſame ſignification.

Ancient Univerſal Hiſtory, vol. 3. p. 441. &c

No leſs various are the opinions of authors as to the exact boundaries of this country; an uncertainty which gave riſe to an obſervation made by Strabo, viz. that the Phrygians and Myſians had diſtinct boundaries; but that it was ſcarce poſſible to aſcertain them. The ſame writer adds, that the Trojans, Myſians, and Lydians, are, by the poets, all blended under the common name of Phrygians, which Claudian extends to the Pifidians, Bithynians, and Ionians. Phrygia Proper, according to Ptolemy, whom we chooſe to follow, was bounded on the north by Pontus and Bithynia; on the weſt by Myſia, Troas, the Ægean Sea, Lydia, Mæonia, and Caria, on the ſouth by Lycia; on the eaſt by Pamphylia and Galatia. It lies between the 37th and 41ſt degrees of north latitude, extending in longitude from 56 to 62 degrees. The inhabitants of this country, mentioned by Ptolemy, are the Lycaones and Anthemiſenii, towards Lycia; and Moccadelis or Moccadine, the Cyddeſes or Cydiſſes towards Bithynia; and between theſe the Peltini or Speltini, the Moxiani, Phylacenſes, and Hierapolitæ. To theſe we may add the Bereeyntes mentioned by Strabo

Phrygia is commonly divided into the Greater and Leſſer Phrygia, called alſo Troas. But this diviſion did not take place till Troas was ſubdued by the Phrygians; and hence it is more conſidered by ſome Roman writers as a part of Phrygia, than Bithynia, Cappadocia, or any other of the adjacent provinces. In after ages, the Greater Phrygia was divided into two diſtricts or governments; one called Phrygia Pacatiana, from Pacatianus, who, under Conſtantine, bore the great office of the præfectus prætorio of the Eaſt; the other Phrygia Salutaris, from ſome miraculous cures ſuppoſed to have been performed there by the archangel Michael. Phrygia.

This country, and indeed all Aſia Minor, as lying in the fifth and ſixth northern climates, was in ancient times greatly celebrated for its fertility. It abounded in all ſorts of grain; being, for the moſt part, a plain country covered with a deep rich ſoil, and plentifully watered by ſmall rivers. It was in ſome parts productive of bitumen and other combuſtible ſubſtances. It was well ſtocked with cattle, having large plains and paſture grounds The air was anciently deemed moſt pure and wholeſome, though it is now in ſome parts thought extremely groſs, great part of the country lying uncultivated.

In Phrygia Major were anciently ſeveral cities of great celebrity; ſuch as APAMEA LAODICEA, HIERAPOLIS, Gordium, &c.—There were alſo ſome famous rivers; ſuch as Marſyas, Mæander, &c. The Mæander is now called *Madre* or *Mindre*, and was much celebrated by the ancients for its windings and turnings; from whence all ſuch windings and turnings have been denominated *mæanders*.

The Phrygians accounted themſelves the moſt ancient people in the world. Their origin, however, is extremely dark and uncertain. Joſephus and St Jerome ſay, they were deſcended from Togarmah, one of Gomer's ſons; and that they were known to the Hebrews under the name of Tigrammanes. The Heathen authors derive them from the Brygians, a people of Macedonia. But this is but mere conjecture; and it is a conjecture totally unſupported, except by the ſimilarity of names. Bochart thinks that the Phrygians were the offſpring of Gomer the eldeſt ſon of Japhet; the word Phrygia being the Greek tranſlation of his name. Joſephus makes Gomer the father of the Galatians; but he, by the Galatians, muſt neceſſarily mean the Phrygians inhabiting that part of Phrygia which the Galatians had made themſelves maſters of: the deſcendants of Gomer being placed by Ezekiel northward of Judæa, near Togarmah (which Bochart takes to be Cappadocia), long before the Gauls paſſed over into Aſia. We are willing to let Gomer enjoy the fine country which Bochart is pleaſed to give him, and allow him the honour of being the progenitor of the Phrygians, ſince we know no other perſon on whom it can be conferred with any degree of probability.

The ancient Phrygians are deſcribed as ſuperſtitious, voluptuous, and effeminate, without any prudence or forecaſt, and of ſuch a ſervile temper, that nothing but ſtripes and ill uſage could make them comply with their duty; which gave riſe to ſeveral trite and well known proverbs (A). They are ſaid to have been the firſt inventors of divination by the ſinging, flying, and

8 feeding

(A) "Phryges ſero ſapiunt, Phryx verberatus melior, Phryx non minus quam Spyntharus, &c.:" which proverbs

Phrygia. feeding of birds. Their muſic, commonly called the *Phrygian mood*, is alleged by ſome as an argument of their effeminacy.

Their government was certainly monarchical; for all Phrygia was, during the reigns of ſome kings, ſubject to one prince. Ninnacus, Midas, Manis, Gordius, and his deſcendants, were undoubtedly ſovereigns of all Phrygia. But ſome time before the Trojan war, we find this country divided into ſeveral petty kingdoms, and read of divers princes reigning at the ſame time. Apollodorus mentions a king of Phrygia contemporary with Ilus king of Troy. Cedrenus and others ſpeak of one Teuthrans, king of a ſmall country in Phrygia, whoſe territories were ravaged by Ajax, himſelf ſlain in ſingle combat, his royal ſeat laid in aſhes, and his daughter, by name Tecmeſſa, carried away captive by the conqueror. Homer makes mention of Phoreys and Aſcanius, both princes and leaders of the Phrygian auxiliaries that came to the relief of Troy. Tantalus was king of Sipylus only, and its diſtrict; a prince no leſs famous for his great wealth, than infamous for his covetouſneſs and other deteſtable vices. That Phrygia was ſubdued either by Ninus, as Diodorus Siculus informs us, or by the Amazons, as we read in Suidas, is not ſufficiently warranted. Moſt authors that ſpeak of Gordius tell us, that the Phrygians having ſent to conſult an oracle in order to know how they might put an end to the inteſtine broils which rent their country into many factions and parties, received for anſwer, that the moſt effectual means to deliver themſelves and their country from the calamities they groaned under, was to commit the government to a king. This advice they followed accordingly, and placed Gordius on the throne.

As to their commerce, all we can ſay is, that Apamea was the chief emporium of all Aſia Minor.—Thither reſorted merchants and traders from all parts of Greece, Italy, and the neighbouring iſlands. Beſides, we know from Syncellus, that the Phrygians were for ſome time maſters of the ſea; and none but trading nations ever prevailed on that element. The country produced many choice and uſeful commodities, which afforded conſiderable exports. They had a ſafe coaſt, convenient harbours, and whatever may incline us to think that they carried on a conſiderable trade. But as moſt of the Phrygian records are loſt, we will not dwell on conjectures ſo difficult to be aſcertained.

We have no ſet form of their laws; and as to their learning, ſince we are told that for ſome time they enjoyed the ſovereignty of the ſea, we may at leaſt allow them a competent ſkill in geography, geometry, and aſtronomy; and add to theſe, from what we have ſaid above, a more than ordinary knowledge of muſic. Phrygia ‖ Phryne.

Some have been of opinion that the Phrygian language bore a great reſemblance to the Greek; but the contrary is manifeſt from the few Phrygian words which have been tranſmitted to us, and carefully collected by Bochart and Rudbeckius. To theſe we may add the authority of Strabo, who, after attempting to derive the name of a Phrygian city from the Greek, concludes, that it is a difficult matter to diſcover any ſimilitude between the barbarous words of the Phrygian language and the Greek. The Phrygian tongue, after the experiment made by Pſammetichus king of Egypt, was looked upon by the Egyptians as the moſt ancient language of the world. But other nations, particularly the Scythians, refuſed to ſubmit to their opinion, as founded on an argument of no real weight. "As the two children (ſay they) had never heard the voice of any human creature, the word *bec*, or *bekkos*, the firſt they uttered, was only an imitation of the goats that had ſuckled them, and happened to be a Phrygian word ſignifying *bread* (B).

We have already ſaid, that the Phrygians were ſuperſtitious; their idols were conſequently very numerous. The chief of theſe was Cybele, who went by a variety of names. (See CYBELE.) They alſo worſhipped Bacchus under the name of *Sabazios*; and his prieſts they called *Saboi*.

The hiſtory of their kings is dark and uncertain, and the dates of their ſeveral reigns and actions cannot now be fixed; we ſhall refer ſuch of our readers, therefore, as wiſh to know what is certain reſpecting them, to the Ancient Univerſal Hiſtory, already quoted more than once in the preſent article. See alſo GORDIUS, MIDAS, &c. For Phrygia Minor, ſee TROY.

PHRYGIAN STONE, in natural hiſtory, is the name of a ſtone deſcribed by the ancients, and uſed by them in dying; perhaps from ſome vitriolic or aluminous ſalt contained in it, which ſerved to enliven or fix the colours uſed by the dyers. It was light and ſpungy, reſembling a pumice; and the whiteſt and lighteſt were reckoned the beſt. Pliny gives an account of the method of preparing it for the purpoſe of dying, which was by moiſtening it with urine, and then heating it red hot, and ſuffering it to cool.—This calcination was repeated three times, and the ſtone was then fit for uſe. Dioſcorides recommends it in medicine after burning; he ſays it was drying and aſtringent.

PHRYGIANS, a Chriſtian ſect. See CATAPHRYGIANS and MONTANIST.

PHRYNE, was a famous proſtitute, who flouriſhed at Athens about 328 years before the Chriſtian era. She was miſtreſs of Praxiteles, who drew her picture,

proverbs intimate their ſervile temper; and ſhow that they were more fit to bewail misfortunes in an unmanly manner, than to prevent them by proper meaſures. Their muſic, too, was ſuited to their effeminate temper. The Doric mood was a kind of grave and ſolid muſic; the Lydian a doleful and lamentable harmony; but the Phrygian chiefly calculated to effeminate and enervate the mind. But this character is contradicted by others.

(B) Goropius Becanus makes uſe of the ſame argument, to prove that the High Dutch is the original or mother-tongue of the world, becauſe the word *beker* in that language ſignifies "a baker."

Phrynicus || Phryxus.

which was one of his beſt pieces, and was placed in the temple of Apollo at Delphi. We are told that Apelles painted his Venus Anadyomene after he had ſeen Phryne on the ſea-ſhore naked, and with diſhevelled hair. Phryne became ſo very rich by the liberality of her lovers, that ſhe offered to rebuild Thebes at her own expence, which Alexander had deſtroyed, provided this inſcription was placed on the walls: *Alexander diruit, ſed meretrix Phryne reſecit*; which was refuſed. See *Plin.* 34. c. 8.——There was another of the ſame name who was accuſed of impiety. When ſhe found that ſhe was going to be condemned, ſhe unveiled her boſom, which ſo influenced her judges, that ſhe was immediately acquitted.

PHRYNICUS, a general of Samos, who endeavoured to betray his country, &c.——A flatterer at Athens.——A tragic poet of Athens, diſciple to Theſpis. He was the firſt who introduced a female character on the ſtage.

PHRYNIS was a muſician of Mitylene. He was the firſt who obtained a muſical prize at the Panathenæa at Athens. He added two ſtrings to the lyre, which had always been uſed with ſeven by all his predeceſſors. He flouriſhed about 438 years before the Chriſtian era. We are told that he was originally a cook at the houſe of Hiero king of Sicily.——There was another of the ſame name, a writer in the reign of Commodus, who made a collection, in 36 books, of phraſes and ſentences from the beſt Greek authors, &c.

PHRYXUS (fab. hiſt.), was a ſon of Athamas king of Thebes, by Nephele. When his mother was repudiated, he was perſecuted with the moſt inveterate fury by his ſtep-mother Ino, becauſe he was to ſit on the throne of Athamas, in preference to the children of a ſecond wife. His mother apprized him of Ino's intentions upon his life; or, according to others, his preceptor; and the better to make his eſcape, he ſecured part of his father's treaſures, and privately left Bœotia with his ſiſter Helle, to go to their friend and relation Æetes king of Colchis. They embarked on board a ſhip, or, as we are informed by the fabulous account of the poets and mythologiſts, they mounted on the back of a ram, whoſe fleece was of gold, and proceeded on their journey through the air. The height to which they were carried made Helle giddy, and ſhe fell into the ſea. Phryxus gave his ſiſter a decent burial on the ſea-ſhore, and after he had called the place *Helleſpont* from her name, he continued his flight, and arrived ſafe in the kingdom of Æetes, where he offered the ram on the altars of Mars. The king received him with great tenderneſs, and gave him Chalciope his daughter in marriage. She had by him Phrontis Melas, Argos Cylindrus, whom ſome call *Cytorus*. He was afterwards murdered by his father-in-law, who envied him the poſſeſſion of the golden fleece; and Chalciope, to prevent her children from ſharing their father's fate, ſent them privately from Colchis to Bœotia, as nothing was to be dreaded there from the jealouſy or reſentment of Ino, who was then dead. The fable of the flight of Phryxus to Colchis on a ram has been explained by ſome, who obſerve, that the ſhip on which he embarked was either called by that name, or carried on her prow a figure of that animal. The fleece of gold is accounted for, by obſerving that Phryxus carried away immenſe treaſures from Thebes. Phryxus was placed among the conſtellations of heaven after death. The ram which carried him to Aſia is ſaid to have been the fruit of Neptune's amour with Theophane the daughter of Altis. This ram the gods had given to Athamas in order to reward his piety and religious life; and Nephele procured it for her children, juſt as they were going to be ſacrificed to the jealouſy of Ino. Phryxus's murder was ſome time after amply revenged by the Greeks; it having occaſioned the famous expedition atchieved under Jaſon and many of the princes of Greece, which had for its object the recovery of the golden fleece, and the puniſhment of the king of Colchis for his cruelty to the ſon of Athamas.

Phthiriaſis, Phthiſis.

PHTHIRIASIS, the LOUSY EVIL, from φθείρ, "a louſe." It is a louſy diſtemper; children are frequently its ſubjects, and adults are ſometimes troubled with it. The increaſe of lice, when in a warm moiſt ſituation, is very great; but a cold and dry one ſoon deſtroys them. On the human body four kinds of lice are diſtinguiſhed: 1. The *pediculi*, ſo called becauſe they are more troubleſome with their feet than by their bite. Theſe are in the heads of children, eſpecially if ſore or ſcabby; and often in thoſe of adults, if they are ſlothful and naſty. 2. Crab-lice, ſee *CRAB Lice*. 3. Body lice; theſe infeſt the body, and breed in the clothes of the naſty and ſlothful. 4. A ſort which breed under the cuticle, and are found in the hands and feet: they are of a round form, and ſo minute as often to eſcape the ſight: by creeping under the ſcarf-ſkin they cauſe an intolerable itching; and when the ſkin burſts where they lodge, cluſters of them are found there. See ACARUS.

A good diet and cleanlineſs conduce much to the deſtruction of lice. When they are in the head, comb it every day; and, after each combing, ſprinkle the pulv. ſem. ſtaph. agr. or coccul. Ind. among the hairs every night, and confine it with a tight cap.

Codrochius, in his treatiſe on lice, ſays, that the powdered coc. Ind. exceeds all other means; and that it may be mixed in the pulp of apple, or in lard, and applied every night to the hair. Some writers aſſert, that if the pulv. cort. rad. ſaſſafr. is ſprinkled on the head, and confined with a handkerchief, it deſtroys the lice in one night.

The body-lice are deſtroyed by any bitter, ſour, ſalt, or mercurial medicine, if applied to the ſkin.

The black ſoap, and the flowers called *cardamine* or *lady's-ſmock*, are ſaid to be ſpecifics in all caſes of lice on the human body.

PHTHISIS, a ſpecies of conſumption, occaſioned by an ulcer in the lungs. See MEDICINE, n° 237, &c.

Since our article MEDICINE was publiſhed, Dr Beddoes has ſuggeſted † a new theory of phthiſis, founded on the prevailing pneumatic doctrine in chemiſtry. Thinking that much cannot be gained by adhering to eſtabliſhed principles and modes of practice, and being unawed by any pretenſions to ſucceſs from experience, he enters into the province of ſpeculation. He fixes on the effect of pregnancy in ſuſpending the progreſs of phthiſis, as a fact which, by its mode of operation,

† *Obſervations on the Nature and Cure of Calculus, Scurvy*, &c.

2 might

Phthiſis. might ſuggeſt a method of diminiſhing the havock occaſioned by this diſtemper. We ſhall give his explanation of this intereſting fact:

"The fœtus has its blood oxygenated by the blood of the mother through the placenta. During pregnancy there ſeems to be no proviſion for the reception of an unuſual quantity of oxygene. On the contrary, in conſequence of the impeded action of the diaphragm, leſs and leſs ſhould be continually taken in by the lungs. If, therefore, a ſomewhat diminiſhed proportion of oxygene be the effect of pregnancy, may not this be the way in which it arreſts the progreſs of phthiſis? and if ſo, is there not an exceſs of oxgyene in the ſyſtem of conſumptive perſons? and may we not, by purſuing this idea, diſcover a cure for this fatal diſorder?"

Dr Beddoes thinks, that this ſuppoſition is countenanced by the deficiency of oxygene in the blood of pregnant women, of aſthmatic patients, and of thoſe who labour under ſea ſcurvy; and by the ſuperabundance of it in the blood of phthiſical perſons, indicated by its colour, as well as by the aggravation of the ſymptoms of conſumption by breathing oxygene air, and by the relief from inſpiring atmoſpheric air mixed with carbonic acid air; and, laſtly, from the ſmall proportion of deaths among ſea-faring people. Suppoſing acids to act by decompoſition, their alleged effects in producing conſumption are conſiſtent with the author's doctrine, as well as the emaciation preceding and accompanying phthiſis. From theſe facts, Dr Beddoes concludes, that "1. The phthiſical inflammation may ſo alter the ſtructure of the lungs, as to cauſe them to tranſmit a more than ordinary portion of oxygene to the blood; or, 2. Some unknown cauſe having enabled them to tranſmit, or the blood itſelf to attract, more oxygene, an inflammation of the lungs might enſue."

From theſe principles, the Doctor thinks himſelf juſtified in propoſing, in a diſeaſe which is incurable by preſent modes of practice, to diminiſh the ſupply of oxygene by the two channels through which it is introduced; namely, through the lungs, by lowering the atmoſpheric air with azotic or hydrogene air; and through the ſtomach, by giving ſuch nouriſhment as contains a ſmall portion of oxygene.

Such is Dr Beddoes's theory of conſumption; on which the following remark has been made by a critic* who poſſeſſes an equal degree of candour and judgment. It is aſſumed by Dr Beddoes, that the blood of pregnant women has a diminiſhed proportion of oxygene: but pregnant women have the ſame circumſcribed ſpot of florid red in their countenances which is apparent in hectics. If, then, the preſence of this colour be ſufficient to prove an exceſs of oxygene in the one caſe, it muſt have the ſame weight in the other. Another queſtion is, whether leſs oxygene be really taken in by the lungs during pregnancy? For although the diaphragm be impeded in the freedom of its action, the frequency of breathing is proportionally increaſed.—A third circumſtance which demands attention is, in what degree the fœtus has its blood oxygenated by the blood of the mother through the placenta. It appears highly probable, that the fœtal blood receives a very trifling ſupply of oxygene from the blood of the mother; that the fœtal heart contains only a ſmall portion of blood, which has been conveyed to the placenta; and that the blood in the heart and arteries of the fœtus is not florid.—For many ingenious arguments on this ſubject, we may refer to Mr Coleman's Diſſertation on ſuſpended Reſpiration.—Leaving theſe things to Dr Beddoes's conſideration, we will preſent our readers with his concluding remarks on this ſubject: Phthiſis.

"The more you reflect, the more you will be convinced, that nothing would ſo much contribute to reſcue the art of medicine from its preſent helpleſs condition, as the diſcovery of the means of regulating the conſtitution of the atmoſphere. It would be no leſs deſirable to have a convenient method of reducing the oxygene to 18 or 20 in 100, than of increaſing it in any proportion. The influence of the air we breathe is as wide as the diffuſion of the blood. The minuteſt portions of the organs of motion, ſenſe, and thought, muſt be affected by any conſiderable change in this fluid. Whether it be that the brain muſt be waſhed by ſtreams of arterial blood, or that the action of every organ is a ſtimulus to the ſyſtem in general, and conſequently to every other organ in particular; it is certain, that when the acceſs of oxygene is cut off from the lungs, the functions of the brain ceaſe: perhaps there may be a mixture of azotic and oxygene airs, more favourable to the intellectual faculties than that which is found in the atmoſphere; and hence chemiſtry be enabled to exalt the powers of future poets and philoſophers. That diſeaſes of exciteiment on the one hand, and debility on the other, might be cured almoſt ſolely by a proper air, one can hardly doubt, as well as ſeveral diſorders at preſent highly dangerous or deſperate, which one cannot, upon the faith of any obvious phenomena, refer to either head. The materia medica might, therefore, undergo a ſtill greater reduction than it has lately undergone, in conſequence of the purification of medicine from its groſſer abſurdities; and hence the treatment of diſeaſes be at once rendered infinitely more pleaſant and more efficacious."

Our author, in a ſubſequent publication*, gives an account of his treating with ſucceſs ſeveral caſes of phthiſis according to the principles of this theory. After diſtinguiſhing conſumptions into two kinds, the florid and the pituitous or catarrhal, he obſerves, "that the ſyſtem may be as variouſly affected by means of the lungs as of the ſtomach: that it is impoſſible to doubt that we are nouriſhed by the lungs as truly as by the ſtomach: and that what we take in at the former entrance, becomes, like our food, a part of the ſubſtance of our ſolids as well as of our fluids. By the lungs we can alſo introduce effectual alteratives of the blood, and by conſequence of all the parts nouriſhed by the blood."

He then acquaints us more particularly with the apparatus requiſite for the practice propoſed. 1ſt, It ſhould be able to furniſh azotic, hydrogene, carbonic, and oxygene airs: our author having, as he ſays, "no intention to confine himſelf to one incurable diſorder. 2dly, The reſervoirs ſhould be large, that the patients may be ſupplied with any quantity that their ſymptoms may require: and, 3dly, It is neceſſary to be able to mix theſe airs with one another, as well as with atmoſpheric air, in any proportion." Theſe objects, we

* *A Letter to Erasmus Darwin, M. D.*

Phul || Phyllis.

told, have been completely attained by a conſtruction not very unlike to that employed in the gazometers of M. Lavoiſier and Dr Van Marum.

PHUL, or Pul, king of Aſſyria, is by ſome hiſtorians ſaid to be Ninus under another name, and the firſt founder of that monarchy: A renowned warrior. He invaded Iſrael in the reign of Manahem, who became tributary to him, and paid him 1000 talents of ſilver for a peace. Flouriſhed 771 B C.

PHUT, or Phuth, the third ſon of Ham (Gen. x. 6.) Calmet is of opinion, that Phut peopled either the canton of Phtemphu, Phtemphuti, or Phtembuti, ſet down in Pliny and Ptolemy, whoſe capital was Thara in Lower Egypt, inclining towards Lybia; or the canton called Phtenotes, of which Buthus was the capital. The prophets often ſpeak of Phut. In the time of Jeremiah, Phut was under the obedience of Necho king of Egypt. Nahum (iii. 9.) reckons up his people in the number of thoſe who ought to have come to the aſſiſtance of No-ammon or Dioſpolis.

PHYLACTERY, in the general, was a name given by the ancients to all kinds of charms, ſpells, or characters, which they wore about them, as amuleta, to preſerve them from dangers or diſeaſes.

Phylactery particularly denoted a ſlip of parchment, wherein was written ſome text of Holy Scripture, particularly of the decalogue, which the more devout people among the Jews wore on the forehead, the breaſt, or the neck, as a mark of their religion.

The primitive Chriſtians alſo gave the name *phylacteries* to the caſes wherein they incloſed the relicks of their dead.

Phylacteries are often mentioned in the New Teſtament, and appear to have been very common among the Phariſees in our Lord's time.

PHYLICA, baſtard alaternus; a genus of the monogynia order, belonging to the pentandria claſs of plants. There are ſix ſpecies, of which three are kept in the gardens of this country; but, by reaſon of their being natives of warm climates, they require to be kept in pots, and houſed in winter. They are all ſhrubby plants, riſing from three to five or ſix feet high, and adorned with beautiful cluſters of white flowers. They are propagated by cuttings.

PHYLLANTHUS, sea-side laurel; a genus of the triandria order, belonging to the monœcia claſs of plants. There are ſix ſpecies, all of them natives of warm climates; and riſe from 12 or 14 feet to the height of middling trees. They are tender, and cannot be propagated in this country without artificial heat.

PHYLLIS (fab. hiſt.), was a daughter of Sithon, or, according to others, of Lycurgus king of Thrace, who received Demophoon the ſon of Theſeus; who, at his return from the Trojan war, had ſtopped on her coaſts. She became enamoured of him, and did not find him inſenſible to her paſſion. After ſome months of mutual tenderneſs and affection, Demophoon ſet ſail for Athens, where his domeſtic affairs recalled him. He promiſed faithfully to return as ſoon as a month was expired: but either his diſlike for Phyllis, or the irreparable ſituation of his affairs, obliged him to violate his engagement: and the queen, grown deſperate on account of his abſence, hanged herſelf, or, according to others, threw herſelf down a precipice into the ſea and periſhed. Her friends raiſed a tomb over her body, where there grew up certain trees, whoſe leaves, at a particular ſeaſon of the year, ſuddenly became wet as if ſhedding tears for the death of Phyllis. According to an old tradition mentioned by Servius, Virgil's commentator, Phyllis was changed by the gods into an almond tree, which is called *phylla* by the Greeks. Some days after this metamorphoſis, Demophoon reviſited Thrace; and when he heard of the fate of Phyllis, he ran and claſped the tree, which, though at that time ſtripped of its leaves, ſuddenly ſhot forth, and bloſſomed as if ſtill ſenſible of tenderneſs and love. The abſence of Demophoon from the houſe of Phyllis has given riſe to a beautiful epiſtle of Ovid, ſuppoſed to have been written by the Thracian queen about the fourth month after her lover's departure.—A country woman introduced in Virgil's eclogues.—The nurſe of the emperor Domitian.—A country of Thrace near mount Pangæus.

Phyſalis || Phyſeter.

PHYSALIS, the winter cherry; a genus of the monogynia order, belonging to the pentandria claſs of plants. There are 16 ſpecies; of which the moſt remarkable is the alkekengi, or common winter-cherry. This grows naturally in Spain and Italy. The roots are perennial, and creep in the ground to a great diſtance if they are not confined. Theſe, in the ſpring, ſhoot up many ſtalks, which riſe to the height of a foot or more, garniſhed with leaves of various ſorts; ſome of which are angular and obtuſe, ſome oblong and ſharp pointed, with long foot ſtalks. The flowers are produced from the wings, ſtanding upon ſlender foot-ſtalks; are of a white colour, and have but one petal. They are ſucceeded by round berries about the ſize of ſmall cherries, incloſed in an inflated bladder, which turns red in autumn, when the top opens and diſcloſes the red berry, which is ſoft, pulpy, and filled with flat kidney-ſhaped ſeeds. Soon after the fruit is ripe, the ſtalks decay to the root. The plant is eaſily propagated, either by ſeeds or parting the roots

PHYSALUS. See Scolopendra.

PHYSETER, or Spermaceti-fish, in zoology, a genus belonging to the order of cete. There are four ſpecies; the moſt remarkable are,

1. The microps, or black-headed cachalot, with a long fin on the back, and the upper jaw conſiderably longer than the under one. A fiſh of this kind was caſt aſhore on Cramond iſle, near Edinburgh, December 22. 1769; its length was 54 feet; the greateſt circumference, which was juſt beyond the eyes, 30: the upper jaw was five feet longer than the lower, whoſe length was ten feet. The head was of a moſt enormous ſize, very thick, and above one-third the ſize of the fiſh: the end of the upper jaw was quite blunt, and near nine feet high: the ſpout-hole was placed near the end of it. The teeth were placed in the lower jaw, 23 on each ſide, all pointing outwards; in the upper jaw, oppoſite to them, were an equal number of cavities, in which the ends of the teeth lodged when the mouth was cloſed. One of the teeth meaſured eight inches long, the greateſt circumference the ſame. It is hollow within-ſide for the depth of three inches, and the mouth of the cavity very wide: it is thickeſt at the bottom, and grows very ſmall at the point, bending very much; but in ſome the flexure is more than in others. Theſe, as well as the teeth of all

Phyſeter. all other whales we have obſerved, are very hard, and cut like ivory. The eyes are very ſmall, and remote from the noſe. The pectoral fins were placed near the corners of the mouth, and were only three feet long: it had no other fin, only a large protuberance on the middle of the back. The tail was a little forked, and 14 feet from tip to tip. The penis ſeven feet and a half long. Linnæus informs us, that this ſpecies purſues and terrifies the porpoiſes to ſuch a degree as often to drive them on ſhore.

2. The catodon, or round headed cachalot, with a fiſtula in the ſnout, and having no back-fin. Of this ſpecies, 102 of different ſizes were caſt aſhore at one time on one of the Orkney Iſles, the largeſt 24 feet in length. The head is round, the opening of the mouth ſmall. Sibbald ſays it has no ſpout-hole, but only noſtrils: But Mr Pennant is of opinion, that the former being placed at the extremity of the noſe, has been miſtaken by him for the latter. Some teeth of this ſpecies are an inch and three quarters long, and in the largeſt part of the thickneſs of one's thumb. The top is quite flat, and marked with concentric lines; the bottom is more ſlender than the top, and pierced with a ſmall orifice: inſtead of a back fin, there was a rough ſpace.

Phyſic || Phyſico-Mathematics

For the method of extracting the ſpermaceti from the brain of theſe creatures, ſee the article SPERMACETI.

PHYSIC, or PHYSICK, the art of healing; properly called MEDICINE. The word is formed from the Greek φυσις, "nature;" in regard medicine conſiſts principally in the obſervation of nature. See PHYSICS and MEDICINE.

PHYSICAL, ſomething belonging to, or really exiſting in, nature. In this ſenſe we ſay a phyſical point, in oppoſition to a mathematical one, which only exiſts in the imagination; a phyſical ſubſtance or body, in oppoſition to ſpirit, or metaphyſical ſubſtance, &c.

PHYSICIAN, a perſon who profeſſes medicine, or the art of healing diſeaſes. See MEDICINE.

Physicians, College of, in London and Edinburgh. See *College of Phyſicians.*

PHYSICO-MATHEMATICS, includes thoſe branches of phyſic which, uniting obſervation and experiment to mathematical calculation, undertake to explain the phenomena of nature.

PHYSICS,

1 General definition of phyſics.

TAKEN in its moſt enlarged ſenſe, comprehends the whole ſtudy of nature; and NATURAL PHILOSOPHY is a term of the ſame extent: but ordinary language, and eſpecially in this country, employs both of theſe terms in a much narrower ſenſe, which it is proper in this place to determine with ſome preciſion.

2 A more particular explanation of the term.

Under the article PHILOSOPHY, we gave a particular account of that view of nature in which the objects of our attention are conſidered as connected by cauſation; and we were at ſome pains to point out the manner in which this ſtudy may be ſucceſsfully cultivated. By a judicious employment of the means pointed out in that article, we diſcover that the objects of our contemplation compoſe an UNIVERSE, which conſiſts, not of a number of independent exiſtences ſolitary and detached from each other, but of a number of ſubſtances connected by a variety of relations and dependencies, ſo as to form a whole which may with great propriety be called the SYSTEM OF NATURE.

This aſſembling of the individual objects which compoſe the univerſe into one ſyſtem is by no means the work of a haſty and warm fancy, but is the reſult of ſober contemplation. The natural hiſtorian attempts in vain to deſcribe objects, by only informing us of their ſhape, colour, and other ſenſible qualities. He finds himſelf obliged, in deſcribing a piece of marble, for inſtance, to tells us that it takes a fine poliſh; that it ſtrikes fire with ſteel; that it burns to quicklime; that it diſſolves in aquafortis, and is precipitated by alkalis; that with vitriolic acid it makes gypſum, &c. &c. &c. and thus it appears that even the *deſcription* of any thing, with the view of aſcertaining its ſpecific nature, and with the ſole purpoſe of diſcrimination, cannot be accompliſhed without taking notice of its various relations to other things. But what do we mean by the *nature* of any thing? We are ignorant of its eſſence, or what makes it that thing and no other thing. We muſt content ourſelves with the diſcovery of its *qualities* or *properties*; and it is the aſſemblage of theſe which we call its *nature*. But this is very inaccurate. Theſe do not conſtitute its eſſence, but are the conſequences of it. Yet this is all we ſhall ever know of its nature. Now the term *property* is nothing but a name expreſſing ſome relation which the ſubſtance under conſideration has to other things. This is true of all ſuch terms. Gravity, elaſticity, ſenſibility, gratitude, and the like, expreſs nothing but certain *matters of fact*, which may be obſerved reſpecting the object of our contemplation in different circumſtances of ſituation with regard to other things. Our diſtinct notions of individuals, therefore, imply their relations to other things. Introduction.

3 All parts of the univerſe evidently connected by their various properties.

The ſlighteſt obſervation of the univerſe ſhows an evident connection between all its parts in their various properties. All things on this earth are connected with each other by the laws of motion and of mind. We are connected with the whole of the ſolar ſyſtem by gravitation. If we extend our obſervations to the fixed ſtars, the connection ſeems to fail; but even here it may be obſerved. Their inconceivable diſtance, it is true, renders it impoſſible for us to obtain any *extenſive* information as to their nature. But theſe bodies are connected with the ſolar ſyſtem by the ſmeneſs of the light which they emit with that emitted by our ſun or any ſhining body. It moves with the ſame velocity, it conſiſts (in moſt of them at leaſt) of the ſame colours, and it is reflected, refracted, and inflected, according to the ſame laws.

In this unbounded ſcene of contemplation, our attention will be directed to the different claſſes of objects

Introduction.

jects nearly in proportion to the intereſt we take in them. There is nothing in which we are ſo much intereſted as our fellow men; and one of the firſt ſteps that we make in our knowledge of nature, is an acquaintance with them. We learn their *diſtinctive* nature by attending to their *characteriſtic* appearances; that is, by obſerving their actions. We obſerve them continually producing, like ourſelves, certain changes in the ſituation or condition of ſurrounding objects; and theſe changes are evidently directed to certain ends *which reſpect themſelves*. Obſerving this ſubſerviency of the effects which they produce to their own accommodation, we conſider this adjuſtment of means to ends as the effect of an INTENTION, as we experience it to be in our own caſe, where we are conſcious of this intention, and of theſe its effects. We therefore interpret thoſe actions of other men, where we obſerve this adjuſtment of means to ends, as marks or ſigns of intention in them ſimilar to our own. And thus a quality, or power, or faculty, is *ſuppoſed* in them *by means of its ſign*, although the quality itſelf is not *immediately* cogniſable by our ſenſes. And as this intention in ourſelves is accompanied by perception of external objects, knowledge of their properties, deſire of good, averſion from evil, volition, and exertion, without all of which we could not or would not perform the actions which we daily perform, we *ſuppoſe* the ſame perception, knowledge, deſire, averſion, volition, and exertion in them.

4 Our attention naturally directed in the firſt inſtance to our fellow-men.

5 Nature of intention.

Thus, by the conſtitution of our mind, we conſider the employment of means, by which ends terminating in the agent are gained, as the natural ſigns of deſign or intention. ART, therefore, or the employment of means, is the natural ſign of intention; and wherever we obſerve this adjuſtment of means to ends, we infer the agency of deſign.

A ſmall acquaintance with the objects around us, obliges us to extend this inference to a great number of beings beſides our fellow men, namely, to the whole animal creation: for in all we obſerve the ſame ſubſerviency to the ends of the agent, in the changes which we find them continually producing in the objects around them. Theſe changes are all adjuſted to their own well being. In all ſuch caſes, therefore, we are forced, by the conſtitution of our own minds, to infer the exiſtence of deſign or intention in theſe beings alſo.

But in numberleſs changes produced by external objects on each other, we obſerve no ſuch fitneſs in the effects, no ſuch ſubſerviency to the well-being of the agent. In ſuch caſes, therefore, we make no ſuch inference of thought or deſign.

6 All objects divided into thinking and unthinking beings.

Thus, then, there is preſented to our obſervation an important diſtinction, by which we arrange all external objects into two claſſes. The firſt reſembles ourſelves, in giving external marks of that thought or intention of which we are conſcious; and we *ſuppoſe* in them the other properties which we diſcover in ourſelves, but cannot *immediately* obſerve in them, viz. thought, perception, memory, foreſight, and all that collection of faculties which we feel in ourſelves, and which conſtitute the animal. The other claſs of objects exhibit no ſuch appearances, and we make no ſuch inference. And thus we divide the whole of external nature into the claſſes of THINKING and UNTHINKING beings.

Our firſt judgments about theſe claſſes will be very inaccurate; and we will naturally aſcribe the differences, which we do not very well underſtand, to the differences in organical ſtructure, which we clearly obſerve. But when we have knocked down or perhaps ſmothered an animal, we find that it no longer gives the former marks of thought and intention, and that it now reſembles the claſs of unthinking beings: And yet it ſtill retains all that fitneſs of organical ſtructure which it had before; it ſeems only to want the intention and the will. This obliges us to conclude that the diſtinction does not ariſe from a difference in organical ſtructure, but from a diſtinct ſubſtance common to all thinking beings, but ſeparable from their organical frame. To this ſubſtance we aſcribe thought, intention, contrivance, and all that collection of faculties which we feel in ourſelves. To this ſubſtance in ourſelves we refer all ſenſations, pleaſures, pains, remembrances, deſires, purpoſes; and to this aggregate, however imperfectly underſtood, we give the name MIND. Our organical frame, which ſeems to be only the inſtrument of information and operation to the mind, we call *our* body.

Introduction.

7 How we come to the knowledge of mind.

8 The nature of mind as underſtood by mankind in rude ages.

As the animating principle is not, like our body, the immediate object of the ſenſes, we naturally conceive it to be a ſubſtance eſſentially different from thoſe which are the objects of our ſenſes. The rudeſt people have ſhown a diſpoſition to form this concluſion. Obſerving that animal life was connected with breathing, it was natural to imagine that breathing was living, and that breath was life. It is a remarkable fact, that in moſt languages the term for expreſſing *breath* is at leaſt one of the terms for expreſſing the ſoul; רוח, πνευμα, *ſpiritus*, in the Hebrew, Greek, and Latin, expreſs both; *gheiſt* or *ghoſt*, in the Teutonic, comes from *gheiſen*, to "breathe or ſigh;" *dūcha* or *dūha*, "the ſoul," in Sclavonic, comes from *duichat*, "to breathe;" ſo in the Gaelic does *anal* come from *anam*; and the ſame relation is found between the two words in the Malay and other eaſtern languages. We believe that moſt perſons can recollect ſome traces of this notion in their early conceptions of things; and many who do not conſider themſelves as uncultivated, believe that the ſoul quits the body *along with the laſt breath*. Among the Tartar nations hanging is conſidered with particular horror, on account of the ungraceful and filthy exit which the ſoul is obliged to make from the body.

9 Their opinions not juſt.

But the obſervation of the ſame appearances of thought and intention in fiſhes and other animals which do not breathe, would ſoon ſhow that this was but a rude conception. Very little refinement indeed is neceſſary to convince us that air or breath cannot be the ſubſtance which thinks, wiſhes, and deſigns; and that the properties of this ſubſtance, whatever it is, muſt be totally different from, and incompatible with, any thing that we know of the immediate objects of our ſenſes.

10 Of the two kinds of ſubſtances in nature, one is the object of reflection alone, the other of the ſenſes.

Hence we are led to conclude that there are two kinds of ſubſtances in nature: One, which is the principle of ſenſation; and therefore *cannot* be the object of our ſenſes, any more than light can be the object of the microſcope. This ſubſtance alone can feel, think, deſire, and propoſe, and is the object of *reflection alone*. The objects of our ſenſes compoſe the other claſs, and therefore can have none of the other properties which are not cogniſcible by the ſenſes. Theſe have all the properties

Introduction.

properties which our senses can discover; and we can have no evidence of their having any other, nor indeed any conception of their having them. This class is not confined to the unorganized masses of matter; for we see that the bodies of animals lose after death that organical form, and are assimilated to all the rest of unthinking beings. It has arisen from such views as this, that while all nations have agreed to call this class of objects by the name BODY, which originally expresses our organical frame, some nations, farther advanced in cultivation or refinement, have contrived an abstract term to express this general substance of which all inanimate beings are composed. Such a term we have in the words *materies*, ὑλη.

II. The distinction between material and immaterial substances very important.

Matter, then, is that substance which is immediately cognoscible by our senses. Whatever, therefore, is not thus immediately cognoscible by our senses is not material, and is expressed by a negative term, and called *immaterial*: hence it is that mind is said to be immaterial. It is of importance to keep in mind this distinction, merely grammatical. Little more is necessary for detecting the sophisms of Helvetius, Mirabeau, and other sages of the Gallic school, who have been anxious to remove the ties of moral and religious obligation by lowering our conceptions of our intellectual nature. It will also serve to show how hastily *they* have formed their opinions who have ascribed to the immediate agency of mind all those relations which are observed in the actions of bodies on each other at a distance. The connecting principles of such relations *e distante* (if there are any such), are not the immediate objects of our senses: they are therefore immaterial. But it does not follow that they are minds. There may be many immaterial substances which are not minds. We know nothing of any object whatever but by the observation of certain appearances, which suggest to our minds the existence and agency of its qualities or powers. Such phenomena are the natural signs of these qualities, and it is to those signs that we must always have recourse when we wish to conceive without ambiguity concerning them. What is the characteristic phenomenon of mind, or what is the *distinguishing* quality which brings it into view? It is INTENTION: and it may be asserted with the utmost confidence, that we have no other mark by which mind is immediately suggested to us, or that would ever have made us suppose that there existed another mind besides our own. The *phenomenon* by which this quality is suggested to us is *art*, or the employment of means to gain ends; and the mark of art is the supposed conduciveness of these ends to the well-being of the agent. Where this train is not observed, design or intention is never thought of; and therefore where intention is not perceived in any immaterial substance, if any such has ever been observed, it is an abuse of language to call it mind. We do not think that even perception and intelligence intitle us to give the name mind to the substance in which they are inherent, because it is from marks of intention alone that we infer the existence of mind; and although these must be accompanied with perception and intelligence, it does not follow that the substance which can perceive and understand must also desire and propose. However difficult we may find it to separate them, they are evidently separable in imagination. And let not this assertion be too hastily objected to; for the separation *has been made* by persons most eminent for their knowledge and discernment. When Leibnitz ascribed to his MONADES, or what we call the ultimate ATOMS of matter, a perception of their situation in the universe, and a motion precisely suited to this perception, he was the farthest in the world from supposing them animated or endowed with minds. It is true indeed that others, who think and call themselves philosophers, are much more liberal in their application of this term. A modern author of great metaphysical eminence says, "I call that *mind* which moves, and that *body* which is moved." This class of philosophers assert that no motion whatever is begun except by the agency of an animating principle, which (after Aristotle) they call *Nature*, and which has in these days been exalted to the rank of a god. All this jargon (for it is nothing else) has arisen from the puzzle in which naturalists think themselves involved in attempting to explain the production of motion in a body at a distance from that body which is conceived as the cause of this motion. After having been reluctantly obliged, by the reasonings of Newton, to abandon their methods of explaining such phenomena by the impulses of an intervening fluid, nothing seemed left but the assertion that these motions were produced by minds, as in the case of our own exertions. These explanations (if they deserve the name) cannot be objected to in any other way than as an abuse of language, and as the introduction of an unmeaning jargon. We have, and can have, no notion of mind different from those of our own minds; and we discover the existence of other minds as we discover the existence of bodies, by means of phenomena which are characteristic of minds, that is, which resemble those phenomena that follow the exertion of our own mental faculties, that is, by the employment of means to attain selfish ends; and where such appearances are not observed, no existence of a mind is inferred. When we see a man fall from the top of a house, and dash out his brains on the pavement, we never ascribe this motion to his mind. Although the fitness of many of the celestial motions for most important purposes makes us suppose design and contrivance somewhere, and therefore a *Supreme Mind*, we no more think of inferring a mind in the earth from the fitness of its motions for purposes most beneficial to its inhabitants, than of inferring a mind in a bit of bread from its fitness for nourishing our bodies. It is not from the mere motions of animals that their minds are inferred, but from the conduciveness of these motions to the well-being of the animal.

12 The mind is not that which produces motion, but that which desires and wills.

The term mind therefore, in the *ordinary language* of all men, is applied to what desires and wills at the same time that it perceives and understands. If we call that mind which *produces motion*, we must derive our notions of its qualities or attributes from observing their effects. We must therefore discover the general laws by which they act, that is, the general laws observed in those motions which we consider as their effects. Now these are the general laws of motion; and in none of these can we find the least coincidence with what we are accustomed to call the laws of mind. Nay, it has been the total want of similarity which has given rise to the distinction which all men, in all ages and

Introduction.

and countries, have made between mind and matter. This distinction is found in all languages; and it is an unpardonable liberty which men take with languages when they use a *term of distinction*, a *specific term*, to express things of a different species. What these authors have been pleased to call *mind*, the whole world besides have called by another name, FORCE; which, though borrowed from our own exertions, is yet sufficiently distinctive, and never leads us to confound things that are different, except in the language of some modern philosophers, who apply it to the laws of the agency of mind; and, when speaking of the force of motives, &c. commit the same mistakes which the followers of Aristotle commit in the use of the term mind. *Force*, in the language of these philosophers, means what connects the operations of mind; as mind, in the language of Lord Monboddo, is that which connects the operations of body.

13 The principle of motion not distinct from matter and mind.

Those are not less to blame who consider this *Nature* of Aristotle, this principle of motion, as an existence or substance different both from matter and from the minds of intelligent creatures. Aristotle calls it in some places ὁστις ψυχη. He might with equal propriety, and equal consistency with his other doctrines, have called mind ὁστις τιλος, or an ὁστις δυναμις. Besides, we have no evidence for the separability of this ὁστις ψυχη from body-as we have for the separability of such minds as our own, the genuine ψυχαι. Nay, his whole doctrines, when maturely considered, assume their absolute inseparability.

14 Elemental minds are an abuse of language.

This doctrine of elemental minds, therefore, as the immediate causes of the phenomena of the material world, is an abuse of language. It is a jargon; and it is a frivolous abuse, for it offers no explanation whatever. The phenomena are totally unlike the phenomena of ordinary minds, and therefore receive no explanation from them; and since our knowledge of these *quasi* minds must be derived entirely from the phenomena, it will be precisely the same, although we express it in common language. We shall not indeed raise the wonder of our hearers, as those do who fill the world with minds which they never suspected to exist; but we shall not bewilder their imaginations, confound their ideas, and mislead their judgments.

15 The dreadful consequences of materialism.

We flatter ourselves that our readers will not think these observations unseasonable or misplaced. Of all mistakes that the naturalist can fall into, there is none more fatal to his progress in knowledge than the confounding things which are essentially different; and of all the distinctions which can be made among the objects of our contemplation, there is none of equal philosophical importance with this between mind and matter: And when we consider the consequences which naturally follow from this confusion of ideas, and particularly those which follow from sinking the mental faculties of man to a level with the operations of mechanics or chemistry, consequences which the experience of the present eventful day shows to be destructive of all that is noble or desirable in human nature, and of all that is comfortable in this life, and which blasts every hope of future excellence—we cannot be too anxious to have this capital distinction put in the plainest point of view, and expressed in the most familiar characters, "so that he who runneth may "read." When we see the frenzy which the reasoning pride of man has raised in our neighbourhood, and hear the dictates of philosophy incessantly appealed to in defence of whatever our hearts shudder at as shocking and abominable; and when we see a man (A), of great reputation as a naturalist, and of professed humanity and political moderation, congratulating his countrymen on the rapid improvement and almost perfection of philosophy; and after giving a short sketch of the constitution of the visible universe, summing up all with a table of elective attractions, and that particular combination and mode of crystallization which constitutes GOD *(horresco referens!)*—is it not full time for us to stop short, and to ask our own hearts "whither are you wandering?"—But sound philosophy, reasoning from effects to their causes, will here listen to the words of our sacred oracles: "By their fruits ye shall know them. Do men gather grapes of thorns, or figs of thistles?" The absurd consequences of the sceptical philosophy of Berkley and Hume have been thought, by men of undoubted discernment, sufficient reasons for rejecting it without examination. The no less absurd and the shocking consequences of the mechanical philosophy now in vogue should give us the same abhorrence; and should make us abandon its blood-stained road, and return to the delightful paths of nature, to survey the works of God, and feast our eyes with the displays of mind, which offer themselves on every hand in designs of the most extensive influence and the most beautiful contrivance. Following the guidance of heavenly wisdom, we shall indeed find, that "all her ways are ways of pleasantness, and all her paths are peace."

Introduction.

16 The extent of philosophical study.

Such is the scene of our observation, the subject of philosophical study. Its extent is almost unbounded, reaching from an atom to God himself. It is absolutely necessary for the successful cultivation of this immense field of knowledge that it be committed to the care of different cultivators, and that its various portions be treated in different ways: and, accordingly, the various tastes of men have given this curiosity different directions; and the study, like all other tasks, has been promoted by this division of labour.

Some philosophers have attended only to the appearances of fitness which are exhibited in every quarter of the universe; and by arranging these into different classes, and interpreting them as indications of thought and intention, have acquired the knowledge of many classes of sentient and intelligent beings, actuated by propensities, and directed by reason.

17 The nature and uses of animal instincts.

While the contemplation of these appearances indicates thought and design in any individual of one of these classes, and brings its propensities and purposes of action, and the ends gained by these actions, into view, the contemplation of these propensities, purposes, and ends, occasions an inference of a much more general

(A) M. de la Metherie, editor of the *Journal de Physique*. See his prefaces to the volumes for 1792 and 1793, January and July.

Introduction.

ral kind. All these intelligent beings give indications of knowledge and of power; but their knowledge bears, in general, no proportion to their power of producing changes in nature, and of attaining important ends; and their power is neither always, nor in the most important cases, the consequence of their knowledge. Where the effect of their actions is most eminently conducive to their important interests, the power of attaining these valuable ends is generally independent on any attention to the fitness of the means, and the exertion is frequently made without even thinking of the important end. The well-being of the individual is secured against any danger from its ignorance, indolence, or inattention, by an instinctive propensity, which leads it to the performance of the necessary action, which is thus made immediately and ultimately desirable, without any regard to its ultimate and important end. Thus, in our own nature, the support of animal life, and the improvement of the means of subsistence by a knowledge of the objects which surround us, are not intrusted to our apprehensions of the importance of these ends, but are committed to the surer guides of hunger and curiosity.

18 There is a connection between the individuals of a class of animals different from that of resemblance.

The same observers discover a connection between the individuals of a class, different from that which arises from the mere resemblance of their external appearance, or even of their propensities and pursuits; the very circumstances which produced the classification. They observe, that these propensities are such, that while each individual seeks only its own enjoyment, these enjoyments are in general such as contribute to the support of the species and the enjoyment of other individuals. Thus, in the classes of animals, and in human nature, the continuance of the race, and the enjoyment of the whole, are not intrusted to the apprehension we entertain of the importance of these ends, but are produced by the operation of sexual love and the love of society.

19 There is also a link of connection between sentient beings of different classes.

The same observers find that even the *different* classes of sentient beings are connected together; and while the whole of each class aim only at their own enjoyment, they contribute, in some way or other, to the well-being of the other classes. Even man, the selfish lord of this sublunary world, is not the unconnected inhabitant of it. He cannot, in every instance, reap all the fruits of his situation, without contributing to the enjoyment of thousands of the brute creation. Nay, it may be proved to the satisfaction of every intelligent man, that while one race of animals, in consequence of its peculiar propensities, subsists by the destruction of another, the sum total of animal life and enjoyment is prodigiously increased. See a very judicious dissertation on this curious and puzzling subject, intitled *A Philosophical Survey of the Animal Creation;* where it appears that the increase of animal life and enjoyment which is produced by this means, beyond what could possibly obtain without it, is beyond all conception. See likewise the last edition of *King's Origin of Evil*, by Dr Law late bishop of Carlisle.

20 The end of this connection is the accumulation of happiness.

Thus the whole assemblage seems connected, and jointly employed in increasing the sum total of possible happiness. This fitness of the various propensities of sentient and intelligent beings, this subserviency to a general purpose, strikes these observers as a mark of intention, evidently distinct from, and independent of, all the particular intentions, and superior to them all; and thus it irresistibly leads them to infer the existence of a SUPREME MIND, directing the whole of this INTELLECTUAL SYSTEM, while the individuals of which it consists appear the unconscious instruments in the hand of a great Artist, with which he executes his grand and beneficent purposes. Introduction.

21 All nature, animate and inanimate, thinking and unthinking, are connected.

But the observation goes yet further. The bodies of the inanimate creation are not only connected with each other by a mutual dependence of properties, and the relation of causation, but they are also connected with the sentient beings by a subserviency to their purposes of enjoyment. The philosopher observes that this connection is admirably kept up by the constancy of natural operations and the expectations of intelligent beings. Had either of these circumstances been wanting, had either the operations of nature been without rule, or had sentient beings no perception or expectation of their uniformity; the subserviency would be totally at an end. This adjustment, this fitness, of which the effect is the enjoyment of the sentient inhabitants of the universe, appear to be the effect of an intention of which this enjoyment is the final cause. This constancy therefore in the operations of nature, both in the intellectual and material world, and the concomitant expectation of sentient beings, appear the effects of *laws* imposed on the different parts of the universe by the Supreme Mind, who has formed both these classes of beings so admirably suited to each other.

22 The origin of natural theology.

To such observers the world appears a WORK OF ART, a system of means employed for gaining certain proposed ends, and it carries the thoughts forward to an ARTIST; and we infer a degree of skill, power, and good intention in this Artist, proportioned to the ingenuity, extent, and happy effect which *we are able to discern* in his works. Such a contemplation of nature, therefore, terminates in NATURAL THEOLOGY, or the discovery of the existence and attributes of GOD.

23 Our mode of reasoning on the operations of God.

Our notions of this *Supreme Mind* are formed from the indications of design which we observe, and which we interpret in the same way as in the actions of men. These notions, therefore, will differ from our notions of other minds only in the *degrees* which we *are able* to observe, and which we assign to these faculties; for the phenomenon or the effect is not only the mark, but also the measure of its supposed cause. These degrees must be ascertained by our own capacity of appreciating the extent, the multiplicity, and the variety of the contrivance. Accordingly, the attributes of the Supreme Mind, in the theological creed of a rude Indian, are much more limited than in that of a European philosopher. In proportion as our understandings are enlarged, and as our acquaintance with the operations of nature around us is extended, we shall perceive higher degrees of power, of skill, and of kind intention: and since we find that the scene of observation is unbounded, we cannot affix any boundaries to these attributes in our own imagination, and we are ready to suppose that they are infinite or unbounded *In their own nature.* When our attentive survey of *this* universe, and a careful comparison of all its parts, as far as we can understand or appreciate them, have made us conclude that it is *one* design, the work of *one* Artist;

Introduction.

Artiſt; we are under the neceſſity of inferring, that, with reſpect to *this univerſe*, his power, wiſdom, and benevolence, are indeed infinite.

24 The ſyſtem of nature is governed by general laws.

When men have been led to draw this concluſion from the appearances of fitneſs which are obſerved everywhere around them, they conſider that conſtancy which they obſerve in natural operations, whether in the material or the intellectual ſyſtem, and that expectation of, and confidence in, this conſtancy, which renders the univerſe a ſource of enjoyment to its ſentient inhabitants, as the conſequences of laws impoſed by the Almighty Artiſt on his works, in the ſame manner as they would conſider the conſtancy in the conduct of any people as the conſequences of laws promulgated and enforced by the ſupreme magiſtrate.

25 The nature and progreſs of the ſtudy of mind.

There can be no doubt of this view of nature being extremely captivating, and likely to engage the curioſity of ſpeculative men; and it is not ſurpriſing that the phenomena of mind have been keenly ſtudied in all ages. This part of the ſtudy of nature, like all others, was firſt cultivated in ſubſerviency to the wants of ſocial life; and the general laws of moral ſentiment were the firſt phenomena which were conſidered with attention. This gradually ripened into a regular ſyſtem of moral duty, accompanied by its congenial ſtudy, the inveſtigation or determination of the *ſummum bonum*, or the conſtituents of human felicity; and theſe two branches of intellectual ſcience were always kept in a ſtate of aſſociation by the philoſophers of antiquity. Juriſprudence, the ſcience of government, legiſlation, and policy, were alſo firſt cultivated as arts, or at leaſt in immediate ſubſerviency to the demands of cultivated ſociety; and all theſe ſo nearly related parts of the ſtudy of human nature, had made a very conſiderable progreſs, in the form of maxims or precepts, for directing the conduct, before ſpeculative men, out of mere curioſity, treated them as ſubjects of philoſophical ſtudy. Our moral ſentiments, always involving a feeling of obligation, are expreſſed in a language conſiderably different from the uſual language of pure philoſophy, ſpeaking of things which *ought to be* rather than of things which *are*; and this diſtinction of language was increaſed by the very aim of the writers, which was generally to influence the conduct as well as the opinions of their ſcholars. It was reſerved for modern times to bring this ſtudy into the pure form of philoſophy, by a careful attention to the phenomena of moral ſentiment, and claſſing theſe according to their generality, and aſcertaining their reſpective ranks by an appeal to experiment, that is, to the general conduct of mankind: and thus it happens that in the modern treatiſes on ethics, juriſprudence, &c. there is leſs frequent reference made to the *officia* or duties, or to the conſtituents of the *ſummum bonum*, than among the ancients, and a more accurate deſcription of the human mind, and diſcrimination of its various moral feelings.

26 The riſe of moral ſentiments and of moral duty.

27 The origin of logic and other intellectual ſciences.

It was hardly poſſible to proceed far in theſe diſquiſitions without attending to the powers of the underſtanding. Differences of opinion were ſupported by reaſonings, or attempts to reaſoning. Both ſides could not be in the right, and there muſt be ſome court of appeals. Rules of argumentation behoved to be acquieſced in by both parties; and it could hardly eſcape the notice of ſome curious minds, that there were rules of truth and falſehood as well as of right and wrong. Thus the human *underſtanding* became an object of ſtudy, firſt in ſubſerviency to the demands of the moraliſts, but afterwards for its own ſake; and it gradually grew up into the ſcience of logic. Still further refinement produced the ſcience of metaphyſics, or the philoſophy of univerſals. But all theſe were *in fact* poſterior to the doctrines of morals; and diſquiſitions on beauty, the principles of taſte, the precepts of rhetoric and criticiſm, were the laſt additions to the ſtudy of the phenomena of mind. And now, ſince the world ſeems to have acquieſced in the mode of inveſtigation of general laws by experiment and obſervation, and to agree that this is all the knowledge that we can acquire of any ſubject whatever, it is to be expected that this branch of philoſophical diſcuſſion will attain the ſame degree of improvement (eſtimated by the coincidence of the doctrines with fact and experience) that has been attained by ſome others.

Introduction.

28 The partial practice of natural philoſophy preceded its ſtudy as a ſcience.

The occupations, however, of ordinary life have often more directed our efforts towards material objects, and engaged our attention on their properties and relations; and as all ſciences have ariſen from arts, and were originally implied in the maxims and precepts of thoſe arts, till ſeparated from them by the curious ſpeculatiſt, the knowledge of the material ſyſtem of nature was poſſeſſed in detached ſcraps by the practitioners in the various arts of life long before the *natural philoſopher* thought of collecting them into a body of ſcientific doctrines. But there have not been wanting in all ages men of curioſity who have been ſtruck by the uniformity of the operations of nature in the material world, and were eager to diſcover their cauſes.

Accordingly, while the moraliſts and metaphyſicians turned their whole attention to the phenomena of mind, and have produced the ſciences of pneumatology, logic, ethics, juriſprudence, and natural theology, theſe obſervers of nature have found ſufficient employment in conſidering the phenomena of the material world.

29 The nature of the material ſyſtem with the definition of that and other terms.

The bodies of which it conſiſts are evidently connected by means of thoſe properties by which we obſerve that they produce changes in each other's ſituation. This aſſemblage of objects may therefore be juſtly called a ſyſtem. We may call it the MATERIAL SYSTEM. It is frequently termed NATURE; and the terms NATURAL APPEARANCES, NATURAL CAUSES, NATURAL LAWS, have been generally reſtricted to thoſe which take place in the material ſyſtem. This reſtriction, however, is improper, becauſe there is no difference in the manner in which we form our notions of thoſe laws, and reaſon from them, both with reſpect to mind and body. Or if there is to be any reſtriction, and if any part of the ſtudy of the univerſe is to be excluded in the application of theſe terms, it is that part only which conſiders moral obligation, and rather treats of what *ought to be* than of what *is*. As has been already obſerved, there is a conſiderable difference in the language which muſt be employed; but ſtill there is none in the principles of inveſtigation. We have no proof for the extent of any moral law but

ntroduc-tion.

30
he unre-ricted nſe in hich me of ieſe terms e uſed, nd its bad onſequen-es.

but an appeal to the feelings of the hearts of men, indicated by the general laws or facts which are obſerved in their actions.

But this is only a queſtion of the propriety of language. And no great inconvenience would ariſe from the reſtriction now mentioned if it were ſcrupulouſly adhered to; but unfortunately this is not always the caſe. Some authors uſe the term *natural law* to expreſs *every* coincidence of fact; and this is certainly the proper uſe of the term. The French writers generally uſe the term *loi phyſique* in this enlarged ſenſe. But many authors, miſled by, or taking advantage of, the ambiguity of language, after having eſtabliſhed a law founded on a copious and perhaps unexcepted induction of the phenomena of the material ſyſtem (in which caſe it muſt be conſidered in its reſtricted ſenſe), have, in their explanation of phenomena, extended their principle much farther than the induction on which they had founded the exiſtence of the phyſical law. They have extended it to the phenomena of mind, and have led their followers into great and dangerous miſtakes. Languages, like every other production of human ſkill, are imperfect. They are deficient in terms, and are therefore figurative. The moſt obvious, the moſt frequent, and the moſt intereſting uſes of language, have always produced the appropriated terms, and the progreſs of cultivation has never completely ſupplied new ones. There are certain analogies or reſemblances, or certain aſſociations of ideas, ſo plain, that a term appropriated to one very familiar object will ſerve to ſuggeſt another analogous to it, when aided by the concomitant circumſtances of the diſcourſe; and this with ſufficient preciſion for the ordinary purpoſes of ſocial communication, and without leading us into any conſiderable miſtakes: and it is only the rare and refined diſquiſitions of the curious ſpeculatiſt that bring the poverty and imperfection of language into view, and make us wiſh for words as numerous as our thoughts. There is hardly a ſentence, even of common diſcourſe, in which there are not ſeveral figures either of ſingle words or of phraſes; and when very accurate diſcrimination is required, it is almoſt impoſſible to find words or phraſes to expreſs diſtinctions which we clearly feel. We believe it impoſſible to expreſs, by the ſcanty vocabulary of the Hebrews, the nice diſtinctions of thought which are now familiar to the European philoſopher. In nothing does this imperfection of language appear ſo remarkably as in what relates to mind. Being a late ſubject of ſeparate diſcuſſion, and intereſting only to a few ſpeculatiſts, we have no appropriated vocabulary for it; and all our diſquiſitions concerning its operations are in continual metaphor or figure, depending on very ſlight analogies or reſemblances to the phenomena of the material world. This makes the utmoſt caution neceſſary; and it juſtifies the Britiſh philoſophers, who have been the moſt ſucceſsful in proſecuting the ſtudy of the intellectual ſyſtem, for having, almoſt without exception, reſtricted the terms natural laws, natural cauſes, natural philoſophy, and ſuch like, to the material ſyſtem. With us pneumatology makes no part of phyſics. And we may venture to affirm, that the ſciences have fared better by the reſtriction of the terms. In no country has the ſpirit of liberal diſcuſſion been more encouraged and indulged than in Britain; and her philoſophers have been equally eminent in both branches of ſcience. Their performances in ethics, juriſprudence, and natural theology, are conſidered by all our neighbours as the fountains of knowledge on theſe ſubjects; and Locke and Clarke are names no leſs familiar on the continent than Newton. The licentious and degrading doctrines of the Gallican ſchool have as yet made little impreſſion here; and man is ſtill conſidered among us as a glorious creature, born to, and fitted for, the nobleſt proſpects. Introduction

31 The term *phyſics* defined as it is generally underſtood in Britain.

Phyſics, then, is with us the ſtudy of the material ſyſtem, including both natural hiſtory and philoſophy. The term is not indeed very familiar in our language; and in place of *phyſicus* and *diſciplina phyſica*, we more generally uſe the terms *naturaliſt* and *natural knowledge*. The term *natural philoſophy*, in its common acceptation, is of leſs extent. The field of phyſical inveſtigation is ſtill of prodigious extent; and its different quarters require very different treatments, make very different returns, and accordingly have engaged in their particular cultivation perſons of very different talents and taſtes. It is of ſome importance to perceive the diſtinctions, and to ſee how the wants and propenſities of men have led them into the different paths of inveſtigation; for, as has been more than once obſerved, all ſciences have ſprung from the humble arts of life, and both go on improving by means of a cloſe and conſtant correſpondence.

32 The phenomena of the material ſyſtem arranged into two claſſes.

All the phenomena of the material ſyſtem may be arranged into two claſſes, diſtinguiſhed both by their objects and by the proper manner of treating them.

The firſt claſs comprehends all the appearances which are exhibited in the *ſenſible motions* of bodies, and their actions on each other producing *ſenſible motion*.

The ſecond claſs comprehends the appearances which are exhibited in the *inſenſible* motions and actions of the inviſible particles of matter.

33 Examples of thoſe of the firſt claſs,

Of the phenomena of the firſt claſs we have examples in the planetary motions, the motions of heavy bodies, the phenomena of impulſe, the motions and actions of machines, the preſſure and motions of fluids, the ſenſible actions of magnetical and electrical bodies, and the motions of light.

34 And of thoſe of the ſecond.

We have examples of the ſecond claſs in the phenomena of heat and mixture, and thoſe exhibited in the growth of animals and vegetables, and many phenomena of ſolid, fluid, magnetical, electrical, and luminous bodies, in which no change of place can be obſerved.

35 This arrangement is apparently natural.

Thus it appears that there is a diſtinction in the phenomena ſufficiently great to warrant a diviſion of the ſtudy, and to make us expect a more rapid improvement by this diviſion. Nay, the diviſion has been made by nature herſelf, in the acquaintance which men have attained with her operations without ſtudy, before ſcience appeared, and while art conſtituted all our knowledge.

36 Of the progreſs of knowledge in rude ages.

Before man had recourſe to agriculture as the moſt certain means of procuring ſubſiſtence, our acquaintance with external ſubſtances was principally that of the natural hiſtorian; conſiſting of a knowledge of their fitneſs for food, medicine, or accommodation, their places of growth or habitation, and the means of

Introduction.

37 The origin of agriculture, phyſic, ſurgery, and chemiſtry.

procuring them, depending on their manner of life or exiſtence. It required a ſtudied attention to theſe circumſtances to give riſe to agriculture, which therefore generally made its appearance after men had been in the practice of keeping flocks; by which means they were more at their eaſe, and had ſome leiſure to attend to the objects around them, and in particular to thoſe circumſtances of ſoil and weather which affected the growth of their paſture.

When agriculture and a rude medicine were thus eſtabliſhed, they were the firſt *arts* which had their foundation in a *ſyſtem of laws*, by which the operations of nature were obſerved to be regulated; and with theſe arts we may begin the *general ſtudy of nature*, which were thus divided into two different branches.

The rude phyſician would be at firſt a collector of *ſpecifics*; but by degrees he would obſerve reſemblances among the *operations* of his drugs, and would claſs them according to theſe reſemblances. He would thus come to attend leſs to the drug than to its mode of operation; and would naturally ſpeculate concerning the connection between the operation and the economy of animal life. His art now becomes a ſcientific ſyſtem, connected by principle and theory, all proceeding on the obſervation of changes produced by one kind of matter on another, but all out of ſight. The frequent recourſe to the vegetable kingdom for medicines would cauſe him to attend much more minutely to the few plants which he has occaſion to ſtudy than the huſbandman can do to the multitude he is obliged to rear. The phyſician muſt learn to think, the huſbandman to work. An analogy between the economy of animal and vegetable life could hardly fail to engage the attention of the phyſician, and would make him a botaniſt, both as a claſſifier of plants and as a philoſopher.

He would naturally expect to unite the ſervices of his drugs by combining them in his recipes, and would be ſurpriſed at his diſappointments. Curious and unexpected changes would frequently occur in his manipulations: the ſenſible qualities, and even the external appearances of his ſimples, would be often changed, and even inverted by their mixture; and their medicinal properties would frequently vaniſh from the compound, and new ones be induced. Theſe are curious, and to him intereſting facts; and he would naturally be inquiſitive after the principles which regulate theſe changes. His ſkill in this would by degrees extend beyond the immediate uſe for the knowledge; and the more curious ſpeculatiſt would lay the foundations of a moſt extenſive and important ſcience, comprehending all the phenomena of heat and mixture.

Along with this, and ſpringing from the ſame ſource, another ſcience muſt ariſe, contemplating the appearances of animal and vegetable life, and founded on a careful obſervation and accurate deſcription of the wonderful machine. The moſt incurious of men have in all ages been affected by the diſplays of wiſdom and contrivance in the bodies of animals, and immediately engaged in inveſtigation into the uſes and functions of their various parts and organs. The phenomena have been gradually diſcriminated and arranged under the various heads of nutrition, concoction, ſecretion, abſorption, aſſimilation, rejection, growth, life, decay, diſeaſe, and death; and, in conformity to the doctrines which have with greater or leſs evidence been eſtabliſhed on theſe ſubjects, the action of medicines, and the whole practice of phyſic and ſurgery, has been eſtabliſhed in the form of a liberal or ſcientific art.

Introduction.

38 The origin of the knowledge of the mechanical powers.

The huſbandman in the mean time muſt labour the ground which lies before him. He, too, is greatly intereſted in the knowledge of the vegetable economy, and forms ſome ſyſtems on the ſubject by which he regulates his labours: but he ſees, that whatever is the nature of vegetable life, he muſt work hard, and he ſearches about for every thing which can tend to diminiſh his labour. The properties of the lever, the wedge, and the inclined plane, ſoon become familiar to him; and without being able to tell on what their efficacy depends, he uſes them with a certain ſagacity and effect. The ſtrength of timber, the preſſure and force of water, are daily ſeen and employed by him and other artiſans who labour for their mutual accommodation; and ſome rude principles on theſe ſubjects are committed to memory. Many tools and ſimple machines are by this time familiar, and thus the *general* properties of matter, and the general laws of the actions of bodies on each other, become gradually matter of obſervation and reflection; and the practical mechanic will be frequently improving his tools and machines. The general aim is to produce a greater quantity of work by the ſame exertion. The attempts to improvement will be awkward, and frequently unſucceſsful. When a man finds, that by increaſing the length of his lever he increaſes his power of overcoming a reſiſtance, a ſmall degree of curioſity is ſufficient to make him inquire in what proportion his advantage increaſes. When he finds that a double length gives him a double energy, he will be ſurpriſed and mortified to find, that at the end of the day he has not performed twice the quantity of work: but, after much experience, he will learn that every increaſe of energy, by means of a machine, is nearly compenſated by an increaſe of time in the performance of his taſk; and thus one of the great and leading principles of practical mechanics was inculcated in a manner not to be forgotten, and the practical mechanic was brought to ſpeculate about motion and force, and by gradual and eaſy ſteps the general laws of ſimple motions were eſtabliſhed.

39 The origin of mathematics.

It is evident that theſe ſpeculations cannot be carried on, nor any conſiderable knowledge acquired, without ſome acquaintance with the art of meaſurement: and the very queſtions which the mechanic wiſhes to ſolve, preſuppoſe ſome advances in this art, which in proceſs of time refined itſelf into mathematics, the moſt perfect of all the ſciences. All the phenomena of ſenſible motion afford employment to the mathematician. It is performed in a double or triple time, through a double or triple ſpace, by a double or triple body, by the exertion of a double or triple force, produces a double or triple effect, is more to the right or to the left, upwards or downwards, &c. In ſhort, every affection of motion is an object of mathematical diſcuſſion. Such a ſcience muſt have appeared ere now in the form of an art, in conſequence of the mutual tranſactions of men. Theſe among an uncultivated people are chiefly in the way of barter. If I want corn from a peaſant, and have nothing to give for it but the cloth which I have made, we muſt fall on ſome way

Introduction.

way of adjusting our terms in respect of the quantity. We should soon discover that the length, and breadth, and depth, of the box or bag, were equally important; and it was not difficult to see, that if any of them were doubled or tripled, the quantity of grain would be so too; if two of them were doubled, the grain would be quadrupled; and if all the three were doubled the quantity of grain would be increased eight times: the same thing would be observed with respect to my cloth. By such transactions as these, a few of the properties of plane and solid numbers and figures would become known, and the operations of multiplication and division, where arithmetic is combined with geometry: and daily observation shows us, that the more abstruse properties of number and figure, which to the generality of mankind are so insignificant, lay hold on the fancy of some individuals with such force, as to abstract them from every other intellectual entertainment, and are studied with a keenness and perseverance almost unequalled in any other walk of science. To most men the performance of a machine is a more attractive object than the properties of a figure, and the property of a figure more entertaining than that of a number; but the fact seems to have been otherwise. Before Pythagoras had invented the theorem that bears his name (see PHILOSOPHY, n° 15. and note H.), and which is among the first elements of geometry, he had reformed the Grecian music by the addition of a note to their scale, and this addition proceeds on a very refined speculation on the properties of numbers; so that among the Greeks arithmetic must have made considerable progress, while geometry was yet in its cradle: and we know to what astonishing length they prosecuted the science of pure geometry, while their knowledge of mechanical principles was almost nothing. Also the Arabs hardly made any addition to the geometry of the Greeks, if they did not rather almost completely forget it; whilst they improved their arithmetic into algebra, the most refined and abstracted branch of human knowledge. There is such a distance, in point of simplicity, between pure mathematics and the most elementary mechanics, that the former continued to make rapid steps to improvement in more modern times, while the latter languished in its infancy, and hardly deserved the name of science till very lately, when the great demand for it, by the increase and improvement in manufactures, both interested many in the study, and facilitated its progress, by the multitude of machines which were contriving on all hands by the manufacturers and artisans: and even at present it must be acknowledged, that it is to them that we are indebted for almost every new invention in mechanics, and that the speculatill seldom has done more than improve the invention, by exhibiting its principles, and thus enabling the artist to correct its imperfections; and now science and art go hand in hand, mutually giving and receiving assistance. The demands of the navigator for mathematical and astronomical knowledge have dignified these sciences; and they are no longer the means of elegant amusement alone, but merit the munificence of princes, who have erected observatories, and furnished voyages of discovery, where the mathematical sciences are at the same time cherished and applied to the most important purposes.

This short sketch of what may be called *the natural history of physical sciences* will not, we hope, be thought improper or unprofitable. It tends to confirm an assertion often alluded to, that the prosecution of the study of nature will be more successful, if we imitate her mode of proceeding, and divide the labour. It will be still further confirmed by attending to the scientific difference of the phenomena, which marks out a different mode of proceeding, and a difference in the knowledge which we shall ultimately acquire, after our most successful researches. Introduction.

40 The connecting principle of concomitant events is totally unknown.

In both classes of phenomena already distinguished (n° 6.) we must grant, that the principle which connects the pairs of concomitant events, rendering the one the inseparable companion of the other, is totally unknown to us, because it is not the immediate object of our perception.

41 In the first class, however, the exertion of this principle may be accurately observed,

But in the phenomena of the first class, we see the *immediate* exertion of this principle, whatever it may be; we can observe the exertion with accuracy; we can determine its kind and degree, which are the signs and measures of the kind and degree of the unperceived cause. This exertion, being always some modification of motion, allows us to call in the aid of mathematical knowledge, and thus to ascertain with the precision peculiar to that science the energy of the cause, judging of the tendency and quantity by the tendency and the quantity of the observed effect.

42 But not in the second;

But in the second class of phenomena the case is very different. In the operations of chemistry, for instance, the *immediate* exertion of the cause is not perceived: all that we observe is the assemblage of particles which obtains before mixture, and that which takes place when it is completed, and which we consider as its result. The procedure of nature in producing the change is unseen and unknown. The steps are hid from our observation. We are not only ignorant of the cause which determines one particle of our food to become a part of our body while others are rejected, but we do not see the operation. We are not only ignorant of the cause which determines a particle of vitriolic acid to quit the fossil alkali with which it is united in Glauber salt, and to attach itself to a particle of magnesia already united with the muriatic acid, which also quits it to unite with the alkali, but we do not see the operation. The particles and their motions are not the objects of our senses; and all that we see is the Epsom salt and common salt separated from the water in which we had formerly dissolved the sal mirabile and the muriated magnesia. The motions, which are the *immediate* effects of the changing causes, and therefore their *only indications, characteristics, and measures*, fitted to show their nature, are hid from our view.

43 And therefore the phenomena of the second class are left unperstood.

Our knowledge therefore of these phenomena must be less perfect than that of the phenomena of the former class; and we must here content ourselves with the discovery of more remote relations and remote causes, and with our ignorance of the very powers of nature by which these changes are brought about, and which are cognoscible only by their immediate effects, viz. the motions which they produce unseen. The knowledge which we do really acquire is somewhat similar to what the mechanical philosopher has acquired when he has discovered, by many experiments and investigations, that magnets attract each other by their dissimilar

Introduction.

milar poles, and repel each other by their similar poles, and do not act at all on any bodies but loadstones and iron. Here we leave undiscovered all that is most curious in the phenomenon, *viz.* how these attractions and repulsions are produced; and even here the magnetical philosopher has the advantage of seeing the agents and the operation.

44 Though some philosophers have attempted to explain them by the doctrine of motion;

But philosophers attending to this circumstance, that, even in these cases, the changes are produced by motions, or consist in motions, however unperceived these may be, have concluded, that the laws according to which nature operates in producing these changes are similar to the laws which regulate her operations in the sensible actions of bodies, or are included in them; and that the motions, though unseen, and the moving forces, are perfectly similar. They have therefore employed similar modes of investigation, applying the laws of impulse, and calling in the aid of mathematical knowledge.

Of this we have many examples in the writings of Dr Freind, Keil, Bernoulli, Hellsham, Boerhaave, Hartley, and others, who have delivered theories of fermentation, solution, precipitation, crystallization, nutrition, secretion, muscular action, nay even of sensation and intelligence, founded, as they think, on the laws of motion, and illustrated and supported by mathematical reasoning. Lord Bacon himself, that careful and sagacious distinguisher of intellectual operations, has gone into the same track in his explanation of the phenomena of fire and combustion: and Sir Isaac Newton has made several attempts of the same kind, although with peculiarities which always characterise his discussions, and make them very different from those of an inferior class.

45 But their attempts have been unsuccessful.

But the success of these philosophers has hitherto been very discouraging: indeed they had no title to expect any; for their whole trains of reasoning have proceeded on analogies which were not observed, but assumed or *supposed* without any authority. There is not that similarity in the phenomenon, or in the visible effect, which is absolutely necessary for a successful reasoning by analogy. We do not observe any local motion, any change of place, which alone enables us to reason mathematically on the subject. And to make the case desperate, this ill-founded anology has been mixed with hypotheses completely gratuitous. Certain forms have been assigned to the particles, and certain modes of action have been laid down for them, for whose reality we have not the least argument or indication: and to complete the matter, these fancied forms and laws of action have been such as are either self contradictory and inconsistent, or they have been such as, if allowed to act in a way analogous to what we observe in the sensible motions of bodies, would produce effects totally different from those which are observed. These atomical theories, as they are called, transgress every rule of philosophical discussion, and even the best of them are little better than trifling amusements. By far the greatest part of them only serve to raise a smile of pity and contempt in every person at all acquainted with mechanical philosophy. Whenever we see an author attempting to explain these hidden operations of nature by invisible fluids, by æthers, by collisions, and vibrations, and particularly if we see him introducing mathematical reasonings into such explanations—the best thing we can do is to shut the book, and take to some other subject. That we may not be thought to speak presumptuously on this occasion, we only beg leave to remind our readers, that the united knowledge of the most eminent mathematicians of Europe has not yet been able to give any thing more than an approximation to the solution of the problem of three bodies; that is, to determine with accuracy the motions of three particles of matter acting on each other in the simplest of all possible manners, *viz.* by forces varying as the squares of the distances inversely: and the vibrations of elastic bodies, of any but the very simplest possible forms, are to this day beyond the reach of investigation. What then should be our expectations in cases where millions of particles are acting at once, of forms unobserved, and with forces unknown, and where the object is not a determination of an average result of many, where the precise state of an individual particle need not be known, but where it is this very precise state of each single particle that we want to know? What can it be but uncertainty and mistake?

Introduction.

46 The advantage derived in these speculations from mathematical philosophy

Notwithstanding these discouraging circumstances, we must observe that this kind of inquiry has greatly improved of late years, along with the improvement and extension of mathematical philosophy, and since philosophers have given over their incessant attempts to explain every thing by impulse; and we need not despair of making still farther advances, if we will content ourselves with going no farther than Newton has done in his explanation of the planetary motions. He has immortalized his own name, and has added immensely to our stock of useful knowledge: yet he has stopped short at the discovery of the fact of universal gravitation; and all who have endeavoured to explain or account for this fact have only exposed themselves to pity. We may perhaps be one day able to demonstrate from the phenomena that the particles of matter have certain mutual tendencies to or from each other, exerted according to fixed or invaried rules; and from these tendencies we may be able to explain many other phenomena, and predict the consequences, with as much certainty and evidence as an astronomer calculates a future eclipse. This would be a great acquintion, and perhaps more is impossible: and the road to this has been hinted by Sir Isaac Newton, who has expressed his suspicion, that as the great movements of the solar system are regulated by universal gravitation, so the mutual actions of the particles of matter are produced and regulated by tendencies of a similar kind, *equally* but not *more* inexplicable, and of which the laws of action are to be discovered by as careful an attention to the phenomena, and by the same patient thinking, which he has employed on the planetary motions. And a beautiful introduction to this new and almost unbounded field of enquiry has been given us by the celebrated Abbé Boscovich, in his Theory of Natural Philosophy, where he has shown how such mutual tendencies, similar in every ultimate particle of matter, and modified by conditions that are highly probable, nay almost demonstrable, will not only produce the sensible forms of solidity, hardness, elasticity, ductility, fluidity, and vapour, under an inconceivable variety

Introduction.

variety of subordinate appearances, and the observed laws of sensible motion, but will go far to explain the phenomena of fusion, congelation, solution, crystallization, &c. &c. &c. both in chemistry and physiology. We earnestly recommend this work to the perusal of all who wish to obtain a distinct notion of the internal constitution of natural bodies, and of the way in which the uniting forces produce their ultimate and sensible effects. Any person, possessed of a moderate share of mathematical knowledge, will be convinced that the process of nature is not very different from what he describes; and that much of what we observe must happen as he says, even although the ultimate atoms of matter are not inextended mathematical points, accompanied with attracting and repelling forces.

47 Our ignorance still great, and the probable increase of knowledge among posterity.

But we have many steps to make before we begin this study: Nature opens to us an immense volume; and we doubt not that our posterity will long find employment in the perusal, even though advancing with the eagerness and success of the last century. We have not yet arrived at the threshold in many parts of this research: In many parts of chemistry, for instance, we are as yet uncertain with respect to the phenomena themselves, which are to be the subjects of this discussion. The composition of bodies must be fully understood before we begin to speak of the forces which unite their particles, or speculate about their modes of action. As long as water was considered as an element, we were ignorant of the forces inherent in its particles; we are perhaps still ignorant of this; but we now know that they are extremely different from what we formerly supposed them to be. It is but in a very few, if in any, cases of chemical combination, that we even know what are the ingredients: till we know this, it is too soon to speculate about their mode of union. Our ignorance in the real events in the animal and vegetable economy is still greater. Our first task therefore is to proceed, as we are now doing, in the accurate examination and classification of the phenomena themselves; and, without attempting to bring them within the pale of mathematical philosophy, by attempting what are called mechanical explanations, let us give up the consideration of these hidden operations, and augment to the utmost our list of secondary laws of visible but remote connections. All the mechanical speculations of the honourable Robert Boyle about the sensible qualities of things are now forgotten; but his chemical experiments preserve all their value, and are frequently referred to. The same may be said of the sagacious Dr Hales, whose fanciful notions of internal conflicts, and collisions, and vibrations, derogate nothing from the value of the curious facts which he has established both in the animal and vegetable economy.

48 The particular divisions of physical science in Britain.

This distinction in the nature of the phenomena, and this difference in the nature of the knowledge which is to be acquired, and the means which are to be employed for the successful prosecution of these two branches of general physics, has occasioned a still farther restriction (at least in Britain) of the term NATURAL PHILOSOPHY. It is particularly applied to the study of the phenomena of the first class, while those of the second have produced the sciences of CHEMISTRY and PHYSIOLOGY.

Natural philosophy and chemistry have generally been made particular institutions in our seminaries of learning, but physiology has more commonly been taught in conjunction with anatomy, medicine, and botany. Introduction.

The phenomena of the first class have been usually called MECHANICAL, in order to distinguish them from those observed in the operations of chemistry, and in the animal and vegetable economy: and the explanations which have been attempted of some of the last, by applying the laws observed in the phenomena of the first class, have been called *mechanical explanations*.

As this first class is evidently but a part of general physics, there is some impropriety in giving the name *natural philosophy* to a course of doctrines which is confined to these alone. Indeed at the first institution of universities, the lectures given in the *Schola Physica* were much more extensive, comprehending almost all the phenomena of the material world: but as all arts and sciences have improved most where the labour has been most divided, it was found more conducive to the advancement of knowledge that separate institutions should be founded for the studies of natural history, chemistry, physiology, &c; and thus the phenomena, purely mechanical, and a few others in magnetism, electricity, and optics, which either were susceptible of mathematical treatment, or had little connection with the studies of chemistry and physiology, were left to the care of the professor of natural philosophy.

As the terms *chemistry* and *physiology* have been applied to two very important branches of general physics, we think that a more specific or characteristic name might be appropriated to the other, and that it might very properly be termed MECHANICAL PHILOSOPHY.

It only remains to make a few observations on the distinctive means of prosecuting these studies with success, and to point out some of the advantages which may reasonably be expected from a careful prosecution of them: and as the second branch has been fully treated under the several articles of CHEMISTRY, PHYSIOLOGY, &c. we shall confine ourselves to what is usually called NATURAL PHILOSOPHY.

49 Mechanical philosophy defined, and its principles explained.

MECHANICAL PHILOSOPHY may, in conformity with the foregoing observations, be defined, "the study of the sensible motions of the bodies of the universe, and of their actions producing sensible motions, with the view to discover their causes, to explain subordinate phenomena, and to improve art."

The principle upon which all philosophical discussion proceeds is, that *every change which we observe in the condition of things is considered by us as an effect, indicating the agency, characterising the kind, and measuring the degree, of its cause.*

In the language of mechanical philosophy, the cause of any change of motion is called a moving or changeing FORCE.

The disquisitions of natural philosophy must therefore begin with the consideration of motion, carefully noticing every affection or quality of it, so as to establish marks and measures of every change of which it is susceptible; for these are the only marks and measures.

Mechanical Philosophy.

sures of the changing forces. This being done, it only remains to apply them to the motions which we observe in the universe.

50 The laws of motion and their application.

From the general principle of philosophical discussion already mentioned, there flow directly two axioms.

1. *Every body perseveres in a state of rest or of uniform rectilineal motion, unless affected by some moving force.*

2. *Every change of motion is in the direction and in the degree of the force impressed.*

These are usually called the LAWS OF MOTION. They are more properly laws of human judgment, with respect to motion. Perhaps they are necessary truths, unless it be alleged that the general principle, of which they are necessary consequences, is itself a contingent though universal truth.

By these two axioms, applied *in abstracto* to every variety of motion, we establish a system of general doctrines concerning motions, according as they are simple or compounded, accelerated, retarded, rectilineal, curvilineal, in single bodies, or in systems of connected bodies; and we obtain corresponding characteristics and measures of accelerating or retarding forces, centripetal or centrifugal, simple or compound.

We have an illustrious example of this abstract system of motion and moving forces in the first book of Sir Isaac Newton's Mathematical Principles of Natural Philosophy. Euler's *Mechanica sive Scientia Motus*, Herman's *Phoronomia sive de Viribus Corporum*, and D'Alembert's *Traité de Dynamique*, are also excellent works of the same kind. In this abstract system no regard is paid to the casual differences of moving forces, or the sources from which they arise. It is enough to characterise a double accelerating force, for instance, that it produces a double acceleration. It may be a weight, a stream of water, the pressure of a man; and the force, of which it is said to be double, may be the attraction of a magnet, a current of air, or the action of a spring.

Having established these general doctrines, the philosopher now applies them to the *general* phenomena of the universe, in order to discover the nature of the forces which really exist, and the laws by which their operations are regulated, and to explain interesting but subordinate phenomena. This is the chief business of the mechanical philosopher; and it may with some propriety be called *the mechanical history of nature.*

51 Of the arrangement of the mechanical phenomena of the universe.

Some method must be followed in this history of mechanical nature. The phenomena must be classed by means of their resemblances, which infer a resemblance in their causes, and these classes must be arranged according to some principle. We have seen no method which appears to us less exceptionable than the following.

52 The generality of the phenomena is the principle of arrangement.

The principle of arrangement is the generality of the phenomena; and the propriety of adopting this principle, arises from the probability which it gives us of more readily discovering the most general actuating forces, whose agency is implicated in all other phenomena of less extent; and therefore should be previously discussed, that we may detect the discriminating circumstances which serve to characterise the subordinate phenomena, and are thus the marks of the distinguishing and inferior natural powers.

Mecha Philoso

The most general of all phenomena is the curvilineal motion of bodies in free space; it is observed through the whole extent of the solar system.

52 The law motion first ap to astro mical p nomena

The mechanical history of nature begins therefore with astronomy. Here, from the general phenomena of the planetary motions, is evinced the *fact* of the mutual deflection of every body towards every other body, and this in the inverse proportion of the squares of the distance, and the direct proportion of the quantity of matter. This is the fact of UNIVERSAL GRAVITATION, indicating the agency, and measuring the intensity, of the universal force of mutual gravity.

Having established this as an universal fact, the natural philosopher proceeds to point out all the particular facts which are comprehended under it, and whose peculiarities characterise the different movements of the solar system. That is, in the language of philosophy, he gives a theory or explanation of the subordinate phenomena; the elliptical motions of the planets and comets, their mutual disturbances; the lunar irregularities; the oblate figure of the planets; the nutation of the earth's axis; the precision of the equinoxes; and the phenomena of the tides and trade winds: and he concludes with the theory of the parabolic motion of bodies projected on the surface of this globe, and the motion of pendulums.

54 The ap cation this sci ence to arts of life.

As he goes along, he takes notice of the applications which may be made to the arts of life of the various doctrines which are successively established; such as chronology, astronomical calculation, dialling, navigation, gunnery, and the measuring of time.

55 The na of grav tion,

If a square parcel of sand be lying on the table, and the finger be applied to any part of it to push it along the table, that part is removed where you will, but the rest remains in its place; but if it is a piece of sandstone of the same materials and shape, and the finger is applied as before, the whole is moved; the other parts accompany the part impelled by the finger in all its motions.

56 And of hesion.

From the moon's accompanying the earth in all its motions round the sun, we infer a moving force which connects the moon and earth. In like manner, we must conclude that a moving force connects the particles of the stone; for we give the name *force* to every thing which produces motion: We call it the force of COHESION; a term which, like gravitation, expresses merely a fact.

This seems to be the next phenomenon of the universe in point of extent.

57 Mode vestig ting th laws of hesion.

Having, from the general phenomenon, established the existence of this force, the philosopher proceeds to ascertain the laws by which its exertions are regulated; which is the ascertaining its distinctive nature and properties. This he does in the same way that he ascertained the nature of planetary gravitation, *viz.* by observing more particularly the various phenomena.

Here is opened a most extensive and varied field of observation, in which it must be acknowledged that very little regular and marked progress has been made. The variety in the phenomena, and the consequent variety in the nature of the connecting forces, appear as yet inconceivably great; and there seems little probability

Mechanical Philosophy.

bability of our being able to detect in them all any fameneſs, combined with the other diſtinguiſhing circumſtances, as we have done in the caſe of gravity. Yet we ſhould not deſpair. Boſcovich has ſhown, in the moſt unexceptionable manner, that although we ſhall ſuppoſe that every atom of matter is endued with a perfectly ſimilar force, acting in a certain determined ratio of the ſmall and imperceptible diſtances at which the particles of matter are arranged with reſpect to each other, the external or ſenſible appearances may, and muſt, have all that variety which we obſerve. He alſo ſhows very diſtinctly how, from the operation of this force, muſt ariſe ſome of the moſt general and important phenomena which characteriſe the different forms of tangible bodies.

We obſerve the chief varieties of the action of this CORPUSCULAR force on the bodies which we denominate *hard*, *ſoft*, *ſolid*, *fluid*, *vaporous*, *brittle*, *ductile*, *elaſtic*. We ſee inſtances where the parts of bodies avoid each other, and require external force to keep them together, or at certain ſmall diſtances from each other. This is familiar in air, vapours, and all compreſſible and elaſtic bodies.

This is evidently a moſt curious and intereſting ſubject of inveſtigation. On the nature and action of theſe corpuſcular forces depends the ſtrength or firmneſs of ſolids, their elaſticity, their power of communicating motion, the preſſure, and motion, and impulſe of fluids; nay, on the ſame actions depend all the chemical and phyſiological phenomena of expanſion, fuſion, congelation, vaporiſation, condenſation, ſolution, precipitation, abſorption, ſecretion, fermentation, and animal and vegetable concoction and aſſimilation.

Out of this immenſe ſtore of phenomena, this inexhauſtible fund of employment for our powers of inveſtigation, the natural philoſopher ſelects thoſe which lead directly to the production or modification of ſenſible motion.

He will therefore conſider,

58 The production of motion by impulſe has been thought the moſt familiar fact in nature.

1. The communication of motion among detached and free bodies, eſtabliſhing the laws of impulſe or colliſion. This has always been conſidered as the elementary doctrine of mechanical philoſophy, and as the moſt familiar fact obſerved in the material world; and in all ages philoſophers have been anxious to reduce all actions of bodies on each other to impulſe, and have never thought a phenomenon completely explained or accounted for till it has been ſhown to be a caſe of impulſe. This it is which has given riſe to the hypotheſes of vortices, ethers, magnetic and electric fluids, animal ſpirits, and a multitude of fancied intermediums between the ſenſible maſſes of matter, which are ſaid in common language to act on each other. A heavy body is ſuppoſed to fall, becauſe it is impelled by a ſtream of an inviſible fluid moving according to certain conditions ſuited to the caſe. The filings of iron are ſuppoſed to be arranged round a magnet, by means of a ſtream of magnetic fluid iſſuing from one pole, circulating perpetually round the magnet, and entering at the other pole, in the ſame manner as we obſerve the ſlote graſs arranged by the current of a brook.

59 But this opinion is very queſtionable.

But the philoſopher who has begun the mechanical ſtudy of nature by the abſtract doctrines of dynamics, and made its firſt application to the celeſtial phenomena, and who has attended carefully to the many analogies between the phenomena of gravitation and coheſion, will be at leaſt ready to entertain very different notions of this matter. He will be ſo far from thinking that the production of motion by impulſe is the moſt familiar fact in nature, that he will acknowledge it to be comparatively very rare; nay, there are ſome appearances in the facts which are uſually conſidered as inſtances of impulſion, which will lead him to doubt, and almoſt to deny, that there has *ever been obſerved* an inſtance of one body putting another in motion by coming into abſolute contact with it, and ſtriking it; and he will be diſpoſed to think that the production of motion in this caſe is preciſely ſimilar to what we obſerve when we gently puſh one floating magnet towards another, with their ſimilar poles fronting each other. There will be the ſame production of motion in the one and diminution of it in the other, and the ſame uniform motion of the common centre of gravity: and, in this caſe of the magnets, he ſees completely the neceſſity of a law of motion, which is not an axiom, but is obſerved through the whole of nature, and which receives no explanation from any hypotheſis of an intervening fluid, but is even totally inconſiſtent with them. We mean, "that every action of one body on another is accompanied by an equal and oppoſite action of that other on the firſt." This is uſually called the *equality of action and reaction*: it is not intuitive, but it is univerſal; and it is a neceſſary conſequence of the perfect ſimilarity of the corpuſcular forces of the ſame kinds of matter. This general fact, unaccountable on the hypotheſis of impelling fluids, is conſidered in the planetary motions as the unequivocal indication of the fameneſs of that gravity which regulates them all. The rules of good reaſoning ſhould make us draw the ſame concluſion here, that the particles of tangible matter are connected by equal and mutual forces, which are the *immediate cauſes* of all their ſenſible actions, and that theſe forces, like gravitation, vary with every change of diſtance and ſituation.

60 Motion ſeems to be produced from the equality of action and reaction.

The laws of colliſion and impulſion being now eſtabliſhed, either as original facts or as conſequences of the agency of equal and mutual forces which connect the particles of matter, the philoſopher conſiders,

61 Of motion as it reſpects the theory of machines, &c.

2. The production of motion by the intervention of ſolid bodies, where, by reaſon of the coheſion of matter, ſome of the motions are neceſſarily confined to certain determinate paths or directions. This is the caſe in all motions round fixed points or axes, or along planes or curves which are oblique to the action of the forces.

62 MECHANICS.

This part of the ſtudy contains the theory of machines, pointing out the principles on which their energy depends, and conſequently furniſhing maxims for their conſtruction and improvement. But theſe obſervations do not complete the diſcuſſion of the mechaniſm of ſolid bodies: they are not only ſolid and inert, but they are alſo heavy; therefore the action of gravity muſt be combined with the conſequences of ſolidity. This will lead to diſcuſſions about the centre of gravity, the theory and conſtruction of arches and roofs, the principles of ſtability and equilibrium, the attitudes of animals, and many particulars of this kind.

63 The nature and definition of fluidity.

3. The philoſopher will now turn his attention to another form, in which tangible matter exhibits many intereſting phenomena, *viz.* FLUIDITY. The firſt thing

Mechanical Philosophy.

to be attended to here is, *What is that particular form of existence?* What is the precise phenomenon which characterises fluidity? What is the definition of a fluid? This is by no means an easy question, and considerable objections may be stated against any definition that has been given of it. Sir Isaac Newton says, that *a fluid is a body whose particles yield to the smallest impression, and by so yielding are easily moved among themselves.* It may be doubted whether this be sufficiently precise; what is meant by the *smallest impression?* and what is *easily* moving? Is there any precise degree of impression to which they do not yield; and do they oppose any resistance to motion? And a stronger objection may be made: It is not clear that a body so constituted will exhibit all the appearances which a body acknowledged to be fluid does really exhibit. Euler offers some very plausible reasons for doubting whether it will account for the horizontal surface, and the complete propagation of pressure through the fluid in every direction; and therefore prefers selecting *this last phenomenon*, the propagation of pressure *quaqua-versum*, as the characteristic of fluidity, because a body having this constitution (on whatever circumstances it may depend) will have every other observed property of a fluid. But this definition is hardly simple or perspicuous enough; and we think that the objections against Newton's more simple and intelligible definition are not unanswerable. Boscovich defines a fluid to be, *a body whose particles exert the same mutual forces in all directions*; and shows, that such particles must be indifferent, as to any position, with respect to each other. If no external force act on them, they will remain in every position, and will have no tendency to arrange themselves in one position rather than another; differing in this respect from the particles of solid, or soft, or viscid bodies; which require some force to change their respective positions, and which recover these positions again when but gently disturbed. He illustrates this distinction very beautifully, by comparing a parcel of balls thrown on quicksilver, and attracting each other, with a parcel of magnets in the same situation. The balls will stick together, but *in any position;* whereas the magnets will always affect a particular arrangement.

63 Of the pressure and equilibrium of fluids, or hydrostatics.

When the characteristic phenomenon of fluidity has been selected, the philosopher proceeds to combine this property with gravity, and establishes the doctrines of HYDROSTATICS, or of the pressure and equilibrium of heavy fluids, the propagation of this pressure in every direction; and demonstrates the horizontality of surface assumed by all perfect fluids.

These doctrines and principles enable us to determine several very interesting circumstances respecting the mutual pressure of solids and fluids on each other; the pressures exerted on the bottoms and sides of vessels; the support and whole mechanism of floating bodies, &c.

65 Of the motion of fluids, or hydraulics.

He then considers how fluids will move when their equilibrium of pressure is destroyed; and establishes the doctrines of HYDRAULICS, containing all the modifications of this motion, arising from the form of the vessels, or from the intensity or direction of the pressure which occasions it. And this subject is completed by the consideration of the resistance which fluids oppose to the motion of solid bodies through them, and their impulse on bodies opposed to their action.

These are very important matters, being the foundations of many mechanical arts, and furnishing us with some of our most convenient and efficacious powers for impelling machines. They are also of very difficult discussion, and are by no means completely investigated or established. Much remains yet to be done both for perfecting the theories and for improving the arts which depend on them.

It is evident, that on these doctrines depend the knowledge of the motions of rivers and of waves; the buoyancy, equilibrium, and stability of ships; the motion of ships through the waters; the action of the winds on the sails; and the whole arts of marine construction and seamanship.

There is another general form of tangible matter which exhibits very different phenomena, which are also extremely interesting; we mean that of VAPOUR. A vapour is a fluid; and all the vapours that we know are heavy fluids: they are therefore subject to all the laws of pressure and impulse, which have been considered under the articles HYDROSTATICS and HYDRAULICS. But they are susceptible of great compression by the action of external forces, and expand again when these forces are removed. In consequence of this compression and expansion, the general phenomena of fluidity receive great and important modifications; and this class of fluids requires a particular consideration. As air is a familiar instance, this branch of mechanical philosophy has been called PNEUMATICS.

Under this head we consider the pressure of the atmosphere, and its effects, both on solid and fluid bodies. It produces the rise of waters or other fluids in pumps and syphons, and gives us the theory of their construction: it explains many curious phenomena of nature, such as the motions in the atmosphere, and their connection with the pressure of the air, and its effect on the barometer or weather glass. Air, when in motion, is called *wind*; and it may be employed to impel bodies. The theory of its action, and of its resistance to moving bodies, are therefore to be considered in this place.

But besides their motions of progression, &c. such as we observe in winds, compressible or elastic fluids are susceptible of what may be termed *internal motion*; a kind of undulation, where the contiguous parts are thrown into tremulous vibrations, in which they are alternately condensed and rarefied; and these undulations are propagated along the mass of elastic fluid, much in the same way in which we observe waves to spread on the surface of water. What makes this an interesting subject of consideration is, that these undulations are the more ordinary causes of sound. A trembling chord, or spring, or bell, agitates the air adjoining to it: these agitations are propagated along the air, and by its intervention agitate the organ of hearing. The mechanism of these undulations has been much studied, and furnishes a very beautiful theory of musical harmony.

The philosopher examines the *law of compressibility* of air and other elastic fluids; and thus gets the knowledge of the constitution of the atmosphere, and of the action of those fluids when employed to impel solid bodies. Gunpowder contains an immense quantity of permanently elastic air, which may be set at liberty by inflammation. When this is done at the bottom of a piece of ordnance, it will impel a ball along the barrel, and

Mechanical philoſophy.

and diſcharge it from the muzzle, in the ſame way that an arrow is impelled by a bow. And thus having diſcovered in what degree this air preſſes in proportion to its expanſion, we diſcover its action on the ball through the whole length of the piece, and the velocity which it will finally communicate to it. Here then is contained a theory of artillery and of mines.

70 Of the converſion of bodies into elaſtic fluids by fire.

Chemiſtry teaches us, that moſt bodies can be converted by fire into elaſtic fluids, which can be employed to act on other bodies in the way of preſſure or impulſe. Thus they come under the review of the mechanical philoſopher; and they have become intereſting by being employed as moving forces in ſome very powerful machines.

These diſcuſſions will nearly exhauſt all the general mechanical phenomena. There remain ſome which are much more limited, but furniſh very curious and important ſubjects of inveſtigation.

71 Of the phenomena of loadſtone, or magneſm.

The phenomena exhibited between loadſtones or magnets and iron have long attracted attention; and the uſe to which the polarity of the loadſtone has been applied, namely, the directing the courſe of a ſhip through the pathleſs ocean, has rendered theſe phenomena extremely intereſting. They are ſpecified by the term MAGNETISM. Conſiderable progreſs has been made in the arrangement and generalization of them; but we have by no means been able hitherto to bring them all under one ſimple fact. The attention has been too much turned to the diſcovery of the ultimate cauſe of magnetiſm; whereas we ſhould have rather employed our ingenuity in diſcovering all the general laws, in the ſame manner as Kepler and Newton did with reſpect to the celeſtial phenomena, without troubling themſelves with the cauſe of gravitation. Dr Gilbert of Colcheſter was the firſt who conſidered the magnetical phenomena in the truly philoſophical manner; and his treatiſe *De Magnete* may be conſidered as the firſt and one of the moſt perfect ſpecimens of the Baconian or inductive logic. It is indeed an excellent performance; and when we conſider its date, 1580, it is a wonder. Æpinus's *Tentamen Theoriæ Magnetiſmi* is a moſt valuable work, and contains all the knowledge which we have as yet of the ſubject.

72 Of electrical phenomena.

There is another claſs of mechanical phenomena which have a conſiderable affinity with the magnetical; we mean the phenomena called ELECTRICAL. Certain bodies, when rubbed or otherwiſe treated, attract and repel other bodies, and occaſion a great variety of ſenſible motions in the neighbouring bodies. Philoſophers have paid much attention to theſe appearances of late years, and eſtabliſhed many general laws concerning them. But we have not been more ſucceſsful in bringing them all under one fact, and thus eſtabliſhing a complete theory of them, than in the caſe of magnetiſm. Franklin and Æpinus are the authors who have been moſt ſucceſsful in this reſpect. Dr Franklin in particular has acquired great celebrity by his moſt ſagacious compariſon of the phenomena; which has enabled him to eſtabliſh a few general laws, almoſt as preciſe as thoſe of Kepler, and of equally extenſive influence. His diſcovery too of the identity of thunder and electricity has given an importance and dignity to the whole ſubject.

73 Theſe are not all mechanical.

There are many phenomena of electricity which cannot be called mechanical, and are of the moſt curious and intereſting kind. As theſe have little connection with any of the other great branches of phyſical ſcience, they have generally been conſidered in treatiſes of natural philoſophy; and along with inquiries into the original cauſe of electricity in general, continue to engage much of our attention.

Mechanical philoſophy.

74 Of the phenomena of viſion.

The appearances which are preſented to us by our ſenſe of ſeeing form another claſs, which have always been conſidered as making a branch of natural philoſophy in all ſeminaries of learning. It does not, however, obviouſly appear, that they are mechanical phenomena. The intimate nature of light is ſtill a ſecret. Fortunately it is not neceſſary to be known to give us a very perfect theory of the chief phenomena. The general laws of optics are ſo few, ſo ſimple, and ſo preciſe, that our theories are perhaps more perfect here than in any other branch of phyſics; but theſe theories are as yet far removed from the rank of primary facts. Many unknown events happen before the phenomenon comes under the hands of the ordinary optician, ſo as to become the ſubjects of the ſimple laws of reflection and refraction. It may even be doubted, and has been doubted, whether the phenomena of optics are caſes of body in motion; whether all the lines which the optician draws are any thing but the directions along which certain *qualities* are exerted. The ſide of a ball which is next the candle may be bright and the other ſide dark, juſt as the ſide of a ball which is next the electrical globe is *minus* and the other ſide *plus*; and all this without any intervening medium. Apparition or viſibility may be a quality of a body, depending on the proximity and poſition of another body, without any thing between them, juſt as weight is; and this quality may be cognizable by our faculty of ſeeing alone, juſt as the preſſure of a heavy body is by our feeling alone.

75 It has been doubted whether light is corporeal,

76 How optics came to be conſidered as a part of mechanical philoſophy.

The firſt thing which made it probable that mechanical philoſophy had any thing to do with the phenomena of optics, was the diſcovery of Mr Roemer, "that apparition was not inſtantaneous;" that ſome time elapſed between the illumination of a body and its being ſeen at a diſtance. He diſcovered, that it was not till 40 minutes after the ſun illuminated one of Jupiter's ſatellites that it was ſeen by an inhabitant of this globe. If therefore a ſun were juſt created, it would be 40 minutes before Jupiter would be illuminated by him, and 200 before the Georgian planet would be illuminated. Here then is motion. It is therefore highly probable that there is ſomething moved; but it is ſtill doubted whether this ſomething, which we call LIGHT, is a matter emitted from the ſhining body, and moving with great velocity, and acting on and affected by other bodies, in the various phenomena of optics; or whether it is a *certain ſtate* of a medium which is thus propagated, as we ſee that waves are propagated along the ſurface of water, or ſonorous undulations through the maſs of air, while the water or air itſelf is hardly moved out of its place. Either of theſe ſuppoſitions makes optics a legitimate branch of mechanical philoſophy; and it is the philoſopher's buſineſs to examine both by the received laws of motion, and ſee which of them gives conſequences which tally with the phenomena. This has been done; and we imagine that a complete incompatibility has been demonſtrated between the conſequences of the un-

77 The nature of light is ſtill undetermined.

Mechanical Philosophy.

dulations of an elastic medium, and the phenomena of optics; while the consequences of the other or vulgar notion on this subject are perfectly consistent with mechanical laws. There are some things in this hypothesis very far beyond our power to conceive distinctly; but they are all similar in this respect to many facts acknowledged by all; and there is no phenomenon that is inconsistent with the legitimate consequences of the hypothesis. This gives it great probability; and this probability is confirmed by many chemical facts, and by facts in the vegetable œconomy, which give strong and almost undeniable indications of light being a body capable of a chemical union with the other ingredients of sublunary bodies, and of being afterwards set at liberty under its own form, as the cause or medium of vision.

78 But this does not affect the science of optics.

But these are questions similar to those about the cause of gravity, and totally unnecessary for establishing a complete theory of the optical phenomena, for explaining the nature of vision, the effects of optical instruments, the cause of colours, the phenomena of the rainbow, halos and perihelions, &c. &c. &c. Only all this theory is unconnected with the principles called mechanical.

79 The probable increase of the above extensive field of observation.

Such is the field of observation to the mechanical philosopher of the present day. We may hope to extend it, and by degrees apply its doctrines even to the unseen motions which take place in chemistry and physiology. But we must, in the first place, perfect our knowledge and description of the sensible motions and actions of bodies. Those of fluids still demand much investigation; and till these are thoroughly understood, it is not time to attempt penetrating further into the recesses of nature.

80 Investigation of the law that action is always equal and opposite to reaction.

In the prosecution of this study, it is found that every change which can be observed in the state of a body, with respect to motion by the action of another body, is accompanied by an equal and opposite change in the state of that other body. Thus, in the phenomena of gravitation, it is observed that the deflections of the sun and planets are mutual. The same thing is observed in the actions of magnets on each other and on iron; it is also observed in the attractions and repulsions of electrical bodies; and it also obtains in all the phenomena of impulse and of corporeal pressure. It is therefore an universal law of motion, that *action is always equal and opposite to reaction*: but this must be considered merely as a matter of fact, a contingent law of nature, like that of gravitation. The contrary is perfectly conceivable, and involves no contradiction. That this is so, is evident from the proceedings of philosophers, who in every new case make it their business to discover by experiment whether this law was observed or not. It was among the last discoveries made by Sir Isaac Newton in his examination of the celestial motions. This being the case, it should never be assumed as a principle of reasoning till its operation has been ascertained by observation. It has been owing to this improper procedure that much false reasoning has been introduced into mechanical philosophy, and particularly into the theory of impulsion or the communication of motion by impulse. In considering this subject, a term has been introduced which has occasioned much wrangling and misconception; we mean the term INERTIA. It serves indeed to abbreviate language, but it has often misled the judgement. When used with cautious attention to every circumstance, it expresses nothing but the necessity of a cause to the production of any effect: but it is generally used as expressing a quality inherent in matter, by which it *resists* any change of state, or by which it maintains its present state. Matter is said to be inert; and as every thing which changes the motion of a body is called a *force*, and as this inertia of A is supposed to change the motion of B, it is called *vis inertiæ*; and yet matter is said to be indifferent as to motion or rest, and to be inactive. These are surely very incongruous expressions. This obscure discourse has arisen from the poverty of all languages, which are deficient in original terms, and therefore employ figurative ones. Force, action, resistance, are all appropriated terms related to our own exertions; and some resemblance between the external effects of these exertions and the effects of the connecting qualities of natural bodies, has made us use them in our disquisitions on these subjects. And as we are conscious that, in order to prevent our being pushed by another from our place, we must resist, exerting force; and that our resistance is the reason why this other man has not accomplished his purpose, we say, that the quiescent body resists being put in motion, and that its inertia is discovered by the diminution made in the motion of the impelling body: and upon the authority of this *vis inertiæ* as a first principle, the phenomena of impulsion are explained, and the law of equal action and reaction is established.

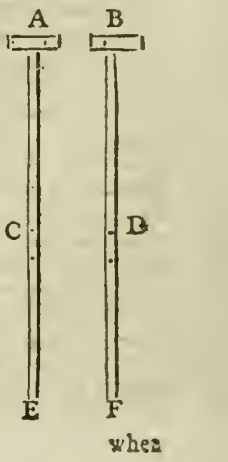
81 The term *inertia* has occasioned much wrangling and misconception on this subject.

Mecha Philoso

But all this procedure is in contradiction to the rules of inductive logic; and the obscurity and confusion which has arisen from this original misconception, the consequent incongruity of language, and the awkward attempts that have been made to botch and accommodate it to the real state of things, have occasioned a dispute, and the only dispute, in natural philosophy which has not yet been settled, and never can be settled, while such misconceptions are allowed to remain.

82 Its proper meaning with an example.

If the word *inertia* be taken as expressing, not a quality of matter, but a law of human judgment respecting matter, as expressing our necessity of inferring the agency of a moving force whenever we observe a change of motion, all difficulties will vanish, and the equality of action and reaction will be inferred, as it should be, from the phenomena of collision. There will be inferred a *vis insita corpori impellenti*, not *quâ moventi*, but *quâ corpori*; and this inference will carry us through all the mysteries of corporeal action, as it conducted Sir Isaac Newton in his grand researches.



Let us just consider how we reason in a new case. Let A and B be two magnets fastened on the ends of two long wooden laths AE, BF, which turn horizontally on pivots C, D, like compass needles, with their north poles fronting each other, 12 inches apart; and let A be pushed towards B, so that it would move uniformly with the velocity of two inches in a second. The phenomena *which have been observed* are as follows: A will gradually diminish its velocity; and when it has advanced about nine inches, will stop completely. B, in the mean time, will gradually acquire motion; and

when

Mechanical Philosophy

when it has advanced about nine inches, will have a velocity of about two inches per second, with which it will continue to move uniformly. Now what is inferred from these phenomena? Because the motion of A is gradually retarded, we infer that a retarding force, that is, a force in the direction BA has acted on it. And since this would not have happened if B had not been there, and always happens when B is there, we infer that B is either its cause or the occasion of its action. The vulgar say that B repels A; so say the dynamists. The abettors of invisible fluids say, that a stream of fluid issuing from B impels A in the opposite direction. All naturalists agree in saying, that an active force connected with B has destroyed the motion of A, and consider this curious phenomenon as the indication and characteristic of a discovery. The same inference is made from the motion produced in B: it is considered by all as effected by a force exerted or occasioned by the presence of A; and the dynamists and the vulgar say that A *repels* B. And both parties conclude, from the equal changes made on both bodies, that the changing forces are equal: here acknowledging, that they *observe* an equality of action and reaction; and they add this to the other instances of the extent of this law of motion.

All this while no one thinks of the inertia or inactivity of B, but, on the contrary, conclude this to be a curious instance of its activity; and most people conclude that both bodies carry about with them a *vis insita* both when at rest and when in motion.

83 is doubtful whether tual contact has er been served.

If other phenomena give unquestionable evidence that, in ordinary collisions, there is the same changes of motion, produced without mathematical contact, the same inferences must be drawn; and a scrupulous naturalist will doubt whether contact should make any change in our reasonings on the subject, and whether actual contact ever has been or can be observed. He will also be convinced, that while this is the general, or perhaps universal, process of nature in producing motion by impulse, all explanations of the action of bodies *e distanti*, by the intervention of ethers and other invisible fluids, are nothing but multiplying the difficulties; for in place of one fact, the approach of one magnet (for instance) to another, they substitute millions of unseen impulses, each of which equally needs an explanation. And if this fluid be supposed to produce its effects by any *peculiarity* in its constitution, as in the case of Newton's elastic ether proposed by him to explain gravitation, the hypothesis substitutes, in the most unqualified manner, millions of similar phenomena for the one to be explained; for there is the same want of a second fluid in order to produce that mutual recess of the particles of the ether which constitutes its elasticity.

84 e folly suppo- g inter- ning ers, &c.

85 e quality odies erely y affect r bodies nscru- e by us.

And this seems to be the limit to our inquiries into all the classes of natural phenomena. We find the masses or the particles of matter endued in fact with qualities which affect the state of other particles or masses, at smaller or at greater distances from each other according to certain general rules or laws. This ultimate step in the constitution of things is inscrutable by us. It is arrogance in the highest degree for us to say, that because we do not comprehend how there is inherent in a body any quality by which another body may be affected at any distance from it, therefore no such quality *is possible*. It is no less so to say, that matter has no active property but that of moving other matter by impulse; and that because it may be so moved, and also by the agency of our own minds, therefore, when it is not moved by impulse, it is moved by minds. The same almighty FIAT which brought a particle of matter into existence could bring those qualities equally into existence; and the *how* in both is equally beyond our comprehension.

Mechanical Philosophy.

But, on the other hand, we must guard against the incurious resting on this consideration as a step to further inquiry. There may be species of matter possessed of the mechanical powers, and which notwithstanding is not cognisable by our senses. All the properties of matter are not known to a person who is both deaf and blind; and beings possessed of more senses may perceive matter where we do not; and many phenomena may really be produced by the action of intervening matter, which we, from indolence or from haste, ascribe to the agency of inherent forces. The industry of philosophers has already discovered intermedia in some cases. It is now certain that air is the conveyer of sound, and it is almost certain that there is such a thing as light. Let us therefore indulge conjectures of this kind, and examine the conjectures by the received laws of motion, and reject them when we find the smallest inconsistency; and always keep in mind that even the most coincident with the phenomona is still but a possibility.

86 This should not, however, stop further inquiries.

We may conclude the whole of these observations with the remark, that these questions about the activity or inactivity of matter are not physical, but metaphysical. Natural philosophy, it is true, commonly takes it for granted that matter is wholly inactive; but it is not of any moment in physics whether this opinion is true or false; whether matter is acted on according to certain laws, or whether it acts of itself according to the same laws, makes no difference to the natural philosopher. It is his business to discover the laws which really obtain, and to apply these to the solution of subordinate phenomena: but whether these laws arise from the nature of some agent external to matter, or whether matter itself is the agent, are questions which may be above his comprehension, and do not immediately concern his proper business.

87 These observations are not physical, but metaphysical.

The account we have now given of natural philosophy points out to us in the plainest manner the way in which the study must be prosecuted, and the helps which must be taken from other branches of human knowledge.

88 The above account points out the best method of study.

The causes, powers, forces, or by whatever name we choose to express them, which produce the mechanical phenomena of the universe, are not observed, and are known to us only in the phenomena themselves. Our knowledge of the mechanical powers of nature must therefore keep pace with our knowledge of the motions, and indeed is nothing different from it. In order to discover and determine the forces by which the moon is retained in her orbit round the earth, we must know her motions. To a terrestrial spectator she appears to describe an ellipse, having the earth in one focus; but, in the mean time, the earth is carried round the sun, and the moon's real path, in absolute space, is a much more complicated figure. Till we know this figure, and the variations in the velocity with

89 This method further explained and exemplified.

Mechanical Philoſophy

with which it is deſcribed, we know nothing of the forces which actuate the moon in her orbit.

90 The meaning of ſome terms uſed in ſpeaking of the celeſtial motions.

When Newton ſays that the forces by which ſhe is retained in this elliptical orbit are directed to the earth, what does he mean? Only this, that the deflection from that uniform rectilineal motion which ſhe would otherwiſe have performed are always in this direction. In like manner, when he ſays that theſe forces are inverſely proportionate to the ſquarea of her diſtances from the earth, he only means that the deflections made in equal times in different parts of her motion are in this proportion. Theſe deflections are conſidered as the characteriſtics and meaſures of the forces. We imagine that we have made all plain when we call this indicated cauſe a *tendency* to the earth; but we have no notion of this tendency to the earth different from the approach itſelf. This word tendency, ſo faſhionable among the followers of Sir Iſaac Newton, is perverted from its pure and original ſenſe. *Tendere verſus ſolem*, is, in the language of Rome, and alſo of Newton, *to go* towards the ſun; but we now uſe the words *tend*, *tendency*, to ſignify, not the *approach*, but the *cauſe* of this approach. And when called upon to ſpeak ſtill plainer, we deſert the ſafe paths of plain language, and we expreſs ourſelves by metaphor; ſpeaking of *niſus*, *conatus ſeſe mutuo accedendi*, *vis centripeta*, &c. When theſe expreſſions have become familiar, the original ſenſe of the word is forgotten, and we take it for granted that the words never had another meaning; and this metaphor, ſprung from the poverty of language, becomes a fruitful ſource of miſconception and miſtake. The only way to ſecure ourſelves againſt ſuch myſtical notions as are introduced by theſe means into philoſophy, is to have recourſe to the way in which we acquire the knowledge of theſe fancied powers; and then we ſee that their names are only names for phenomena, and that univerſal gravitation is only an univerſal mutual approach among the parts of the ſolar ſyſtem.

91 The abſurdity of reaſoning *à priori*.

There is one caſe in which we fondly imagine that we know the cauſe independent of the effect, and that we could have predicted the phenomenon *à priori*: we mean the caſe of impulſe: and hence it is that we are ſo prone to reduce every thing to caſes of impulſion, and that we have fallen upon all theſe ſubterfugea of ethers and other ſubtile fluids. But we might have ſaved ourſelves all this trouble; for after having, by much falſe reaſoning and gratuitous aſſumptions, ſhown that the phenomenon in queſtion *might have been produced* by impulſe, we are no nearer our purpoſe, becauſe that property by which matter in motion puts other matter in motion, is known to us only *by* and *in* the effect.

92 We know nothing of the immediate cauſe of motions except by a knowledge of the motions themſelves.

The fair and logical deduction from all this is, that we muſt not expect any knowledge of the powers of nature, the immediate cauſes of the motions of bodies, but by means of a knowledge of the motions themſelves; and that every miſtake in the motions is accompanied by a ſimilar miſtake in the cauſes. It is impoſſible to demonſtrate or explain the gravitation of the planets to him who is ignorant of the properties of the ellipſe, or the theory of gunnery to him who does not know the parabola.

A notion has of late gained ground, that a man may become a natural philoſopher without mathematical knowledge; but this is entertained by none who have any mathematics themſelves; and ſurely thoſe who are ignorant of mathematics ſhould not be ſuſtained as judges in this matter. We need only appeal to fact. It is only in thoſe parts of natural philoſophy which have been mathematically treated, that the inveſtigations have been carried on with certainty, ſucceſs, and utility. Without this guide, we muſt expect nothing but a ſchool-boy's knowledge, reſembling that of the man who takes up his religious creed on the authority of his prieſt, and can neither give a reaſon for what he imagines that he believes, nor apply it with confidence to any valuable purpoſe in life. We may read and be amuſed with the trifling or vague writings of a Nollet, a Ferguſon, or a Prieſtley; but we ſhall not underſtand, nor profit by the truths communicated by a Newton, a D'Alembert, or De la Grange.

Mecha Philoſo

93 A man not be good n ral phi pher w out be mathe cian.

Theſe obſervations, on the other hand, ſhow us the nature of the knowledge which may be acquired, and the rank which natural philoſophy holds among the ſciences.

94 The m tions o dies, th only ob of obſe tion, a ſubject pure m thema diſquiſ

Motions are the real and only objects of our obſervation, the only ſubjects of our diſcuſſion. In motion is included no ideas but thoſe of ſpace and time, the ſubjects of pure mathematical diſquiſition. As ſoon, therefore, as we have diſcovered the fact, the motion, all our future reaſonings about this motion are purely mathematical, depending only on the affections of figure, number, and proportion, and muſt carry along with them that demonſtration and irreſiſtible evidence which is the boaſt of that ſcience. To this are we indebted for that accuracy which is attained, and the progreſs which has been made in ſome branches of mechanical philoſophy; for when the motions are diſtinctly and minutely underſtood, and then conſidered only as mathematical quantities, independent of all phyſical conſiderations, and we proceed according to the juſt rules of mathematical reaſoning, we need not fear any intricacy of combination or multiplicity of ſteps; we are certain that truth will accompany us, even though we do not always attend to it, and will emerge in our final propoſition, in the ſame manner as we ſee happen in a long and intricate algebraic analyſis.

95 Mechanical philoſophy, therefore, which is cultivated in this way, is not a ſyſtem of probable opinions, but a *diſciplina accurata*, a demonſtrative ſcience. To poſſeſs it, however, in this form, requires conſiderable preparation. The mere elements of geometry and algebra are by no means ſufficient. Newton could not have proceeded *ſine* "*ſua matheſi facem preferente*:" and, in creating a new ſcience of phyſics, he was obliged to ſearch for and diſcover a new ſource of mathematical knowledge. It is to be lamented that the taſte for the mathematical ſciences has ſo prodigiouſly declined in this country of late years; and that Britain, which formerly took the lead in natural philoſophy, ſhould now be the country where they are leaſt cultivated. Few among us know more than a few elementary doctrines of equilibrium; while, on the continent, we find many authors who cultivate the Newtonian philoſophy with great aſſiduity and ſucceſs, and whoſe writings are conſulted as the fountains of knowledge by all our countrymen who have occaſion to employ the diſcoveries in natural philoſophy in the arts of life. It is

Mech phiſo thus c vated demo tive ſc

96 The la table of ma matics Britai

to

Mechanical philosophy

to the foreign writers that we have recourse in our seminaries, even for elementary treatises; and while the continent has supplied us with most elaborate and useful treatises on various articles in physical astronomy, practical mechanics, hydraulics, and optics, there has not appeared in Britain half a dozen treatises worth consulting for these last forty years; and this notwithstanding the unparalleled munificence of our present sovereign, who has given more liberal patronage to the cultivators of mathematical philosophy, and indeed of science in general, than any prince in Europe. The magnificent establishments of Louis XIV. originated from his insatiable ambition and desire of universal influence, directed by the sagacious Colbert. And his patronage being exerted according to a regular plan in the establishment of pensioned academics, and in procuring the combined efforts of the *most eminent* of all countries, his exertions made a conspicuous figure, and filled all Europe with his eulogists. But all this was done without the smallest self-denial, or retrenchment of his own pleasures, the expences being furnished out of the public revenues of a great and oppressed nation; whereas the voyages of discovery, the expensive observations and geodetical operations in Britain, and the numberless unheard-of pensions and encouragements given to men of science and activity, were all furnished out of the private estate of our excellent sovereign, who seems to delight in repaying, by every service in his power, the attachment of a loyal and happy nation. It is therefore devoutly to be wished that his patriotic efforts were properly seconded by those whom they are intended to serve, and that the taste for the mathematical sciences may again turn the eyes of Europe to this country for instruction and improvement. The present seems a most favourable era, while the amazing advances in manufactures of every kind seem to call aloud for the assistance of the philosopher. What pleasure would it have given to Newton or Halley to have seconded the ingenious efforts of a Watt, a Boulton, a Smeaton, an Arkwright, a Dollond? and how mortifying is it to see them indebted to the services of a Belidor, a Bossut, a Clairaut, a Boscovich?

97 Notwithstanding ample encouragement from the crown.

We hope to be pardoned for this digression, and return to our subject.

98 Mechanical philosophy almost wholly a mathematical study.

It appears from what has been said, that mechanical philosophy is almost wholly a mathematical study, and that it is to be successfully prosecuted only under this form: but in our endeavours to initiate the young beginner, it will be often found to require more steadiness of thought than can generally be expected for keeping the mind engaged in such abstract speculations. The object presented to the mind is not readily apprehended with that vivacity which is necessary for enabling us to reason upon it with clearness and steadiness, and it would be very desirable to have some means of rendering the conception more easy, and the attention more lively. This may be done by exhibiting to the eye an experiment, which, though but a single fact, gives us a sensible object of perception, which we can contemplate and remember with much more steadiness than any mere creature of the imagination. We could, by an accurate description, give such a conception of a room that the hearer should perfectly comprehend our narration of any occurrence in it: but one moment's glance at the room would be infinitely better. It is usual therefore to employ experiments to assist the imagination of the beginner; and most courses of natural philosophy are accompanied by a series of such experiments. Such experiments, connected by a slight train of argumentative discourse, may even serve to give a notion of the general doctrines, sufficient for an elegant amusement, and even tending to excite curiosity and engage in a serious prosecution of the study. Such are the usual courses which go by the name of experimental philosophy: but this is a great misapplication of the term; such courses are little more than *illustrations* of known doctrines by experiments.

99 Experiments are, however, necessary to ensure the attention of young minds.

Experimental Philosophy

Experimental Philosophy.

100 Experimental philosophy defined and explained.

Experimental Philosophy is the investigation of general laws, as yet unknown, by experiment; and it has been observed, under the article Philosophy, that this is the most infallible (and indeed the sole) way of arriving at the knowledge of them. This is the *Novum Organum Scientiarum* strongly recommended by Lord Bacon. It was new in his time, though not altogether without example; for it is the procedure of nature, and is followed whenever curiosity is excited. There was even extant in his time a very beautiful example of this method, viz. the Treatise of the Loadstone, by Dr Gilbert of Colchester; a work which has hardly been excelled by any, and which, when we consider its date, about the year 1580, is really a wonderful performance.

The most perfect model of this method is the Optics of Sir Isaac Newton. Dr Black's Essay on Magnesia is another very perfect example. Dr Franklin's Theory of Electricity is another example of great merit. That the investigation is not complete, nor the conclusions certain, is not an objection. The method is without fault; and a proper direction is given to the mind for the experiments which are still necessary for establishing the general laws.

101 A good treatise on the method of inquiry by experiment very necessary.

It were much to be wished that some person of talents and of extensive knowledge would give a treatise on the method of inquiry by experiment. Although many beautiful and successful examples have been given as particular branches of inquiry, we have but too many instances of very inaccurate and inconclusive investigations. Experiments made at random, almost without a view, serve but little to advance our knowledge. They are like shapeless lumps of stone, merely detached from the rock, but still wanting the skill of the builder to select them for the different purposes which they may chance to serve; while well-contrived experiments are blocks cut out by a skilful workman, according as the quarry could furnish them, and of forms suited to certain determined uses in the future edifice. Every little series of experiments by Margraaf terminates in a general law, while hardly any general conclusion can be drawn from the numberless experiments of Pott. Lord Bacon has written much on this subject, and with great judgment and acuteness of distinction; but he has exceeded in this, and has fatigued his readers by his numerous rules; and there is in all his philosophical works, and particularly in this, a quaintness and affectation that greatly obscure his meaning, so that this most valuable part of his writings is very little read.

102 An objection to experimental inquiry.

A formidable objection has been made to this method of inquiry. Since a physical law is only the expression

Experimental Philosophy.

expreſſion of a general fact, and is eſtabliſhed only in conſequence of our having obſerved a ſimilarity in a great number of particular facts; and ſince the great rule of inductive logic is to give the law no greater extent than the induction on which it is founded—how comes it that a few experiments muſt be received as the foundation of a general inference? This has been anſwered in very general terms in the article PHILOSOPHY. But it will be of uſe to conſider the ſubject a little more particularly. Our obſervations on this ſubject are taken from in the diſſertation on evidence by Dr Campbell in his *Philoſophy of Rhetoric*.

103 The objection anſwered, with examples ſhowing the nature and certainty of this mode of inquiry.

An attentive conſideration of the objects around us, will inform us that they are generally of a complicated nature, not only as conſiſting of a complication of thoſe qualities of things called accidents, ſuch as gravity, mobility, colour, figure, ſolidity, which are common to all bodies; but alſo as conſiſting of a mixture of a variety of ſubſtances, very different in their nature and properties; and each of theſe is perhaps compounded of ingredients more ſimple.

Moreover, the farther we advance in the knowledge of nature, we find the more reaſon to be convinced of her conſtancy in all her operations. Like cauſes have always produced like effects, and like effects have always been preceded by like cauſes. Inconſtancy ſometimes appears in Nature's works at *firſt ſight;* but a more refined experience ſhows us that this is but an appearance, and that there is no inconſtancy: and we explain it to our ſatisfaction in this way.

Moſt of the objects being of a complicated nature, we find, on an accurate ſcrutiny, that the effects aſcribed to them ought often to be ſolely aſcribed to one or more of theſe component parts, while the others either do not contribute to them, or hinder their production; and the variety of nature is ſo great, that hardly any two individuals of the ſame ſpecies are in every reſpect like any other. On all theſe accounts we expect diſſimilitudes in the phenomena accompanying perfectly ſimilar treatment of different ſubjects of the ſame kind; but we find, that whenever we can be aſſured that the two ſubſtances are perfectly alike, the phenomena ariſing from ſimilar treatment are the ſame: and long and extenſive obſervation teaches us, that there are certain circumſtances which inſure us in the perfect ſimilarity of conſtitution of ſome things. Whenever we obſerve the effect of any natural agent on one, and but one, of theſe, we invariably expect that the ſame will be produced on any other.

Should a botaniſt meet with a plant new to him, and obſerve that it has ſeven monopetalous flowers, he will conclude with the utmoſt confidence that every plant of this ſpecies will have monopetalous flowers; but he will not ſuppoſe that it will have ſeven, and no more than ſeven, flowers. Now theſe two facts ſeem to have no difference to warrant ſuch a difference in the concluſion; which may therefore ſeem capricious, ſince there is but one example of both.

But it is not from this example only that he draws the concluſion. Had he never before taken notice of any plant, he would not have reaſoned at all from theſe remarks. But his mind runs immediately from this unknown ſpecies to all the known ſpecies of this genus, and to all the genera of the ſame order; and having experienced in the *figure* of the flower an uniformity in every ſpecies, genus, and order, which admits of no exception, but, in the *number* of flowers, a variety as boundleſs as are the circumſtances of ſoil, climate, age, and culture, he learns to mark the difference, and draws the above-mentioned concluſions. Thus we learn, that *perfect* uniformity is not to be expected in any inſtance whatever, becauſe in no inſtance is the ſimplicity of conſtitution ſufficiently great to give us aſſurance of perfect uniformity in the circumſtances of the caſe; and the utmoſt that our experience can teach us is a quick diſcrimination of thoſe circumſtances which produce the occaſional varieties.

Experimental Philoſophy.

The nearer that our inveſtigations carry us to the knowledge of *elementary* natures, the more are we convinced by general experience of the uniformity of the operations of real elements; and although it may perhaps be impoſſible for us ever to arrive at the knowledge of the ſimpleſt elements of any body, yet when any thing *appears* ſimple, or rather ſo exactly uniform, as that we have invariably obſerved it to produce ſimilar effects on diſcovering any *new* effect of this ſubſtance, we conclude, from a general experience of the efficient, a like conſtancy in the energy as to the reſt. Fire conſumes wood, melts lead, and hardens clay. In theſe inſtances it acts uniformly, but not in theſe only. We have always found, that whatever of any ſpecies is conſumed by it in one inſtance, has been conſumed by it on trial at any time. If therefore a trial be made for the firſt time of its influence on any particular ſubſtance, he who makes it is warranted to conclude that the effect, whatever it may be, is a faithful repreſentative of its effects on this ſubſtance in all paſt and future ages. This concluſion is not founded on this ſingle inſtance, but upon this inſtance combined with the general experience of the regularity of this element in its operations.

This general concluſion, therefore, drawn from one experiment, is by no means in oppoſition to the great rule of inductive logic, but, on the contrary, it is the moſt general and refined application of it. General laws are here the real ſubject of conſideration; and a law ſtill more general, viz. *that nature is conſtant in all its operations*, is the inference which is here applied as a principle of explanation of a phenomenon which is itſelf a general law, viz. *that nature is conſtant in this operation*.

The foundation of this general inference from one experiment being ſo firmly eſtabliſhed, it is evident that experiments muſt be an infallible method of attaining to the knowledge of nature; and we need only be ſolicitous that we proceed in a way agreeable to the great rule of inductive logic; that is, the ſubject muſt be cleared of every accidental and *unknown* circumſtance, and put into a ſituation that will reduce the intereſting circumſtance to a ſtate of the greateſt poſſible ſimplicity. Thus we may be certain that the event will be a faithful repreſentative of every ſimilar caſe: and unleſs this be done in the preparation, nothing can reſult from the moſt numerous experiments but uncertainty and miſtakes.

104 Mathematics do not ſuperſede the uſe of experiment.

The account which has been given of mechanical philoſophy would ſeem to indicate that experiment was not of much uſe in the farther proſecution of it. The two laws of motion, with the aſſiſtance of mathematics, ſeem fully adequate to the explanation of every phenomenon;

Experimental Philosophy.

phenomenon; and so they are to a *certain degree*. But this degree is as yet very limited. Our mathematical knowledge, great as it is in comparison with that of former times, is still insufficient for giving accurate solutions even of very simple (comparatively speaking) questions. We can tell, with the utmost precision, what will be the motions of two particles of matter, or two bodies, which act on each other with forces proportioned to the squares of the distances inversely; but if we add a third particle, or a third body, acting by the same law, the united science of all Europe can only give an approximation to the solution.

105 Experiment often the only resource.

What is to be done then in the cases which come continually before us, where millions of particles are acting at once on each other in every variety of situation and distance? How shall we determine, for instance, the motion of water through a pipe or sluice when urged by a piston or by its own weight? what will be its velocity and direction? It is impossible, in the present state of mathematical knowledge, to tell with any precision or certainty. And here we must have recourse to experiment. But if this be the case, must the experiment be made in every possible variety of situation, depth, figure, pressure? or is it possible to find out any general rules, founded on the general laws of motion, and rationally deduced from them? Or, if this cannot be accomplished, will experiment itself furnish any general coincidences which show such mutual dependences, that we may consider them as indications of general principles, though subordinate, complicated, and perhaps inscrutable? This can be discovered by experiment alone.

106 Accurate experiments cannot always be made.

The attention of philosophers has been directed to each of these three chances, and considerable progress has been made in them all. Numerous experiments have been made, almost sufficient to direct the practice in many important cases, without the help of any rule or principle whatever. But there are many cases, and these of by far the greatest importance, such as the motion of a ship impelled by the winds, resisted by the water, and tossed by the waves, where distinct experiments cannot be made.

107 Example of the necessity of experiment.

Newton, Bernoulli, D'Alembert, and others, have laboured hard to deduce from the laws of motion rules for determining what may be called the *average* motion of water in these circumstances, without attempting to define the path or motion of any individual particle; and they have actually deduced many rules which have a great degree of probability. It may here be asked, why do you say *probability?* the rules, as far as they go, should be *certain*. So they are: they are strict deductions from their premisses. But the premisses are only *suppositions*, of various degrees of probability, assumed in order to simplify the circumstances of the case, and to give room for mathematical reasoning; therefore these deductions, these rules, must be examined by experiment. Some of the suppositions are such as can hardly be refused, and the rules deduced from them are found to tally precisely with the phenomena. Such is this, "that the velocities of issuing water in similar circumstances are in the subduplicate ratio of the pressures." And this rule gives a most important and extensive information to the engineer. Other suppositions are more gratuitous, and the rules deduced from them are less coincident with the phenomena. The patient and sagacious Newton has repeatedly failed in his attempts to determine what is the *absolute velocity* of water issuing from a hole in the bottom of a vessel when urged by its weight alone, and the attempts of the others have hardly succeeded better. Experiment is therefore absolutely necessary on this head.

Experimental Philosophy.

Those who have aimed at the discovery of *rules* purely experimental on this subject, have also been pretty successful; and the Chevalier Buat has, from a comparison of an immense variety of experiments made by himself and various authors, deduced an empirical rule, which will not be found to deviate from truth above one part in ten in any case which has yet come to our knowledge.

This instance may serve to show the use of experiments in mechanical philosophy. It is proper in all cases by way of illustration; and it is absolutely necessary in most, either as the foundation of a characteristic of a particular class of phenomena, or as argument in support of a particular doctrine. Hydrostatics, hydraulics, pneumatics, magnetism, electricity, and optics, can hardly be studied in any other way; and they are at present in an imperfect state, and receiving continual improvement by the labours of experimental philosophers in all quarters of the world.

108 The advantage derived from the study of philosophy

Having in the preceding paragraphs given a pretty full enumeration of the different subjects which are to be considered in the study of natural philosophy, it will not be necessary to spend much time in a detail of the advantages which may reasonably be expected from a successful prosecution of this study. It stands in no need of panegyric: its intimate connection with the arts gives it a sufficient recommendation to the attention of every person. It is the foundation of many arts, and it gives liberal assistance to all. Indebted to them for its origin and birth, it has ever retained its filial attachment, and repaid all their favours with the most partial affection.

109 In navigation,

To this science the navigator must have recourse for that astronomical knowledge which enables him to find his place in the trackless ocean: and although very small heaps of this knowledge are sufficient for the mere pilot, it is necessary that the study be prosecuted to the utmost by some persons, that the unlearned pilot may get that scanty pittance which must direct his routine. The few pages of tables of the sun's declination, which he uses every day to find his latitude, required the successive and united labours of all the astronomers of Europe to make them tolerably exact: and in order to ascertain his longitude with precision, it required all the genius of a Newton to detect the lunar irregularities, and bring them within the power of the calculator; and, till this was done, the respective position of the different parts of the earth could not be ascertained. Vain would have been the attempt to do this by geodætical surveys independent of astronomical observation. It is only from the most refined mechanics that we can hope for sure principles to direct us in the construction and management of a ship, the boast of human art, and the great means of union and communication between the different quarters of the globe.

110 In architecture,

A knowledge of mechanics not much inferior to this is necessary for enabling the architect to execute some

Experimental Philosophy.

fome of his greateſt works, ſuch as the erection of domes and arches, which depend on the niceſt adjuſtment of equilibrium. Without this he cannot unite economy with ſtrength; and his works muſt either be clumſy maſſes or ſimſy ſhells.

111 In gunnery and other engines, &c.

The effects of artillery cannot be underſtood or ſecured without the ſame knowledge.

The whole employment of the engineer, civil or military, is a continual application of almoſt every branch of mechanical knowledge; and while the promiſes of a Smeaton, a Watt, a Belidor, may be confided in as if already performed, the numberleſs failures and diſappointments in the moſt important and coſtly projects ſhow us daily the ignorance of the pretending crowd of engineers.

The microſcope, the ſteam-engine, the thunder-rod, are preſents which the world has received from the natural philoſopher; and although the compaſs and teleſcope were the productions of chance, they would have been of little ſervice had they not been ſtudied and improved by Gilbert, Halley, and Dollond.

But it is not in the arts alone that the influence of natural philoſophy is perceived: it lends its aid to every ſcience, and in every ſtudy.

112 In law,

It is often neceſſary to have recourſe to the philoſopher in diſputes concerning property; and many examples might be given where great injuſtice has been the conſequence of the ignorance of the judges. Knowledge of nature might have prevented many diſgraceful condemnations for ſorcery.

113 In hiſtory,

The hiſtorian who is ignorant of natural philoſophy eaſily admits the miraculous into his narrations, accompanies theſe with his reflections, draws conſequences from them, and fills his pages with prodigies, fables, and abſurdity.

114 In medicine,

It is almoſt needleſs to ſpeak of the advantages which will accrue to the phyſician from this ſtudy. So cloſe is the connection between it and medicine, that our language has given but one name to the naturaliſt and to the medical philoſopher. Indeed, the whole of his ſtudy is a cloſe obſervation of the laws of material nature, in order to draw from them precepts to direct his practice in the noble art of healing. During the immaturity of general knowledge, while natural philoſophy was the only ſtudy which had acquired any juſt pretenſion to certitude either in its principles or method of inveſtigation, the phyſicians endeavoured to bring the objects of their ſtudy within its province, hoping by this means to get a more diſtinct view of it; and they endeavoured to explain the abſtruſe phenomena of the animal functions by reducing them all to motions, vibrations, colliſions, impulſes, hydroſtatic and hydraulic preſſures and actions, with which the mechanical philoſophers were ſo ardently occupied at that time. But unfortunately their acquaintance with nature was then very limited, and they were but little habituated to the rules of juſt reaſoning; and their attempts to explain the economy of animal life by the laws of mechanics did them but little ſervice either for the knowledge of diſeaſes or of the methods of cure. The mechanical theories of medicine, which had conſiderable reputation about the end of laſt century, were many of them very ingenious, and had an impoſing appearance of ſymmetry and connection; but are now forgotten, having all been formed on the narrow ſuppoſition that matter was ſubject only to mechanical laws

Experimental Philoſophy.

But the diſcovery of error diminiſhes the chance of again going wrong, eſpecially when the cauſe of error has been diſcovered, and the means pointed out of detecting the miſtakes; and the vital principle muſt combine its influence with, or operate on, the properties of rude matter. It appears therefore evident that a knowledge of the mechanical laws of the material world is not only a convenient, but a neceſſary, accompliſhment to the phyſician. We are fully juſtified in this opinion, by obſerving medical authors of the preſent day introducing into medicine theories borrowed from mechanical philoſophy, which they do not underſtand, and which they continually miſapply. Appearance of reaſoning frequently conceals the errors in principle, and ſeldom fails to miſlead.

115 In religion.

But there is no claſs of men to whom this ſcience is of more ſervice than to thoſe who hold the honourable office of the teachers of religion. Their knowledge in their own ſcience, and their public utility, are prodigiouſly hurt by ignorance of the general frame and conſtitution of nature; and it is much to be lamented that this ſcience is ſo generally neglected by them, or conſidered only as an elegant accompliſhment: nay, it is too frequently ſhunned as a dangerous attainment, as likely to unhinge their own faith, and taint the minds of their hearers. We hope, however, that few are either ſo feebly rooted in the belief of the great doctrines of religion as to fear this, or of minds ſo baſe and corrupted as to adopt and inculcate a belief which they have any ſuſpicion of being ill-founded. But many have a ſort of horror at all attempts to account for the events of nature by the intervention of general cauſes, and think this procedure derogatory to the Divine nature, and inconſiſtent with the doctrine of his particular providence; believing, that "a ſparrow does not fall to the ground without the knowledge of our heavenly Father." Their limited conceptions cannot perceive, that, in forming the general law, the Great Artiſt did at one glance ſee it in its remoteſt and moſt minute conſequence, and adjuſt the vaſt aſſemblage ſo as completely to anſwer every purpoſe of His providence. There never was a more eager inquirer into the laws of nature, or more ardent admirer of its glorious Author, than the Hon. Robert Boyle. This gentleman ſays, that he will always think more highly of the ſkill and power of that artiſt who ſhould conſtruct a machine, which, being once ſet a going, would of itſelf continue its motion for ages, and from its inherent principles continue to anſwer all the purpoſes for which it was firſt contrived, than of him whoſe machine required the continual aid of the hand which firſt conſtructed it. It is owing to great inattention that this averſion to the operation of ſecondary cauſes has any influence on our mind. What do we mean by the introduction of ſecondary cauſes? How do we infer the agency of any cauſe whatever? Would we ever have ſuppoſed any cauſe of the operations of nature, had they gone on without any order or regularity? Or would ſuch a chaos of events, any more than a chaos of exiſtences, have given us any notion of a forming and directing hand? No ſurely. We ſee the hand of God in the regular and unvaried courſe of nature, only becauſe it is regular and unvaried. The philoſo-

perimen- l philo- ophy.

pher expreſſes this by ſaying, that the phenomena proceed by unalterable laws. Greatly miſtaken therefore are they who think that we ſuperſede the exiſtence of mind and of providence when we trace things to their cauſes. A phyſical law being an unvaried fact, is an indication, and the ſtrongeſt poſſible indication, of an unerring mind, who is incapable of change, and muſt do to day what He always did: for to change

ergufon's ures on ics.

is to deviate from what is beſt*. The operations of unerring mind will therefore be regular and invariable. Phyſical laws, therefore, or ſecondary cauſes, are the beſt proofs of unerring wiſdom. Such regularity of conduct is univerſally conſidered as indications of wiſdom among men. The wiſe man is known by the conſtancy of his conduct, while no man can depend on the future conduct of a fool.

And what aſtoniſhing evidences of wiſdom do we not obſerve in the general laws of the material world? They will ever be conſidered by the intelligent philoſopher as the moſt glorious diſplay of inconceivable wiſdom, which has been able, by means ſo few and ſo ſimple, to produce effects which by their grandeur aſtoniſh our feeble underſtandings, and by their inexhauſtible variety elude all poſſibility of enumeration.

While the teachers of religion remain ignorant of the beautiful laws of nature, the great characteriſtics of the wiſdom and goodneſs of the Almighty Creator, their hearers are deprived of much ſublime pleaſure; God is robbed of that praiſe which he would have received from an enlightened people; and the only worſhip he receives is tainted with mean notions of his attributes, and groundleſs fears of his power.

Let not our minds be haunted with fear of the pernicious effects of philoſophy, in conſequence of the dreadful exploſion which the vanity of man has lately made in France. The ruffians who now rule in that unhappy country, through the ſupport of the licentious mob of Paris, are continually imputing to the illumination of philoſophy the ardour which now animates them in the cauſe of liberty; and they are continually ſaying, that juſtice and morality are the order of the day. But their whole phraſeology is equally a perverſion of every thing in language and in ſentiment. The ſacred name of philoſophy is as unfit for their faithleſs and bloody mouths as the names of liberty or virtue, and is equally miſapplied. No wonder that religion fled from the torch of their philoſophy: for their philoſophy conſiſts expreſsly in the confounding the moſt diſtinct claſſes of phenomena and of beings, in aſſimilating the heavenly animating ſpark within us to a piece of rude matter, and in degrading man to the level of the brutes, and thus ſhutting out his faireſt proſpects. It is not by the ordinary dialectics of the theologian that this ſacrilegious confuſion can be rectified: this requires an intimate acquaintance with what is characteriſtic of mind, and what is characteriſtic of matter, and a comprehenſive view of the general laws which regulate the appearances in both claſſes of objects. Thus, and thus alone, will the divine be able to confute the deteſtable ſophiſms of Mirabeau and Diderot and the other *ſoi-diſant* ſages of France; and perſuade their willing hearers to "render unto Cæſar the things that are Cæſar's, and to God the things that are God's."

Experimental philoſophy.

But beſides theſe advantages which accrue to different claſſes of men from this ſtudy, there are ſome effects which are general, and are too important to be paſſed over unnoticed.

116 And in other ſciences.

That ſpirit of diſpaſſionate experimental inquiry which has ſo greatly promoted this ſtudy, will carry with it, into every ſubject of inquiry, that preciſion and that conſtant appeal to fact and experience which characteriſe it. And we may venture to aſſert, that the ſuperior good order and method which diſtinguiſh ſome of the later productions in other ſciences, have been in a great meaſure owing to this mathematical ſpirit, the ſucceſs of which in natural philoſophy has gained it credit, and thus given it an unperceived influence even over thoſe who have not made it their ſtudy.

117 More general advantages of philoſophy.

The truths alſo which the naturaliſt diſcovers are ſuch as do not in general affect the paſſions of men, and have therefore a good chance of meeting with a candid reception. Thoſe whoſe intereſt it is to keep men in political or religious ignorance, cannot eaſily ſuſpect bad conſequences from improvements in this ſcience; and if they did, have hardly any pretext for checking its progreſs. And diſcoveries accuſtom the mind to novelty; and it will no longer be ſtartled by any conſequences, however contrary to common opinion. Thus the way is paved for a rational and diſcreet ſcepticiſm, and a free inquiry on other ſubjects. Experiment, not authority, will be conſidered as the teſt of truth; and under the guidance of fair experience we need fear no ill as long as the laws of nature remain as they are.

Laſtly, ſince it is the buſineſs of philoſophy to deſcribe the phenomena of nature, to diſcover their cauſes, to trace the connection and ſubordination of theſe cauſes, and thus obtain a view of the whole conſtitution of nature; it is plain that it affords the ſureſt path for arriving at the knowledge of the great cauſe of all, of God himſelf, and for forming proper conceptions of him and of our relations to him: notions infinitely more juſt than can ever be entertained by the careleſs ſpectator of his works. Things which to this man appear ſolitary and detached, having no other connection with the reſt of the univerſe but the ſhadowy and fleeting relation of coexiſtence, will, to the diligent philoſopher, declare themſelves to be parts of a great and harmonious whole, connected by the general laws of nature, and tending to one grand and beneficent purpoſe. Such a contemplation is in the higheſt degree pleaſant and cheering, and cannot fail of impreſſing us with the wiſh to co-operate in this glorious plan, by acting worthy of the place we hold among the works of God, and with the hopes of one day enjoying all the ſatisfaction that can ariſe from conſcious worth and conſummate knowledge; and this is the worſhip which God will approve. "This univerſe (ſays Boyle) is the magnificent temple of its great Author; and man is ordained, by his powers and qualifications, the high prieſt of nature, to celebrate divine ſervice in this temple of the univerſe."

Physiognomics. PHYSIOGNOMONICS, among phyſicians, denote ſuch ſigns as, being taken from the countenance, ſerve to indicate the ſtate, diſpoſition, &c. both of the body and mind: and hence the art of reducing theſe ſigns to practice is termed *phyſiognomy*. Physiognomics.

PHYSIOGNOMY,

1 Various definitions of phyſiognomy ancient and modern.

IS a word formed from the Greek φυσις *nature*, and γινωσκω *I know*. It is the name of a ſcience which occupied much of the attention of ancient philoſophers, and which, ſince the revival of learning, has in a great degree been diſregarded. Till of late it has ſeldom in modern times been mentioned, except in conjunction with the exploded arts of magic, alchemy, and judicial aſtrology. Within the two laſt centuries, no doubt, the bounds of human knowledge have been greatly extended by means of the patient purſuit of fact and experiment, inſtead of the haſty adoption of conjecture and hypotheſis. We have certainly diſcovered many of the ancient ſyſtems to be merely creatures of imagination. Perhaps, however, in ſome inſtances, we have decided too rapidly, and rejected real knowledge, which we would have found it tedious and troubleſome to acquire. Such has been the fate of the ſcience of phyſiognomy; which certainly merits to be conſidered in a light very different from alchemy and thoſe other fanciful ſtudies with which it had accidentally been coupled. The work lately publiſhed by M. Lavater on the ſubject has indeed excited attention, and may perhaps tend to replace phyſiognomy in that rank in the circle of the ſciences to which it ſeems to be intitled.

It does not appear that the ancients extended the compaſs of phyſiognomy beyond *man*, or at leaſt animated nature: But the ſtudy of that art was revived in the middle ages, when, miſled probably by the comprehenſiveneſs of the etymological meaning of the word, or incited by the prevalent taſte for the marvellous, thoſe who treated of the ſubject ſtretched the range of their ſpeculation far beyond the ancient limits. The extenſion of the ſignification of the term was adopted univerſally by thoſe naturaliſts who admitted the theory of ſignatures (ſee SIGNATURE); and phyſiognomy came thus to mean, the knowledge of the *internal* properties of *any* corporeal exiſtence from the *external* appearances. Joannes Baptiſta Porta, for inſtance, who was a phyſiognomiſt and philoſopher of conſiderable eminence, wrote a treatiſe on the phyſiogoomy of *plants (philognomonica)*, in which he employs phyſiognomy as the generic term. There is a treatiſe likewiſe *De Phyſiognomia Avium*, written we believe by the ſame perſon. In the *Magia Phyſiognomica* of Gaſpar Schottus, *phyſiognomia humana* is made a *ſubdiviſion* of the ſcience.

Boyle too adopts the extenſive ſignification mentioned, which indeed ſeems to have been at one time the uſual acceptation of the word (A). At preſent phyſiognomy ſeems to mean no more than "a knowledge of the moral character and extent of intellectual powers of human beings, from their external appearance and manners." In the Berlin Tranſactions for the years 1769 and 1770 there appears a long controverſial diſcuſſion on the ſubject of the *definition* of phyſiognomy between M. Pernetty and M. Le Cat, two modern authors of ſome note. Pernetty contends, that *all knowledge whatever* is phyſiognomy; Le Cat confines the ſubject to the *human face*. Neither ſeems to have hit the medium of truth. Soon after the celebrated book of Lavater appeared. He indeed defines phyſiognomy to be, "the art of diſcovering the *interior* of *man* by means of his *exterior*;" but in different paſſages of his work he evidently favours the extended ſignification of Pernetty. This work gave occaſion to M. Formey's attack upon the ſcience itſelf in the ſame Berlin Tranſactions for 1775. Formey ſtrenuouſly controverts the extent aſſigned by Lavater to his favourite ſcience.

2 Pythagoras probably brought this ſcience to Greece.

Before the era of Pythagoras the Greeks had little or no ſcience, and of courſe could not be ſcientifical phyſiognomiſts. Phyſiognomy, however, was much cultivated in Egypt and India; and from theſe countries the ſage of Samos probably introduced the rudiments of this ſcience, as he did thoſe of many others, generally deemed more important, into Greece.

3 It was a profeſſion in the time of Socrates.

In the time of Socrates it appears even to have been adopted as a profeſſion. Of this the well-known anecdote of the deciſion of Zopyrus, on the real character of Socrates himſelf judging from his countenance, is ſufficient evidence. Plato mentions the ſubject; and by Ariſtotle it is formally treated of in a book allotted to the purpoſe.

4 General outline of Ariſtotle's opinions on this ſubject.

It may be worth while to give a brief outline of Ariſtotle's ſentiments on the ſubject.

Phyſiognomy, he in ſubſtance obſerves, had been treated of in three ways: Some philoſophers claſſed animals into genera, and aſcribed to each genus a certain mental diſpoſition correſponding to their corporeal appearance. Others made a farther diſtinction of dividing the genera into ſpecies. Among men, for inſtance, they diſtinguiſhed the Thracians, the Scythians, the Egyptians, and whatever nations were ſtrikingly different in manners and habits, to whom accordingly they aſſigned the diſtinctive phyſiognomical characteriſtics. A third ſet of phyſiognomiſts judged of the actions and manners of *the individual*, and preſumed that certain manners proceeded from certain diſpoſitions. But the method of treating the ſubject adopted by Ariſtotle himſelf was this: A peculiar form of body is invariably accompanied by a peculiar diſpo-

(A) They'll find i' the phyſiognomics
O' th' planets all mens deſtinies. HUDIBRAS.

diſpoſition of mind; a human intellect is never found in the corporeal form of a beaſt. The mind and body reciprocally affect each other: thus in intoxication and mania the mind exhibits the affections of the body; and in fear, joy, &c. the body diſplays the affections of the mind.

From ſuch facts he argues, that when in man a particular bodily character appears, which by prior experience and obſervation has been found uniformly accompanied by a certain mental diſpoſition, with which therefore it muſt have been neceſſarily connected; we are intitled in all ſuch caſes to infer the diſpoſition from the appearance. Our obſervations, he conceives, may be drawn from other animals as well as from men: for as a lion poſſeſſes one bodily form and mental character, a hare another, the corporeal characteriſtics of the lion, ſuch as ſtrong hair, deep voice, large extremities, diſcernible in a human creature, denote the ſtrength and courage of that noble animal; while the ſlender extremities, ſoft down, and other features of the hare, viſible in a man, betray the mental character of that puſillanimous creature.

Upon this principle Ariſtotle treats of the corporeal features of man, and the correſpondent diſpoſitions, ſo far as obſerved: he illuſtrates them by the analogy juſt mentioned, and in ſome inſtances attempts to account for them by phyſiological reaſoning.

At the early period in which Ariſtotle wrote, his theory, plauſible certainly, and even probable, diſplays his uſual penetration and a conſiderable degree of knowledge. He diſtinctly notices individual phyſiognomy, national phyſiognomy, and comparative phyſiognomy. The ſtate of knowledge in his time did not admit of a complete elucidation of his general principles; on that account his enumeration of particular obſervations and precepts is by no means ſo well founded or ſo accurate as his method of ſtudy. Even his ſtyle, conciſe and energetic, was inimical to the ſubject; which, to be made clearly comprehenſible, muſt require frequent paraphraſes. Ariſtotle's performance, however, ſuch as it is, has been taken as the groundwork and model of every phyſiognomical treatiſe that has ſince appeared.

The imitators of this great man in the 16th and 17th centuries have even copied his language and manner, which are ſententious, indiſcriminate, and obſcure. His comparative phyſiognomy of men with beaſts has been frequently though not univerſally adopted. Beſides his treatiſe expreſsly on the ſubject, many incidental obſervations on phyſiognomy will be found interſperſed through his other works, particularly in his hiſtory of animals.

5 [Theophraſtus's ethic characters on an important branch of phyſiognomy.] Next after Ariſtotle, his diſciple and ſucceſſor Theophraſtus would deſerve to be particularly mentioned as a writer on the ſubject in queſtion. His ethic characters, a ſingular and entertaining performance, compoſed at the age of 99, form a diſtinct treatiſe on a moſt important branch of phyſiognomy, *the phyſiognomy of manners*: but the tranſlations and imitations of La Bruyere are ſo excellent, that by referring to them we do greater juſtice than would otherwiſe be in our power, both to Theophraſtus and to our readers. We cannot, however, omit obſerving, that the accuracy of obſervation and livelineſs of deſcription diſplayed in the work of Theophraſtus will preſerve it high in claſſical rank, while the ſcience of man and the prominent characteriſtics of human ſociety continue to be objects of attention.

6 [Other Greek authors on this ſubject.] Polemon of Athens, Adamantius the ſophiſt, and ſeveral others, wrote on the ſubject about the ſame period. Lately there was publiſhed a collection of all the Greek authors on phyſiognomy: the book is intitled, *Phyſiognomiæ veteris ſcriptores Græci. Gr. & Lat. a Franzio Altenb.* 1780, 8vo. From the number of theſe

7 [The ſcience was then coupled with ſomething of the marvellous.] authors, it appears that the ſcience was much cultivated in Greece, but the profeſſors ſeem ſoon to have connected with it ſomething of the marvellous. This we have cauſe to ſuſpect from the ſtory told by Apion of Apelles: *Imaginem adeo ſimilitudinis indiſcretæ pinxit, ut (incredibile dictu) Apion Gramaticus ſcriptum reliquerit quemdam ex facie hominum addivinantem (quos metopoſcopos vocant) ex iis dixiſſe aut futuræ mortis annos, aut præteritæ*‡. The novitiates of the Pythagorean ſchool were ſubjected to the phyſiognomic obſervation of their teachers, and it is probable the firſt phyſiognomiſts by profeſſion among the Greeks were of this ſect. They, too, to whom, from the nature of their doctrines and diſcipline, myſtery was familiar, were the firſt, it is likely, who expoſed the ſcience of phyſiognomy in Greece to diſgrace, by blending with it the art of divination.

‡ Pliny Nat. Hiſt. lib. 35. § 35. 36. 37.

8 [The obſervations of Roman and other writers.] From the period of which we have been treating to the cloſe of the Roman republic, nothing worthy of remark occurs in the literary hiſtory of phyſiognomy. About the laſt mentioned era, however, and from thence to the decline of the empire under the later emperors, the ſcience appears to have been cultivated as an important branch of erudition, and aſſumed as a profeſſion by perſons who had acquired a ſuperior knowledge in it.

In the works of Hippocrates and Galen, many phyſiognomical obſervations occur. Cicero appears to have been peculiarly attached to the ſcience. In his oration againſt Piſo, and in that in favour of Roſcius, the reader will at the ſame time perceive in what manner the orator employs phyſiognomy to his purpoſes, and find a curious inſtance of the *ancient* manner of oratorical *abuſe*.

Many phyſiognomical remarks are to be found likewiſe in the writings of Salluſt, Suetonius, Seneca, Pliny, Aulus Gellius, Petronius, Plutarch, and others.

That in the Roman empire the ſcience was practiſed as a profeſſion, ample evidence appears in the writings of ſeveral of the authors juſt mentioned. Suetonius, for inſtance, in his *Life of Titus*, mentions that Narciſſus employed a *phyſiognomiſt* to examine the features of Britannicus, who predicted that Britannicus would not ſucceed, but that the empire would devolve on Titus.

9 [This ſcience fell with the Roman empire, &c.] The ſcience of phyſiognomy ſhared the ſame fate with all others, when the Roman empire was overthrown by the northern barbarians. About the beginning of the ſixteenth century it began again to be noticed.—From that time till the cloſe of the ſeventeenth, it was one of the moſt faſhionable ſtudies. Within that ſpace have appeared almoſt all the approved modern authors on the ſubject (B.)

It

(B) They are, Bartholem. Cocles, Baptiſta Porta, Honeratus Nuquetius, Jacobus de Indagine, Alſtedius. Michael

It has been unfortunate for phyſiognomy, that by many of theſe writers it was held to be connected with doctrines of which the philoſophy of the preſent day would be aſhamed. With theſe doctrines it had almoſt ſunk into oblivion.

10 Particular ſtudies have peculiarly prevailed at particular times.

In every period of the hiſtory of literature there may eaſily be marked a prevalence of particular ſtudies. In the early period, for inſtance, of Grecian literature, *mythological morality* claimed the chief attention of the philoſophers. In the more advanced ſtate of learning in Greece and in Rome, *poetry*, *hiſtory*, and *oratory*, held the pre eminence. Under the latter emperors, and for ſome time afterwards, the hiſtory of *theological controverſies* occupied the greateſt part of works of the learned. Next ſucceeded *metaphyſics*, and *metaphyſical theology*. Theſe gave place to *alchemy*, *magic*, *judicial aſtrology*, the doctrine of ſignatures and ſympathies, the *myſtic*, *theoſophic*, *and Roſicrucian theology*, with phyſiognomy. Such were the purſuits contemporary with the ſcience which is the object of our preſent inquiry. It is no matter of ſurpriſe, that, ſo aſſociated, it ſhould have fallen into contempt. It is not unuſual for mankind haſtily to reject valuable opinions, when accidentally or artificially connected with others which are abſurd and untenable. Of the truth of this remark, the hiſtory of theology, and the preſent tone of theological opinions in Europe, furniſh a pregnant example.

To phyſiognomy, and the exploded ſciences laſt mentioned, ſucceeded *claſſic philology*; which gave place to *modern poetry* and *natural philoſophy*; to which recently have been added the ſtudies of *rational theology*, *chemiſtry*, the *philoſophy of hiſtory*, the *hiſtory of man*, and the *ſcience of politics*.

11 The obſervations of the writers of the preſent century on this ſubject.

About the commencement of the eighteenth century, and thence forward, the occult ſciences, as they are termed, had declined very conſiderably in the eſtimation of the learned; and thoſe who treated of phyſiognomy forbore to diſgrace it by a connection with thoſe branches of ideal learning with which formerly it had been invariably conjoined. In Britain, Dr Gwither noticed it with approbation.—His remarks are publiſhed in the Philoſophical Tranſactions, vol. xviii.; and Dr Parſons choſe it for the ſubject of the Croonean lectures, publiſhed at firſt in the ſecond ſupplement to the 44th volume of the Philoſophical Tranſactions, and afterwards (1747) in a ſeparate treatiſe, entitled *Human Phyſiognomy explained*.

The obſervations, however, of theſe writers, as well as of Lanciſius, Haller, and Buffon, relate rather to the tranſient expreſſion of the paſſions than to the permanent features of the face and body. The well-known characters of Le Brun likewiſe are illuſtrative of the tranſient phyſiognomy, or (as it is termed) pathognomy.—See *Passions in Painting*.

12 We find nothing very important till the controverſy between Pernetty and Le Cat.

During the preſent century, although phyſiognomy has been now and then attended to, nothing of importance appeared on the ſubject till the diſcuſſion already mentioned between Pernetty and Le Cat, in the Berlin Tranſactions. The ſentiments of theſe authors, in ſo far as relates to the *definition* of phyſiognomy, have been above noticed. Their eſſays are beſides employed in diſcuſſing the following queſtions: 1*ſt*, Whether it would or would not be advantageous to ſociety, were the character, diſpoſition, and abilities, of each individual ſo marked in his appearance as to be diſcovered with certainty?

2*dly*, Whether, on the ſuppoſition that by the higheſt poſſible proficiency in phyſiognomy, we could attain a knowledge in part only of the internal character, it would be advantageous to ſociety to cultivate the ſtudy, mankind being in general imperfect phyſiognomiſts?

No reaſoning *a priori* can poſſibly determine theſe queſtions. Time and experience alone muſt aſcertain the degree of influence which any particular acquiſition of knowledge would have on the manners and characters of mankind; but it is difficult to conceive how the *reſult* of any portion of knowledge, formerly unknown, and which mankind would be *permitted* to diſcover, could be any thing but beneficial.

13 Lavater's celebrated work.

Soon after this controverſy in the Berlin Tranſactions, appeared the great work of M. Lavater, dean of Zurich, which has excited no inconſiderable portion of attention in the literary world. The work itſelf is magnificent: that circumſtance, as well as the nature of the ſubject, which was ſuppoſed to be fanciful, have contributed to extend its fame; and certainly, if we may judge, the book, though many faults may be detected in it, is the moſt important of any that has appeared on the ſubject ſince the days of Ariſtotle. Lavater profeſſes not to give a complete ſynthetical treatiſe on phyſiognomy, but, aware that the ſcience is yet in its infancy, he exhibits fragments only illuſtrative of its different parts. His performance is no doubt defultory and unconnected. It contains, however, many particulars much ſuperior to any thing that had ever before appeared on the ſubject.

With the ſcholaſtic and ſyſtematic method adopted by the phyſiognomiſts of the laſt and preceding centuries, Lavater has rejected their manner of writing, which was dry, conciſe, indeterminate, and general: his remarks, on the contrary, are for the moſt part preciſe and particular, frequently founded on diſtinctions extremely acute. He has omitted entirely (as was to be expected from a writer of the preſent day) the aſtrological reveries, and ſuch like, which deform the writings of former phyſiognomiſts; and he has with much propriety deduced his phyſiognomical obſervations but ſeldom from anatomical or phyſiological reaſoning. Such reaſoning may perhaps at ſome future period become important; but at preſent our knowledge of facts, although extenſive, is not ſo univerſal as to become the ſtable foundation of particular deductions. Lavater has illuſtrated his remarks by engravings; a method firſt adopted by Baptiſta Porta.—

Lavater's

Michael Schottus, Gaſpar Schottus, Cardan, Taiſnierus, Fludd, Behmen, Barclay, Claromontius, Conringius, the commentaries of Auguſtin Niphus, and Camillus Balbus on the Phyſiognomica of Ariſtotle,—Spontanus, Andreas Henricus, Joannes Digander, Rud. Goclenius, Alex. Achillinus, Joh. Prætorius, Jo. Belot, Guliel. Gratalorus, &c. They are noticed in the Polyhiſtor. of Morhoff, vol. i. lib. 1. cap. 15. § 4. and vol. ii. lib. 3. cap. 1. § 4.

Lavater's engravings are very numerous, often expreſſive, and tolerably executed.

The opinions of this celebrated phyſiognomiſt are evidently the reſult of actual obſervation. He appears indeed to have made the ſcience his peculiar ſtudy, and the grand purſuit of his life. His performance exhibits an extended comprehenſion of the ſubject, by a particular attention to *offeal* phyſiognomy, and the effect of *profiles* and *contours*. His ſtyle in general is forcible and lively, although ſomewhat declamatory and digreſſive. His expreſſions are frequently preciſe, and ſtrikingly characteriſtic; and the ſpirit of piety and benevolence which pervade the whole performance render it highly intereſting.

The defects of the work, however, detract much from the weight which Lavater's opinions might otherwiſe challenge. His imagination has frequently ſo far outſtript his judgment, that an ordinary reader would often be apt to reject the whole ſyſtem as the extravagant reverie of an ingenious theoriſt. He has clothed his favourite ſcience in that affected myſterious air of importance which was ſo uſual with his predeceſſors, and deſcribes the whole material world to be objects of the univerſal dominion of phyſiognomy*. He whimſically conceives it neceſſary for a phyſiognomiſt to be a well-ſhaped handſome man †. He employs a language which is often much too peremptory and decifive, diſproportioned to the real ſubſtance of his remarks, or to the occaſion of making them. The remarks themſelves are frequently oppoſite in appearance to common obſervation, and yet unſupported by any illuſtrations of his.

Lavater certainly errs in beſtowing too great a reliance on ſingle features, as the foundation of deciſion on character. His opinions on the phyſiognomy of the ears, hands, nails, and feet, of the human ſpecies, on hand-writing, on the phyſiognomy of birds, inſects, reptiles, and fiſhes, are obviouſly premature, as hitherto no ſufficient number of accurate obſervations have been made, in regard to either of theſe particulars, to authorize any concluſion. He has erred in the oppoſite extreme, when treating of the important topic of national phyſiognomy, where he has by no means proſecuted the ſubject ſo far as facts might have warranted. We muſt farther take the liberty to object to the frequent introduction of the author's own phyſiognomy throughout the courſe of his work. His ſingular remarks on his own face do not ſerve to prejudice the reader in favour of his judgment, however much his character may juſtify the truth of them. We muſt regret likewiſe, for the credit of the ſcience, that the author's ſingularly fanciful theory of apparitions ſhould ſo nearly reſemble a revival of the antiquated opinions of the ſympathiſts.

To theſe blemiſhes, which we have reluctantly enumerated, perhaps may be added that high impaſſioned tone of enthuſiaſm in favour of his ſcience everywhere diſplayed throughout the work of this author, which is certainly very oppoſite to the cool patient inveſtigation befitting philoſophy. To that enthuſiaſm, however, it is probable that in this inſtance (as is, indeed, no unfrequent effect of enthuſiaſm) we are indebted for the excellency which the author has attained in his purſuit; and it poſſeſſes the ſalutary tendency of putting us on our guard againſt a too implicit acquieſcence in his phyſiognomical deciſions.

17 His work was attacked in the Berlin Tranſactions by M. Formey.

In the Berlin Tranſactions for 1775, there appears a formal attack upon Lavater's work by M. Formey. This eſſay we have already mentioned. After diſputing the propriety of the extenſive ſignification applied by Lavater and Pernetty to the term phyſiognomy, M. Formey adopts nearly the ſame definition which we conceive to be the moſt proper, and which we have put down as ſuch near the beginning of this article. He allows that the mental character is intimately connected with, and ſenſibly influenced by, every fibre of the body; but his principal argument againſt phyſiognomy is, that the human frame is liable to innumerable accidents, by which it may be changed in its external appearance, without any correſpondent change of the diſpoſition; ſo that it ſurpaſſes the extent of the ſkill of mortals to diſtinguiſh the modifications of feature that are natural from thoſe which may be accidental. Although, therefore, the ſcience of phyſiognomy may be founded in truth, he infers that the Deity only can exerciſe it.

M. Formey further contends, that education, diet, climate, and ſudden emotions, nay even the temperaments of anceſtors, affect the caſt of human features; ſo that the influence of mental character on theſe features may be ſo involved with, or hidden by, accidental circumſtances, that the ſtudy of phyſiognomy muſt ever be attended by hopeleſs uncertainty. Theſe objections are worthy of notice, but they are by no means concluſive.

18 Lavater's mode of treating his ſubject.

We ſhall give a ſpecimen of M. Lavater's manner of treating the ſubject on the oppoſite ſide of the queſtion: a ſpecimen, not in Lavater's preciſe words, but conveying more ſhortly an idea at once of his ſentiments, and of his manner of expreſſing them.

19 Phyſiognomy is juſtly called a ſcience.

No ſtudy, ſays he, excepting mathematics, more juſtly deſerves to be termed *a ſcience* than phyſiognomy. It is a department of phyſics, including theology and belles lettres, and in the ſame manner with theſe ſciences may be reduced to rule. It may acquire a fixed and appropriate character; it may be communicated and taught.

Truth or knowledge, explained by fixed principles, becomes ſcience. Words, lines, rules, definitions, are the medium of communication. The queſtion, then, with reſpect to phyſiognomy, will thus be fairly ſtated. Can the ſtriking and marked differences which are viſible between one human face, one human form, and another, be explained, not by obſcure and confuſed conceptions, but by certain characters, ſigns, and expreſſions? Are theſe ſigns capable of communicating the vigour or imbecility, the ſickneſs or health, of the body; the wiſdom, the folly, the magnanimity, the meanneſs, the virtue, or the vice, of the mind?

20 Experiments limited in extent.

It is only to a certain extent that even the experimental philoſopher can purſue his reſearches. The active and vigorous mind, employed in ſuch ſtudies, will often form conceptions which he ſhall be incapable of expreſſing in words, ſo as to communicate his ideas to the feebler mind, which was itſelf unable to make the diſcovery: but the lofty, the exalted mind, which ſoars beyond all written rule, which poſſeſſes feelings and

and energies reducible to no law, muſt be pronounced unſcientific.

21 Phyſiognomical truth may be defined and communicated to a certain length.

It will be admitted, then, that to a certain degree phyſiognomical truth may as a ſcience be defined and communicated. Of the truth of the ſcience there cannot exiſt a doubt. Every countenance, every form, every created exiſtence, is individually diſtinct, as well as different, in reſpect of claſs, race, and kind. No one being in nature is preciſely ſimilar to another. This propoſition, in ſo far as regards man, is the foundation-ſtone of phyſiognomy. There may exiſt an intimate analogy, a ſtriking ſimilarity, between two men, who yet being brought together, and accurately compared, will appear to be remarkably different. No two minds perfectly reſemble each other. Now, is it poſſible to doubt that there muſt be a certain native analogy between the external varieties of countenance and form and the internal varieties of the mind? By anger the muſcles are rendered protuberant: Are not, then, the angry mind, and the protuberant muſcles, as cauſe and effect? The man of acute wit has frequently a quick and lively eye. Is it poſſible to reſiſt the concluſion, that between ſuch a mind and ſuch a countenance there is a determinate relation?

Every thing in nature is eſtimated by its phyſiognomy; that is, its external appearance. The trader judges by the colour, the fineneſs, the exterior, the *phyſiognomy* of every article of traffic; and he at once decides that the buyer "has an honeſt look," or "a pleaſing or forbidding countenance."

22 This knowledge, however improved, would not be detrimental to man.

That knowledge and ſcience are detrimental to man, that a ſtate of rudeneſs and ignorance are preferable and productive of more happineſs, are tenets now deſervedly exploded. They do not merit ſerious oppoſition. The extenſion and increaſe of knowledge, then, is an object of importance to man: and what object can be ſo important as the knowledge of man himſelf? If knowledge can influence his happineſs, the knowledge of himſelf muſt influence it the moſt. This uſeful knowledge is the peculiar province of the ſcience of phyſiognomy. To conceive a juſt idea of the advantages of phyſiognomical knowledge, let us for a moment ſuppoſe that all phyſiognomical knowledge were totally forgotten among men; what confuſion, what uncertainty, what numberleſs miſtakes, would be the conſequence? Men deſtined to live in ſociety muſt hold mutual intercourſe. The knowledge of man imparts to this intercourſe its ſpirit, its pleaſures, its advantages.

23 It affords great mental gratification.

Phyſiognomy is a ſource of pure and exalted mental gratification. It affords a new view of the perfection of Deity, it diſplays a new ſcene of harmony and beauty in his works; it reveals internal motives, which without it would only have been diſcovered in the world to come. The phyſiognomiſt diſtinguiſhes accurately the permanent from the habitual, the habitual from the accidental, in character. Difficulties, no doubt, attend the ſtudy of this ſcience. The moſt

24 Difficulties in the ſtudy

minute ſhades, ſcarcely diſcernible to the unexperienced eye, denote often total oppoſition of character. A ſmall inflexion, diminution, lengthening or ſharpening, even though but of a hair's breadth, may alter in an aſtoniſhing degree the expreſſion of countenance and character. How difficult then, how impoſſible indeed, muſt this variety of the ſame countenance render preciſion? The feat of character is often ſo hidden, ſo maſked, that it can only be detected in certain, perhaps uncommon, poſitions of countenance. Theſe poſitions may be ſo quickly changed, the ſigns may ſo inſtantaneouſly diſappear, and their impreſſion on the mind of the obſerver may be ſo ſlight, or theſe diſtinguiſhing traits themſelves ſo difficult to ſeize, that it ſhall be impoſſible to paint them or deſcribe them in language. Innumerable great and ſmall accidents, whether phyſical or moral, various incidents and paſſions, the diverſity of dreſs, of poſition, of light or ſhade, tend to diſplay the countenance often in ſo diſadvantageous a point of view, that the phyſiognomiſt is betrayed into an erroneous judgment of the true qualities of the countenance and character. Such cauſes often occaſion him to overlook the eſſential traits of character, and to form a deciſion on what is purely accidental.—How ſurpriſingly, for inſtance, may the ſmallpox diſfigure the countenance, and deſtroy or confound, or render imperceptible, traits otherwiſe the moſt deciſive?

25 May or may not be obviated.

We ſhall, then, continues Lavater, grant to the oppoſer of phyſiognomy all he can aſk; and yet we do not live without hopes that many of the difficulties ſhall be reſolved which at firſt appeared inexplicable.

26 The nature of Lavater's work.

He then proceeds to a ſpecific illuſtration of his ſubject under a great variety of titles, in which he treats of human nature in general, and of each particular feature ſeparately.

To enumerate the different diviſions of his book would not be more ſatisfactory to our readers than the peruſal of the *contents* of the book itſelf; and an attempt to epitomize even the eſſential ſubſtance of the vaſt multiplicity of matter contained in his eſſays, (which are yet only *fragments*, and to which indeed he himſelf does not pretend to give any higher appellation), would extend this article to a diſproportionate length. Such an abridgement, after all, would convey no ſolid information on a ſubject which merits all the time and ſtudy that an attentive peruſal of Lavater's works at large would require.

27 Probable cauſes of the diſpute in which ſcience has fallen.

From the hiſtorical deduction of the literary progreſs of phyſiognomy which we have thus attempted to lay before our readers, it appears, that although the ſcience has fallen into diſrepute, there can ſcarcely be mentioned a period in which any cultivation of ſcience took place when phyſiognomy was not likewiſe the ſtudy, nay ſometimes even the profeſſion, of men of the moſt eminent abilities and the greateſt learning.

The reaſons why at preſent ſo little attention is paid to the ſubject probably are,

1ſt, That it has been treated in conjunction with ſubjects now with propriety exploded: And,

2dly, That it has been injured by the injudicious aſſertions and arguments of thoſe who have undertaken its defence.

Sometimes, however, the wiſe and the learned may err. The uſe of any thing muſt not be rejected for no better reaſon than that it is capable of abuſe. Perhaps the era is not diſtant when phyſiognomy ſhall be reinſtated in the rank which ſhe merits among the valuable branches of human knowledge, and be ſtudied with that degree of attention and perſeverance which a ſubject deſerves ſo eſſentially connected with the ſcience of man.

That there is an intimate relation between the diſpoſitions

28 There is a relation between the diſpoſitions of the mind and the features of the face.

poſitions of the mind and the features of the countenance is a fact which cannot be queſtioned. He who is ſinking under a load of grief for the death of an affectionate wife or a dutiful child, has a very different caſt of features from the man who is happy in the proſpect of meeting his miſtreſs. A perſon boiling with anger has a threatening air in his countenance, which the moſt heedleſs obſerver never miſtakes; and if any particular diſpoſition be indulged till it become habitual, there cannot be a doubt but that the correſponding traces will be ſo fixed in the face as to be diſcernible by the ſkilful phyſiognomiſt, under every effort made to diſguiſe them. But when we attempt to decide on a man's intellectual powers by the rules of this ſcience, we are often deceived; and in this reſpect we have reaſon to believe that Lavater himſelf has fallen into the groſſeſt miſtakes.

PHYSIOLOGY,

1 Definition.

IS a Greek word, which, in ſtrict etymology, ſignifies that which diſcourſes of nature: but in its common uſe, it is reſtricted to that branch of phyſical ſcience which treats of the different functions and properties of living bodies; while by living bodies are meant thoſe which are by a certain organized ſtructure enabled to grow and propagate their kind.

By this definition, phyſiology muſt neceſſarily have for its object the explanation of that internal organical economy in plants and animals, which nature has deviſed for the preſervation of the individual, and for the continuance and propagation of the ſpecies.

2 Diviſion.

It is naturally divided into two kinds, particular and general. The former treats of the properties and functions of the individual or ſpecies, as may be ſeen in the article ANATOMY; the latter is the ſubject of our preſent diſcuſſion, and treats of thoſe functions and properties which are general or common to all living bodies.

3 Utility of phyſiology.

To the genuine naturaliſt no ſubject preſents ſuch a field of amuſement and inſtruction. When as complete as the ſtate of cotemporary ſcience will admit, it will exhibit a general reſult of all thoſe experiments and obſervations that have purpoſely been made or occaſionally contributed to illuſtrate the phenomena of animated matter; and when it ſhall reach that ſummit of perfection to which the efforts of genius may carry it, it may be enabled to diffuſe a light, of which the naturaliſt of the preſent day can have no juſt or adequate conception: Particularly in phyſic, anatomy, botany, and in natural hiſtory, its happy effects may be numerous and great. On many occaſions it may there introduce order for confuſion, certainty for doubt; and may be expected to enthrone ſcience in various places which are now occupied by fancy and conjecture.

4 Its near approach to metaphyſics, and the difference pointed out.

Of all the branches of phyſical ſcience it certainly makes the neareſt approach to the region of metaphyſics; but yet there is a difference between theſe, though it may not be very eaſy to point out the preciſe line of termination. Phyſiology, as already defined, being that ſcience which has for its object the organical economy of living bodies, the word organical, we think, here ſhould mark the diſtinction.

Wherever the economy of living bodies indicates deſign, and cannot reſult from any combination or ſtructure of organs, it muſt be ſuppoſed the effect of ſomething different from matter, and whoſe explanation belongs to that which is called *metaphyſics*, or which we might term the *philoſophy of mind*. By aſcribing indeed to the glandular contents within the cranium and to that ſiction animal ſpirits, the motives of action, the ſuperficial and ill informed may have been led to an opinion that perception, memory, and imagination, are the functions of the cerebrum, the medulla oblongata, and cerebellum; that the ſoul is a conſequence of organization; and the ſcience which treats of it only a particular branch of phyſiology. But mind and its faculties are now ſo well underſtood and inveſtigated, that this opinion can ſeldom prevail but where penetration is not remarkable for its acuteneſs, or where reflection, reading, and reſearch, have long been confined within the limits of a narrow circle.

Preliminary obſervations.

Inſtead of mind being the effect of organization, we readily allow that every living ſyſtem of organs ſuppoſes mind, and that in the ſtudy of ſuch ſyſtems the phyſiologiſt muſt often meet with many phenomena that are leſs ſingular than ſimple perception, and yet for which he cannot account by any knowledge which he poſſeſſes of organic powers. This truth we partly acknowledge, when, like ancient Athens erecting her altars to unknown gods, we retreat to thoſe aſylums of ignorance, the vis inſita, the vis nervea, the vis vitalis, the vis medicatrix, and a number of others of the ſame kind.

5 The bounds of phyſiology, and the conſequences of not attending to them.

We chooſe here to mark preciſely the bounds of phyſiology, becauſe we have always been led to imagine that it would be extremely fortunate for ſcience that all its diviſions were accurately defined, that each were reſtricted to its own ſphere, where alone it is uſeful, and were never allowed to make encroachments on the province of another, where its only tendency can be to miſlead and ſubvert all ideas of arrangement.

In its progreſs of improvement, phyſiology has been much and often retarded from a want of attention to this circumſtance. The time has been when its place was occupied almoſt entirely by an abſurd and ridiculous philoſophy, which accounted for every thing by an hypotheſis, and which pretended to cure wounds a hundred miles diſtant by a powder of ſympathy.

6 Introduction of logic into phyſiology.

Nay, as if its nature were not yet aſcertained, in ſome books whoſe titles promiſe much information on the functions of organs, we meet with only a pleaſing account of deſign and intelligence, and a few leſſons, when the fancy is warm, how to exclaim and how we ſhould wonder; or, after ſimilar profeſſions in the titles of others, we are preſented with only a curious diſplay of the art of logic. To a fact or two we ſee numerous chains of reaſoning appended. On theſe chains are hanging important and general concluſions; and theſe concluſions afterwards uniting, ſuſpend an elaborate

Preliminary observations.

borate system of pathology. The whole has a wonderfully specious appearance; but upon applying the touchstone of experiment, the system falls, the conclusions turn out to be false, the chains are found connected with the fact by only a conjecture or some popular opinion of the time; most of their links are creations of fancy, and their joinings such logical associations as have no analogy or prototype in nature.

7 And of mathematics.

Instead of logic, however, a pompous parade of mathematical learning has been *sometimes* introduced. This has always an imposing aspect, and its presence here may require to be examined with some care. It must be allowed, that it would have indeed been rather surprising if logic and metaphysics had been employed, and mathematics carrying science in their name had not been thought of. Their character had always been deservedly high; and there was scarcely a department of knowledge to which they had not in some respect contributed their aid: their researches, too, had not been confined to mere number and quantity alone; they had explained the momentum of bodies, and all those motions which arise from percussion and gravitation; they had ascertained the distance of the stars, the velocity, magnitude, and orbits of the planets; they had accounted for the phases of the moon, the phenomena of eclipses, and return of comets; and bringing their knowledge from the heavens to the earth, they had shown the causes of the days and nights, of the years and the seasons, in all their varieties throughout the globe: they had taught the chronologer how to dispose of the periods of time, and how he might best assist the historian to arrange his events: they had pointed out the origin of tides; had informed the mariner how to direct his course through the ocean; and had taught the geographer how to describe the regions of the earth, and assist the traveller in his laudable pursuits after knowledge and science: they, in short, had unfolded the wonders of mechanism; and, diffusing light over every branch of that philosophy which is called *mechanical*, and has long been dignified with the name of *natural*, had afforded the finest specimens of reasoning with which the human mind is acquainted.

8 Introduced by Bellini.

A science of such distinguished utility could hardly fail to excite the admiration of all who knew it, or even had heard of it. And at a period when it was fashionable, it was scarcely possible for the physiologist to pass it unnoticed: the truth is, he very soon discovered its excellency. Bellini of Florence first introduced it; and it was at last so warped with physiology, that there were some who could hardly conceive a physiology existing without it.

9 Extended by Borelli,

The justly celebrated Professor Borelli, one of its most enthusiastic admirers, employed it so well in showing how the muscles acted as ropes and the bones as levers, that he thence explained with the happiest effect the phenomena of standing, of walking, of leaping, of flying, and of swimming, in different animals: this task he performed in the first part of his famous work *De Motu Animalium*. But, wishing to know more of the animal economy, and feeling himself inspired with new hopes, he ventured in the second to explain also in the same way the interior motions and their proximate causes on the principles of mechanism: he there gives a minute account of the motion of the muscles, of the heart and its pulsation, of the circulating blood, of the office of the lungs, the kidneys, and the liver, of the nervous fluid and the seminal secretion; of vegetation, generation, nutrition, of hunger and thirst, of pain, of lassitude, and the heat of fever.

Preliminary observations.

Mathematics by him were considered as almost universal interpreters; for except the mechanical he seemed to acknowledge no other secondary powers in nature. He thought, with Plato, that God himself was always geometrising; and was fully persuaded that physical knowledge could not be acquired but through the medium of geometrical demonstrations and forms. These opinions had begun to be general, when his learned work was published at Rome in the year 1676; and they were no unequivocal symptoms that the reigning philosophy of that time was now in the last stage of decay.

Still, however, as the spirit of that philosophy was not wholly extinguished, physiology continued to be much infected with its metaphysical and logical disputes, and with its physical doctrines of forms of particular ferments, its antipathies, sympathies, its occult qualities, and subtile atoms.

10 By Pitcairn and others.

For these reasons, in his inaugural dissertation at Leyden, delivered in the year 1692, the learned Pitcairn expresses a wish that medicine were made a distinct science; that it were established on mechanical principles, on fewer postulates, and more data; and that it were supported by a clear train of mathematical reasoning, which would defy the attacks of the sophist, and which would not be liable to the fluctuations of opinion and prejudice. These sentiments were warmly supported by the great Boerhaave, who, in his aphorisms, has founded his reasonings on the structure of the parts and the laws of mechanics, and to whom an edition of Borelli was dedicated in 1710.

11 Abused.

Pitcairn, however, was not content with barely expressing his wishes. Seeing with regret that the state of medicine could never be improved as long as it was connected with the philosophy which was then in fashion, he seemed anxious to effect a separation; and for such a step he wished to have only some plausible pretext. This pretext *was not long wanting*; and was, to be sure, one of the most whimsical that could well have presented itself to his fancy. It occurred to him that the study of medicine was prior to philosophy; that it had begun its course with astronomy, at the time when diseases were supposed the consequence of offended Deity; that all along, as it had shared the fate of astronomy, and had equally suffered in the common disgrace of judicial astrology, it was highly reasonable, in his opinion, that it should still follow the fate of its friend; that it should be established on similar principles, and should be demonstrated by that reasoning which might experience the shock of ages without being moved. So attached was he to the geometrical mode of demonstration, that in his dissertations he appeared to consider it as indeed the only species of evidence, excepting the senses, that could be relied on. But here he was certainly venturing too far; so rash an opinion, and one which, had he previously consulted with prudence, might have been suppressed, was fatal to his cause. We must here therefore date the commencement of those attacks to which his system was afterwards exposed. Such an indiscreet species of pedantry was but ill calculated to procure a generally favourable reception for a book with so extraordinary a title as the *Physico-mathematical*

Preliminary observations.

mathematical Elements of Medicine. Many learned and ingenious men, the greater part of whose knowledge had depended chiefly on the evidence of testimony, were now disposed to examine, with a steady and awakened eye, his boasted demonstrations. The consequence was that which might have been expected: the result of their inquiries was wholly inauspicious to those new applications of geometry; they found that his facts and experiments were few, that his postulates were endless, and that no mathematical reasoning whatever could extract truth from a false hypothesis, or could fairly deduce a general conclusion from particular premises. The Doctor, they observed, had imposed upon himself, in imagining that either certainty or truth was naturally inherent in any mere geometrical forms; these forms, they said, had been often abused: Plato had thought them somewhat divine; the superstitious had employed them as charms; Pythagoras had made them the symbols of his creed; and even in the writings of the learned Professor himself they frequently served no other purpose but to give an air of importance to trifles; to bestow on error the appearance of science; and to give a simple and a trite remark the look of research, and of acute and profound erudition.

12 Rejected.

13 Perhaps too rashly.

It is unnecessary to recal here the satyrical wit, or more properly the scurrilous abuse, with which this system and its author were treated. The mechanic physiology has now sunk into such contempt, that the most illiterate affect to smile at the mention of its name; they seem to forget, or, what is more probable, they never knew, that it once was honoured with the great names of Borelli, Boerhaave, and Newton; and their reading perhaps cannot inform them that it was a noble step to improvement; that it explained the structure of the eye, the movement of the bone, and force of the muscle, and that it may yet perhaps be the means of many interesting discoveries in the living body: discoveries, however, which Heaven will reserve for other minds than those which it makes merely to receive the impressions of the day.

14 Introduction of chemistry.

A frequent mistake into which the mechanical philosophers had fallen, was their hopes of being able to account for digestion by the muscular force and action of the stomach. The more they reasoned from this supposition, the more widely they wandered from the truth. A thought of Vallisneri, that in acting mechanically, the stomach was as liable to be affected as its contents, gave a hint to Reaumur. On this hint he began immediately a set of experiments; and from a number that were clear and decisive, concluded that digestion was performed by a solvent. Here was a fair introduction to chemistry; the action of solvents was never yet satisfactorily explained by mechanic powers. A new era therefore commences; and chemistry now, in physiological investigations, holds that place which was formerly possessed by geometry and mechanics.

15 Chemical investigations.

Nor is chemistry undeserving of this rank. From a small beginning, and from modestly professing to observe merely the different phenomena which are the effects of heat and of mixture, it has risen like astronomy to the first eminence among the sciences. By its numerous researches it has found widely diffused over nature a variety of singularly active bodies, which are called *salts*. Of these salts it has noticed some which change a blue vegetable tincture into green, and others which change that tincture into red: the former of these it has called *alkalis*, and the latter are known by the name of *acids*. It has observed, that when acids and alkalis are brought into contact, and either of them nearly in a fluid state, they encounter with violence, effervescence and heat, and form a salt, which being neither acid nor alkaline, is called *neutral*. It has been remarked that all these salts, whether volatile or fixed, whether fluid or concrete, have each permanently uniform characters; and that, though sometimes blended in a mixture, or made to evanish in a solution, yet when they are separated they resume their taste, their smell, their colour, and their form, and exhibit, as before, the same power in dissolving earths, metals, and stones, and in making inflammable bodies to smoke, to kindle, and explode with a loud noise. All, however, act not alike upon all bodies; those acids which dissolve iron remain quite harmless upon gold. And chemistry here has been led to observe that particular salts show a preference for particular bodies, that there is in them an appearance of choice, and that their character is never to be known but by studying their different elective attractions.

16 Discoveries concerning salts.

Preliminary observations.

17 Gases.

Besides salts, chemistry of late has also discovered a number of bodies that are still more wonderful, still more active, and some of them at least still more widely diffused over nature. These are certain aeriform fluids which are called *gases*: these gases, like the mind itself, are discernible only by their effects; all are elastic, and all are combined with the principle of heat. Their kinds are various; some are inflammable, some are saline and soluble in water, some are neither the one nor the other, and some distinguished by the name of *airs*, maintaining combustion and respiration: their importance is such that there is not a single process in chemistry, nor perhaps one regular process in nature, "in which the phenomena of the disengagement or fixation of heat, and the disengagement or fixation of elastic fluids, are not observed either separately or together." Two of these fluids compose water, two the nitric acid, two ammonia, and three of them are found in atmospheric air; one of them is thought, with a good deal of reason, to be the alkaligenous principle in bodies, and two of them to be the constituents of oil: the principle of acidity is already known to be one of the two which compose water. The same fluid oxidates metals, supports flame during combustion, communicates heat to the circulating blood, and maintains life in the act of respiration.

By that knowledge which it thus has acquired of salts and of gases, by its more ingenious modes of analysis, and by some discoveries which it has made concerning the nature of heat and of light, chemistry is now able to account for many phenomena that before were inexplicable. In France particularly it has been recently extending its researches with a good deal of ardour towards the phenomena of both the animal and vegetable kingdoms: it has there found its salt and its gases, its heat, and its light, active and busy.

18 The food of plants.

It is more than a century since it observed that plants were nourished by pure water and atmospheric air; that from these alone they derived their extracts, their mucilage, their oil, their coal, their acids, their alkalis, and aroma. But since the discovery of different kinds

Preliminary observations.

of elaſtic fluids, it has farther remarked that they grow rapidly in hydrogenous gas (A), and in air mixed with carbonic acid; that aſſiſted by light their leaves abſorb hydrogene from water, carbone from the acid of which they are ſo fond; and thus decompoſing the one and the other, diſengage from both the oxigenous principle or vital air, and reſtore to the atmoſphere ſalubrity and health.

19 Animal powers.

Leaving vegetables, which, by analyſis in cloſe veſſels and in red-hot pipes, it has reduced to hydrogene, oxigene, azote, and charcoal, it has made diſcoveries no leſs important in the animal kingdom. It has found that the food of the nobler animals, which immediately or remotely is prepared by vegetables, is generally acted upon by a ſolvent: it has proved by experiment that the animal organs can fix azote; can decompoſe atmoſpheric air; can form lime, iron, and carbonic acid, as well as vegetables, produce a number of ſaline ſubſtances, which no art could detect in their food. Nor is it here that ſuch diſcoveries are meant to terminate; theſe ſeemingly creative powers of vegetation and of animalization, with other phenomena in the ſtructure and economy of living bodies, chemiſtry imagines that it will yet be able to explain. We may ſafely venture, however, to predict that ſomething more than its preſent knowledge of the various effects of heat and of mixture will in this caſe be found neceſſary to enſure ſucceſs. The late diſcovery of elaſtic fluids and their ſingular properties afford the ſtrongeſt reaſons to ſuſpect that we yet may be ignorant of many agents which nature employs in the functions of bodies. But whatever be the truth, we are almoſt certain that theſe agents diſcovered by the chemiſts are not alone concerned. Electricity, magnetiſm, and what have been called animal electricity and animal magnetiſm, muſt not be excluded from acting ſome part. The growth of plants, it is well known, is conſiderably affected by the electrical ſtate of the atmoſphere; it is ſenſibly promoted by a proper uſe of the vegeto-electrometer, and has been ſaid to indicate a difference between the negative and poſitive electricities, whether theſe be kinds or ſtates of the fluid. Such too is our preſent knowledge, that electricity as yet ſeems the only cauſe to which we can aſcribe the ſeeming chemical affinities of the dew; its conſtant practice in avoiding ſome bodies, its predilection for others, and particularly its attachment to the living points of plants and of leaves: nor is this electricity wholly unconnected with the animal kingdom; when we think of its ſingular ſondneſs for points, it occurs that one intention of our hairs may probably have been to collect and diffuſe it. It is plainly excited in eroſs rubbing the hair of ſome animals, and when we wear ſilk, it is frequently accumulated upon the ſurface of our own bodies.

20 Electricity and magnetiſm.

The iron found in plants and in animals is certainly ſomewhat of a ſtriking circumſtance, and cannot be denied to be one reaſon why magnetiſm ſhould not be wholly overlooked.

21 Animal electricity,

As for animal electricity, or what has been called ſo, it is now, we believe, generally allowed to hold an important place in the ſyſtem. It is very perceptible in all thoſe nerves which are ſubſervient to voluntary motions; nor is it limited to theſe alone. In ſeveral inſtances where metals were applied to the nerves of the heart, which nature has deſtined to ſpontaneous motions, they were ſeen to awaken the dormant powers in the muſcular fibres of that viſcus. We here ſpeak only of the nerves; but the Torpedo, the Gymnotus electricus, and Silurus electricus, poſſeſs a particular ſtructure of organs for collecting this fluid, for diſcharging it at pleaſure, and for giving a ſhock. If thoſe who are accuſtomed to the common kind of electrical experiments, may at firſt be ſurpriſed that this electric fluid in the animal is not diſcharged from the nerves by water, or any other metallic conductor that is pure and unmixed, another fact, which is fully as ſtriking, though it has not been hitherto mentioned by any obſerver known to us, appears to merit equal attention: Cut away the leg of a frog, uncover a part of the crural nerve, place the limb now on a table on which an electrifying machine is working, you will ſee the muſcles ſtrongly convulſed at every ſpark which you draw from the conductor, but remaining motionleſs upon the diſcharge of the Leyden phial.

Preliminary obſervations

22 And animal magnetiſm.

Animal electricity naturally ſuggeſts animal magnetiſm. This laſt has been productive of more wonders in the human frame than all the preceding agents together. Under the management of Meſmer at Paris, and his pupil Deſlon, it filled all who obſerved its effects with ſurpriſe and aſtoniſhment. It ſeemed to unhinge the powers of the mind, and affect the whole animal economy; it excited the moſt extraordinary emotions; it rouſed and allayed the different paſſions; it changed averſion into love, and love into averſion; it created pain, it healed wounds, and cured diſeaſes as if by inchantment.

Theſe diſcoveries were made by a quack, who knew not the cauſe by which he produced ſo ſingular appearances. The celebrated Franklin, who firſt ſuppoſed that the electrical fluid was the thunder, was placed at the head of thoſe gentlemen who demonſtrated that this ſpecies of magnetiſm was the ſame power that had long been known under the name of *imagination*.

This laſt diſcovery, if the bluſhing pride of modern philoſophy could but ſtoop to improve an important hint, though originally ſuggeſted by an empiric, might greatly enlarge our knowledge of mind, and explain ſome things in the animal economy which appear yet to require a ſolution. At any rate, it ſufficiently proves that the influence of mind is very extenſive in the higher parts of animal creation. Many facts would argue that it increaſes as we riſe in the ſcale: but the ſole intention here was to ſhow, that chemical agents are neither almighty nor everywhere preſent; that in the internal organical economy of living bodies they act but a part; and that, like the other agents in nature, they are obliged to confine their operations within thoſe limits which the great Author of being has preſcribed.

23 The uſe of anatomy in ſtudy

The aid which anatomy affords to phyſiology is now to be conſidered. Phyſiology in general and the phyſiology

(A) Hydrogenous gas acts with more energy than any other ſubſtance in diſſolving carbone; it mixes with carbonic acid and with azote, and ſometimes holds in ſolution ſulphur and phoſphorus. See Fourcroy's Diſcourſe on modern chemiſtry.

Preliminary observations.

ſtudy of anatomy are ſo cloſely connected, that, as Haller imagined, they can hardly be ſeparated even in idea. In his opinion, the man who ſhould attempt to become a phyſiologiſt without anatomy, would act as wiſely as the mathematician who, without ſeeing the wheels or the pinions, or without knowing the ſize, the proportions, or the materials of any machine, would yet preſume from mere calculation to determine its powers, its properties, and uſes. In this compariſon, the importance of anatomy, we are really perſuaded, is not repreſented in a light too ſtrong; nor does that medium through which it has been viewed appear to have magnified beyond nature.

24 Anatomy a diſtinguiſhed branch of human knowledge.

Whether art or ſcience, anatomy is one of thoſe eminent accompliſhments without which no one is able to proſecute his ſtudies with half that pleaſure and ſucceſs which he might in either the animal or vegetable kingdoms. Having been always accuſtomed to aſſign it one of the higheſt and moſt honourable places among thoſe branches of human knowledge which are ſtyled liberal, we muſt be excuſed if we dwell a little in expoſing an attempt to convert it to a craft.

25 The illiberality of ſome of its profeſſors.

It is with ſurpriſe, and a mixture of regret, that we ſee a writer of diſtinguiſhed merit wiſhing thus to degrade it, and ſeeking to confine it as well as phyſiology to that profeſſion which chanced to be his own. The dignity of a ſcience, which he conſidered as his glory and his pride, ſhould have certainly extinguiſhed in a generous mind the low and diſguſting policy of his trade. It is indeed with reaſon that he thinks it unfortunate, "that thoſe who, from the nature of their education, are beſt qualified to inveſtigate the intricacies, and improve our knowledge of the animal economy, are compelled to get their living by the practice of a profeſſion which is conſtant employment." We lament the misfortune as much as he can; but we reaſon not from it in the ſame way. Inſtead of complaining that "idle profeſſional men," particularly "of the church, ſhould become philoſophers and phyſiologiſts as it were inſtinctively," we are happy to learn that men of enlightened and cultivated minds are thus ſo readily diſpoſed to aſſiſt us; that nature conducts them as it were by inſtinct; and that happily they enjoy all that leiſure which is deemed ſo neceſſary for ſuch an undertaking. The genius of ſome, and the liberal education which they all muſt have had opportunities of acquiring, by no means impreſs us with any unfavourable ideas of their aid.

Our author allows them to look through microſcopes and examine the red globules of the blood: They may too, he ſays, view animalculæ, and give us a candid relation of what they ſee; but ſhould not preſume to carry their reaſoning into a ſcience of which they can know nothing, or hope to throw light on a ſubject which it is impoſſible they can underſtand. But, to ſpeak freely, after conſidering the great phyſiological diſcovery of Prieſtley with reſpect to *reſpiration*, the moſt important probably, not even excepting that of the *ſyſtem of abſorbents*, that the ſcience has witneſſed in the preſent age, we ſee no grounds for preſcribing ſuch laws or fixing ſuch limits: and although he may treat the illuſtrious Reaumur and Abbé Spalanzani as nothing more than makers of experiments, and declare a reſolution to place no confidence in thoſe which are made by *gentlemen* and *prieſts*; he will not certainly deny that others have as well as he a juſt right to think for themſelves. Preliminary obſervations.

Were ſuch ſentiments to become univerſal, it is difficult to ſay what would be the conſequence. In this country, the law and the church require from their members a formal certificate, that, beſides the profeſſional, they have alſo attended ſome literary claſſes at the univerſity. To our medical claſſes boys are admitted from the ſhop and from the ſchool, and may afterwards paſs the two colleges of ſurgeons and phyſicians, by exhibiting a little ſkill in their art, or at leaſt by paying the ſtated fees. On theſe accounts, being anxious already for the fate of a profeſſion which we reſpect, and conſidering the degeneracy to which it is expoſed, not we hope the degeneracy into which it is ſinking, we ſhould be ſorry to ſee it deprived of that reſpectability which it may derive from the countenance of men poſſeſſing general literature and ſcience.

It is very true, that gentlemen and prieſts may not be anatomiſts; and not a few anatomical diſputes might ſeem to inſinuate, that perſons may be very eminent anatomiſts without being either gentlemen or prieſts. Still, however, there is nothing incompatible in thoſe characters; and, were we to judge from their writings, it was certainly a thing of which Bacon, Newton, and Locke, never dreamed, that the ſtudy of the prieſt, or the mere circumſtance of being a gentleman, was to blunt their acuteneſs for phyſical reſearch, or in after times to affect their reputation as men of genius.

"When men have begun to reaſon correctly (ſays Dr Hunter), and to exerciſe their own judgment upon their obſervations, there muſt be an end to deluſions. Many doctrines of old phyſicians and of old women will meet with proper contempt; the tyranny of empty pomp and myſtery of phyſic will be driven out of the land, and forced to ſeek ſhelter among leſs cultivated ſocieties of men."

If the learned profeſſions wiſh to be reſpected, let them reſpect each other: for our part, we eſteem them all: and whatever aſſiſtance either they or others may afford to phyſiology, they may be aſſured that they will not find us anywiſe diſpoſed to detract from its merit. Diveſted of prejudice, we value as highly the diſcovery of Prieſtley, which explains reſpiration, as if it had come from Albinus or Haller; and with as much readineſs acknowledge obligations to the celebrated painter Leonardo da Vinci, as if he had been a doctor of phyſic. See ANATOMY, p. 667.

26 Their labours and diſcoveries.

But while we are thus impartial to others, we would not be unjuſt to profeſſional anatomiſts. Their learning, their patience, and ardour, have been great; and candour obliges us to aſſert their claim to the moſt numerous and important diſcoveries that have yet been made in phyſiological ſcience. The pains which they have taken, the prejudices which they have ſurmounted, and thoſe feelings which they have ſacrificed in deſcribing the parts of the dead body, place their labours beyond all praiſe.

But their diſcoveries have not been confined to a mere knowledge and deſcription of parts. In the ſtill fabric, juſt as in a time-piece or a broken orrery without motion, the whole preſents a very confuſed and even an unintereſting appearance. In this caſe, ſhould the man of reflection happen to aſk, where are the organs of the different functions? all would be ſilence,

and

Preliminary observations.

and nothing would be found to make a reply to such an inquiry. The arterial system is relaxed and empty; the muscular fibre cannot be roused; the heart has ceased from its wonted beatings; and the nerve refuses to convey sensations. On this scene the eye of the anatomist could not be expected to dwell long with much satisfaction. Curiosity would induce him to look beyond it, and study the design. He would soon perceive, that to know the uses of the several parts, they must be seen alive and in action. But here new difficulties would arise, and feelings of compassion would exclaim against any farther pursuit. The natural zeal, however, of inquiry, the good of mankind, and the love of science in a generous mind, are not easily resisted.

To his lasting praise, and the singular improvement of true physiology, the anatomist has examined the living body, and has there observed, that all motion proceed immediately from the muscular fibre; that the muscular fibre again derives its power from the nerve, which terminates in the brain; that fibre, and nerve, and the whole system, are nourished by the blood which comes from the heart; and that the waste of blood is supplied by the lacteals, which absorb nutritious matter from the food as it passes along the intestinal canal.

He has also observed, that the blood, which is in continual motion, has a circular course; that other vessels along with the lacteals are employed to absorb; and by means of injection has shown the route of the different fluids as clearly in the dead as they could have been seen in the living subject.

When his eyes have failed in tracing objects that were too minute for unaided sight, he has called in the help of the microscope, and discovered the red globules of the blood, animalculæ in the semen, and the anastomoses of the arteries and veins; and when the microscope could lead him no farther, he has had recourse to chemical analysis, and made discoveries equally important in demonstrating the bodies which compose the several fluids and the solids.

Besides these services which the anatomist has rendered to physiology, the science is likewise greatly indebted to him for those various and ingenious methods which he has taken to diffuse his knowledge. Whatever has occurred remarkable or rare, he has studied to preserve either dried or in fluids that resist putrefaction. By corroding the parts which he has injected in a certain acid, he has given an idea of the vascular system, which is at once instructive and elegant. Where it has been necessary to destroy the parts when incapable of preservation, or where the preservation would have been expensive, he has not neglected to represent them in models of wax, or to perpetuate them in accurate casts of lead or of stucco: and, lastly, that the valuable fruits of his labours might not be confined in his room of preparations or to his pupils, he has described most of them in drawings, has multiplied his drawings by correct engravings; he has even published his numerous engravings, and to render them intelligible, has illustrated each with copious explanations.

27 The views of the anatomist of en too confined.

From this account it might be supposed that the anatomist has done all that can be reasonably expected from him. If we drew, however, such a conclusion, we might certainly be charged with precipitation. His views have hitherto been too confined, nor have they been directed with all that skill which a rational and comprehensive physiology would require. As if chiefly guided by the rant of the poet, that "the noblest study of mankind is man," he has cultivated his art principally with an eye to medicine and surgery; and while he has dissected the human body with a tedious minuteness, he has seldom looked into those of brutes but when he has wished to illustrate a theory or establish an hypothesis.

Preliminary observations.

28 Obstacles the way a more liberal study of anatomy.

As some apology for such a conduct, there is indeed but little immediate or pecuniary advantage to be derived from comparative anatomy; and those who have heard of the fox and the grapes will readily perceive, that few will be disposed to commend a science which reflects not much credit on their knowledge, and which they are led from sentiments of pride to treat as either contemptible or useless. The decisive tone and affected air of superior discernment being not unusually a very tender part of the character, they often form that mark of distinction which is seldom resigned but with the utmost degree of reluctance. It is, however, allowed, that any opposition from these causes ought not to frighten an aspiring genius. His nobler mind should look beyond pecuniary prospects; and he ought to have fortitude enough to despise the sneers and malevolence of pompous ignorance. The other difficulties which he has to encounter in his own estimation may not be so small.

29 The want of a nomenclature

In seeking to enlarge the field of inquiry, he will soon experience that he wants a language, or at least a nomenclature fitted to express the different objects which must necessarily occur in his researches. He will find too that he wants those proper classifications of the animal kingdom, which are equally necessary both to abridge and direct his labours.

30 Origin of the anatomical nomenclature

The first nomenclature of the anatomist was formed upon the dissection of brutes; and most of its terms, as the *rete mirabile*, are now useless, or tend to mislead those who employ them in their dissections of the human body. The few of its parts which still are retained, as the different names and divisions of the gut, are much more applicable to the usual appearances in certain quadrupeds, than to any thing which we meet with in man.

This first nomenclature declined with the studies which gave it birth, and with the decline of that superstition which permitted no other studies of the kind. Since the days of Vesalius the human body has been chiefly dissected; and the nomenclature which has thence arisen, and has since been assuming the form of a language, if adapted at all, is peculiarly adapted to that subject. Were we now therefore disposed to examine the internal economy of animals in general, we should see at once that the present nomenclature is as ill suited to comparative anatomy as the former nomenclature was to the dissection of the human body. The several facts which confirm this assertion are but too numerous. To give one or two: In a late work, *The Physiology of Fishes*, the celebrated author is obliged to inform his reader in a note, that when he makes use of the following terms, superior, inferior, anterior, and posterior, the fish is supposed to be standing erect in the attitude of man: and in his ingenious *Contemplation on Nature*, Bonnet, besides the absurd practice of calling nerve by the name of marrow, has been pleased to observe, that in certain insects the spinal mar-

row

row is not in the ſpine, but in the oppoſite ſide of the body, running longitudinally along the breaſt.

Applying occaſionally this nomenclature to the ſmall number of birds and quadrupeds which we have diſſected, it was much ſtrained with reſpect to their ſkeletons. Even forced analogy could not bring it to expreſs many diſtributions of the nerves and blood veſſels; and when it was employed in naming the muſcles, in moſt caſes it turned out to he uſeleſs or abſurd.

We were firſt led to obſerve its defects on hearing of the nameleſs bones of the pelvis, called the os ilium, the os iſchium, and the os pubis, united behind by an os ſacrum, which is tipped with a coccyx or bone of a cuckow: we thought it likewiſe ſomewhat remarkable to find a goat, a boat, and a conch ſhell, among the external parts of the ear; and within the tympanum a hammer and its ſhaft, a ſtithy, a ſtirrup, and a periwinkle. But theſe defects were moſt ſeriouſly felt in raiſing the different muſcles of a dog, and comparing them ſeverally with Albinus's tables. Theſe tables and muſcles, to our great ſurpriſe, did not reflect that mutual light upon one another which we expected. To obtain here more accurate ideas we got the comparative myography of Douglas. At one glance the etymological table of this work demonſtrated the confuſion and the imperfection of the nomenclature. In his, as in other books of myography, the muſcles are explained by deſcribing their origins, inſertions, and uſes: but the table ſhows, that their names are never, excepting only in a few caſes, derived from any of theſe three circumſtances, which in every deſcription are uniformly noticed in all muſcles. Their names on the contrary are frequently taken from their particular form and appearance in the human body, or from thoſe circumſtances which are conſtantly varying in every animal; juſt as if muſcles of the ſame origin, inſertion, and uſe, ſhould in all animals have a ſimilar colour, a ſimilar mode of inſertion and origin, a ſimilar compoſition and variety of parts, a ſimilar courſe and direction of fibres, a ſimilar figure and ſhape, a ſimilar paſſage through certain places, a ſimilar proportion with reſpect to one another, or ſhould be formed of a ſimilar ſubſtance.

If we paſs to the membranes, as expreſſed in this nomenclature, we ſhall not diſcover that their names are more philoſophical. A periofteum covers the bones, a pericranium the ſkull; the cavity of the thorax is lined with a pleura, that of the abdomen with a peritoneum; and what is ſurely ſomewhat remarkable, bones which are hollow have a periofteum on their inſide: the membranes in the ſkull are by way of diſtinction denominated *mothers*; the one which lies next to the cranium is the dura mater or hard-hearted mother, while that which immediately enwraps the brain is the mater pia or the affectionate mother.

Of all the terms, however, that occur, the cavity of the ſkull contains the moſt extraordinary collection: we there meet with a Turkiſh ſaddle and with the feet of a ſea-horſe, with a ring, with a lyre, with a ſickle, with a bridge, with a writing pen, and a wine-preſs. A few of theſe names belong to the ſubſtance of the brain itſelf: where one part is called from its hardneſs the callous body, another from ſome fancied analogy the medullary ſubſtance, and a third from being on the outſide is named the corticle, and from its colour the cineritious. Theſe are not all: there are beſides footſtalks of the cerebrum and cerebellum; the thighs and arms and fore and hind legs of a grand diviſion, the medulla oblongata; there is alſo a vault and two or three pillars, one pair of ſtriated bodies, two beds, and a couple of horns; ſome cavities which, from a ſuppoſed reſemblance to ſtomachs, are called ventricles choroid coats; two bodies, named from the olive, two from a pyramid, and one from a rine, which is chiefly remarkable for having once been thought the reſidence of the ſoul. At ſome diſtance in the cerebellum we are however pleaſed to meet with a name that is ſomewhat elegant, the *tree of life*. In this there is a degree of refinement, which muſt ſtrike one as it comes unexpectedly. The following names are in the loweſt ſtyle of obſcenity: they are wormlike and mammillary proceſſes, they are nates, teſtes, an anus, and a vulva; which, in order to ſave the bluſhes of our readers, we ſhall leave in the language in which they were conceived. A ſingular part is placed immediately under a funnel, and is named from its uſe the pituitary gland; it was meant originally to ſecrete a phlegm, but it holds that office now as a ſinecure (B).

Ridiculous and whimſical as many of theſe appellations are, they generally have ſome alluſion to their ſubject, and are by no means the moſt exceptionable in this nomenclature. The names of diſcoverers which have been impoſed upon various parts, contain no deſcription at all; and the only purpoſe which they can ſerve is not to promote the intereſt of ſcience, but to immortalize the anatomiſts. As many of thoſe have not been more than inſenſible to fame, they or their friends have taken the freedom to introduce parts to our notice, not by telling us what is their nature, but by demonſtrating who was the firſt that obſerved them. Upon reading therefore the catalogue of names that occur in anatomy, one would imagine that many of theſe ingenious diſſectors had ſuppoſed themſelves not the diſcoverers but the inventors of ſeveral parts in the animal economy. In our vaſcular ſyſtem is the ring of Willis, the vein of Galen, and the large wine-preſs of Herophilus. We have in our brain the bridge of Varolius; and in our nerves we poſſeſs the property of various diſcoverers. The holes of Vidius, and the caverns of Highmore, are in our bones; ſome ſmall muſcles in the ſole of our foot is the fleſhy maſs of Jacobus Sylvius; a part of our eye is the membrane of Ruyſch; and in thoſe caſes where they are to be found, Couper lays claim to particular glands; two canals from our mouth to our ears are the tubes of Euſtachius;

(B) That our readers may judge whether or not theſe names be fairly tranſlated, we ſubjoin the originals here in a note. In the ear, *tragus*, *ſcapha*, *concha*, *malleus*, *incus*, *ſtapes*, *cochlea*: in the cavity of the ſkull, *ſella Turcica*, *pedes hippocampi*, *annulus Williſii*, *pſalloides vel lyra*, *falx duræ matris*, *pons Varolii*, *calamus ſcriptorius*, *torcular Herophili*, *corpus calloſum*, *ſubſtantia medullaris*, *ſubſtantia corticalis vel cinerea*, *pedunculi cerebri et cerebelli*, *femora*, *brachia*, *crura anteriora et poſteriora medullæ oblongatæ*, *fornix*, *corpora ſtriata*, *thalami nervorum opticorum*, *cornua nervorum opticorum*, *corpora olivaria*, *corpora pyramidalia*, *glandula pinealis*, *arbor vitæ*, *tubercula mammillaria*, *appendices vermiformes*.

Preliminary observations.

chius; the duct of our pancreas is the right of Virsungus; Poupart has a ligament almost in our groin; a lobe of our liver belongs to Spigelius; and the female would certainly stare at being told, that among the distinguishing marks of her sex are the tubes of Fallopius, a tench's mouth, and several vestiges of the devil's teeth *.

* *Morsus diabeli.*

32 The persons most apt to perceive these defects.

The man who will readily observe the defects of this nomenclature is not he who has learned it already, and who no longer is acquiring his ideas through its imperfect and confused medium; nor is it he whose studies are confined to the human body, the particular subject on which it was formed: He who will sensibly feel its inconvenience is the young anatomist, who must receive his knowledge through its channel, commit its vocables to his memory, and use them afterwards in recalling his ideas. Another who must soon perceive its failings, is he who engages in comparative anatomy, and who is anxious to extend his views beyond that which the foolish indolence of conceited bombast has called the *microcosm*. A third will be he who has remarked the numerous synonymes which different authors have thought themselves warranted to substitute in place of the old terms: for these repeated attempts at amendment are a strong proof of that estimation in which it is held by the anatomical writers in general: And, lastly, that man cannot hesitate long to pass upon it a condemnatory sentence, who, like Wilkins, Locke, Condillac, and Reid, is a person of extensive and profound reflection, who is well acquainted with the intimate connection between accurate expressions and accurate ideas; who knows how much the improvements of language are able to facilitate the progress of science; or who has experienced the wondrous effects that have already resulted from the example and labours of Linnæus, and particularly from the new nomenclature in chemistry, which can hardly be too much valued and admired.

33 Hints respecting a new nomenclature.

Our intention here is not to suggest a particular plan for any new anatomical nomenclature: the state of our knowledge may in this respect be yet too imperfect, and perhaps it may be necessary to see more of the animal economy, before we should venture on such an undertaking. We may however, in general, observe, that this nomenclature, like the languages of nations, ought not to be formed with any view to an individual, a species, or genus; and after that be carelessly extended by fanciful analogies to new objects, and from these again be extended to others; thus making metaphor to spring out of metaphor without end, until the original figure be lost, and revived and lost again, times without number. It ought to contain as many as possible of those terms which, understood in their primary sense, might apply to the whole animal kingdom and living bodies, without any metaphorical expressions, if, in describing the tastes and colours, such expressions can be avoided. Instead of the words anterior, posterior, inferior, and superior, which are perpetually shifting their meaning with a change of attitude, it ought to have words of one constant invariable import, expressing the regions of the head and the back and their two opposites. These terms, with right and left, would be found in anatomy to answer nearly the same purpose that the degrees of longitude and latitude, or the points of the compass, do in geography. Every part would then be considered as lying within or as pointing to six different regions, the right, the left, the head, the back, and their two opposites. If more particular descriptions were wanted, the definitive terms might then be taken from the more immediately surrounding parts; thus giving an account of the ethmoid bone, D'Azyr borrows the definitive words from the regions of the cranium, the sincipital, basilar, facial, and occipital; or from the regions in immediate contact, the cerebral, palatine, nasal, and sphenoidal.

Preliminary observations.

If an object attainable, this nomenclature too should be derived from one origin, and not like the present be a wild incoherent Babylonish gibberish of a number of mixtures. It ought to aim at conveying its ideas with clearness and precision, and yet fully, concisely, and promptly. In point of simplicity it ought to study the ease of the memory in receiving, retaining, and in recollecting. To prevent a needless multiplicity of terms, it ought to avoid puerile minutiæ, which serve no end but to render description tedious and confused; it ought to avoid such trivial divisions, as those of the gut into duodenum, jejunum, ileum; or those of the artery into subclavian, axillary, brachial; and, lastly, it ought to be formed on a plan containing certain rules of construction for giving names not only to parts already discovered, but to those parts which are still unknown, or which distinguish individual and species.

In imposing names, it might perhaps be of some advantage to examine not only together, but separately, the great constituent parts of the system; as the bones, the ligaments, the cartilages, the muscles, the membranes, and the glands; the nervous, the sanguiferous, and absorbent systems; and all these with their properties and uses perspicuously arranged. How far a regularity in composition, and a uniform variety of terminations, might be of use in this nomenclature, can best be conjectured from their great importance in the new philosophical language of chemistry.

It has been observed, that such a nomenclature, to encourage and assist the comparative anatomist, is still wanting; and it also was remarked, that we yet are unacquainted with proper classifications of animals, peculiarly fitted to direct and abridge the anatomist's labour, and to satisfy the inquiries of the physiologist.

34 The present physiological arrangement too confined.

Our present physiological arrangements are, like our nomenclature, principally suited to the human body. To take our instance from the celebrated Haller, he begins his Outlines with the simple fibre, and the cellular texture, of which he is anxious to compose as many of the solids as he can. He then proceeds to more of the organs, describing with great erudition and care their different uses and structure in man. These organs, however, which he describes, and those analogous with respect to their structure, are confined to a part of the animal creation. As different classes of the animal kingdom have with similar functions various kinds of organs, and as one function is consequently performed in different ways, it is evident that organs ought not to form the general divisions in any physiological system of arrangement, because we should then have a new arrangement for every new species of organs. Of this truth Haller and others have not been ignorant. They have also divided their subject into

35 Two kinds of arrangement, according to the functions, or according to their organs.

Preliminary observations.

functions; but ſtill they are functions in the manner performed by the human body. This body has engroſſed ſo much of phyſiology, that we often ſee the functions explained with ſcarcely any alluſion to their organs; as theſe are ſuppoſed to be always the ſame, and already known from the uſual diſſections.

36 Haller's phyſiology refers chiefly to the human body.

Haller's phyſiology is profeſſedly that of the human body. His conduct here was ſeemingly the effect of general cuſtom: it did not ariſe from any contempt of comparative anatomy. There have been few who eſteemed it ſo highly, who have ſtudied it more, or applied it ſo ſkilfully. He declares there are many parts of our bodies whoſe functions can never be fully explained, unleſs we examine their ſtructure in quadrupeds, in birds, in fiſhes, and even in inſects; though he therefore had diſſected of human ſubjects to the number of 350, yet the number which he diſſected of brutes, and, what is more, diſſected alive, was much greater. Numerous, however, as were his diſſections, they were too confined for general phyſiology. That requires a range more extenſive; and, to ſhorten the labour, different claſſifications of animals from any of thoſe to be uſually met with. This aſſertion hardly needs a proof.

37 Zoological and phyſiological arrangement.

There is nothing more certain, than that were the anatomiſt to diſſect animals as they occur in the ſyſtem of Linnæus, or any other naturaliſt, his toil would be immenſe, and the knowledge which he thence would acquire of functions would ſcarcely be found to bear to it even the ſmalleſt proportion. By this obſervation we mean not to object to thoſe ingenious claſſifications which Linnæus and others have employed to facilitate the ſtudy of zoology. All their claſſifications may be uſeful; and many diſplay that extent and clearneſs of comprehenſion, that diſtinguiſhing acuteneſs, and that laudable ardour for the intereſt of ſcience, which ought to render their authors immortal, and intitle them to the gratitude of future ages. Yet theſe ſyſtems are formed with a view different from that which principally ought to direct the phyſiologiſt. They were meant to contain a full enumeration of the objects of zoology ſo far as known; to exhibit them arranged in different claſſes and ſubordinate diviſions, according to ſuch obvious and diſtinct marks as might ſtrike at a glance, or appear on a curſory examination. To him who is entering on the ſtudy of zoology, they ſhow at once the extent of his ſubject; they elevate his mind by the grandeur of the proſpect; and when better employed than in pleaſing the fancy or in rouſing the rapturous feelings of a poet, they draw his attention to thoſe ſignificant and marked ſigns in which the language of nature is written. They aſſiſt his judgment in the art of arrangement, and give to his memory a power of recollection which it had not before. To the natural hiſtorian they perform a ſervice equally important, if not eſſential, to his undertaking: to him they ſupply the place of chronology; and inſtruct his readers by the chain of connection which they give to his thoughts, and by that perſpicuity which they invariably beſtow on his language.

Preliminary obſervations.

38 Difference between them.

Theſe arrangements, however, with all their advantages, are not the arrangements which the phyſiologiſt would wiſh the anatomiſt to obſerve in his diſſections. They are certainly uſeful in ſtudying the manners, diſpoſitions, and habits of different animals, and all that part of the outward economy which indicates ſomething of their wiſdom and deſign. But they little illuſtrate that internal ſtructure on which this outward economy is founded, or tend to explain the more ſecret functions which, not depending on the will of the creature, only diſplay the power and omniſcience of him who made it. This conſequence is eaſily conceived, from conſidering the difference between zoology and what has been here defined phyſiology. Zoology is chiefly led to examine the animal kingdom as it uſually preſents itſelf to the eye, including a great variety of objects; phyſiology only that ſingle part of the animal economy which is chiefly made known by anatomy and chemiſtry. Zoology has been wont to divide its kingdom into ſo many claſſes or orders of animals; phyſiology would naturally divide its economy into ſo many functions. Zoology has ſubdivided its claſſes by certain obvious and exterior marks, as the teeth and the claws; phyſiology would naturally ſubdivide its functions by the many varieties of thoſe organs which are deſtined to perform them, as the different kinds of lungs and of ſtomachs. Zoology but curſorily mentions the functions as forming a part of the hiſtory of animals; phyſiology takes notice of animals only when they are of uſe to illuſtrate its functions. From this compariſon it will readily appear, that things which are primary in a zoological will often be ſecondary in a phyſiological ſpecies of arrangement; and that things which are primary in a phyſiological will often be no more than ſecondary objects in a zoological. This is very conſpicuouſly the caſe in one of the grand diviſions of Linnæus into mammalia, where the important ſecretory organs of the milky fluid are noticed only, like the colour of hair or the length of a tail, as a good outward mark of diſtinction; and likewiſe in the excellent table of D'Aubenton, where the function of digeſtion is not even alluded to at all; although he had complained that there was more of art than of nature in the common arrangements, that claſſification by outward marks had confounded things of a different ſtructure, and that the leſſer diviſions ſhould be made only by marks relating to the functions.

Preliminary observations.

39 Daubenton's arrangement.

ANIMALS.

With a Head.							The moſt part without a Head.
Noſtrils.						Without Noſtrils.	
Ears.						Without Ears.	
Two Ventricles in the Heart.		One Ventricle in the Heart.				The Heart variouſly formed or unknown.	
Warm Blood.		Blood nearly cold.				A whitiſh Fluid inſtead of Blood.	
Inſpiration and Expiration of the Air at ſhort Intervals.		Inſpiration and Expiration of the Air at long Intervals.		Admiſſion of Air by Gills.		Admiſſion of the Air by Spiracula.	No apparent Entrance to admit air.
Viviparous.		Oviparous.					
With Teats.		Without Teats.					
1ſt Order. QUADRUPEDS.	*2d Order.* CETACEOUS ANIMALS.	*3d Order.* BIRDS.	*4th Order.* OVIPAROUS QUADRUPEDS.	*5th Order.* SERPENTS.	*6th Order.* FISHES.	*7th Order.* INSECTS.	*8th Order.* WORMS.
Four Feet and hairy Skin.	Fins and no Hair.	Feathers.	Four Feet and no Hair.	Scales without Feet or Fins.	Scales with Fins.	Antennæ.	Neither Feet nor Scales.

Preliminary observations.

Preliminary observations.

It is plain from this table, and from what we have mentioned concerning Haller, that it would be injuſtice to anatomiſts and naturaliſts to ſay they have never paid any attention to the phyſiological modes of arrangements. It can only be ſaid that they have not paid to them all that attention which they deſerve; and that no general phyſiological ſyſtem of arrangement, excepting D'Azyr's, has, ſo far as we know, been yet attempted.

40 Whence materials might be collected for a phyſiological arrangement.

How ſuch an arrangement ought to be made is eaſily deſcribed, though by no means very eaſily executed. It needs not a proof that functions ſhould form its primary diviſions; that its ſubdiviſions ſhould be the varieties of theſe functions; that the whole ſhould be both diſtinguiſhed and explained by the kinds and varieties of thoſe organs, by which they are performed; that the deſcriptions of theſe organs might partly be collected from the ſeveral works of natural hiſtorians and comparative anatomiſts, as from the diſſections of the French academy, from numerous fragments of the *Curieux de la Nature*, from the collections of Blaſius and Vallentini, from the writings of Haller, from the works of the celebrated Hunters and Monros, from the publications of Hewſon and Cruikſhank, and thoſe who have lately been making diſcoveries in the ſyſtem of abſorbents. D'Azyr has mentioned a great many more. He particularly recommends Perrault, Du Verney, Collins, and D'Aubenton, on Birds and Quadrupeds; Charas, Roeſel, and Fontana, on Reptiles; Ray and Willoughby, Artedi, the Gouans, and Brouſſonet, on Fiſhes; Swammerdam, Malpighi, and Reaumur, the Geoffroys, Bonnet, and Lyonnet, on Inſects; and, laſtly, the curious reſearches of Willis, Ellis, and Donati; of Trembley, Baker, Baſter, and Boadſch; of Forſkal, of Adanſon, of Muller, Pallas, Spalanzani, and Diquemare, concerning Worms, Zoophytes, and Polypes. Where any errors are to be corrected, or where any deficiencies are to be ſupplied, it is needleſs for us to obſerve that recourſe muſt be had to new examinations and to new diſſections, where it may be of ſome uſe to attend to the foods of animals, to their places of abode, and their modes of life, as circumſtances leading to ſome internal varieties of ſtructure. To the liſt of authors we might have added Campfer on Fiſhes; and we ſhould not forget the excellent writings of D'Azyr himſelf, whoſe table of phyſiological arrangement is a work of merit that beſpeaks reflection, ingenuity, and labour, and which follows here, with only a ſmall variation in form.

Preliminary observations.

41 D'Azyr's arrangement.

A TABLE *of the* FUNCTIONS *or* PROPERTIES *of* LIVING BODIES.

1. DIGESTION.	4. RESPIRATION.	7. GENERATION.
2. NUTRITION.	5. SECRETION.	8. IRRITABILITY.
3. CIRCULATION.	6. OSSIFICATION.	9. SENSIBILITY.

Every body in which one or more of theſe functions are obſerved is to be conſidered as poſſeſſing organization and life.

1 DIGESTION.

Living Bodies which have

- One or more ſtomachs, eaſily diſtinguiſhable from the œſophagus and inteſtinal canal, — Man. Quadrupeds. Cetaceous animals. Birds. Cruſtaceous animals.
- A ſtomach diſtinguiſhable only by certain expanſions from the œſophagus and inteſtinal canal, — Oviparous quadrupeds. Serpents. Cartilaginous fiſhes. Fiſhes properly ſo called.
- An alimentary canal, not diſtinguiſhable into œſophagus, ſtomach, and inteſtines, — Inſects. Worms. Zoophytes.
- Neither ſtomach nor inteſtines, — Plants.

2 NUTRITION.

Living Bodies whoſe nutritious juices are abſorbed

- By veſſels beginning from internal cavities, — Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents. Cartilaginous fiſhes. Fiſhes properly ſo called. Inſects. Cruſtaceous animals. Worms.
- By veſſels opening upon the external ſurface, — Plants.

3 CIRCULATION.

- Living Bodies
  - With blood
    - Having a heart with two ventricles and two auricles, — Man. Quadrupeds. Cetaceous animals. Birds.
    - With one ventricle divided into several cavities and two auricles, — Oviparous quadrupeds. Serpents.
    - With one ventricle and one auricle, — Cartilaginous fishes. Fishes properly so called.
  - With a whitish fluid
    - Whose heart is formed of one longitudinal vessel, tuberous and contractile, in which there is a whitish fluid instead of blood, — Crustaceous animals. Insects. Worms. In some crustaceous animals there is observed something resembling a heart.
  - With juices
    - In which no heart has been yet observed, but only vessels filled with juices of a nature different from that of blood, — Zoophytes. Plants.

4 RESPIRATION.

- Living Bodies
  - Which respire
    - By lungs free from all adhesion, and spongy, — Man. Quadrupeds. Cetaceous animals.
    - By lungs free from all adhesion, vesicular, and muscular, — Oviparous quadrupeds. Serpents.
    - By lungs adhering to the ribs, and provided with appendages, — Birds.
    - By gills of different forms, — Cartilaginous fishes. Fishes properly so called. Crustaceous animals.
    - By stigmata or holes in different rings, — Insects. Earth worms.
    - By an opening called trachea, or by external fringes, — Aquatic worms.
    - By tracheæ, — Plants.
  - In which there have been discovered neither stigmata nor tracheæ, — Polypes.

5 SECRETION.

- Living Bodies — There are no bodies in which secretions are not carried on.

6 OSSIFICATION.

- Living Bodies
  - Whose skeleton is
    - Internal and osseous, — Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents. Fishes properly so called.
    - Internal and cartilaginous, — Cartilaginous fishes.
    - External and corneous, — Perfect insects. Lithophytes.
    - External and cretaceous, — Crustaceous animals. Shell-fish. Madrepores. The greatest part of Zoophytes.
    - External and ligneous, — Plants.
  - Which have no skeleton, — Insects in their first state. Worms. Polypes.

7. GE-

Preliminary observations.

7 Generation.	Living Bodies	Which are	Viviparous,	Man. Quadrupeds. Cetaceous animals.
			Oviparous, whether the evolution of the eggs takes place within or without the female,	Birds. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called. Insects. Crustaceous animals. Worms. Plants.
			Which propagate by slips,	Worms. Polypes. Plants.
8 Irritability.	Living Bodies	Which have	A body muscular or contractile,	Greatest part of insects in the first state of their transformation. Worms. Polypes.
			Muscles covering the skeleton,	Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called.
			A skeleton covering the muscles,	Perfect insects. Crustaceous animals.
			No muscular power; no spontaneous movements,	Plants.
9 Sensibility.	Living Bodies	Which have	Nerves and brain easily distinguishable from the spinal marrow,	Man. Quadrupeds. Cetaceous animals. Birds. Oviparous quadrupeds. Serpents. Cartilaginous fishes. Fishes properly so called.
			Nerves and brain scarcely distinguishable from the spinal marrrow,	Insects. Crustaceous animals. Worms.
			In which there have not yet been discovered nerves or brain, or spinal marrow,	Zoophytes. Plants.

The above table, which has its divisions marked by the functions, and their kinds and varieties by the kinds and varieties of those organs by which they are performed, differs considerably from a zoological. Borrowing its several marks of distinction from internal characters, it more clearly demonstrates the difference between the mineral, vegetable, and animal, than any system that attempts to arrange by outward appearances.

42 Difference between mineral, vegetable, and animal.

No minerals, whatever be their forms or the regularity and beauty of their figures, were ever said to possess any thing like organs of nutrition; and however frequently some may recover their lost shapes, they are never supposed either to produce, or assist in producing, their own kind by generative powers. And no plants, however much may be said of animals that want a nervous system and a heart, and are fixed, without the power of locomotion, to one place; we say no plants, though some may represent a few of the simpler effects of sensation, and others may be free to float through the ocean, were ever said to discover any signs of voracity, to possess any thing resembling a stomach, to distend their body by swallowing their food, to apply their food to the mouths of absorbents opening internally; and when the nutritious juices were extracted, to eject it *in cumulo*. It has been said that zoophytes present similar phenomena. But what are zoophytes? One half of their name would imply that they are animals, and another half would insinuate that they are plants. D'Auberton reasons with clearness on this subject. True, says he, the greatest part of them are branched like plants, and like plants are composed of concentric circles. Some have a soft exterior substance which is called bark, and a hard interior

which

Preliminary observations.

which is called wood. Along their branches, and at their extremities, they put forth veſicles which reſemble buds; and when a part fails from the whole, it is ſufficient, like a vegetable ſlip, to produce a zoophyte: but do theſe appearances prove that they are plants?

If ramifications conſtitute a plant, then many cryſtallizations will be plants; the ſhootings of froſt on our windows will be plants; the ſilver tree of Diana a plant; our veins will be plants, our arteries plants; and our very feet which ramify into toes, and our hands into fingers, will have ſome title to be called plants. The truth is, ramification is not univerſal in the vegetable kingdom; and although it be general, it is no more peculiar to plants, than ſwimming is to fiſhes or flying to birds. If concentric circles conſtitute a plant, ſome bones of animals will then be plants, and ſome minerals muſt alſo be plants. The wood and the bark are only two metaphorical expreſſions, which with equal propriety might have been uſed of the bone and perioſteum. But once ſuppoſe the zoophyte a plant, it was natural to carry on the analogy, and certainly neceſſary to have it provided with wood and bark; though it muſt be allowed that a corneous ſubſtance is not what we commonly mean by bark, nor an evidently hard calcareous ſubſtance what we mean by wood. The ſmall veſicles, except in appearance, have no ſimilarity to buds or fruits: they are the reſidences of ſmall polypes, to whom the whole ſtructure has been owing, by whom the whole either is now or has been inhabited, and to whom it anſwers the ſame purpoſe as the ſhell does to teſtaceous animals.

43 Difference between living bodies and machines.

After thus endeavouring to point out the boundaries between the mineral, the plant, and the animal (A), before we begin to treat of the functions, we muſt alſo take notice of another diſtinction; the want of which has occaſioned much unneceſſary trouble, and has given riſe to not a few ridiculous diſputes. This is the diſtinction between living bodies and ſome ingenious contrivances of art, which are called machines. It has not been aſſerted that any machine can either grow or propagate its kind; that it can aſſimilate the particles of matter that come in contact; that it is able to repair the injuries which it may ſuffer; that it can accommodate itſelf to circumſtances, can create heat when the cold is keen, or cold when the heat becomes too violent: yet it has been ſuppoſed, from eſtabliſhed prejudices, and from the ſucceſſive evolution of parts in plants and in animals, that there is an analogy between a machine and a living body. The living body has been called a machine; and notwithſtanding the acknowledged truth of that obſervation ſo often repeated ſince the days of Hippocrates, That the whole is a circle, that nothing is firſt and nothing laſt in the animal economy, we are ſtill talking as if living bodies were nought but machines; we are ſtill reaſoning as if the parts had exiſted in ſucceſſion, had acted in ſucceſſion, were combined in ſucceſſion; we are ſtill ſeeking for what is prior and what is poſterior, for what is derived and what is original in point of ſtructure, as if we were examining a work of art; we ſpeak gravely of the viſcera, of the thorax deriving a coat from the membranous pleura, the abdominal viſcera from the peritoneum, and the branches of nerves deriving a pair from the dura and pia mater of the head; we argue with people who maintain that faſciæ are nervous expanſions, and the muſcles themſelves but nervous productions: and although we be hardly able to conceive how the brain could be nouriſhed without blood thrown from the heart, or the heart move without the aſſiſtance of nerves from the brain, we are ſtill diſputing about which was prior and which was poſterior in point of exiſtence; a diſpute that will probably terminate as ſoon as that of the ancients, whether the firſt eggs were from birds, or the firſt birds were hatched out of eggs.

Preliminary observations.

44 The vital organs ſeemingly coeval in point of exiſtence.

45 Functions form a circle.

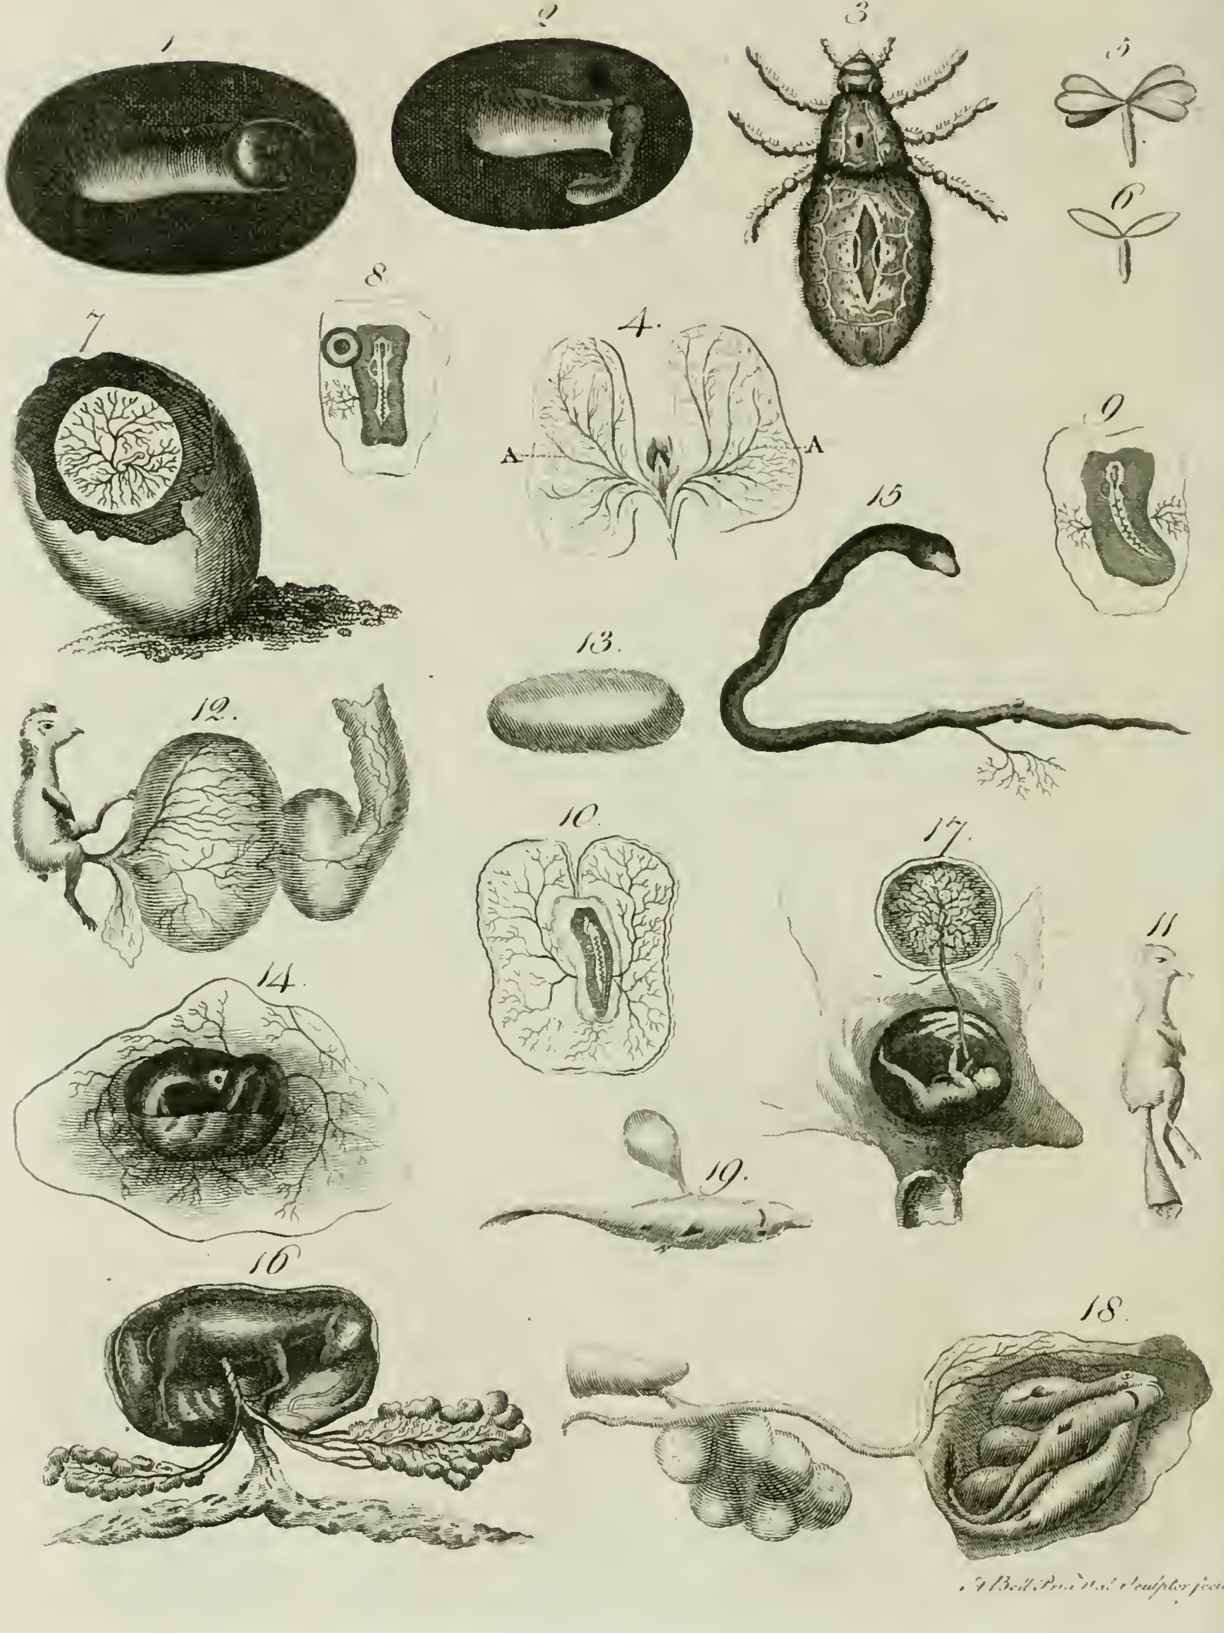
Theſe dark and inſcrutable myſteries of nature we preſume not to explain: they point out almoſt the creative hand, and bring us almoſt into the immediate preſence of that Being by whom we live, move, and exiſt; and before whom the truly feeling and elevated mind is leſs diſpoſed to examine than adore. We are only to obſerve, that from this coeval formation of parts which the microſcopic part of anatomy has often diſtinguiſhed from their evolutions, and from this mutual dependance of organs one on another, we are left at freedom to begin at any part of the circle, and treat of the general properties and functions of living bodies.

We now venture on a rude ſketch of the order and manner in which theſe properties may be explained, and in which the facts in general phyſiology may be afterwards arranged. Another opportunity may produce ſomething more full and correct. In the preſent ſketch, many imperfections will no doubt be found; we already are able to foreſee many from our own inability to treat the ſubject according to its merit. And perhaps the reader, who is poſſeſſed of temper and candour, will impute ſome to the newneſs of the plan, and the preſent infant ſtate of the ſcience.

Without blaming the arrangement of d'Azyr, whoſe genius and labours we ſhall always reſpect, we have been induced to adopt the following, from thoſe reaſons with which the reader is now to be acquainted.

Attending minutely to a living body, which already has eſcaped from the ſeed, the egg, or membranes of the parent, which is wholly diſengaged from the placenta,

(A) It is curious to obſerve how careleſs we are in annexing preciſe ideas to our words. Bonnet ſuppoſes that in ſome world more perfect than ours, the rocks may be organized, plants may feel, brutes may reaſon, and men may be angels. In this paſſage the form was all that ſeems to have entered into his idea of the man and the brute; and ſo new was his notion of a perfect world, that one who believed in the metempſychoſis, would naturally imagine that he here had been fancying a ſtate for the damned, where angry Heaven was to ſetter the angel in the form of a man, a man in that of a brute, a brute in that of a vegetable, and a vegetable in that of an uncouth rock. How much to be pitied would the creatures be that reaſoned and felt, and were at the ſame time more incapable of moving than an oyſter or a limpet!



A. Bell Prin. Wal. Sculptor fecit

Preliminary observations. 46 The arrangement of functions in this article.

placenta, and depends for the future on the operations of its own organs (B), we may obſerve, that in order to live, it muſt be allowed the free uſe of air, as applied by the organs of—*Reſpiration.*

That, in order to grow, it muſt have likewiſe a ſupply of food, which is a ſubſtance ſomehow adapted to its conſtitution; and which, on being received into the ſyſtem, is

Prepared by—*Digeſtion,*
Taken up by—*Abſorption,*
Diſtributed by—*Circulation,*
Aſſimilated by—*Nutrition,*
And the whole carried on by means of—*Secretion.*

We next may obſerve, that in order to enjoy the free exerciſe of theſe functions, it muſt be ſecured from the more common and external injuries of its ſituation; and that this is done by certain integuments originally produced, and when it is neceſſary, afterwards renewed by that function; which, till we receive a new nomenclature, we ſhall venture to call by what may be rather an uncouth word—*Integumation,*

We again may perceive, that theſe functions are all dependant on a general principle—*Irritability:*

By which the ſyſtem is rendered by ſtimulants ſuſceptible of—*Motion;*

Accommodates itſelf to different circumſtances by means of—*Habit;*

Alters its ſhape by ſucceſſive—*Tranſformation;*

Produces the ſpecies by—*Generation;*

And when the buſineſs of life is finiſhed, is, after many a languid affection from the influence of—*Sleep,*

At laſt ſubjected to the general fate of all living bodies—*Death.*

Theſe we imagine are the general properties of living bodies; and ſuch is the order in which we are now to take a ſhort and curſory view of them.

Sect. I. *Reſpiration*

Is that function by which air is brought into the ſyſtem, and by which it is prepared in particular organs, that in ſome reſpect ſucceed the placenta in the general economy. For as any interruption of the uſual intercourſe between the placenta and fœtus in ovo proves ſoon fatal, ſo when that communication naturally ceaſes, and the new one ſucceeds between the lungs and external air, it is likewiſe found, that any preternatural interruption of this laſt is in all living bodies preſently attended with various ſymptoms of increaſing languor, and in many with an almoſt inſtantaneous death. Reſpiration. 47 Reſpiration defined.

So eſſential is reſpiration to the ſyſtem, that ſnails, chameleons, and ſome other animals, can live for years upon air alone. We have ſeen a chameleon that lived and was vigorous for twenty two months without any food, and which might have continued to live much longer but for an unfortunate bruiſe by a fall. 48 Its importance to living bodies.

Other phenomena equally demonſtrate the importance of air to the living body. The frog leaps away wanting its heart; it ſurvives the loſs of the greateſt part of its ſpinal marrow. Without its head, it lives for ſome days, and its heart continues to circulate its blood (C). Spalanzani took one from the back of a female, cut off his head, and after performing this whimſical experiment, ſaw the gallant return to his miſtreſs, graſp her in his arms, and finiſh the act which he had begun: And Borelli found, that eels and ſerpents, though their bodies be opened, and the whole of their viſcera be taken out, are able to move for a day after; and yet notwithſtanding, in all theſe animals, the life is obſerved to be ſuddenly extinguiſhed when the all-vivifying air is excluded. Even the ſmalleſt inſect has died, and the plant loſt its vegetative power, when retained for any while in a vacuum. The fiſh itſelf, when placed under the exhauſted receiver, has ſtarted anxiouſly to the ſurface of the water in queſt of freſh air; and finding none, has ſunk to the bottom and expired in convulſions.

It

(B) To give a general view of the manner in which living bodies are nouriſhed and ſupported in the egg and uterus, and before they begin to depend entirely on their own organs, we have ſubjoined a plate (ſee Plate CCCXCI.), repreſenting embryos of various kinds. The three firſt figures are from Swammerdam: the firſt is the membrane containing the inſect, the ſecond the membrane after the eſcape of the inſect, the third is the inſect itſelf, fed by abſorbents, opening on different parts of the body.

The fourth, fifth, and ſixth figures, are from Grew: the fourth is a bean, ſpreading its ſeminal roots into the lobes. In the fifth and ſixth the lobes of the ſeed are ſeen converted into ſeminal leaves.

The ſeventh to the twelfth repreſent the tranſformtions of the chick in ovo: the firſt of theſe figures is from Aquapendens; the reſt are from Blaſius, who got them from Malpighi.

The remaining figures are all from Aquapendens: the two laſt repreſent a fiſh that is ſometimes oviparous and ſometimes viviparous.

Plants and animals are here obſerved ſpreading their roots in a ſimilar manner. The proper proportions are overlooked, not being neceſſary to convey the idea which is here intended.

(C) "Two days (ſays Dr Monro) after cutting off the head of a frog at its joining with the firſt vertebra, I found it ſitting with its legs drawn up in their uſual poſture; and when its toes were hurt, it jumped with very conſiderable force. Its heart likewiſe continued to beat about forty times in a minute, and ſo ſtrongly as to empty itſelf and circulate the blood.

"In ſeveral frogs, after cutting off the back part of the ſix undermoſt true vertebræ, I took out all that part of the ſpinal marrow with the cauda equina which they cover. The lower extremities were rendered inſenſible to common injuries, and lay motionleſs: yet the frogs lived ſeveral months thereafter, and the wounded parts of their backs cicatriſed, and the bones of their legs which I fractured were reunited, the blood circulating freely in their veſſels." *Experiments on the Nervous Syſtem*, made chiefly with the view of determining the nature and effects of animal electricity.

Respiration.

If objections should be made to these trials performed in a vacuum, if it should be said that under the receiver the shrivelled fruit swells and turns plump, that the body of the frog is strangely inflated, that its turgid eyes grow prominent in its head, and that thin phials corked full of air are broke by its expansion; still there are facts which do not admit of the like equivocal interpretation. All living bodies will die in the air which they have respired; and when ice covers the whole of the water, many of the fishes are known to perish; or if an opening be made in the ice, to hasten to the air, and rather than retire, quietly suffer themselves to be caught.

491 Seeming exceptions

To this general dependance of life upon respiration, there occur but few things like an exception: these are some serpents and worms and crustaceous animals found alive in the hearts of stones, some insects that were found in wood, and a number of toads which in different places have been taken from the hearts of trees and of rocks, where they left an impression, and where they were supposed in some cases to have lived for centuries without air. These facts, real or pretended, have been the cause of much speculation. Some philosophers, who imagine that nature is always obliged to act agreeably to those ideas which they have already formed of her laws, are, notwithstanding the high authorities by which some of these facts are attested, disposed to doubt them. General analogy, which regularly opposes singular phenomena, is upon their side; and without her concurrence, they will grant existence to no living body that will not submit to the old established modes of respiration. Others again, who would not presume to dictate for nature, who have long experienced that she is not forward to obtrude her secrets, and who can believe that she may have still some to communicate, consider these facts as something new which she means to impart; and as one of the instances where she seems to deviate from general analogy in adhering to her grand accommodating principle by which she fits every living body for a certain range of varying circumstances.

50 Animals inclosed in stones, &c.

These last, receiving the facts as sufficiently authenticated, have studied only how to account for them.

51 Opinions on this subject.

When stones therefore were thought coeval with the world itself, they supposed their toads to have sprung from the ova that were scattered through the earth at its first formation; they did not recollect, that if the earth must have existed before these ova could have been sown, and that if the stones were coeval with the earth, the ova could not have entered their substance. When they afterwards learned that the consolidation of stones is an operation still carried on in the mineral kingdom, they acknowledged their ova to be less ancient, but did not perceive that all these ova involved suppositions that cannot be admitted by sound reason. For how was an ovum to grow without air and without food? and how particularly was it to grow with such a force as to make an impression in a solid rock? This would imply a power of expansion scarcely to be equalled by gun-powder, and which we ought not to be rash in ascribing to the nutritive effects of abstinence and nothing. Were it not for the toad, the expansion itself might have found a solution in *a theory of the Earth*, which has cast all its stones in a foundery under the water, where the moisture might have rendered them apt to be formed with numerous cavities. Respiration.

Perhaps the way to remove these difficulties concerning the toad, would be to ascertain its mode of existence in the heart of the stone. Suspecting that the air communicated somehow with the solitary cell, we procured a toad that was crawling out from its den in the evening. It was put into a glass just large enough to hold it with ease. The mouth of the glass was filled with cork sufficiently close to retain water; the glass was then laid on its side, and the animal respired for several days without discovering signs of uneasiness: but supposing that air might still be admitted, the cork received a covering of wax, and the animal died ten hours after.

From this experiment, and the fate of toads when put under an exhausted receiver, from an air passage in the crust of chrysalids, from the porous texture of the white speck, or the opening which the snail leaves in the membrane that is spread over the mouth of its shell, we were led to think on d'Aubenton's remark, that the inclosed toads might have breathed, and that the wood has been always cleft, and the stone broken, before it was shown how the external air was excluded †.

† *Encyclop. de Methodique*, tom. 2. partie 2. p. 610.

On farther reflection, our own experiment appeared inconclusive; and d'Aubenton's remark, after close examination, seemed not entitled to much attention. He would have it supposed that a toad is lurking in every block of stone and of wood; and on this supposition would have an inquiry to be regularly made, whether or not there be any communication between this supposed animal and air; because, when the stone or wood is in fragments, the attempt to disprove such communication is in his opinion impossible.

But are we certain that the admission of external air would remove the difficulty? We are not so positive now as we were upon this subject. In the summer months, we recollect to have drowned frogs which were living in the fields, by keeping them some hours under water: but if we allowed them to rise to the surface, and respire at pleasure, they became at last so accustomed to that element, that if the temperature was not much above that of spring-water, they lay in the bottom not only for days but for weeks together.

In the winter season, it is well known that frogs are sometimes discovered in clusters below stones and under water in the neighbourhood of springs; and often seen in the bottom of ponds, marshes, and ditches, where water is collected, and the whole surface covered with ice. In this situation, we have frequently examined their sides and their nostrils, and can venture to assert, that they did not respire in the same manner that they did when on land: for the moment that this animal is put under water, the palpitating motions of its sides and its nostrils are observed to cease; and Chaptal has seen them suspending respiration as it were at pleasure even when in air ‡.

While they move, however, and exhibit indications of active life, we would not say that air is excluded. In the roots of plants, in aquatic worms, in polypes, and in the placenta itself, the same organs seem to perform the double office of lungs and absorbents. When

Respiration.

under water, what are the functions of these organs in frogs and in toads? It is not disputed that in moist places they can live longest without food; and some phenomena which have been observed relating to this subject appeared to us not unworthy of attention. In the beginning of the summer 1793, while we were making a few experiments on the nervous influence with some metals, a frog was taken out of the water in the dusk of the evening, and put into a deep and wide-mouthed glass till next morning: but next morning a quantity of water was found in the glass, the animal was dead, its mouth full of foam, and the greater part of its body covered with froth. The following autumn a boy came with a couple of toads wrapt up in tow. Till we had leisure to make our experiments, they were allowed to remain as they were for three days in the corner of a room. When taken out, their colour was pale, their bodies much swelled, and a quantity of water collected between the skin and the muscles. When held in the hand with their head upwards, the water was evacuated downwards by the anus. It was one of these toads that afterwards died when confined in the glass without air. Its body was put into a solution of madder for two days; and when the skin and muscles were removed, the bones, which are still preserved, were found red. A live frog in the same solution, though allowed to breathe, expired in a few hours. In three days its bones became of the red colour, but not so deep as that of the toad's. Another frog died in the solution; but the bones, from age or some other cause, did not receive the colour of the madder. In all cases the skins were found red.

52 Some things relating to frogs and toads.

53 Different functions of their absorbents.

As we know not how far the great accommodating principle of nature may be extended, perhaps the absorbents opening externally may in these animals sometimes supply the place of the lungs, as the lungs supplied the place of the gills which they used when tadpoles, and as the gills had formerly supplied the place of a placenta, or the primary absorbents, through which they derived their nourishment in ovo.

54 What sorts of stones inclose animals, and what sort of animals are inclosed.

Those stones which inclose animals are known to be such as have gradually assumed the solid form, and those animals which have been inclosed are known to be such as in other cases have been subjected to the torpid state: But this state has not been examined with all the attention which it deserves. From this state, Bonnaterre says, in his introduction to Ereptology *, that it is impossible to rouse the animal by the loudest noise, the rudest shock, or the deepest wound; the internal motion is just sufficient to preserve the system from that decomposition to which animal substances are exposed. It retains only the form of what it was. It appears neither to live nor to grow; and the whole mass, if what is exposed to the air be excepted, is not sensibly altered while the torpor continues. All the senses are shut up; all their functions are entirely suspended: digestion is no longer in the stomach; all respiration has apparently ceased; and it has been doubted whether or not this function be in some cases at all retained. When the genial warmth, however, returns, in six, in eight, or in ten months, according to that variety of climates between the frigid poles and the tropics, the animal revives. But the question is, if the first circumstances in which the animal became torpid had been artificially or naturally continued, how long in this way might the different functions of life have been suspended; and how far are we warranted by the analogy of seeds and of eggs to lengthen this period of their existence, without supposing a decomposition or destruction of organs?

* *Encyclopedie Methodique.*

Respiration.

55 Eggs and seeds preserved long when air is excluded.

Experiments must tell what are the limits which nature has here prescribed to herself. New eggs, when covered with varnish, or placed under the exhausted receiver, are secured against the attacks of corruption. Bomare, in his Dictionary, has mentioned three, which, protected from air, were found fresh in the wall of a church after a period of 300 years (n).—And if it be true that a snake found in a block of marble died as soon as exposed to the air, or if the parts in contact with air be the only ones which in torpid animals appear to be changed, it would seem probable that a total exclusion of this varying and active element would tend more to the preservation of torpid animals, in certain instances, than a free admission, which, in those cases where all vital functions have ceased, is regularly found a principal agent in their dissolution.

56 Heriſſant's experiments respecting the toad.

M. Heriſſant of the French Academy was the first philosopher who, by means of experiment, thought of interrogating nature herself upon this subject. On the 21st of February 1771, he with great accuracy shut up three toads from the air, two of which were taken out alive on the 8th of April 1774. D'Aubenton says†, after a period of 18 months; but in this instance we depend more on the friend ‡ of Fontana, who has mentioned the dates. The two toads were again inclosed, and Heriſſant died before there was a second inspection. D'Aubenton says, that when taken out their bodies were hard and shrivelled, and their whole moisture totally absorbed. A fourth toad that had been inclosed was heard to croak whenever the box in which it was confined happened to be shaken. Since that period the practice is common of confining snails in a sealed phial, where they exist in torpor for years.

† *Encycl. Method. Hist Nat.* tom. 2. Ovipares. ‡ *Dict. de Merveilles de la Nat.* Animaux Vivans Renfermés

These phenomena still excite wonder, but to wonder less, and examine more, would sooner procure us that information which we are wanting. In these observations concerning toads, have no circumstances been overlooked? Has it been determined whether they lived in the heart of stones, or, existing merely in a torpid state, had come alive when exposed to air? We have seen a toad that was dead for two days; its body was opened; its heart was seen motionless, but exposed to air in a few seconds it began to beat.—Considering the complex function of absorbents, we perhaps might conceive how a toad could live in the clefts of rocks, or the hearts of trees, where there is moisture; but has it yet been determined whether all stones in which toads have been found supplied them with moisture? We at least are certain that they did not

(n) See Bomare, under the article Œuf; and a fuller account of the same eggs in the *Dictionaire de Merveilles de la Nature*, under Œuf.

Respiration.

abſorb the animal fluids, like the plaſter uſed by the French academicians.

One of the toads was heard to croak after being incloſed. In making their experiments, has it, therefore, been thought a matter of indifference by the French philoſophers, whether the animal was immured alive in the full exerciſe of all its functions, or exiſting only in its torpid ſtate? and with reſpect to this ſingular ſtate, (might not the queſtions be fairly put), have its ſeveral kinds, have the cauſes which induce it, or thoſe degrees to which it may be carried in different animals, been yet aſcertained? Is not our knowledge of the torpid ſtate at this moment principally the reſult of caſual obſervation? Has it not been oftener than once ſuppoſed that the torpor of all animals is ſimilar, or takes place to a ſimilar degree? Have not torpid animals been therefore ſpoken of in general terms? and has it not been aſſerted that they retain a portion of heat and internal motion? though ſome have been found congealed in the ice, and many been dried to ſuch a degree that they could be revived only by moiſture.

57 Queries reſpecting this kind of experiments.

"That ſnakes and fiſhes, after being frozen, have ſtill retained ſo much of life as when thawed to reſume their vital functions, is a fact," ſays Mr Hunter, "ſo well atteſted, that we are bound to believe it." How came it, we would aſk, that fiſhes which had been frozen by this truly ingenious phyſiologiſt never recovered? He recovered parts of different animals which had been frozen? Had the ſnakes and fiſhes of which he had heard been only partially congealed in the ice? or had the fiſhes which he ſelected for theſe experiments been properly choſen? or may all animals with equal fairneſs be made the ſubject of ſuch experiments? and may all tranſitions from heat to cold, and from cold to heat, whether ſlow or rapid, if not in the extremes, be viewed as nearly of the ſame conſequence? Are all ſeaſons and conditions of body equally favourable to this ſtate of torpor? and will theſe cauſes which induce torpor by operating externally in the months of autumn be able to continue it by the like action in the months of ſpring? We can anſwer, no.

58 Reabſorption of fat in the torpid ſtate.

It has been ſaid that animals ſubſiſt in their torpid ſtate by the reabſorption of fat. Has it therefore been proved that all animals, not to ſay living bodies, are poſſeſſed of fat? or if they be, has it been demonſtrated that they have a ſuperfluous quantity to be reabſorbed? Has it been ſhown that their waſte of fat is always occaſioned by this reabſorption; or has this reabſorption in all caſes been of that kind to counteract the effects of abſtinence? If it has not been proved that all animals contain fat, and that this fat is reabſorbed in their torpid ſtate, ought not the general aſſertion to be limited? Granting that in many reſpects it were true, have not philoſophers been here amuſing themſelves with logic, where they could have been employed in making experiments? Have they not ventured to give us concluſions, where we had reaſon to expect facts? and on this account has not their conduct been ſomewhat ſimilar to that of navigators who, ſailing along the coaſt of Patagonia on one ſide, and obſerving a few men of an uncommon ſtature, have from thence peopled the whole of the country with a race of giants? or rather to that of ſome calculators, who, from ſeeing a few parts of a continent, have ventured to give a map of the whole, to deſcribe kingdoms that are yet unexplored; and by their ſkill in addition and ſubtraction to exhibit the figure, the extent, and proportion of lands unknown?

Reſpiration.

Leaving therefore the torpid ſtate as one of thoſe ſubjects with which we at preſent are little acquainted, and of which we therefore cannot ſpeak with certainty in the general abſtract language of ſcience; it will naturally be aſked, In what reſpect is air ſo neceſſary to all living bodies in their active ſtate, and how it contributes to the regular performance of the different functions?

59 Opinions of the ancients reſpecting the uſe of reſpiration.

The ancients, who were led by the heat of the blood to ſuppoſe a vital ſpark in the heart, who had noticed the appearance of ſmoke in the breath, and who had obſerved that fire was extinguiſhed when deprived of air, naturally inferred that the end of reſpiration was to ſupport their imaginary flame, to ventilate the blood in the arteries and lungs, and to keep alive their vivifying ſpark. They were far, however, from being agreed as to the manner how this was effected. Some were of opinion that a certain principle of the air was abſorbed, to which they gave the name of *the provender of life* †, or the food of the ſpirit ‡; while others were perſuaded that the air acted as a refrigeratory, and was merely intended to moderate the fire, to aſſiſt in expelling the fuliginous vapour, and preſerve the ſyſtem in an equal temperature.

† Pabulum vitæ.
‡ Spiritus alimentum.

The moderns, who, after all their reſearches, have been unable to diſcover this vital ſpark of the ancients, are more puzzled to aſſign an adequate cauſe for the heat than for any cold which they diſcover. To account for this ſingular phenomenon, they have been ranſacking nature for cauſes; and perceiving that putreſcence, mixture, and friction, are in many inſtances accompanied with heat, have thence conjectured that they ſometimes operate in producing the warmth of the living body. But theſe are theories which have been imported from the hot-bed, the laboratory, and mechanic's ſhop, and which have never yet been countenanced by phyſiological facts and obſervations. No one has been able to ſhow that putreſcence exiſts in a healthy ſtate, except in the feces: no one has proved that any mixture which regularly occurs in the elementary canal or veſſels, generates heat; and though friction has been a favourite hypotheſis, yet thoſe circumſtances, in which it evidently produces heat, have not been diſcovered in the living body; and it is not determined whether it be there a friction of the fluids, a friction of the ſolids, or a friction of the fluids and ſolids together.

60 Opinion of Verheyen.

Of animal heat, the moſt rational theory, we think, is one which properly belongs to the laſt century; it is confirmed by modern diſcoveries, and has aſcribed this heat to reſpiration. Many had obſerved, that thoſe animals which reſpire moſt have the warmeſt blood (E).

Lower

(E) Quod autem animalia calidiora fortius reſpirent, non probat reſpirationem illis potius datam eſſe, ad ſanguinis refrigerium, quam calorem illum inteuſum produci a validiori reſpiratione: imo poſterius non tantum æque, at magis probabile apparet: quia ſecundum omnium ſententiam calido vivimus, frigido extinguimur.

Respiration.

Lower demonſtrated, that this blood received a new and a brighter colour in paſſing through the lungs (F). Verheyen and Borelli both proved, that the air loſt ſomething by coming in contact with that organ (G). Mayow ſhowed, that this ſomething which the air loſes is contained in nitre (H). Experience taught the workers in nitre, that this ſomething was abſorbed from the air (I): and Verheyen remarked, that it is alſo abſorbed by the lungs; and is probably that which maintains combuſtion; which qualifies the air for giving ſupport to animal life, and imparts to the blood the vermilion colour (K).

61 Supported by a diſcovery of Dr Prieſtley's.

How well the whole of this reaſoning was founded, is proved by the late diſcoveries of Prieſtley and other chemiſts. There is now obtained, in a ſeparate ſtate, an aerial fluid, which maintains both life and combuſtion, and gives a vermilion colour to the blood. It is extracted in a very large quantity from nitre; is one of the component parts of the atmoſphere, and the vital principle of that element; without which, in moſt animals, life is extinguiſhed. From ſome phenomena which happen in combuſtion, it has been termed *principium forbile*. It was called dephlogiſticated air by Prieſtley the firſt diſcoverer; as the great acidifying cauſe in nature, the French nomenclature has given it the name of *oxygenous gas*; and, as one of the cauſes on which the exiſtence both of fire and of life depends, it is named *empyreal* or *vital air*.

62 Reſpiration the cauſe of animal heat, and how this heat is produced.

Late diſcoveries have ſhown farther, how this air may in reſpiration produce heat. From the moſt accurate inveſtigations, it appears, that caloric, or the principle of heat, is a diſtinct ſubſtance in nature; that it combines with different bodies in different degrees; that it is the cauſe of fluidity in all; and that, in proportion to that capacity which they have for it, and to that diſtance at which they are removed from the fluid ſtate, the more or leſs caloric they contain. Aeriform bodies being all therefore exceedingly fluid, it muſt be evident, that when they are fixed or condenſed in the blood, and made to approach nearer ſolidity, a quantity of heat muſt be evolved. A part of this is very plainly evolved in the lungs where the air is abſorbed, as appears by the breath; and a part evolved by the action of veſſels, as appears from nearly an equal heat over the ſyſtem, from the partial heat of a morbid part, and the ſudden tranſition from heat to cold, and from cold to heat, over the ſurface, when the veſſels are affected by either internal or external ſtimuli. When the heat, thus evolved by the gradual fixation of that body with which it was combined, has been ſucceſsful in making its eſcape by the lungs and integuments, the blood returns in a dark and a ſluggiſh ſtream by the veins, and mingles again with the genial fluid, which before gave it ſpring, activity, and life.

Reſpiration.

Of that oxygene which remains in the ſyſtem, part is employed in forming different ſaline combinations and ſupplying the waſte occaſioned by that conſtant reabſorption; which, from many experiments that have been made with ſolutions of matter, is known to take place in the ſolid bones. The uſe of that oxygenous gas which returns with the breath, is beſt underſtood after knowing its affinities. Its baſis oxygene, combining with hydrogene, which is the baſis of inflammable air, forms water; and combining with carbone, the carbonic acid. It carries, therefore, back with the breath a part of the carbone produced by the ſlight combuſtion of the blood, and a quantity of hydrogene ariſing from the watery fluid decompoſed.

63 Cauſes which compoſe the atmoſphere which we breathe, and their uſe in reſpiration.

But oxygenous gas does not alone enter the lungs. Of 100 parts of the atmoſphere, but 28 are oxygenous gas, $\frac{1}{100}$ is carbonic acid, and 72 are azotic gas (L). Theſe laſt, though intended chiefly for other beings different from man, which are in immenſe numbers on the globe, but which, like him and the nobler animals are not formed

(L) Theſe are nearly the proportions.

Respiration.

ed to breathe the empyreal air, must notwithstanding be of some important and essential use to all living bodies. It has accordingly been found by experiment, that pure and unmixed oxygenous gas cannot be breathed for any very considerable time without danger; that some azote is contained in the blood, and has been extracted from the muscular fibre, when properly treated with the nitric acid. According to Berthollet, five of its parts with one of hydrogene forms ammonia or volatile alkali; which dispels the glandular tumours of the body, and prevents the coagulation of blood and the thickening of mucus which arise from acids (M). The azotic gas may therefore in part unite with hydrogene, may prevent the coagulation of serum, the catarrhous formation of viscid mucus, and many combinations that oxygene might form, injurious to the system. The carbonic acid, which is $\frac{28}{100}$ of carbone and $\frac{72}{100}$ of oxygene, may also be necessary in regulating the effects of the other two. In aerated water, its uses are very generally known: it allays the pain of the urinary bladder when excited by calculus; it has been employed in the cure of wounds, and been thought useful in the pulmonary phthisis. It is generated in the lungs of those animals which respire oxygene. In small proportions it favours the growth of the vegetable tribes. These tribes readily decompound it; and, with the addition of other prepared oxygene from water, restore what is pure to the general mass of the vital fluid, that plants and animals might thus live by the mutual performance of kind offices.

We return again to animal heat. Every theory that pretends to account for animal heat, ought also to account for that singular equality of heat which the system preserves, or endeavours to preserve, in different temperatures. The above theory explains it simply in the following manner.

64 How an animal preserves its natural warmth in a cold temperature.

Venous blood, if exposed to the air, is known to absorb a portion of oxygene, and assume that colour which it has in the pulmonary veins and aorta. Suppose an absorption of a similar kind taking place in the lungs, a fact which may be proved by decisive experiments; it is plain that the oxygene by this absorption must recede from its gaseous or fluid state; that a quantity of heat must be therefore evolved, which, along with the heat of the refluent blood, is carried away by that vapour which issues from the lungs. In the course of circulation, the oxygene will naturally incline with hydrogene to form water; it will tend likewise to the formation of many other compounds; and, as it enters into new states, and is farther removed from gaseous fluidity, it must still be giving out a portion of heat. If the surrounding temperature be cold, this separation will be easily effected. The caloric will, in that case, be greedily absorbed from the interior surface of the lungs and exterior surface of the whole body. The oxygene, meeting with the necessary temperature, will readily pass into new forms; and the venous blood returning to the lungs, will demand a supply which will be either greater or less according as the cold, by favouring the escape of the caloric, and promoting new combinations with oxygene, had removed it from the point of usual saturation. Respiration.

65 And its natural coolness in a warm temperature.

The gradual evolution of heat is a proof that the temperature must be sometimes reduced before the oxygene can properly enter into all the usual combinations of the system. Suppose the body then to be placed within a hot circumambient atmosphere. This atmosphere, if warmer than the animal, will be more apt to part with heat than to receive it; and the oxygene absorbed, being thus unable to dispose of its caloric, will be prevented from passing into those combinations and forms where heat is evolved. The venous blood will therefore conduct it back to the lungs, and make a demand for a new supply; but proportionally less according as the hot circumambient air, by preventing the escape of the caloric, and the usual facility of new combinations, has confined its removal to a smaller distance from the point of saturation.

In this last case the thing principally entitled to notice is a very curious effort of nature to resist the growing increase of heat. In the warm atmosphere, as during violent muscular exertion, the exhaling vapours is commonly discharged in a greater quantity from the surface of the body; and consequently the heat furnished with an excellent temporary conductor, that in some measure counteracts the dangerous effects from without.

66 The air respired by plants and insects different from what is respired by man.

After all, the reader is not to suppose that he here has received a general theory of respiration. All living bodies are not supported by the same kind of aerial food. Oxygenous gas has indeed been honoured with the flattering appellation of vital air; and nitrogenous gas been usually distinguished by that degrading epithet azotic; a word which signifies destructive of life. But though man, and all the warm-blooded animals that have yet been examined, may die in respiring the nitrogenous gas, this gas however, which constitutes more than two thirds of the whole atmosphere, may in general be called the vital air of the vegetable tribes, and of not a few of the orders of insects which thrive and live in it. For while man, and others which respire as he does, emit both the hydrogene and carbone, and return the nitrogene not sensibly diminished; most vegetables and many insects eagerly inhale them, and emit oxygene as noxious or useless. These effects are the indications of a radical difference in constitution. Even the fibres of those living bodies which exhale oxygene, will, after death, attract it so powerfully, as to decompose the nitric acid; but those bodies which inhale nitrogene, have so very weak an affinity to oxygene, and so strong a one to some of the bodies with which it is combined, that they can easily decompose water and carbonated air.

67 Respiration of fishes, and their temperature.

What fishes respire is not ascertained. Neither the change of the air, nor of the water which they occasion when in close vessels, have, so far as we know, been fully examined. Chaptal is assured, that, like other animals, they are sensible of the action of all gases. Fourcroy

(M) Weak volatile alkali dissolves mucus, whose morbid viscidity Fourcroy has ascribed to a too great absorption of oxygene.

Respiration.

croy says, that they do not generate the carbonic acid; and that the air which Priestley and he found in the air vesicles of carp was nitrogene gas. Their thermometrical heat is so low, that in D'Aubenton's table they are reckoned among the cold-blooded animals.

68 Temperature of plants.

The temperature of plants is still lower. The heat of a tree which the very ingenious Hunter examined, though several degrees above that of the atmosphere when below the 56th division of Fahrenheit, was always several degrees below it when the weather was warm. When taken out, the sap was observed to freeze at 32°; while in the tree, it would not freeze below 47°. The very profuse perspiration of vegetables greatly moderates the heat in their surface; and as air which absorbs moisture expands, and becomes thereby specifically lighter, there is a regular current produced, and evaporation rapidly promoted by the dense air displacing the rarefied.

69 How the natural heat of living bodies is to be estimated.

To adopt here a general language with respect to the heat which is developed in all living bodies, it is proportioned to the quantity of matter which is by means of the vital powers reduced to a state more nearly approaching solidity; to the kinds of the substances which are reduced, and to the degrees and kinds of the reduction.

In all living bodies there appear to be certain degrees of heat, peculiarly fitted for carrying on their various economical operations. What these are, in the different kinds of plants and animals, is not known. The bear, the hedge hog, the dormouse, and the bat, may probably not digest when reduced to 70°, 75°, or 80°. The frog, however, will digest at 60° (N); and the birch before it at arrives at 47° (O). It would seem that respiration, besides imparting aerial food, was intended to preserve and regulate these different degrees of heat. It raises the heat after a meal; it suffers it to fall in the time of sleep; it withdraws the supply when the atmosphere is warm, and increases it again when the atmosphere is cold. It should therefore be remembered, that heat merely is not the object which is solely aimed at in respiration. All living bodies have their congenial degrees of heat. The regulation of these is important: on the one side, it prevents the dissipation, on the other the coagulation, of their fluids; it preserves the living power of their organs; and, by a natural and proper temperature, assists their action in mixing, composing, in decomposing, and in variously preparing the different parts for secretion, excretion, absorption, reabsorption, and assimilation (P).

Respiration.

70 Certain degrees of heat natural to every species.

71 Regulated by respiration.

As various fixations of the vascular fluid are regularly taking place in the different parts of the living body, and as air is not the only fluid concerned, it should almost be unnecessary again to observe, that the whole of the heat is not evolved in the lungs, nor the whole that is evolved disengaged from air.

It

(N) See observations on certain parts of the animal economy by Mr Hunter. We allude here to his experiments and observations on animals, with respect to the power of producing heat.

(O) See Dr Walker's excellent Paper on the motion of the sap in trees, 1st volume *Philosophical Transactions, Edinburgh.*

(P) The ingenious Dr Crawford has published a theory of animal heat different from that which we have here presented to our readers. Assuming as a fact, that heat and phlogiston are two opposite principles in nature, he goes on as follows.

"Animal heat seems to depend upon a process similar to a chemical elective attraction. The air is received into the lungs containing a great quantity of absolute heat; the blood is returned from the extremities highly impregnated with phlogiston; the attraction of the air to that of the phlogiston is greater than that of the blood. This principle will therefore leave the blood to combine with the air: by the addition of the phlogiston, the air is obliged to deposit a part of its absolute heat; and, as the capacity of the blood is at the same moment increased by the separation of the phlogiston, it will instantly unite with that portion of heat which had been detached from the air.

"We learn from Dr Priestley's experiments with respect to respiration, that arterial blood has a strong attraction to phlogiston (become a vague word with different meanings in different authors). It will consequently, during the circulation, imbibe this principle from those parts which retain it with the least force, or from the putrescent parts of the system: and hence the venous blood, when it returns to the lungs, is found to be highly impregnated with phlogiston. By this impregnation its capacity for containing heat is diminished. In proportion, therefore, as the blood which had been dephlogisticated by the process of respiration becomes again combined with phlogiston in the course of circulation, it will gradually give out that heat which it had received in the lungs, and diffuse it over the whole system.

"To account for the stability of animal heat, he observes, that as animals are continually absorbing heat from the air, if there were not a quantity of heat carried off equal to that which is absorbed, there would be an accumulation of it in the animal body. The evaporation from the surface, and the cooling power of the air, are the great causes which prevent this accumulation: and these are alternately increased and diminished in such a manner as to produce an equal effect. When the cooling power of the air is diminished by the summer heats, the evaporation from the surface is increased: and when, on the contrary, the cooling power of the air is increased by the winter colds, the evaporation from the surface is proportionally diminished." See *Crawford on Animal Heat*, p. 73—84.

Besides, supposing that the principles of fire and inflammability are opposites in nature; this theory supposes that the blood, while in the lungs, gives out phlogiston and takes in heat; but that, during the remaining course of circulation, it gives out heat and takes in phlogiston: it supposes, that this phlogiston is collected from parts that retain it with little force, or from the putrescent parts of the system; it is not said where: it

supposes

Respiration.

It may farther be remarked, that the whole of the air does not enter by the lungs; much is contained in the liquid and solid parts of the food. It is extricated often in the process of digestion; and when the organs are vigorous and healthy, is made subservient to the general economy. If the organs, however, should happen to be languid, it scorns their authority, which cannot be enforced; from being friendly, it soon becomes inimical to the system, and threatening danger accumulates, not only in the stomach and intestines, but in other cavities. It has been found in the cellular membrane; in certain vesicles formed for itself; in the uterus; in an abscess; and in gun-shot wounds: It has sometimes burst from the vagina with a sort of noise *. And in a nephritic complaint of a horse, we have observed it flowing in a stream from what the farriers denominate the *sheath*.

73 All the air in a living body does not enter by the lungs, nor is contained in them.

In some kinds of aquatic plants, in eggs, and in a variety of fishes, there are certain vesicles containing air, which seem to have certain necessary functions allotted them by nature. In the plants and in fishes they were once supposed to have been wholly intended for swimming (Q). It was remarked, that those fishes which remain constantly at the bottom of the water have no air vesicle; and that a fish whose vesicle was burst by means of the torricellian vacuum, though it lived for a whole month after in a pond, was never able to rise to the surface †. The practice, however, which some fishes have of ascending at times to inhale air, and descending after their vesicle is filled ‡; the communication which, in some fishes, this air vesicle has with the stomach; that power in the pigeon and some other birds of introducing air into the crop ‖; and lastly, the air which is uniformly found in impregnated eggs—would tempt us to believe that these natural collections of air, with their other uses, may perform some essential service in nutrition.

73 Respiratory organs.

Having explained the general intention of respiration, we are now to inquire, what are the kinds of respiratory organs, and in what manner their functions are performed? The preceding table has in some measure made us acquainted with this subject. Some animals breathe by a trachea and lungs; insects, by either stigmata or tracheæ, opening into air vessels; plants, by air vessels and leaves; fishes, and numbers of the watery element, if they do not breathe, at least receive air by their gills; the fœtus in ovo, the polypus tribe, and many more organized bodies, by the same organs which convey their food.

Respiration.

74 Absorbents.

The absorbents appear to be the first and most general way by which living bodies are supplied with air: the mouths of these vessels are like small tubercles, scattered over the body of the insect while wrapt in its membrane. In the horse and the bird they are blood-vessels spreading on a membrane, and deriving nourishment from the uterus or egg, that had been itself nourished by absorbents: In a cow, they are vessels which, spreading on a membrane, terminate in glands; these glands being opposite to others which adhere to the uterus; and the membranous and uterine glands, when in contact, inclosing a third gland like a kernel. In man, they are vessels spreading on a membrane, and entering a large glandular body called the *placenta*. In the mouse and the hare, they are likewise vessels branching on a membrane, and entering a placenta: this placenta, when it happens to be fixed, receives large veins from the parent, and which may be either inflated or injected from the cavity of the uterus.

75 Respiratory organs lay in exercising their functions.

Those which are properly respiratory organs, exercise not their function till circulation and nutrition are begun: though, if the observation of Garman be just, that the air may become a real food for the class of spiders, or if it be true that the larvæ of ants as well as of several insects of prey, increase in bulk, and undergo their metamorphoses without any other nourishment than air §, this law is not universal. It may, however, be doubted, whether some moisture be not absorbed. With regard to the ant, we have reason to suspect that the observations on which such a conclusion was founded have not been accurate.

§ *Chaptal's Elements of Chemistry*, vol. iii. § art 5.

76 Sometimes renewed, sometimes changed to a different kind.

Not only are the respiratory organs thus late in exercising their functions; in many vegetables a great part of them is annually renewed and laid aside in the torpid state. In those insects which undergo the most remarkable kinds of transformation they suffer a change; and in all those animals which spend their earlier days in the water, and afterwards come to live in the air, they are altered in kind.

In

---

supposes that the blood, in passing through the lungs, receives heat only: that the whole of this heat is evolved in the lungs by precipitation; and is thence diffused over the system as from a centre or focus: in which case, we must also suppose that the lungs are the warmest part of the body; and that the heat of the other parts will be in proportion to their distance from the lungs, or the length of the vessels through which it has passed.

As for the stability of animal heat, this theory ascribes it entirely to foreign causes; to the different degrees of evaporation; or to the varying states of the air.

The singular meaning which this theory gives to the word *phlogiston*, must strike every one who knows the etymology of that word. The celebrated Stahl found it in the Greek; and applied it naturally to signify pure elementary fire, or the most pure and simple inflammable principle in a state of combination. Mr Kirwan has since used it to express hydrogene: Dr Priestley has called the azotic phlogisticated air; and Dr Crawford, who seems to take phlogiston in the sense of Mr Kirwan, speaks likewise as if he understood it in the sense of Dr Priestley. Mr Kirwan's phlogisticated air however, will not kindle without oxygene: Dr Priestley's will extinguish fire: and Dr Crawford's is directly opposed to that principle. These are not the ancient doctrines of Stahl: they are new ideas expressed in one of his antiquated words; the meaning of that great man is neglected. The sounds which he uttered, like the dead language of an old ritual, are among a few still in veneration.

(Q) Borelli has shewn how, by contracting the air vesicle or allowing it to expand, the fish can rise, sink, or remain stationary in the water. *Borelli de Natatu.*

Respiration.

In all living bodies the proper function of one part of the respiratory organs is, to secrete from the water or air that particular aeriform fluid which mingles with their juices, and which is necessary to life and nutrition. In many cases these organs are placed externally, and are always in contact with the air or water from which they secrete. In other cases they are lodged internally; and air or water are then alternately admitted and expelled by varieties of organs which serve as auxiliaries.

The plants secrete their aeriform fluid from water and air. They receive air along with the liquids of their absorbents, which open on the roots, the trunk, and the branches, and upon the inferior surfaces of leaves; or, if nature has plunged these leaves under water, the absorbents open and imbibe their fluids on both sides. In many, however, the upper surface of the leaf is intended to inhale air. Bonnet observed, that when this surface was applied to the water the leaf died soon; but that when the lower surface was applied, it lived for months. It has also been remarked, that the upper surfaces of some leaves will repel water; and that the death of the leaf will ensue when its breathing pores are obstructed with oil *. We hence learn why aquatic plants rise up to the surface of the water and spread their leaves in the open air: and as it is proved by Ingenhouze and others, that the respiration of many leaves is assisted by light, we see a reason why plants growing in a dark room turn to the place where light is admitted; why the flowers and the leaves of many plants follow the diurnal course of the sun; why the branches of trees, which require much light, die when placed in a thick shade; why moonshine in autumn contributes so much to the ripening of grain; and why leaves and branches are arranged in such a manner as least to intercept that quantity of light which nature has allotted to the genius of each.

The air vessels in the body of plants are those vessels which contain juices but at certain times, and which during the greatest part of the season are filled with air †. This air is collected from the sap of the roots as it passes along the diametral insertions, and from those vessels which open upon the trunk and upon the leaves ‡. Like pulmonary tubes, which are seen branching through the bodies of insects, they perform an office similar to that of the trachea and bronchia; and are those general receptacles of air from which the neighbouring parts of the plant secrete what is needed: for in plants and a certain number of insects, the functions of the lungs, the stomach, and the heart, are generally diffused. The several parts can respire, digest, and circulate fluids on their own account; and if they should chance to be severed from the whole, can live and grow, and propagate their kind.

The air vessels are surrounded by those which contain a liquid during the whole time of the growth. They are the largest vessels of the wood, as distinguished from the bark; and in the leaves they may sometimes be seen even without the assistance of glasses. Their cavity is formed by certain fibres which wind spirally like a cork-screw. In the leaf they generally approach and recede like the filaments of nerves; but they never inosculate from one end of the plant to the other, except at the extremities §; they resemble the pulmonary tubes of insects by their general dispersion over the system, and the spiral rings of which they are composed (R); they differ in this, that the pulmonary tubes are frequently observed to anastomose in their larger branches, as the ramifications of a vein or artery do in their smaller capillary twigs.

§ Grew's *Anat. of Plants*, B. 3. ch. 3. § 17—29.; and B. 4. parer. ch. 4. § 17—19.

The respiratory organs, which are similar either to the gills of fishes or the lungs of man, can hardly here claim a description, as their nature and forms are so generally known. There is one circumstance, however, in birds which arrests our attention: the cells of their bones, and the numerous vesicles of their soft parts which communicate with the lungs, have been deservedly a matter of surprise to most physiologists. In accounting for their use, the ingenious Hunter supposed that they lessened the specific gravity and assisted flying; that being the circumstance which he thought most peculiar to birds. Learning afterwards that they were in the ostrich and not in the bat, he supposed that they were appendages to the lungs. In amphibious animals, in the snake, viper, and many others, he observed, that "the lungs are continued down through the whole belly in form of two bags, of which the upper part only can perform the office of respiration with any degree of effect, the lower having comparatively but few air vessels (S)." In these animals, the use of such a conformation of the lungs was to him evident. "It is in consequence of this structure," said he, "that they require to breathe less frequently than others." From this reasoning he naturally

79 And opinions concerning the pulmonary appendages in birds, &c.

(R) See the spiral rings in the pulmonary tubes of a bee, Plate XVII. fig. 10. Swammerdam's Book of Nature, or History of Insects.

(S) The same observations were long ago made by the immortal Harvey. After observing that both the transverse and longitudinal membranous diaphragms of birds contributed to respiration, he adds, "Et alia, ut nunc taceam. Avis præ cæteris animalibus non modo facillime respirat, sed vocem etiam in cantu diversimode modulatur: cum tamen ejus pulmones lateribus et costis adeo affixi sunt, ut parum admodum dilatari, assurgere, et contrahi possint.

Quinetiam (quod tamen a nemine hactenus observatum memini) earum bronchia sive asperæ arteriæ fines in abdomen perforantur. Aeremque inspiratum intra cavitates illarum membranarum recondunt. Quemadmodum pisces et serpentes intra amplas vesicas in abdomine positas, eundem attrahunt et reservant, eoque facilius natare existimantur. Et ut ranæ ac bufones cum æstate vehementius respirant, aeris plus solito in vesiculas numerosissimas absorbent (unde earum tam ingens tumor) quo eundem postea in coaxatione liberaliter exspirent. Ita in pennatis pulmones potius *transitus et via ad respirationem* videntur quam hujus adequatum organum. *De Generat. Animal.* Exercit. 3.

Reſpiration. turally inferred, that the motion of flying might render the frequency of reſpiration inconvenient; and that a reſervoir for air might therefore become ſingularly uſeful. The bat and the oſtrich, however, are here as formidable objections as before. The bird reſpires frequently when at reſt, and when it flies to our boſom from the hawk; that frequency ſeems to have been increaſed by what is a general and a common cauſe, an increaſed degree of muſcular exertion. Had air cells been intended merely to prevent the effects of a rapid motion on reſpiration, we might expect to ſee them in greyhounds and a number of quadrupeds, much more readily than in ſome birds whoſe flights are neither rapid nor long.

This great phyſiologiſt was not aware that the circumſtance moſt peculiar to birds was not their act of flying, but their feathers, which contain a large quantity of air, and which require a regular ſupply, whether they ſoar on the wings of the eagle, or remain on the ground, attending the oſtrich (T).

Both in amphibious animals and birds, the air of the veſicles has paſſed the reſpiratory ſurface of the lungs. In the tracheæ of plants and the pulmonary tubes and veſicles of inſects, it is only proceeding on its way to be reſpired. Would it be worth while to inquire whether vegetable ſubſtances, and thoſe which are called corneous in animals, require a different preparation of air from what is the common preparation of lungs? whether hair grows beſt, or the cuticle thickeſt over ſoft parts that are cellular and ſpongy (U)? and whether the animals that bear horns have larger ſinuſes in the frontal bone of their cranium than others? From the general diffuſion of air through the birds, and the ſituation of their veſicles beyond the lungs, it would appear that the pulmonary viſcus in theſe animals does not reſpire or ſecrete air for the whole ſyſtem; and we are certain, that in plants and inſects moſt parts reſpire the air for themſelves, and that there is no particular part appointed to ſecrete air for the whole.

Reſpiration

We here ſpeak of reſpiratory organs as thoſe which ſecrete an aeriform fluid from water and air; but our language probably had been more accurate had we called them the organs in which an aeriform fluid is abſorbed by their liquid contents, as theſe flow by, either wholly or in part, in their courſe through the ſyſtem. It was long denied that any abſorption of the air took place from the pulmonary ſurface; and ſpeculative reaſoners had attempted to prove that no air could paſs to the blood through the membranes of the lungs, becauſe air had refuſed upon ſome occaſions to paſs through pieces of wet leather that had been expoſed to it for that purpoſe. Borelli, however, endeavoured to ſhow how air in the lungs might mingle with the blood, and how ſome alwaya diſappeared in reſpiration. There are few doubts now entertained on this ſubject. Venous blood incloſed in a bladder by the celebrated Prieſtley diſcovered ſuch an attraction for oxygene, that it abſorbed the aeriform fluid through all the coats of the reſiſting medium, exhibiting an inſtance and beautiful illuſtration of the chemical affinities which take place in this function.

Air abſ
ed by th
fluids wh
paſs alon

tory org

(T) "The uſe of this retention (of the air in the veſicles of birds) is not well known to us, at leaſt in reſpect of the upper pouches; ſo in regard of the lower ones. The uſe of this retention has been explained in the deſcription of the OSTRICH: where it was ſhown that there is a probability that the air contained in the lower pouches ſerves to compreſs the viſcera, and make them riſe upwards. Some do think that this retention of air ſerves birds to render them lighter in flying, likeas the bladder which is in fiſh helps them to ſwim. And this conjecture would have ſome foundation, if the air contained in the bladders of birds were as light in proportion to the air in which they fly, as the air contained in the bladders of fiſh is in proportion to the water in which they do ſwim. But to ſay ſomething which hath at leaſt a little more probability, waiting till we have a more certain knowledge of the truth and uſe of this retention of air, we conſider that the birds generally riſing very high, and even to the place where the air is a great deal lighter than it is near the earth, might be deprived of the principal advantages of reſpiration for want of an air whoſe weight might make on the heart and arteries the compreſſion neceſſary to the diſtribution and circulation of the blood: If they had not the faculty of containing a long time a portion of air, which being rareſied by the heat which this retention produceth therein, might, by enlarging itſelf, ſupply the defect of the weight of which the air that they do breathe in the middle region is deſtitute. For if there be a great many birds which do never riſe very high into the air, whoſe lungs have notwithſtanding theſe bladders in which the air is retained; there are alſo a great many that have wings which they uſe not for flying. And it may be obſerved, that there are found ſome parts in animals which have not any uſe in certain ſpecies, and which are given to the whole genus, by reaſon that they have an important uſe in ſome of the ſpecies. It is thus that in ſeveral kinds of animals the males have teats like the females; that moles have eyes; oſtriches and caſſowars wings; and that land tortoiſes have a particular formation of the veſſels of the heart which agrees only with water tortoiſes, as it is explained in the deſcription of the TORTOISE." *The Anatomical Deſcription of a Caſſowar*, by the Royal Academy of Sciences at Paris. We can hardly anſwer for the juſtneſs of this reaſoning, which maintains that the genus has uſeleſs parts merely in complaiſance to the ſpecies.

(U) Nails and hair grow after death, and a quantity of air is evolved in putrefaction.

Respiration.

the leaf to the sun. We see them producing these oscillatory motions in the branching gills of the *pulex arborescens*. When the breathing surface is within the body, we discover them again in the tracheæ of plants, whose cavity is formed by a spiral fibre that is seemingly intended for some kind of peristaitic motion. We detect them likewise in the pulmonary tubes, in the spiral rings, and in the abdominal movements of insects. We see them in fishes swallowing the water and propelling it onward through the fringes of the gills. In the frog, we note them by the motions of the pouch between the sternum and the lower jaw. After this animal is divided transversely behind the fore legs, this pouch continues to fill and to empty itself downwards by the traebea where the lungs were. When the whole integuments and some of the muscles between the jaw bone and sternum are removed, we see how the pouch was dilated and contracted by a broad cartilage connected with the trachea, and attached by muscles to the inside of the sternum and the neighbouring parts. When the pouch is enlarged, the air rushes in through the two nostrils at that time expanded; and when it is contracting, the glottis starts up with an open mouth to the middle of the pouch, and the air is pressed down through the trachea to the lungs. This amusing sight will sometimes continue for a whole hour. In man and all the warm-blooded quadrupeds, the thorax or cavity where the lungs are placed is dilated and contracted by the diaphragm and muscles attached to the ribs. In the time of dilatation the glottis opens, as we see in birds: the air rushes in, supports the incumbent weight of the atmosphere, and enables the thorax to expand wider. The expanding powers having made at last their usual effort, their antagonists succeed, exert their force, and the air is expelled.

82 Auxiliary organs of respiration.

83 Assisted by the pressure of the atmosphere.

In applying either the water or air to the breathing surface, all these auxiliary organs are assisted by the circumambient fluid which presses equably on all sides. When a Florentine flask is applied to the mouth, and all communication between the larynx and external air entirely cut off, it requires an effort to bring the air of the flask into the lungs. The weight of the atmosphere is therefore assisting in respiration; and the air, whether in the lungs or the thorax (x), must not be so dense as that which is without. When Verheyen perforated the thorax of a dog, and restored the equilibrium betwixt the external and internal air, the respiration of the lungs ceased, though for some time the alternate admission and expulsion of air was continued through canulas introduced into the wounds.

84 How this pressure raises the thorax.

It cannot surely be asked here, how the pressure of the atmosphere should be assisting in raising the thorax, and thus seemingly counteract itself? The heat of the lungs expands the air as soon as it enters. The air rapidly absorbs moisture; and though not usually noticed by philosophers, yet the sudden expansion, which is always the consequence of that absorption, is a very general phenomenon in nature. By this heat, or by this absorption, the air would occasion greater dilatation, were it not for the lungs, which seek to collapse; the cartilages of the sternum, which seek to recoil; and the stretched-out muscles, which either spontaneously, or directed by the will, endeavour to contract and produce expiration. Respiration.

Having seen how the air will rush in on the opening of the glottis, we may also conceive how the shutting of the glottis will resist the force of internal expansion, and support a weight laid upon the breast. The confined air will expand equally on all sides, and the pressure must be great before the space which falls to the glottis can exceed its own muscular force and the weight of the atmosphere. It is this diffused pressure of fluids that produces such striking wonders in hydraulics; and which explains how the droppings of the ureters should expand the bladder even to a palsy, and overcome the abdominal muscles.

85 How the expansion is continued.

86 Opinions concerning the organs of respiration.

To account for the action of these organs which serve as auxiliaries in respiration, there have been supposed an appetite for air which prompts as a stimulus; an influence of the will, though we breathe while asleep; and a natural instinct, which indeed may exist, but explains nothing. In specifying the several organs concerned, we have heard of an expansile power of the lungs, of a certain pressure of the phrenic nerve, of a muscular diaphragm, and of the action of oblique intercostals. But these explanations are from a limited view of the subject. The expressions used may indeed be general; but their meaning is particular, narrow, and confined; and their allusion is only to man, or perhaps to a few of the warm-blooded quadrupeds: for where are the intercostals of the frog? where is the muscular diaphragm of birds? where the pressure of their phrenic nerve? and where the expansile power of their lungs?

87 What organs form articulate sounds.

It is fortunate for man that these assisting respiratory organs are in some measure subject to his will. By this subjection he produces vocal sound when he pleases, divides it into parts, varies it by tones, forms it into words, and enjoys the distinguished and numerous advantages that may be derived from a spoken language.

Sect. II. *Digestion.*

88 Digestion.

As respiration succeeded the placenta in one of its offices by maintaining life, the function of digestion succeeds it in another by either continuing or supporting the growth of the living body. It depends on respiration for a portion of heat, and is that function by which the liquid and solid food undergoes its first preparation in the system.

89 Gaseous fluids compose the substance of all living bodies, and two of the gases form WATER.

Though gaseous fluids, including the principles of heat and light, may be proved to nourish and compose the substances of all living bodies, yet a part only can enter the system in a gaseous state. This part is changed by the lungs, or by those fluids which they contain. The organs of digestion, before they can act on aerial bodies, must have them reduced to some new form. For the food of vegetables, this form requires to be water, whose 100 parts are found to consist of 84½ of oxygene and 15½ of hydrogene. See WATER.

(x) Supposing that there be any in the thorax.

Digeſtion. When the gaſes have paſſed through both the watery and vegetable ſtates, they, as juices or ſolids, become the food of a great many animals. Theſe animals produce new changes, and by their preparation the gaſes become the food of others which are called carnivorous; and then the carnivorous and all living bodies, when the vivifying principle has ceaſed within them, and when they are haſtening to a ſtate of diſſolution, are devoured by others who feed on corruption, are partly converted into water and gas, and become in their turn the food of the kinds on which they had fed.

As theſe effects of the digeſting and aſſimilating powers are more ſurpriſing than any chemical proceſs of art, it may not be unpleaſing to take a more particular view of them. It has long been obſerved, that thoſe animals which are not carnivorous feed upon plants; and, ſince the days of Van Helmont and Boyle, it has been ſuſpected that plants live upon water and air. This ſuſpicion has now been confirmed by

90 Vegetables live in pure water. numerous experiments. Plants have been raiſed from diſtilled water without earth, and, inſtead of requiring a vegetable mould, have ſpread their roots in moſs, in paper, in cotton, in pieces of cloth, in pounded glaſs, and powder of quartz. From theſe facts, the ingenious Chaptal has been led to ſuppoſe that ſoils act but as ſo many ſponges, affording water in different proportions, and in different ways; and that all that the plant wants from the ſoil is a firm ſupport, a permiſſion to extend its roots where it chooſes, and that proportioned ſupply of humidity which will ſecure it againſt the alternatives of being inundated or dried up. To

91 Uſe of ſoil to vegetables. anſwer, however, theſe ſeveral conditions, he allows it to be neceſſary in many caſes "to make a proper mixture of the primitive earths, as no one in particular poſſeſſes them. Siliceous and calcareous earths (he ſays) may be conſidered as hot and drying, the argillaceous as moiſt and cold, and the magneſian as poſſeſſing intermediate properties. Each, in particular, has its faults, which render it unfit for culture. Clay abſorbs water, but does not communicate it; calcareous earth receives and gives it too quickly; but the properties of theſe earths are ſo happily oppoſed that they correct each other by mixture. Accordingly we find, that by adding lime to an argillaceous earth, this laſt is divided, and the drying property of the lime mitigated, at the ſame time that the ſtiffneſs of the clay is diminiſhed. On theſe accounts it is that a ſingle earth cannot conſtitute manure, and that the character of the earth intended to be meliorated ought to be ſtudied before the choice of any addition is decided on. The beſt proportions of a fertile earth for corn are three eighths of clay, two eighths of ſand, and three eighths of the fragments of hard ſtone. Digeſtion.

92 Uſe of agriculture to vegetables. The advantages of labour conſiſt in dividing the earth, aerating it, deſtroying uſeleſs or noxious plants, and converting them into manure by facilitating their decompoſition."

So far is vegetable mould from communicating any thing new to plants, that it rather owes its formation to them*, and if ſea ſalt ſhould at times be requiſite to marine vegetations, it is to be remembered that ſalts, ſulphur, and lime, are all products of organized bodies; that iron (y) itſelf has been diſcovered in plants and animals; and that even diamonds, quartz, cryſtals, ſpars, gypſum, &c. are found only in thoſe earths that are partly compoſed of an impoveriſhed vegetable reſidue, which provident nature ſeems to have reſerved for the reproduction or reparation of the earthy and metallic ſubſtances of the globe; while the vegetable mould on theſe organic parts that remain are made to ſerve as nouriſhment for the growth of ſucceeding plants (z).

* *Chaptal's Elem. of Chem.* vol. iii. part 4. § 2. the beginning, and § 5. art. 3.

93 Earths and metals vegetable productions.

If thoſe earths in which plants are reared, and which contain no vegetable mould, ſhould ever be ſenſibly diminiſhed in weight, a circumſtance, we believe, which ſeldom takes place if proper precaution be uſed to prevent it; yet if it ſhould happen, it ſhould not in that caſe be forgotten that gaſes are the general cements in nature; that they mix intimately with the hardeſt bodies; and that this ſenſible diminution of weight

---

(y) Whether iron exiſts formally in organized bodies, or is the reſult of decompoſition, it derives its origin ultimately from gaſes. Blood gradually decompoſed by putrefaction yielded not only more ſalts and lime, but much more iron than blood, ſuddenly decompoſed by lime. Though the greater part of an animal or vegetable, therefore, be without ſuch ſubſtances as ſalt, lime, iron; yet when decompoſed its parts may recombine, and thus produce them. See *Surgical and Phyſical Eſſays*, by Mr John Abernethy.

(z) "Vegetables in their analyſis preſent us with certain metals, ſuch as iron, gold, and manganeſe. The iron forms near one-twelfth of the weight of the aſhes of hard wood, ſuch as oak. It may be extracted by the magnet. We read in the *Journaux de Phyſique* an obſervation, in which it is affirmed that it was found in metallic grains in fruits. Vegetables watered with diſtilled water afford it as well as others.

"Beecher and Kunckel aſcertained the preſence of gold in plants. M. Sage was invited to repeat the proceſſes by way of aſcertaining the fact. He found gold in the aſhes of vine twigs, and announced it to the public. After this chemiſt, moſt perſons who have attended to this object have found gold, but in much leſs quantity than M. Sage announced. The moſt accurate analyſes have ſhown no more than two grains, whereas M. Sage had ſpoken of ſeveral ounces in the quintal. The proceſs for extracting gold from the aſhes conſiſts in fuſing them with black flux and minium.

"Scheele obtained manganeſe in the analyſis of vegetable aſhes.

"Lime conſtantly enough forms ſeven-tenths of the fixed reſidue of vegetable incineration. Next to lime, alumine is the moſt abundant earth in vegetables, and next magneſia. Siliceous earth likewiſe exiſts, but leſs abundantly; the leaſt common of all is the barytes. *Chaptal's Elements of Chemiſtry*, Part iv. § 3. art. 15.

See Salts, Sulphur, Iron, Lime, in *Elements of Chemiſtry*. See the *Matrix of Diamonds*; ſee *Chaptal*, vol. iii. Part 4. § 5. art. 3.

Digeſtion.

weight may be owing entirely to ſome diſſolution of the ſolid parts, and the conſequent extrication of the gaſeous fluids (A).

"Before we had acquired a knowledge of the conſtituent principles of water," reſumes Chaptal, "it was impoſſible to explain or even to conceive the growth of plants by this ſingle aliment. In fact, if the water were an element, or indecompoſable principle, it would afford nothing but water in entering into the nutrition of the plant, and the vegetable would of courſe exhibit that fluid only; but when we conſider water as formed by the combination of the oxygenous and hydrogenous gaſes, it is eaſily underſtood that this compound is reduced to its principles, and that the hydrogenous gas becomes a principle of the vegetable, while the oxygene is thrown off by the vital forces. Accordingly we ſee the vegetable almoſt entirely formed of hydrogene. Oils, reſins, and mucilage, conſiſt of ſcarcely any thing but this ſubſtance; and we perceive the oxygenous gas eſcape by the pores where the action of light cauſes its diſengagement."

But though water conſtitute the aliment of plants, we muſt not ſuppoſe that it is the aliment of theſe alone: the leech and the tadpole* are nouriſhed by water, and many animals have no other food. "Rondelet§ cites a great number of examples of marine animals which cannot ſubſiſt but by means of water by the very conſtitution of their organs. He affirms, that he kept during three years a fiſh in a veſſel conſtantly maintained full of very pure water. It grew to ſuch a ſize, that at the end of that time the veſſel could no longer contain it. He relates this as a very common fact. We likewiſe obſerve the red fiſhes which are kept in glaſs veſſels, are nouriſhed, and grow, without any other aſſiſtance than that of water properly renewed †."

* *Surgical and Phyſiological Eſſays by Mr Abernethy. Lib. de ſenſ. lib i. cap. 12.*

§ 94 Some animals live in water alone.

† *Chaptal's Elem. of Chem. vol. iii. part 4. § 2. art. 2.*

The ingenious Borelli, who knew that plants and ſeveral animals ſubſiſted wholly by water and air, was likewiſe of opinion that ſome animals lived upon ſand. He could diſcover nothing but ſand in the ſtomachs of many teſtaceous animals that live in the water, and particularly in the ſtomachs of the ſmaller kinds that live buried in the ſand of the ſea. He could not conceive what elſe could be the food of thoſe ſmall fiſhes or worms which penetrate the ſubſtance of the hardeſt rocks, and form excavations that always bear a proportion to their bulk. He had regularly found that the ſtomachs of ſwans which he had examined were full of ſand; and, recollecting the pebbles in the gizzards of fowls, he was led to infer that theſe ſubſtances were ſomehow diſſolved in a gaſtric juice, and ſerved to nouriſh the harder parts, as the ſhells, the feathers, and the bones (B). Theſe ſentiments, on a ſlight view, might not be unnatural. From obſerving children of depraved appetites ſwallowing ſand, aſhes, and cinders; from having ſometimes met with ſand in the ſtomachs of wild ducks; from the uſual fæces of the earth-worm; and from the diſſection of ſeveral toads dug up in a garden, in whoſe ſtomachs we could ſee nothing but a quantity of earth, with pieces of coal, ſtone, and of ſlate, that had accidentally happened to be mixed with it (C), we long entertained a ſimilar opinion with this celebrated author: but on recollecting

Digeſtion.

95 Some animals ſuppoſed to live upon ſand, and why.

(A) What follows is from the 33d additional note of Dr Darwin's *Botanic Garden*.

"Dr Prieſtley obtained air of greater or leſs purity, both vital and azotic, from almoſt all the foſſil ſubſtances he ſubjected to experiment. Four ounce weight of lava from Iceland, heated in an earthen retort, yielded twenty ounce meaſures of air.

4	ounce weight of	Lava	gave 20	ounce meaſures of air.

"In this account the fixed air was previouſly extracted from the limeſtones by acids, and the heat applied was much leſs than was neceſſary to extract all the air from the bodies employed."

(B) A ſimilar inference was made by Mr Burt upon opening the ſtomach of the pangolin of Hindoſtan. See PANGOLIN.

(C) The third ventricle had a ſtrange body faſtened to its interior membrane. This body was compoſed of a hard membrane, in which there was gravel incloſed. Geſner ſays the chamois is accuſtomed to ſwallow gravel to clear his tongue and throat from the phlegm, which is apt to cover them, and deſtroy the appetite. *Anat. Deſcription of the Chamois or Gemp*, by the French Academy.

Digeſtion. ing that many ſubſtances which enter the ſtomach are not nutritious; conſidering the balls of hair and of feathers which the carnivorous animals return, and that quantity of fæcal matter which is diſcharged by the inteſtines; having frequently experienced that a ſenſe of fulneſs removes hunger, and obſerved perſons as it were by inſtinct preſſing on the empty ſtomach with their hand—we began to ſuſpect that the ſwallowing of ſand, and a number of other indigeſtible ſubſtances, might not be to nouriſh but to prevent ſome cravings of the ſtomach, and that theſe cravings were in part occaſioned by a deficiency of the uſual preſſure which it receives from the neighbouring parts. In this opinion we were more confirmed, by hearing it was cuſtomary among ſome of the tribes of the north of Aſia

96 Uſe of balls or ſand in the ſtomach. to repel or mitigate the attacks of hunger by placing a board over the region which is called epigaſtric, and compreſſing it gradually by means of cords as the ſtomach collapſes; and by learning afterwards, on a further inquiry, that a ſimilar practice, and from ſimilar motives, was likewiſe common with ſome individuals in this country; who, to alleviate the ſenſation of hunger, ſtraiten the epigaſtric region with their handkerchief. This practice, however, being often impoſſible with the brute kind, inſtead of bringing the neighbouring parts to preſs on the ſtomach, they are obliged to diſtend the ſtomach, and to bring it to preſs on the neighbouring parts. Of the two ways of producing this preſſure, the laſt is certainly the moſt natural. Senebier has ſuppoſed that diſtenſion of the ſtomach is the cauſe of the ſecretion of the gaſtric liquor; but how well or ill his opinion may be founded, daily experience permits not a doubt, that, in order to ſatisfy the calls of hunger, the ſtomach requires not only to be nouriſhed, but to be filled, or at leaſt to have ſomething like a ſenſe of fulneſs; and this may probably be one reaſon for thoſe balls which are found in the ſtomachs of the chamois, which likewiſe ſwallows ſand, and in the ſtomachs of the cow, the ſheep, and of the horſe, "when they do paſs away the winter in ſnowy mountains, where they can find no graſs" (D).

97 The organs of digeſtion in the vegetable. From this general view of the food, the natural tranſition is to thoſe organs by which it is prepared. As all plants are fed on nothing groſſer than liquids, we ſee the reaſon why they are all nouriſhed by abſorbents, and why, inſtead of one common alimentary canal, they are furniſhed with a number of capillary veſſels, which by their action aſſiſt the living power in moving the fluids along the trunk, the branches, and the leaves. Theſe fluids are obſerved to move between the different ligneous circles, and the more copiouſly as the wood is younger or the nearer the circles are to the bark. In the circles themſelves, it has been remarked that the ſap veſſels, from being empty during a great part of the growing ſeaſon, have been called air veſſels; that they are formed of ſpiral fibres, adapted to ſome periſtaltic motion(E): and it is plain, that by this ſtructure they are well fitted to propel their contents, whether water or air, upwards or downwards, backwards or forwards, according to the different poſitions of the plant. Digeſtion.

98 Their action how promoted. Beſides the particular action of the veſſels, a general conculſion is received from the movement of the waters or winds, which ſerves as an exerciſe; a general dilatation is occaſioned by both moiſture and heat; and a general contraction by dryneſs and cold, which produce a motion ſomething ſimilar to that of the thorax‡.

‡ *Borelli de Motu Generat. et Vegetat. Plantarum*, prop. 132.

In the ſpringing ſeaſon the ſap aſcends through the empty veſſels before the leaves begin to appear. When the veſſels are filled through their whole extent, the buds ſwell, the leaves ſpread, and the flowers blow; the evaporation from the ſurface is increaſed; the ſap is diminiſhed by the abſorption; the ſucciferous veſſels now ceaſe to bleed(F); and the roots being unable to ſupply the waſte, the rains and the dews enter by the trunk, the branches, the leaves, and the petals of the flowers. When the evacuations are immoderately increaſed by exceſſive heat, or preternaturally obſtructed by the plucking of the leaves, by too much humidity, or other cauſes which prevent perſpiration, the plant ſoon either ſickens or dies. The chyle, which is formed in the ſap veſſels, has generally ſomething of a ſaccharine taſte.

99 Abſorption of moiſture in the vegetable.

100 In the animal. Conſidering the forms of animal food, we may naturally expect in the animal kingdom a greater variety of thoſe organs employed in digeſtion. Moſt animals have indeed, like the vegetable, both inhaling and exhaling veſſels, by which ſome of their fluids are abſorbed, and evacuations regularly carried on. Except, however, in thoſe animals which ſubſiſt by liquids, theſe veſſels are of little importance in receiving food or ejecting what is fæcal from the ſyſtem. In theſe animals the abſorbents terminate in a hollow viſcus, which is called the alimentary canal, where the fluids undergo a preparatory change, and are partly reabſorbed for aſſimilation. In all others the food enters by a proboſcis (G), or by an aperture which is called the

(D) Bartholine, quoted by the French Academy, thought that theſe balls were compoſed of the hair which the cows lick from their ſkin, or of the wool which the ſheep eat. But the horſe does not lick himſelf, and many of theſe balls ſeem to be compoſed of ligneous fibres. The balls which are found in the chamois are called by Velſchius *German bezoar*. See *Anat. Deſcription of Chamois or Gemp*, by the French Academy.

(E) "The ſuperior part of the inteſtine, which contained about thirteen inches, had a very particular ſtructure; for, inſtead of the ordinary circumvolutions of the inteſtines, the cavity of this was tranſverſely interrupted with ſeveral ſeparations, compoſed of the membranes of the inteſtine folded inwards. Theſe ſeparations were near half an inch diſtant from each other, and turned round like the ſhell of a ſnail or of a ſtaircaſe with an open newel." *Anat. Deſcription of the Sea-fox*, ibid. Theſe membranous folds running ſpirally, are not uncommon in the alimentary canals of animals.

(F) This happens in a great many plants.

(G) Every perſon may have an opportunity of ſeeing a proboſcis in a number of thoſe winged inſects which extract juices from plants. It is very eaſily diſcernible in the butterfly. In this inſect it is a fine moveable tube,

Digeſtion

101 Food triturated in the mouth or ſtomach

the *mouth*: this mouth is properly the entrance of the alimentary duct. It is very generally furniſhed with a tongue (H), which is uſually aſſiſting in deglutition; and if the food be of that nature to require cutting, tearing, or grinding, it is likewiſe furniſhed with the proper inſtruments (I) for theſe operations. When the food is teſtaceous or ſome hard vegetable ſubſtance, and theſe inſtruments not in the mouth, ſomething ſimilar may generally be expected in a more remote part of the canal. The crab and the lobſter have accordingly grinding teeth in their ſtomach, and granivorous fowls have a powerful gizzard lined with a thick corneous ſubſtance. It poſſeſſes the compreſſing force of the jaws; and ſmall pebbles which the animals ſwallow ſerve it for teeth.

102 In what manner diluted

Beſides mere trituration or grinding, the ſolid food will often require to be mixed with ſome additional liquid (K). In thoſe carnivorous animals which chew, this liquid during the time of maſtication flows into the mouth from certain glands placed in the neighbourhood. In ſome ſpecies of the ape kind a previous dilution takes place in two pouches ſituated on the ſides of the lower jaw. In granivorous birds this dilution is very uſually performed in a ſac (L), which is a dilatation of the canal; and the food being macerated there by the glands or exhaling veſſels, gradually paſſes down (M), as is needed, to be triturated and farther prepared in the ſtomach. In the ruminating kind the dilution is performed in a ſimilar manner: but theſe having no muſcular ſtomach fitted for grinding, inſtead of deſcending the food is brought up again into the mouth, and is then after the proper maſtication ſent to the ſtomach. If the food require no maſtication, it is ſent directly that way at firſt: a circumſtance which ſhows a curious diſcernment with reſpect to foods, and proves that their alimentary canal is ſubject to the action of voluntary muſcles as far as the ſtomach. Some of thoſe birds which have a diluting ſac or ingluvies ſeem likewiſe to ruminate.

103 In different animals.

This in the parrot was obſerved by the gentlemen of the French academy. It has ſince been obſerved in rooks, macaws, cockatoos, and others: and Mr Hunter, to whom phyſiology is ſo much indebted, diſcovered, that the male and the female pigeon ſecrete in their ingluvies a certain liquor for feeding their young; and that moſt kinds of what have been thought ruminating birds do very often in expreſſing their fondneſs regurgitate their food. Yet both this and another ſpecies of regurgitation which is very common with thoſe animals that ſwallow indigeſtible ſubſtances with their food, ſhould be carefully diſtinguiſhed from rumination.

104 Rumination of birds.

105 Part of the ſtomach ſerves as a reſervoir.

To the ruminating kinds the diluting ſac is by no means peculiar. The porpoiſe has one, though it does not ruminate; and many of thoſe animals which have none, as the rat, the hog, and the horſe, have a part of the ſtomach covered with a cuticle, and which muſt therefore principally ſerve as a reſervoir. The gullets of ſeveral fiſhes and ſerpents are ſacs of this kind. It frequently happens that a part of their prey is projecting from the mouth, while another part fills up the gullet and gradually deſcends, to be reduced in the ſolvent below. So very dilatable are the ſtomachs and gullets of ſome animals, that ſerpents have been often ſeen to ſwallow whole animals which, prior to the gorging, were larger than themſelves; and many polypes, and even ſome of the louſe kind, will, by ſwallowing food, more than double their own bulk.

106 Number of ſtomachs.

Applying *ſtomach* as a general word to the different ventricles of the canal, we may here obſerve, that every ſpecies of animals which ruminate have two ſtomachs, or at leaſt two diviſions in one; that ſome have three, as the gazella; and ſome four, as the cow, the dromedary, and the ſheep: but it muſt not be ſuppoſed that the number of ſtomachs is any proof of a ruminating power. It was ſaid already that the porpoiſe has two; the porcupine has three diviſions in one; and the ſingular caſſowar, although it be found to have four ſtomachs, does not rumi-

---

tube, poſſeſſing a great variety of action. It ſerves for a hand, a mouth, and a gullet; and when not extended in ſearch of food, it is coiled up in circular folds. The elephant has both a mouth and proboſcis, and this proboſcis is one of the moſt ſingular of living organs.

(H) The crocodile has no tongue; the oſtrich, the ſeal, and ſome others, have forked tongues; the cormorant has a double tongue; ſome, like the eagle, have a cartilaginous tongue; ſome, like the porcupine, have it toothed. We have found a bone in the tongue of a gooſe; the tongue of the cameleon is a hollow trunk like a proboſcis; the tongue of the frog is forked and long—it is rolled up in the mouth, and originates from the fore-part of the lower jaw. In ſome the tongue is the organ of taſte; in others, the inſtrument for ſeizing their prey. In diſtinguiſhing foods moſt animals rely chiefly on ſmell.

(I) Theſe inſtruments are corneous, bony, or calcareous; they are teeth or bills; their ſituation is the tongue, the jaws, the palate, or the ſtomach. Many teeth ſeem intended only for attack or defence, for ſeizing, killing, or retaining the prey. This is remarkable in the fangs of ſerpents, and in the large tuſks of the elephant, the barbirouſſa, and ſome other animals, where they have ſome reſemblance to horns, and project from the mouth. The philodotus and ant-eater have no teeth; the larvæ of inſects have generally two, which are placed externally, and cut like a forceps.

(K) There are many perſons whoſe tongues and mouths are naturally dry, and when they ſwallow a piece of bread muſt call for water or ſome other moiſtener. This complaint is even ſometimes general in a family, and is propagated like an hereditary evil through its different branches. Cockatoos and parrots have likewiſe dry mouths.

(L) The buſtard has no ſac of this kind; but the œſophagus is remarkable for the largeneſs of its glands.

(M) In the oſtrich the œſophagus paſſes down and returns, and the crop opens from below upwards into the gizzard.

Digestion.

ruminate; nor, although granivorous, is any one of the four a gizzard.

Somewhat different from these expansions which we have been mentioning as existing in the first part of the alimentary canal, is a sort of pouch(N) which hangs from the neck and the lower mandible of several birds, and which, like the two pouches of apes, may be used either to macerate the food or to carry provisions from a distance to their young. The pelican, a native of warm countries, employs this pouch sometimes to carry a quantity of water; and another native of the same countries, we mean the dromedary, was observed to have at the top of the second of the four ventricles a number of square holes, which being the orifices of as many cavities between the membranes which compose the ventricle, reminded the gentlemen of the French academy of those large reservoirs of water which Pliny mentions to be in camels; and for which, according to his story, their guides have opened them sometimes in cases of extreme thirst.

107 Reservoirs of water in the pelican and camel.

We come now to one of the principal agents in digestion. Independent of the fluids which mingle with the food in the mouth, the gullet, or macerating sacs, there is one denominated the *gastric juice*, and which, either by itself or along with others from the aliments or system, acts in some measure as a solvent. It is secreted from large glands at the entrance of the gizzard, from vessels or glands in the coats of the stomach, and perhaps most plentifully near the pylorus: it powerfully resists the putrefactive fermentation; it coagulates milk and the white of an egg; it dissolves food even when inclosed in metallic tubes; and when life ceases, it acts frequently on the very stomach from which it was secreted. Its taste, its colour, and its solvent powers, are different in different classes of animals. It seems to be modified according to the age, the health, the habit, and the different aliments on which they live. The sick and the child are incapable of digesting the food that is proper for a healthy man. The hawk kind, after loathing bread and throwing it up without any change, can be gradually brought to take it for food; and Gassendi has mentioned a certain lamb which, being fed on bread, cheese, and on flesh, refused afterwards to taste grass*. But what is most surprising in the gastric juice is, that it spares all living bodies, as those worms which exist in the stomach, and the stomach itself while it is alive; and it differs otherwise from a chemical solvent, in that it has an assimilating power, and reduces all substances, whether animal or vegetable, on which it acts, to a certain fluid of determinate properties, which is called *chyle*.

108 The gastric juice.

* *Borelli de Nutritione Animal.* prop. 194.

Besides the gastric, the food again, after passing through the stomach, is mingled with a greenish saponaceous liquor, which is called *bile*, and which flows either immediately from the liver or from a vesicle into which it had regurgitated as into a blind gut; at the same time nearly it is mingled with another resembling the saliva from the pancreas or sweet bread; a gland or glands whose place is supplied in a great many fishes by a number of vermicular appendages to the stomach.

109 The bile and pancreatic juice.

Digestion.

In short, from one extremity of the alimentary canal to the other, fluids are perpetually flowing into its cavity from glands, vessels, or organic pores; and the membranes constantly secreting a mucus to protect themselves from the acrimony of their contents. This acrimony must often be considerable near to that end of the canal where the fæces are discharged; for as the first part of the canal has generally one or more dilatations which are called *stomachs*, and secretes at least one fluid which is strongly antiseptic, so the last part has generally appendages which are called *cæca*, where the food always remains for some time, and where, from the quantity of animal matter that happens to be mixed with it, it becomes putrescent. The office of the cæca is sometimes supplied by the largeness and convolutions of the colon(O); to which gut the ileum cannot, when it enters laterally, so easily communicate its peristaltic motion. As the stomachs were the receptacles of the food when it entered, the cæca are receptacles of the fæcal matter before it be discharged. They are of various forms and capacities; they are often larger than the stomach itself; are often composed of proportionally thin and transparent membranes; and from their contents have often a colour somewhat resembling that of the gall-bladder. Their number is different in different animals. Some have but one. The birds which have them have generally two; the bustard has three; and Swammerdam has dissected insects which had four. As some stomachs have a number of folds which hang pendulous within their cavity, and increase their surface, so have often the cæca as well as some portions of the canal. The cæcum of both the rabbit and the hare is curiously formed. It is large and beautiful; it is rolled up like a cornu ammonis; it has the like outward appearance; and a fold running spirally is observed within. The animals which live on vegetable food have usually the greatest length of the canal, and the greatest number of stomachs and of cæca: yet the cassowar, which has no gizzard, has no cæcum; and the polype, which is said to be all stomach, is properly speaking rather all cæcum.

110 Other juices.

111 The cæca of the alimentary canal.

To see more fully the process of digestion, we must not overlook that general and organic action which takes place through the whole alimentary canal. The power of mastication exerted in the mouth is obvious to all. But the force of some stomachs has till very lately been known to few; we allude here to that of the muscular or gizzard kind: for Abbé Spallanzani has divided stomachs into three sorts; the muscular, the membranous, and intermediate. The immortal Borelli, who was probably the first that tried the force of the muscular stomachs by throwing into them nuts of filberds, hollow spheres of glass, hollow cubes of lead, small pyramids of wood, and several other very hard substances, supposed that the power exerted by the stomach of the Indian cock(P) was equal to 3350 pounds

112 Action of the alimentary canal.

113 Strength of muscular stomachs first estimated by Borelli.

(N) A pouch of this kind is observed in our common rook.

(O) The bear, whose intestines are 40 feet long, has nothing resembling a colon or a cœcum.

(P) The original is *gallus Indicus*, which in the writings of Longalius, Gesner, and Aldrovandus, means a

Digestion. pounds weight. The force of an intermediate stomach cannot be so great, and that of a membranous one must be still less. Each seems to have more of the solvent as it has less of the muscular power. The most membranous are assisted by the action of the neighbouring parts, and expell their contents as readily as the strongest. The muscular sort is either wholly or principally confined to certain kinds of birds and of fishes, as nature has meant that the grain or the shells which they use as food should first be triturated before it be subjected to the gastric juice. This comminution takes place in their stomach, because it is plain that had bones or muscles, fully equal to all these effects, been placed in the head, the form of the animal must have been altered, or that equilibrium which it preserves in those fluid elements through which it moves been completely overturned.

114 Motions of the alimentary canal.

As to the movements of the alimentary canal, the direction of hairs found in the stomachs, and the balls of hair which are thrown up, would appear to indicate a circular motion. The intestinal part has a motion similar to that of a worm, and is called the *vermicular* or *peristaltic*. Here every portion retains its own motion, although it be separated from the rest by ligatures. The stomach of the polype, the gullets of the ruminating kinds, and the cœca, have this motion in different directions at different times; and that observed in the alimentary canal of a louse is, when viewed through a microscope in the time of action, amazingly rapid; the stimulating causes employed are the food, the different liquors with which it is mixed, the air, the nerves where they exist, and a portion of heat. Some degree of heat is necessary to every process of digestion both in the animal and vegetable kingdom: what that degree is depends on the nature of the living body; and is various according to its age, its health, its employments, and habits. The ingenious Hunter has mentioned the digestive and generative heats; and those gardeners who are versant in the operations of hot-houses, have on their thermometers the swelling, flowering, and the ripening heats, with a great many others for the several plants which they mean to raise.

Digestion.

115 The kinds of stimuli employed.

Among the other causes of digestion some authors have ranked fermentation: and it must be allowed, that something similar to the putrefactive fermentation takes place in the cœca and the lower extremity of the intestine, and that the vinous and acetous fermentations but too frequently occur in our stomach when that viscus is morbidly affected (q).

115 The vinous, acetous, and putrefactive fermentations.

Much of the history of living bodies relates to the different degrees of heat, the varieties of soil, and the kinds of food concerned in digestion. The plants grow where the soil and the heat are congenial to their nature; and those which admit of the greatest variety with respect to soil, and the largest range on the

117 Heat necessary to digestion.

---

bird different from the *coeq d'Inde* or Turkey cock. Johnston has called it *gallus Persicus*. See *The Anatomical Description of two Indian Cocks* by the French Academy. *Gallina Indica* is Ainsworth's Latin for the Guinea hen. See *Borelli de Nutrit. Animal.* Prop. 189, 190, 191.

(q) "It may be admitted as an axiom (says Mr Hunter), that two processes cannot go on at the same time in the same part of any substance; therefore neither vegetable nor animal substances can undergo their spontaneous changes while digestion is going on in them; a process superior in power to that of fermentation. But if the digestive power is not perfect, then the vinous and acetous fermentation will take place in the vegetable and the putrefactive in the food of those animals which live wholly on flesh. The gastric juice therefore preserves vegetables from running into fermentation and animal substances from putrefaction; not from any antiseptic quality in the juice, but by making them go through another process, prevents the spontaneous change from taking place.

"In most stomachs there is an acid, even although the animal has lived upon meat for many weeks: this, however, is not always the case; therefore we must suppose it is only formed occasionally. Whether the stomach has a power of immediately secreting this acid, or first secretes a sugar which afterwards becomes acid, is not easily ascertained: but we should be inclined to suppose from analogy the last to be the case; for animals in health seem to have the power of secreting sugar, as I find in the milk, and sometimes in the urine from disease. The acid prevails sometimes to so great a degree as to become a disease, attended with very disagreeable symptoms; the stomach converting all substances which have a tendency to become acid into that form: the sugar of vegetables, and even sometimes vinous spirits, turning directly into acid.

"To ascertain whether there is an acid naturally in the stomach, it will be proper to examine the contents before the birth, when the digestive organs are perfect, and when no acid can have been produced by disease or any thing that has been swallowed. In the slink calf, near the full time, there is acid found in the stomach, although the contents have the same coagulating powers with those of animals who have sucked.

"Spallanzani gives the opinion of authors respecting digestion; and so anxious is he to combat the idea of its being fermentation, that he will hardly allow that fermentation ever takes place in the stomach. That fermentation can go on in the stomach, there is no doubt. It is often found that milk, vegetables of all kinds, wine, and whatever has sugar in its composition, become much sooner sour in some stomachs than they would if left to undergo a spontaneous change out of the body; and even spirits in certain stomachs almost immediately degenerate into a very strong acid. All oily substances, particularly butter, very soon become rancid after being taken into the stomach; and this rancidity is the effect of the first process of the fermentation of oil. Mr Sieffert has been able to restore rancid oils to their original sweetness, by adding to them their due quantity of fixed air; the loss of which I consider as the first process in this fermentation, similar to what happens in the fermentation of animal and vegetable substances." *Observations on Digestion by Mr Hunter.*

Digestion.

the scale of heat, are the farthest dispersed over the globe. As every soil has usually some regular supply of moisture, the plants that can live upon that supply extend their roots under the surface where their liquid food is the least exposed to evaporation, and meeting there with the constant nourishment which they require, they remain in that situation for life (R). If their trunks be so feeble as to need a support, they creep on the ground, they climb the face of a neighbouring rock, or cling to the body of some of the stately children of the forest. Their range for food is extremely limited: it is chiefly confined to the small space which happens to be occupied by their roots and branches; yet if any uncommon exertion be necessary, the branches will bend, and the leaves turn to drink of the water that is passing by. If the roots be laid bare, they will again plunge into the earth; if a stone or a ditch be thrown in the way, they will move round or will dip downwards, and spread into the soil on the other side: if there they arrive at one that is unfriendly, they will not enter; but if a favourite earth should be near, though not in their direction, they will twist about, advance as they grow, and at last meet it. In all these cases the prop, the water, and soil, must be necessary; they must also be within a very small distance, otherwise the plants cannot perceive them, or will fail in their langu'd attempts to approach them.

118 One invention of the locomotive power in living bodies to procure food

119 Exerted by plants.

It may be considered as a general fact, that wherever food is liberally supplied for a whole lifetime in one place, the creatures which use it have seldom much locomotive power, or much inclination to exercise it in a long continued and progressive line. The curious insect is therefore observed to deposit its offspring in those places where the prospect of genial warmth and of plenty seem to preclude the future necessity of wandering or research; and when this offspring is about to pass into a new state, and the organs foretel that a change or perhaps a variety of food will soon be required, the appearance either of wings or of legs do likewise foreshow that the power of locomotion is to be increased. Even nobler animals in their fœtal state, where they live upon one species of food, and where that is afforded in regular plenty, do spread out their roots, adhere to their soil, and become as stationary as the plant itself; and even when that supply is withdrawn, and they are expelled, yet if the state into which they emerge be helpless and feeble, if their organs of digestion have a weak solvent or masticating power, particularly adapted to some easily assimilated food, and if that food be presented either by their parent or nature without their exertion, their powers of locomotion is not great, nor is it exercised in wandering afar. It is when the organs of digestion are strong, and the appetite inclines to variety of aliment, that they are disposed and feel themselves able to wander in search of it; and that then they may be ready to move at intervals from place to place, when the enemy comes or the spirit prompts them, nature has directed them to solid food, and has given them a large alimentary canal with stomachs, with convolutions, and cœca, where they may lay up provisions for a journey; but afraid to entrust them with too much freedom, lest in their excursions they might wander from the places where subsistence is found, there are two appetites, hunger and thirst, which never fail in a state of health to remind them of their duty.

120 Farther observations on the locomotive power.

Digestion.

This variety of food, and the manner in which it is affected by climate, are the cause of the many and singular migrations from spot to spot, from country to country, and from sea to sea: they are the cause of a state of torpor in the hedgehog and the bear, and they partly explain the provident foresight of the ant and of the bee. Animals of great locomotive power, in order to provide for themselves and their offspring, remove to a distant country or climate when they see the signs of approaching famine. Those of less locomotive power, and who are incapable of migrating far, as if warned by heaven, lay up a store for the scarcity to come; or should their food be of that kind as not to be easily preserved for a season, they receive no secret warning to hoard it at the time when it fails, their system becomes susceptible of torpor, and they are enabled to sleep through the storm of trouble and of want. The source of this want is in most instances to be traced to the nature of the plant and insect. The plant which has little heat of its own depends on the sun or some other agent for one of the great causes of digestion. When this agent refuses the necessary heat, the plant must decline; its leaves, its juices, and its fruits must fail. The insect tribe, which had no other food, or which like the plant could not maintain their vivifying warmth, must likewise submit to the same fate. The various animals which live on either the one or the other, according to their several dispositions and characters, retire to their flores, to their dens of torpor, or migrate to a country to which they are led by unseen guides to share in its abundance. Of these last the rail (S) and the swallow are the only two which are sometimes arrested, and which, with the bear, the hedgehog, and the toad, are obliged to remain in the dwellings of torpor till the genial season of warmth and of plenty.

121 Some final causes of the torpid state.

Sect. III. *Absorption.*

When the food has undergone the first preparation, which is called *digestion*, and the chyle (T) is formed in the

(R) Many of the fat plants live chiefly by the absorption of moisture from the air; and many sea-plants float through the ocean, and having plenty of food wherever they go, they send out no roots in order to search for it.

(S) All the birds on the lakes of Siberia are said by Professor Gmelin to retreat southward on the commencement of frost, except the rail, which sleeps buried in the snow. Account of Siberia quoted by Dr Darwin in his *The Loves of the Plants*.

(T) The chyle of different living bodies has not yet been analysed; in man it is generally a whitish fluid resembling milk, and yielding water, oil, sugar, and a coagulable lymph.

Abſorption. the alimentary canal or ſap-veſſels, it is thence taken up by means of abſorption for the uſe of the ſyſtem. From the veſſels it paſſes into the whole cellular tiſſue, compoſed of veſicles, and cloſely interwoven with all the vaſcular part of the plant. From the veſicles or utricles of the cellular tiſſue it enters the vaſa propria and glands, which contain and prepare the fluids and ſecretions peculiar to the ſpecies.

122 Farther progreſs of the food in plants.

123 In animals.

In the animal economy it was always ſuppoſed that the chyle was abſorbed by the ramifications of the red veins ſpreading on the gut, till the 1622, when Aſellius an Italian diſcovered the lacteals (u) running on the meſentery of a living dog, and printed his account of them in 1627. As he had not traced their courſe very far, he naturally thought that they went to the liver, which was then imagined to be the organ of ſanguification. This opinion, with reſpect to the place where they entered the veins, continued to be general till 1651, when Pecquet in France publiſhed his account of the thoracic duct (x). With great candour this author acknowledged, that he had been led to make the diſcovery by obſerving a whitiſh fluid mixed with the blood in the right auricle of the heart of a dog, which kind of animal it had been cuſtomary to diſſect alive ſince the time of Aſellius. "This practice of opening living animals furniſhed likewiſe occaſions (ſays Dr Hunter) of diſcovering the lymphatics. This good fortune fell to the lot of Rudbec firſt, a young Swediſh anatomiſt, and then to Thomas Bartholine (y) a Daniſh anatomiſt, who was the firſt who appeared in print upon the lymphatics. His book came out in 1653, that is, two years after that of Pecquet; and then it was evident that they had been ſeen before by Dr Highmore and others, who had miſtaken them for lacteals; but (adds Dr Hunter) none of the anatomiſts of thoſe times could make out the origin of the lymphatics, and none of the phyſiologiſts could give a ſatisfactory account of their uſe (z)." He had not known that Gliſſon, who wrote in 1654, has aſcribed to theſe veſſels the office of carrying the lubricating lymph from the ſeveral cavities back into the blood; and that Frederic Hoffman has expreſſed the doctrine of their being abſorbents very explicitly *.

124 The lacteals diſcovered in 1622.

125 Thoracic duct diſcovered in 1651.

126 Lymphatics diſcovered before 1653.

Abſorption.

127 Uſe of the lymphatics diſcovered before 1654.

* *Medic. Ration. Syſtem.* lib. i. § 2. cap. 3.

It was on the 19th of June 1664 that Swammerdam diſcovered the valvea of theſe veſſels; and Ruyſch, who had ſeen them, perhaps very nearly about that time, firſt gave an account of them in a ſmall treatiſe which he publiſhed at the Hague in 1665.

128 Their valves diſcovered in 1664.

The beſt mode of demonſtrating the lymphatics we probably owe to the celebrated Nuck, who, as a ſpecimen of that complete ſyſtem of Lymphography which he meant to publiſh (A), printed in 1691 his adenography, or deſcription of the glands. In this treatiſe he not only tells us how he brought them into view, but in his plates repreſents many of them as filled with his new mercurial injections; a happy invention, which perhaps was ſuggeſted by remarking the extreme ſubtility of mercury when employed in the cure of venereal infection.

129 Injected with mercury before 1691.

A method by which he inflated theſe veſſels led him to ſuppoſe that they took their origin from veins or arteries, either immediately or through the intervention of ſome follicles (B). The celebrity of his name procured credit to this miſtake; and notwithſtanding

(u) We learn from Galen, that the lacteals in kids had long before been ſeen by Eraſiſtratus, who called them *arteries*.

(x) This duct had been ſeen before by Euſtachius. See *Euſtach. de Vena ſine pari.*

(y) The diſcoveries of Rudbec and Bartholine were made in the years 1651 and 1652, about which time Jolyffe an Engliſhman ſaw alſo the lymphatics.

(z) Drs Hunter and Monro claim the merit of having found out the true uſe of the lymphatics. The former ſays that he taught it in his lectures ſo early as 1746, and appeals to his pupils for the truth of the aſſertion. The latter ſeems to have made the diſcovery in 1753; and in 1755 publiſhed an account of it in a theſis *De Teſtibus in variis Animalibus*. Before the printing of this theſis, Dr Black told him that the ſame opinions concerning the valvular lymphatics had been long entertained by Dr Hunter. In 1756 Dr Monro attended Dr Hunter's lectures in London; heard the whole doctrine of the lymphatics very fully explained; and in 1757 reprinted his opinion at Berlin without taking notice of Dr Hunter's, who charges him with plagiariſm; and the charge is retorted by Dr Monro.

(A) Lymphographiæ, quod offertur ſpecimen, ubi lectori non ingratum percepero ad alias tranſiturus tum partes, non minus quam hæ, lymphaticis ductibus ſuperlucentes. *Præfatio ad Adenographiam.*

Nuck had traced lymphatics on the exterior parts of the head and neck, on the membrane of the lungs, on the ſpaces between the ribs, in the loins, on the diaphragm, on the heart, the ſpleen, on the liver, the gall-bladder, on the ſtomach, on the meſentery, on the tunica albuginea of the teſtes, in the feet, and in the hands. Ita (continues he), ut multiplici experientia et variis partium præparationibus eo uſque pervenerim ut *integrum lymphaticorum ſyſtema* a capite ad calcem mihi compoſuerim, cujus delineationem libenter tecum communicabo, ubi partium nonnullarum hactenus nondum ſatis examinatarum, Lymphographiam abſolverimus. *Anton. Nuck de Inventis novis Epiſtola Anatomica ad D. D. B. G. Mod. Doct.*

(B) Quidam nervos conſtituunt vaſorum lymphaticorum principia; alii glandulas minores; alii membranas: nec deficiunt qui a tendinoſa muſculorum parte eadem deducunt. Sed miſſis aliorum ſententiis, dicam modo; varia me hanc circa ſpeculationem molitum fuiſſe, variis experimentis (irrito licet ordinario conatu) varia tentaſſe, caſuque tandem nonnulla detexiſſe quæ lucem, hic adferre poſſunt.

Ante triennium, mundando lieni vitulino intentus, omnique ſanguine, aquæ tepidæ ope, jam eloto, copioſum in arteriam ſplenicam infudi aërem, et, ſpiritu fortius adacto, non tantum plurimas exiguas in ſuperficie lienis vidi elevari veſiculas, ſed ex iiſdem veſiculis vaſa prodire lymphatica, flatu etiam turgida et lienem perreptantia vidi, et quo diutius arteria fuit inflata, eo majorem notavi vaſorum numerum, ita ut, hac arte per inflictum

Absorption.

the founder opinion of Gliſſon, of Hoffman, and ſome others, the old notion that the veins performed the office of abſorbents came ſo far down as the great names of Haller and of Meckel. The arguments, however, by which it was ſupported are ſhown now, and particularly by thoſe of the Hunterian ſchool, to have been injections that were not ſkilful, obſervations that were not accurate, and concluſions that were not logical; while the boaſted aſſertion that birds and fiſhes were without lacteals and without lymphatics, has been diſproved by the fortunate diſcoveries of Mr Hewſon and Dr Monro. Excepting, therefore, in the penis and placenta, and in thoſe animals whoſe veins may be injected from the gravid uterus, the lymphatics ſeem to perform the whole buſineſs of abſorption. They contain a fluid that is coagulable like the lymph of the blood, and are called valvular to diſtinguiſh them from the arteries that do not admit the red globules. They derive their origin from the cellular membrane, from the different cavities, and from the ſurface. Some authors ſay that they have ſeen them in the brain (c), and theſe Maſcagni has ventured even to deſcribe in prints. That ſome indeed may exiſt in the brain, has not been denied; but to believe that they have been found, and to truſt aſſertions which are not countenanced by the obſervations of ſkilful anatomiſts, requires a faith which for our part we do not pretend to. Both they and the lacteals derive their name from the colour of the fluids which they contain. They both empty themſelves into the veins; but moſt of the lymphatics in the human ſubject, and all the lacteals, firſt unite in the thoracic duct, which near the heart leads into the courſe of the circulation.

130 Diſcovered in birds and fiſhes.

131 Have been ſeen in the brain.

Sect. IV. *Circulation.*

After part of the food is converted into chyle, and this chyle abſorbed by the lacteals, and brought into the courſe of the circulation, it remains to be diſtributed to all the different parts of the ſyſtem. On this account, Hippocrates ſpeaks of the uſual and conſtant motion of the blood ‡, of the veins and arteries as the fountains of human nature, as the rivers that water the whole body, and which if they be dried up man dies §. He ſays that the blood veſſels are for this reaſon everywhere diſperſed through the whole body; that they give ſpirits, moiſture, and motion; that they all ſpring from one; and that this one has no beginning and no end, for where there is a circle there is no beginning (d). In ſuch language was the prince of phyſicians accuſtomed to expreſs his vague ideas of a circulation; for ſo far was he from having acquired accurate conceptions on this ſubject, that when he ſaw the motions of the heart, he believed that the auricles were two bellowſes to draw in air, and to ventilate the blood.

Circulation.

132 Hippocrates ſpoke of the circulation of the blood, but his language is vague.

‡ *Hippocrat. de Morbis*, p. 127.

§ *Hippocrat. De Corde.*

When after his time anatomy came to be more ſtudied, the notions of the ancients reſpecting the blood were better defined; and, however chimerical they may ſeem to us, they were partly derived from diſſection and experiment. On opening dead bodies, they found that the arteries were almoſt empty (e), and that very nearly the whole of the blood was collected in the veins, and in the right auricle and ventricle of the heart. They therefore concluded that the right ventricle was a ſort of laboratory; that it attracted the blood from the Cavæ; by ſome operation rendered it fit for the purpoſe of nutrition, and then returned it by the way that it came. From the almoſt empty ſtate of the arteries, they were led to ſuppoſe that the right ventricle prepared air, and that this air was conveyed by the arteries to temper the heat of the ſeveral parts to which the branches of the veins were diſtributed.

133 Arteries diſcovered to be almoſt without blood in dead bodies.

To this laſt notion entertained by Eraſiſtratus, Galen added an important diſcovery. By certain experiments, he proved that the arteries contained blood as well as the veins. But this diſcovery was the occaſion of

134 Proved by Galen to contain blood in living bodies.

---

fluctum vaſis lymphaticis vulnus aer immiſſus, membrana linealis fere tota lymphaticis ductibus obſeſſa fuerit viſa.

Ab eo tempore conjicere cœpi vaſorum lymphaticorum principia ab arteriarum ſurculis emanare, idque aliquando intermedia veſicula, aliquando deficiente veſicula, immediate ab ipſa arteria venave. *Adenographia curioſa*, cap. 4.

(c) Sed rogare videris, utrum in cerebro etiam vaſa occurrant lymphatica? Quamvis ex recentioribus, nonnulli in eorum deſcriptione ſatis liberales, eadem concedant et facile admittant: Verum, quod paſſim obſervo, ſyſtemata in proprio cerebro formant et viſcera ex ſuo placito componunt: ad experimenta enim provocati nihil egregii præſtare valent. Nunquam hac in parte, ut ingenue loquar, hactenus Scopum attingere potui. Interim non negandum cenſeo aliquando cerebri lymphatica in una aut altera parte fuiſſe viſa; et non ita pridem, anatomicus quidam mihi amiciſſimus, inter alia inventa, hæc nobiſcum, communicat. "Vidi, inquit, lymphaticum in cerebro Bovino, quod examine tuo (ut originem ſcias et inſertionem) erit digniſſimum. Non longe a glandula pineali, a qua ramos forte habet, incumbit plexui choroideo, ad infundibuli latera ſeſe extendens." Ante biennium ductum lymphaticum ex pini glandula eodem modo ut aliis glandulis, exeuntem vidi. Ita ut quidem certiſſimum, et cerebrum ſuos habere rivulos aquoſos, ſed nondum diſtincte, in lucem protractos. *Epiſt. Anat.*

(d) *Hippocrat. de Venis.* "Plato, in his Timæus, ſpeaks of the heart as a watch-tower completely fortified, as the knot of the veins, and the fountain from whence the blood ariſes, and briſkly circulates through all the members. The blood he calls the paſture of the fleſh; and adds, that for the ſake of nouriſhing the remoteſt parts, the gods have opened the body into a number of rivulets like a garden well ſtocked with plenty of canals, that the veins might by this means receive their ſupply of moiſture from the heart as the common ſource, and convey it through all the ſluices of the body." The reſt of the paſſage cited by Longinus is as full of nonſenſe as it well can hold: and indeed Longinus ſeems chiefly to have admired it for ſomething which had ſtruck him as divine and unparalleled in its tropes, as making the head a citadel, the neck an iſthmus, the vertebræ hinges, and the fleſh a rampart. See *Longinus on the Sublime*, § 32.

(e) Eraſiſtratus opened dead bodies at Alexandria.

Circulation.

of some embarrassment. How was the blood to get from the right to the left ventricle? To solve the difficulty in which his new discovery had involved him, he supposed that the branches of the veins and arteries anastomosed (F); that when the blood was carried to the lungs by the pulmonary vein, it was partly prevented by the valves from returning; that therefore during the contraction of the thorax it passed through the small inosculating branches to the pulmonary vein, and was thence conveyed along with the air to the left ventricle to flow in the aorta (G). This opinion, so agreeable to fact, unfortunately afterwards gave place to another that was the result of mere speculation.—This notion was, that the left ventricle received air by the pulmonary vein, and that all its blood was derived through pores in the septum of the heart.

135 How Galen supposed the blood to pass between the right and left ventricle of the heart.

The passage thro' the septum being once suggested, and happening to be more easily conceived than one thro' the lungs, it was generally supposed the only one for a number of centuries; and supported likewise, as it was thought by Galen's authority, it was deemed blasphemy in the schools of medicine to talk of another. In 1543, however, Vesalius having published his immortal work upon the structure of the human body, and given his reasons in the sixth book why he ventured to dissent from Galen, he particularly showed how it was impossible that the blood could pass through the septum of the heart. His reasoning roused the attention of anatomists; and every one grew eager to discover the real passage which the blood must take in going from the right to the left ventricle. The discovery of this fell first to the lot of Michael Servede, a Spanish physician, who published his opinion, and revived the old doctrine of Galen, in 1553 (H). But his opinion did not spread at the time; the book in which it made its appearance contained heresy, and was therefore destroyed by public authority. Fortunately, however, the same discovery was again made by Realdus Columbus, professor of anatomy first at Padua and afterwards at Rome, who printed his account of it in 1559. Many others who were engaged in the same research were equally successful, and Andreas Cæsalpinus even singularly lucky. It appears by his peripatetic questions printed at Venice in 1571, and reprinted there with his medical questions in 1593, that he knew not only the lesser circulation, but had observed that there were times when the blood flowed from the branches of the veins towards their trunks, and that veins swelled between their ligature and the extremities, and not between the ligature and the heart. From these observations, he necessarily inferred that the veins and arteries anastomosed; and having also contemplated the nature of all the valves which were then known, and had been known since the days of Galen, he ventured to assert that the blood could not return by the arteries to the left ventricle. One should imagine that from such conclusions he must have discovered the true circulation; but he did not. Being a zealous peripatetic, he thought himself bound to maintain with Aristotle that the blood flowed, like the tides of Euripus, backwards and forwards in the same channel; and therefore supposed that it flowed from the arteries into the veins in the time of sleep, and from the veins back into the arteries in the time of waking. The greater circulation, so far as we can learn, was not even dreamed of by this writer. A farther step was yet to be made towards its discovery; and this was reserved for another professor of the Paduan school.

136 Another opinion, supposed to be Galen's, refuted by Vesalius.

137 Vesalius roused the attention of anatomists to discover the true passage of the blood between the ventricles.

138 The passage discovered, and Galen's opinion revived, by Michael Servede and others.

Circulation.

132 The whole circulation very nearly discovered by Cæsalpinus.

140 Had almost forced itself upon Fabricius ab Aquapendente.

In 1574, Hieronymus Fabricius ab Aquapendente, while he was seeking for a cause to explain the varicose swellings of some veins which had arisen from friction and ligature, he to his great joy and astonishment discovered their valves in one of his dissections: and here again the true theory of circulation seemed almost unavoidable. Yet whoever reads the small treatise *De Venarum Ostiolis*, first printed by Fabricius in 1603, will soon perceive that he was as far from entertaining a just notion of the circulation as his predecessors. Notwithstanding all that he saw, he still was of opinion that the blood flowed from the heart to the extremities even in the veins. He thought that the valves were intended by nature only to check and moderate its force. He calls them an instance of admirable wisdom, and mistakes his own awkward conjecture for one of the designs of infinite intelligence. In another respect, it must be confessed that he bore no inconsiderable share in promoting the discovery of the circulation (I). By writing on the valves, the formation of the fœtus, and the chick in ovo, he directed the attention of his pupil Harvey to those subjects where it was likely that the motion of the blood would frequently occur.

141 At last discovered and fully demonstrated by his pupil Harvey.

Harvey was born at Folkston in Kent in 1578, completed his studies at the university of Cambridge, went to Padua, and was there admitted to the degree of doctor, with unusual marks of approbation, in 1602. He examined the valves with more accuracy than

(F) In toto est mutua anastomosis atque osculorum apertio arteriis simul cum venis. *De Usu*, part 6. cap. 10.

(G) It was the opinion of Galen, that the motion of the lungs and the pulse of the arteries was to cool the blood, and to expel the fuliginous vapour. That he had just ideas of the lesser circulation through the lungs, and of the true nature of the valves, is evident from the passages cited by Harvey, *De Motu Cordis*, Exercitat. 1. cap. 7.

(H) The words in which he mentions this discovery are these: "Non per parietem cordis, uti vulgo creditur, sed magno artificio a dextro cordis ventriculo, longo per pulmones ductu agitatur sanguis subtilis." Being born at Villa Nuova, in the kingdom of Arragon, he sometimes called himself Michael Villanovanus, or simply Villanovanus. In the title of all his books he takes the name of *Reves*, which is formed from Servede, by throwing out the *de* and transposing the five letters that remain. The book in which his discovery was mentioned was printed clandestinely, and intitled *Christianity Restored*. Being first imprisoned at Vienne in Dauphiny, and afterwards allured to Geneva by the treachery of his correspondent and confident John Calvin, he was, by a servant of that reformer's, accused of blasphemy, and condemned to the flames in 1553.

(I) Almost the whole merit of his discovery is due to the Paduan school, of which Cæsalpinus as well as Columbus was once a professor.

Circulation.

than his maſter Fabricius; and explained their uſe in a treatiſe which he publiſhed ſome time after. It is uncertain when he firſt conceived his celebrated doctrine of the circulation; but about the 1616 he taught it in his lectures, and printed it in 1628. He was the firſt author who ſpoke conſiſtently of the motion of the blood, and who, unbiaſſed by the doctrine of the ancients, drew rational concluſions from his experiments and obſervations. His books preſent us with many indications of a great mind, acute diſcernment, unwearied application, original remark, bold inquiry, and a clear, forcible, and manly reaſoning (κ); and every one who conſiders the ſurpriſe which his doctrine occaſioned among the anatomiſts of thoſe days, the ſtrong oppoſition that it met with from ſome, and thoſe numerous and powerful prejudices which it had to encounter from the ſanction of time and of great names, muſt allow it was new, and that the author has from its importance a title to rank in the firſt claſs of eminent diſcoverers ancient or modern.

142 The merit of Harvey in this diſcovery.

143 How the blood is circulated

His diſcovery ſhowed, that in moſt animals the blood circulates in arteries and veins, and through the medium of one, two, or of more hearts: that in arteries it moves from the trunk to the branches; and that, meeting there with the branches of veins, it returns in a languid ſtream to the heart; that the heart communicates a new impulſe; that it drives it on to the trunk of the arteries; and that the arteries, by the thickneſs of their coats, exerting a force, do puſh it onwards again into the veins.

In every part of this circulating courſe, there are valves ſituated where it is neceſſary; they are meant to prevent the return of the blood; they are at the beginnings of the great arteries, and are found in different places of the veins where their feeble action requires to be aſſiſted.

The veins, before they enter the heart, generally expand into a thin muſcular bag, which is called the *auricle*. It receives the blood while the heart is contracting; and when the heart admits of dilatation, contracts itſelf, and throws the blood into the ventricle.

We have here called the ventricle a heart; though what is uſually meant by the heart be a ventricle and auricle; or ſometimes a ventricle and two auricles, where the veins approach in different directions, and, without bending to meet one another, expand at two different places. Two hearts are ſometimes united, ſo as in appearance to form but one.

144 In different animals.

From our having mentioned more than one heart, it will be ſuppoſed that the modes of circulation are various. In ſome animals the heart throws its blood to the remoteſt parts of the ſyſtem (λ); in other animals it throws its blood only into the reſpiratory organs: from theſe organs it is collected by the branches of veins; and theſe branches, uniting in a trunk, convey it to an artery, which renews the impulſe, and acts as a heart. In a third ſet of animals, the blood from the reſpiratory organs is carried by the veins to another heart; and this ſecond heart, united in the ſame capſule with the firſt, diſtributes the blood by the channel of its arteries to the ſeveral parts. In the human fœtus, and the fœtus of thoſe animals which have two hearts, a part of the blood, without taking the paſſage through the lungs, proceeds directly from auricle to auricle. In amphibious animals, the auricular paſſage continues open during their life, and is employed, when the breathing ceaſes, under the water. In many inſects, a number of hearts, or expanſions which anſwer the purpoſe of hearts, are placed at intervals on the circulating courſe; and each renews the impulſe of the former, where the momentum of the blood fails. In the *Sepia Loligo* the two ſeparate parts of the gills are each ſupplied by a heart of its own: the blood from both is collected into one; which, by two arteries opening at two different parts, ſend it at once to the oppoſite extremities. In numbers of animals, the heart, like the ſtomach, is in the extremity oppoſite to the head.

Circulation.

145 How the circulation is demonſtrated in dead bodies.

After the diſcovery of the circulation, the moſt intereſting object with anatomiſts was to demonſtrate it in a clear, ſatisfactory, and eaſy manner. Harvey, to ſhow it with every advantage that he could think of, was obliged to open animals alive: but whether the animals were dead or alive, the larger branches of the veins and arteries were only to be ſeen, and even theſe but in certain caſes, when they happened occaſionally to be full of blood. That admirable method, which is now obſerved in demonſtrating the courſe of the circulation, we owe to the great anatomiſts of Holland who flouriſhed in the laſt century. About 1664, Regnier de Graaf invented the ſyringe, which is now uſed; and, accompanied with a print, publiſhed an account of it in 1669. His injection was uſually a thin fluid of a blue green or ſome other colour; this injection tranſuded through the veſſels, allowed them to collapſe by its general diffuſion, and broke out through the firſt opening that happened in its way. A fluid which hardened after being injected, and which preſerved the veſſels diſtended, was a happier contrivance. This at firſt was either melted tallow or wax, of a colour ſuiting the taſte of the anatomiſt. So early as the year 1667, the celebrated Swammerdam injected the veſſels running on the uterus with ceraceous matter; and, jealous

146 Diſcovery of De Graaf,

147 Of Swammerdam,

(κ) Dr Hunter ſays, that "none of his writings ſhow him to have been a man of uncommon abilities. It were eaſy to quote (he ſays) many paſſages which bring him nearly to a level with the reſt of mankind. He lived almoſt 30 years after Aſellius publiſhed the Lacteals, yet to the laſt ſeemed moſt inclined to think that no ſuch veſſels exiſted. Thirty hours at any time ſhould have been ſufficient to remove all his doubts; but this ſubject taken up in ſelf-defence (continues the Doctor) grows unpleaſant." Dr Hunter was here thinking of his own diſcovery when brought in compariſon with that of Harvey's. When this compariſon was leſs immediately in view, he ſays that "Dr Harvey, as appears by his writings, was certainly a firſt-rate genius for ſagacity and application; and his name is deſervedly immortal on account of the many obſervations and improvements he made in anatomy and phyſiology." *Dr Hunter's Firſt Introductory Lecture.*

(λ) We never exclude the action of the arteries.

Circulation.

jealous left another ſhould claim the merit of ſuch an invention, he tranſmitted preparations, accompanied with plates, and with a full account of his method, to the Royal Society of London in 1672. Soon after, his friend Ruyſch acquired ſuch ſkill in the art of injecting, that he has not been ſurpaſſed by any ſince his time. He diſcovered veſſels in many parts where they were not ſuppoſed to have had an exiſtence; and, contrary to the opinion of the great Malpighi, he ſhowed that even many of the glands were entirely vaſcular; and that what had been ſuppoſed excretory ducts, deriving their origin from ſome follicle, were but terminations of arteries continued: yet even Ruyſch could not exhibit in all caſes the courſe of the veſſels ſo well as we do now. Another diſcovery was yet to be made for demonſtrating their ſmall capillary branches running through a part. This was reſerved for the very ingenious Dr Nicholls of London; who invented the method of corroding the fleſhy parts with a menſtruum, and leaving the wax, as it was moulded by the veſſels, entire.

148 Of Ruyſch.

149 Of Dr Nicholls.

From theſe reſearches, which evince circulation to be a function ſo general among animals, ſome are diſpoſed to think it takes place in all living bodies. But notwithſtanding the faſhionable language of circulating fluids, of veins, arteries, and even of valves in the vegetable ſtructure; yet nothing performing the office of a heart, and nothing that ſeems to conduct fluids in a circular courſe, has been found in plants. In the vegetable kingdom, the chyle is diſtributed to all the parts from the numerous veſſels which convey the ſap: and theſe veſſels, being fitted by their ſtructure to carry the ſap either downwards or upwards, from the branches to the roots, or from roots to the branches; is the reaſon why plants inverted in the ground will ſend forth roots from the place of their branches, and ſend forth branches from the place of their roots. Even a ſimilar diſtribution of the chyle takes place in ſome animals. In the human tœnia, in the faſciola hepatica of ſheep, and in moſt polypes, the chyle, without a circulating ſyſtem, is conveyed directly to the different parts from the alimentary canal. The taſte for circulation may at laſt ſubſide. Till the buſineſs of abſorption from the inteſtines was, of late, fully ſecured to the lacteals, we were wont to have alſo learned diſſertations upon a circular motion of the bile. The jaunt which it took was not very cleanly; but it was ſocial: it went with the fœces down the inteſtines, and returned with the blood in the meſeraic veins.

150 Circulation not univerſal in living bodies.

151 None in plants nor in ſome animals.

Circulation.

152 A ſuppoſed circulation of the bile.

Beſides the circulation, another circumſtance reſpecting the blood, which ſometimes has engaged the thoughts of phyſiologiſts, is the colour which it has in moſt animals. The late Mr Hewſon was of opinion, that the lymphatics, with the ſpleen (M) and the thymus, contributed greatly to the formation of the red globules. He was ſeemingly led to entertain this opinion from that attention to the lymphatics which made him aſcribe much to their power, and from ſeeing red particles in the abſorbents which riſe from the ſplenic and the thymic gland. His reaſoning, however, though very ingenious, is not concluſive. The celebrated Nuck, who had often obſerved a reddiſh fluid in the lymphatics, aſſures us, without any hypotheſis, that ſuch an appearance was always preternatural; and was either occaſioned by a ſcarcity of lymph, or by ſome irregular and too much accelerated motion of the blood (N).

153 Opinions concerning the red colour of the blood.

It is well known that the blood receives its vermilion colour in paſſing through the lungs; that animals with lungs have the blood redder than thoſe which are ſeemingly without that organ; and that the colour, as well as the heat, is in proportion to the extent and perfection of the lungs. It has alſo been obſerved, that oxygenous gas is abſorbed in reſpiration; and been proved by experiment, that the red globules of the blood, and the red only, contain iron. It thence would appear, that the colour is owing to iron calcined by the pure air, and reduced to the ſtate of a red oxid. From this manner of conceiving the phenomena, ſays Chaptal, we may perceive why animal ſubſtances are ſo advantageous in aſſiſting and facilitating the red dye (O).

154 Reſpiration changes the colour of the blood.

A great variety of experiments have ſhewn how much the colour and conſiſtence of the blood is altered by

(M) Before we can expect to arrive at a proper knowledge of the ſpleen, we have firſt to examine its form, its proportion, its ſituation, its numbers, and its different circumſtances in different animals; and as yet this has been done only in a few caſes. The gentlemen of the French Academy found, that in the demoiſelle it was like the liver, in the buſtard like the kidney of a quadruped, in the chamois round and flat, in the lynx narrow and long, in ſome animals proportionally large, in others proportionally ſmall; that in the gazella it was joined immediately to the ſtomach, without a vas breve; that in the caſtor, again, it was attached to the left ſide of the ſtomach by eight veins and arteries, and as many vaſa brevia; that in the otter it was faſtened to the epipiploon, in the Canada ſtag to the great ventricle; and they found that in the porcupine and ſea-fox it was double. Since their time Dr Monro has obſerved two large ſpleens, one attached to the ſmall and the other to the large curvature of the ſtomach of the ſqualus ſquatina or angel-fiſh, whoſe blood contains few red particles; and the ſame eminent phyſiologiſt found in a ſturgeon no fewer than ſeven, one of the ſize of a dried horſe-bean, and the reſt about the bulk of a dried garden-pea.

(N) Interim non diffiteor vaſa illa lymphatica lympham ſubinde vehere rubicundo colore tinctam, loturæ carnis ad inſtar ſe habentem. Hoc autem nunquam contingit in ſtatu naturali, verum poſt nimium et irregularem ſanguinis motum. Vel in quibus humidum (ob defectum alimenti) deficit, qua occaſione plerique humores vitiantur, et colore præternaturali tinguntur. Quid mirum itaque hiſce in caſibus et lympham reddi ſanguineam. *Adenographia*, cap. 5.

(O) *Chaptal's Chemiſtry on the Properties of the Blood.* The phyſiologiſts of laſt century accounted for the red colour in another way. Rubedo ſanguinis (ſays Verheyen) pro magna parte procedere videtur ab alimentorum particulis ſalinis ac ſulphureis ſeu oleoſis exaltatis. Cujus non leve indicium eſt, quod lixivium ex cineribus vulgari modo paratum notabiliter rubeat, in quo, præter aquam, vix aliud quam ſal et ſulphur reperibile eſt:—et lac

(quod

Nutrition

155 Action of the veſſels changes the colour and qualities of the blood.

by the mere action of the veſſels; and this diſcovery has enabled us to conjecture with more certainty than we did formerly, why in infants and phlegmatic perſons the blood is paler, in the choleric more yellow, and in the ſanguine of vermilion red. It explains likewiſe, in ſome meaſure, why the blood varies in the ſame individual, not only with regard to the ſtate of health, but likewiſe at the ſame inſtant; and why the blood which circulates through the veins has not the ſame intenſity of colour, nor the ſame conſiſtence, as that of the arteries; and why the blood which flows through the organs of the breaſt differs from that which paſſes languidly through the viſcera of the lower belly. This power of the veſſels over the blood will bring us alſo to the true cauſe why the veſſels vary in the denſity of their coats and in their diameters; why they are ſometimes convoluted in a gland; why they ſometimes depoſite their contents in a follicle; why they are ſometimes of a ſpiral form; why the branches ſtrike off at various angles; why they are variouſly anaſtomoſed; why they ſometimes carry the blood with diſpatch and ſometimes ſlowly through a thouſand windings. By thoſe means their action is varied, and the blood prepared in numerous ways to anſwer the ends of nutrition and ſecretion.

156 Great variety of this action.

Sect. V. *Nutrition.*

Nutrition is the function which aſſimilates the food in the ſeveral parts, and which finiſhes the proceſs already begun in the ſtomach, in the lungs, and the vaſcular ſyſtems. In perfect animals ſome of the ſtages of this proceſs are diſtinctly marked. The chyle, which has ſome reſemblance to milk, is the work of the alimentary canal: it undergoes ſome new changes by the action of the lacteals and of their glands, when they exiſt. In the courſe of circulation it paſſes along the reſpiratory organs, and is mixed with oxygene or ſome other gas: by this mixture, the conſequent heat, and the action of the veſſels, it is turned into blood. The blood, when examined, ſpontaneouſly ſeparates into three parts; an albuminous part or a ſerum, a coagulable lymph (P), and red globules. The two firſt are analagous to the white parts of an egg, by which the chick in ovo is nouriſhed; the globules have ſome reſemblance to the yolk, which ſerves afterwards as food to the chick in the more advanced period of life. The three parts contain each a variety of principles which are originally compoſed of gaſes: theſe principles, conveyed through veſſels of various forms, of various diagonals, and with various degrees of motion and of heat, and all along varying as they paſs, arrive at laſt on the confines of the parts which are wrapt up in a cellular tiſſue or ſome other membrane. The tiſſue or membrane gives a new change; the parts nouriſhed perform the office of ſecreting organs; and as the action of the veſſels is varied according to the place to which they are tending and the parts which they enter, we partly ſee the manner in which bone, muſcle, cartilage, and nerve, are all ſecreted from a common maſs.

157 Food changed by different organs.

Nutrition.

In worms and polypes, the function of nutrition is after digeſtion carried on almoſt entirely by the cellular tiſſue; and in plants by a tiſſue cellular and veſicular. In all living bodies the cellular tiſſue, beſides giving a form to the parts, and beſides preventing friction and coheſion, certainly performs ſome important office. Many have thought it the organ of nutrition; and it ſurely is one of the organs employed in aſſiſting to aſſimilate the nutritious fluid. But it ſhould be remembered, that all the parts of the living body are aſſimilating organs; that each part aſſimilates for itſelf; and that the ſtomach, the reſpiratory organs, the veſſels, and nerves where they exiſt, are aſſiſtant to the whole and to one another.

158 Aſſimilated by the cellular tiſſue and the parts which are nouriſhed.

It is ſingular how any ſhould have imagined that the nerves are peculiarly the organs of nutrition, or that growth ſhould be owing to the addition of ſome organic and vivifying particles pre exiſting in the food. Theſe phyſiologiſts have not demonſtrated the exiſtence of nerves in all living bodies; and theſe organic and vivifying particles have as yet been diſcovered but in their fancy. Dr Monro has condeſcended to prove, that the limb of a frog can live and be nouriſhed, and its wounds heal, without any nerves: and Mr Hunter has given many curious inſtances of a living and nutritious power in the blood.

159 Opinions concerning nutrition and the organs concerned.

In plants and animals, the aſſimilating power has always certain limits preſcribed to it: its influence is very generally confined to the ſort of food congenial to the ſpecies: and its ſtrength is varied according to circumſtances; as the age, the habits, and the ſtate of health. Thoſe which are young aſſimilate faſter than thoſe which are old; and one ſpecies, which may partly be owing to the nature of their food, will aſſimilate much faſter than another. Certain worms that feed on animal and vegetable ſubſtances will, in 24 hours after their eſcape from the egg, become not only double their former ſize, but will weigh, according to Redi, from 155 to 210 times more than before. Moſt oils are of very difficult aſſimilation; and thoſe which are eſſential will often reſiſt the long continued and the varied action of the living organs; will mingle with

160 The rapidity and ſlowneſs of aſſimilation in different circumſtances.

161 Eſſential oils difficultly aſſimilated.

(quod ſulphure abundare probat butyri inflammabilitas), ſi coquatur cum ſale lixivioſo, colorem plane ſanguineum contrahat; quod ſimiliter decoctum ex aqua, ſulphure vulgari, et ſale tartari ad confectionem lactis ſulphuris patatum rubeſcat; quod cereviſia et quædam alia diuturniori coctione ruborem contrahentia, iiſdem principiis ſcateant, &c.

Ad intenſiorem ſanguinis rubedinem multum quoque contribuunt particulæ nitroſæ, quæ beneficio reſpirationis ex aere in ſanguinis maſſam jugiter tranſmittuntur: ſiquidem color ille coccineus magiſque ſplendens quo paſſim ſanguis arterioſus a venoſo diſtinguitur, in pulmonibus jugiter alitur ac renovatur.

Rubediuem autem hoc modo facile excitari poſſe amplius confirmatur ex eo, quod vitrum, etiam centum librarum capax per unicam unciam ſpiritus nitri rarefacti, omnino repletum appareat materia rubeſcente. *Verheyen de Sanguificatione.* Verheyen uſes the word ſulphur for any inflammable ſubſtance.

(P) Senac was the firſt who diſcovered this lymph.

Secretion. with the parts, and, undecompounded, communicate their flavour.

An aſſimilating power is not peculiar to living bodies; it is obſerved in ferments and contagion, and is ſo obvious with reſpect to flame which is neither living nor organized, that whole nations who have ſeen it feeding on inflammable ſubſtances, have been diſpoſed to think it was animated, to call it the principle of life itſelf, and to pay it a kind of religious homage as the proper emblem of that Being by whom the whole univerſe is upheld.

162 Aſſimilating power of flame.

In living bodies nutrition is only a ſpecies of ſecretion.

Sect. VI. *Secretion*

Is a function in which a part is ſeparated from the whole, and generally with ſome change of its qualities. In the caſe of nutrition it was obſerved, that all parts ſecrete for themſelves; and that ſome few, as the lungs, the ſtomach, the veſſels, and the nerves, officiate beſides for the general uſe of the whole ſyſtem. If all the ingeſta were to remain and to be aſſimilated, the body would go on continually increaſing. But living bodies are conſtantly in a ſtate of waſte and repair. In moſt animals part of the ingeſta is carried off by evacuation, without having entered the mouths of the abſorbents; part, which enters the abſorbents and veins, is thrown off by exhaling arteries or the urinary paſſage: and experiments with madder prove that the lymphatics, beſides originating from all the cavities and carrying back the lubricating fluids, do enter the ſubſtance of the hardeſt bones, and convey particles that had been aſſimilated back into the blood.

163 Every living body in a ſtate of conſtant waſte and repair.

164 An office not generally aſcribed to the abſorbents.

This office has not been generally aſcribed to the abſorbents; nor has it been very generally ſuppoſed that the blood receives the excrementitious matters of the ſyſtem, and that one intention of the circulation was either to return them for reaſſimilation, or to diſcharge them by exhaling veſſels or by the kidneys. Decayed parts, however, are diſcovered in the feces evacuated by the inteſtines, in the clouds, the ſediment, and colour of the urine, and by the ſmell of the perſpirable matter. The two laſt, on certain occaſions, and for ſome time, have often ſupplied the place of one another; and all the three, the feces, the urine, and perſpirable matter, we have reaſon to believe are remarkably diſtinguiſhed by two kinds of odour; the one peculiar to the whole ſpecies, the other peculiar to the individual. By the perſpirable matter which adheres to the ground, and of which the odour is diffuſed by moiſture, the dog not only diſtinguiſhes a man from any other animal, but is able to trace his maſter through a crowd.

165 Sweat and urine interchanged, and their odour.

The natural evacuations of plants, and of ſome few animals which feed by abſorbents, are all by perſpiration or exhaling veſſels. The urine in quadrupeds is before emiſſion collected in a veſicle, and thence carried off by the genital organ. In birds, and in a number of fiſhes, the ureters empty themſelves into the rectum, and their contents are evacuated along with the feces.

166 Evacuations of plants by exhaling veſſels.

Beſides being uſed to denote the function, the word ſecretion is ſometimes employed for the matters ſecreted. In this ſenſe there are various ſecretions. Beſides the feces, the urine, and the ſweat, and the vapour from the lungs, which are excrementitious, there are ſecretions which anſwer uſeful purpoſes in the ſyſtem. Of theſe the moſt important and general are the bile, the ſaliva, the gaſtric juice, and the pancreatic, which aſſiſt in digeſtion; the lymph and the fat, which lubricate the parts; the mucus, which protects them from acrid ſubſtances; the nervous fluid, which forms a very conſpicuous link between body and mind; the ſeminal fluid employed in generation to propagate the ſpecies; and the lacteal intended for ſome while to ſupport the young after they emerge from the fetal ſtate.

167 Some matters evacuated, ſome ſecreted for uſeful purpoſes.

168 The ſaliva.

The ſaliva is a fluid that mixes with the food in the time of maſtication. In man it is ſecreted from the parotid, the ſublingual, and ſubmaxillary glands (o); it is watery and ſomewhat viſcid; it is found to retard and moderate fermentation: it has ſometimes a tendency to form calculi like the urine. By theſe concretions it incruſts the teeth and ſometimes obſtructs the ſalivary ducts. It is the ſeat of the rabies canina.

169 Concretions formed by it.

170 The gaſtric juice.

Upon firſt examination the gaſtric liquor ſeems to poſſeſs a ſolvent power upon animal and vegetable ſubſtances without any great preference of affinity. The reaſon is, it varies according to the nature of the aliment; "it is ſometimes acid, ſometimes inſipid. Brugnatelli has found (ſays Chaptal) in the gaſtric juice of carnivorous birds and ſome others a diſengaged acid, a reſin, and an animal ſubſtance, united with a ſmall quantity of common ſalt. The gaſtric juice of ruminating animals contains ammoniac, an extractive animal ſubſtance, and common ſalt. In our time the phoſphoric acid has been found diſengaged in the gaſtric juice" of the graminivorous kinds.

171 The bile.

"The bile ſecreted by the liver is glutinous or imperfectly fluid like oil, of a very bitter taſte, a green colour inclining to yellow, and froths by agitation like the ſolution of ſoap. Its conſtituent principles are water, a ſpiritus rector, a coagulable lymph, a reſinous

(o) Theſe glands are very rarely met with in birds. It is mentioned as a ſingular circumſtance in the demoiſelle of Numidia, that "in the lower beak, on both ſides of the tongue, under the inward tunicle of the mouth, there were found two glandulous bodies, from whence proceeded ſeveral lympheducts which opened into the mouth, and there diſcharged, being ſqueezed, a white and viſcous humour. There were two of them towards the upper part a great deal bigger than the others. The tongue was fleſhy at top and cartilaginous underneath, as in hens.

"The tunicle of the palate was rough, with a great number of little nipples and of hard and membranous points. It likewiſe included a glandulous body, which ſhot forth two great ductuſes opening into the mouth. There was diſcovered a great quantity of other little glands at the ſides of the larynx, which had alſo ſome lympheducts." *Anat. Deſcript. of the Demoiſ. of Num. by the French Academy.*

Secretion.

oil, and ſoda. The reſinous part differs from vegetable reſins; becauſe theſe do not form a ſoap with fixed alkalis; becauſe they are more acrid and inflammable; and becauſe the animal reſin melts at the temperature of 40 degrees, and acquires a fluidity ſimilar to that of fat. From fat it differs in not being ſoluble in cold alcohol, in which reſpect it approaches to ſpermaceti, which alcohol cannot diſſolve without heat.

Bile, like other ſoaps, removes ſpots of oil from theſe ſubſtances to which they are adherent; when its paſſages are obſtructed the motion of the inteſtines becomes languid. It is neither alkaline nor highly putreſcent. In putreſaction it yields ſomething of a muſky colour; the foſſil alkali precipitates from it a green ſediment; and with diſtilled vinegar it produces a mixture neither acrid nor ſweet. Like ſaliva and urine, it has a tendency to form concretions which are called *biliary calculi* or *gall-ſtones*. They are ſometimes found of an irregular texture, of a brown, black, yelloviſh, or greeniſh colour. They ſometimes conſiſt of tranſparent chryſtalline laminæ, like mica or talc, and are ſometimes radiated from the centre to the circumference. They are always inflammable, of a more ſolid conſiſtence than the generality of animal oils, and reſemble ſpermaceti both in their ſolidity and chryſtallization; they are ſoluble in ardent ſpirit when aſſiſted by a moderate heat: the warm ſolution, when filtered, depoſites by cooling a number of laminated white brilliant cryſtals, ſuch as Poulletier de la Salle found in the bile, and which have been compared to the ſalt of benzoin, the concrete acid of borax, and to ſpermaceti. Many of their characters indicate that they are a ſubſtance of the ſame nature with the laſt mentioned. Fourcroy found that the ſubſtance of which theſe cryſtals are compoſed exiſts not only in the cryſtallized gall-ſtones or bile; he obſerved it to a very conſiderable degree in a human liver which had been expoſed to the air for ſeveral years, and had loſt its volatile parts by putrefaction. He detected it alſo in a ſaponaceous form in bodies which had been many years buried under ground; and lately Dr Pearſon of London has artificially converted the muſcular fibre into a ſubſtance of a ſimilar kind, highly inflammable, and reſembling ſpermaceti (R).

172 Concretions formed by it.

173 Muſcular fibre converted into fat.

The pancreatic juice reſembles the ſaliva, and was examined in the laſt century, with a good deal of care, by De Graaf and Swammerdam. It has often been obſerved forming ſtony concretions (S).

174 The pancreatic juice.

The lymph conſiſts chiefly of water, but, like the ſerous part of the blood, contains a ſubſtance which is coagulable by heat, by acids, and by ſpirit of wine. It is found in the cellular membrane, in the ventricles of the brain, in the pericardium, on the ſurface of the pleura, in the abdomen, in the burſæ mucoſæ, and in the joints under the name of *ſynovia*, where it has more than an ordinary degree of viſcidity and of the lubricating quality. Sometimes, when it ſtagnates in the ſheathes of the tendons and burſæ mucoſæ, it acquires a thickneſs and forms indolent tranſparent tumors, which become at laſt gelatinous. It is ſecreted chiefly by arteries.

175 The lymph.

Secretion.

176 Fat.

Animal fat is a ſubſtance of a nature ſimilar to thoſe oils which are called *fat* in the vegetable kingdom. Its colour is uſually white, ſometimes yellow, and its taſte inſipid. Its conſiſtence is various in different animals. In cetaceous animals and fiſhes it is nearly fluid: in carnivorous animals more fluid than in the furgivorous: in birds, finer, ſweeter, and more unctuous, and generally leſs ſolid, than in quadrupeds. In the ſame animal it is more ſolid near the kidneys and under the ſkin than in the vicinity of the moveable viſcera. As the animal grows old it becomes yellower and more ſolid; and in moſt animals is more copious in winter than in ſummer. In man and ſome other animals, it is collected in particular follicles of the cellular membrane, accumulated in great quantities in the groin, in the axilla, in the epipiploon around the kidneys and around the blood-veſſels: it is likewiſe ſecreted on the ſurface of the ſkin which it protects from acrid ſubſtances, and where it ſometimes concretes, often from a want of cleanlineſs, in the form of ſmall worms. In cetaceous animals and fiſhes it is generally diſpoſed in certain reſervoirs, ſuch as the cavity of the cranium and the vertebræ; in ſome it is chiefly confined to the liver; in ſerpents, inſects, and worms, to the viſcera of the lower belly, where it is diſpoſed in ſmall lumps, and only a ſmall quantity found on the muſcles and under the ſkin: in frogs it is collected in certain bags which diverge, as it were, from a common trunk, and ſeem like appendages to the ovaria and teſtes. In many places it ſeems to be ſecreted by organic pores, and under the ſurface of the ſkin by glands. It is accumulated from a diminution of perſpiration, from the nature of the aliments, from morbid affection, and from idioſyncraſy. It is of the ſame nature as the fixed oil of plants; and Lorry has found a ſtriking analogy between it and the bile *.

177 Its kinds in different animals.

178 Where found in different animals.

179 Analogous to the bile.

* See *Fourcroy.*

It is a bad conductor of heat, and preſerves the warmth of thoſe regions where it is ſituated. It is more adheſive and leſs apt to evaporate than water, and is therefore a better lubricating fluid. When reabſorbed, it counteracts the ſaline impregnation if too copious;

180 Its uſes.

(R) The means which he uſes is digeſtion in water; and the proceſs ſuppoſes a previous acquaintance with what is common and what peculiar to the fibre and the fat. He maintains that the fibre is entirely compoſed of carbone, oxygene, hydrogene, and azote. In a high temperature theſe are decompoſed, or at leaſt ſeparated, without producing fat. But when the fibre is kept in water in a low temperature, the carbone unites with the hydrogene of the water, and forms a fat reſembling ſpermaceti, and highly inflammable. Part of the oxygene, too, uniting with azote, forms the nitric acid; and part of the azote uniting with the hydrogene conſtitutes ammonia; ſo that three ſubſtances are thus formed.

(S) De Graaf was of opinion, that calculi might be formed in all glands. He had ſeen them above twenty times in the pineal gland, that was long thought the reſidence of the ſoul:—He ſays, too, that they occur more frequently in the pineal gland of Frenchmen than of Dutchmen; and very pleaſantly aſſigns this reaſon, that the volatile ſpirit of a Frenchman requires more ballaſt than that of a Hollander. *De Succo Pancreatico*, cap. 7.

Secretion.

copious; and its nutritive power is as three to one when compared to that of the muſcular fibre. Theſe properties may partly ſerve to explain its uſes around the ſeveral branches of the blood-veſſels in thoſe parts which require warmth, and in thoſe which are anywiſe expoſed to motion. They will likewiſe account for its being more copious in winter than in ſummer (T); and for its being found in great quantities in the marmot, the dormouſe, in the bear, and thoſe animals in general which are conſtrained to a long abſtinence. It forms ſometimes ſteatomatous tumours, and contains the ſebacic acid, which acts readily on lead, copper, and iron.

181 Vegetable fat.

The vegetable fat is contained chiefly in the fruit; and is known by the names of *fat oil*, *ſweet oil*, and *oil by expreſſion*. It freezes in different degrees of heat, and varies according to the nature of the plant by which it is afforded.

182 The mucus.

The mucus is more viſcid than the lymph, and is not coagulable by fire or alcohol. It is mild, not diſpoſed to corruption, nor ſoluble in water. This ſecretion is performed by glands. Theſe glands, in the pulmonary phthiſis, ſecrete often a mucus that reſembles pus, and occaſions a ſuſpicion of ulcers where there are none. Mucus is found in the noſe, through the whole length of the alimentary canal from the mouth to the anus, in the aſpera arteria, in the bronchia, in the kidneys, ureters, bladder, and moſt of all in the urethra. It forms hard ſtony concretions ſometimes in the lungs.

183 Concretions formed by it.

184 The ſeminal fluid.

The ſeminal fluid has been ſeldom the ſubject of chemical analyſis. It is heavier than water, ſoluble in urine, deliqueſces in air and with heat, it hardens with the fixed alkali, and is not coagulable by alcohol. It contains a number of animalculæ; and in the ſyſtem in which it is ſecreted, it affects the paſſions, the manners, and the voice, the taſte of the muſcles, the ſecretion of fat, and the growth of the hair. In many fiſhes this fluid is contained in a ſort of bags. In moſt animals it is ſecreted by glands, which are called *teſtes*, and is accumulated in the vaſa deferentia, or where they exiſt in the ſeminal veſicles. Of theſe veſicles Swammerdam obſerved long ago, that in the ſcorpion they were probably "adapted by nature to ſecrete a ſeminal matter different from that ſupplied by the teſticles; they are largely (he ſays) ſupplied with glandules to anſwer that purpoſe, and conſiſt of a conſiderably thick and ſpongy ſubſtance." Mr Hunter ſince has endeavoured to ſhow that they ſecrete a particular fluid in all animals.

185 The nervous fluid.

So little are we acquainted with the nervous fluid, that ſome have doubted of its exiſtence. The diſcovery, however, of Galvani, and the numerous experiments that have ſince been making on animal electricity, leave us not without all hope that ſomething yet may be known of its properties that will greatly illuſtrate ſeveral phenomena in the animal economy.

186 The milky fluid.

The lacteal ſecretion is generally confined to one ſex, and is peculiar to the claſs of mammalia, though ſomething ſimilar may perhaps be ſecreted in the crops of pigeons.

It would be impoſſible here to enumerate or to tell the uſes of all the different kinds of ſecretions in living bodies. We cannot enumerate all that we know without running into tedious detail. The eſſential oils, the camphor, the gums, the balſams, the reſins, and many others, are various ſecretions of the vegetable kingdom. Each ſpecies of plant and animal has generally ſome peculiar ſecretion; and this ſecretion in the individual has often ſome diſtinguiſhing quality, diſcoverable by taſte, by colour, or by ſmell. Theſe different ſecretions have likewiſe each their particular uſes. We know the intention of the oily juice with which the bird dreſſes its feathers, of the glutinous fluid of the fiſh, of the viſcid mucilage of the ſnail; we ſee the purpoſe for which the viper ſometimes employs its virulent humour, and for which the ſcuttle-fiſh ejects its ink: but yet we know only in part.

Secretion.

187 Each ſpecies has peculiar ſecretions.

188 Cauſe of difference among the ſecretions.

The difference among the various ſecretions of the ſame ſyſtem ſeem principally owing to a difference of ſtimulants, and to ſome difference in the action, the form and the irritable power of the ſecretory organ. Paſſions of the mind very often affect the ſecretions; and it frequently happens that paſſion and medicine affect one ſecretory organ and not another. It is therefore probable that the organs of ſecretion, and the ſmalleſt fibre is an organ of this kind: we ſay, it is probable that the organs of ſecretion, like the eye, the ear, and all the different organs of ſenſe, are each affected in ſome meaſure by peculiar ſtimulants; as the ſtomach by hunger, the fauces by thirſt, and the genital organs by venereal orgaſmus.

189 To what reduced by chemical analyſis.

Fermentative mixture, and ſome original impregnation of the organs, have alſo been brought to explain the ſeveral phenomena of ſecretion. We conclude with obſerving, that however much the various fluids of living bodies may differ in appearance, chemical analyſis has generally reduced them to a water, a gluten, a ſaline impregnation, and an oil.

Sect. VII. *Integumation.*

190 Integumation.

All living bodies are furniſhed with one, two, or with more integuments, which are prepared by ſecretory organs, and which are a defence againſt thoſe injuries to which their ſituation is commonly expoſed. Of theſe integuments, ſome prevent the diſſipation of the fluids, ſome again reſiſt acrid and corroſive ſubſtances, ſome are indigeſtible in the ſtomach, and ſome are ſeemingly incorruptible in the earth. By theſe properties they preſerve ſeeds and the ova of inſects for a number of years, waiting the change of ſoil or of ſeaſon. They protect both from the action of weak membranous ſtomachs, and make thoſe animals who chooſe to ſwallow them contribute likewiſe to their propagation. The gelatinous ſubſtance ejected by birds, and called the *tremella-noſtoc* or *ſtarfall*, we have lately found, by numerous experiments, to be a ſubſtance of this kind. It is nothing elſe than the oviducts of frogs, which, as the embryo in form of an egg moves along their winding canal, are intended by nature to ſecrete that tranſparent and viſcid glaire which

191 Some integuments indigeſtible in the ſtomach, and reſiſt corruption in the earth.

(T) The efficient cauſe may be diminiſhed by perſpiration.

Integumation.

which conſtitutes the albuminous part of the ovum, and feeds and protects the embryo in water (u).

192 Some integuments form a defence by their hardneſs;

Some integuments are chiefly uſeful by their ſtrength and hardneſs. The ſhells of the beetle are an excellent defence for the membranous wings which the creature is ſeen to pack up in folds when it inclines to creep into the earth. The ſhell of the ſnail lodges the inteſtines (x) when the animal comes forth to ſearch for its food, and it furniſhes a ſafe retreat for the body when any danger is threatened from without. Some animals, confined to their ſhells, can open and cloſe them by a muſcular power; and ſome ſhells, like the ſcales obſerved on fiſhes and inſects, are diſpoſed into plates, ſo as to be no hinderance to motion. Several inſects which ſpend a part of their time in the water always compoſe a ſhell for themſelves where it is needful. The uſual materials are ſand, ſtraws, or mud, which they cement by a viſcid ſecretion. The ſhells of moſt inſects are corneous. Swammerdam found that cretaceous ſhells are compoſed of layers of indurated membranes, and that they are ſometimes covered with a cuticle.

193 By their hair, down, or feathers;

Some integuments are covered with feathers, ſome with hair or a thick down. Beſides many other obvious uſes of theſe coverings, they ſerve in general to repel inſects; and being bad conductors of heat, maintain a genial and neceſſary warmth.

194 By their prickles;

When the integuments are covered with prickles, they repel attacks by the ſtrength of their points, or by the venom which they infuſe, as the ſtings of nettles and the downs of ſome inſects and plants.

195 By a viſcid ſecretion;

When they are moiſtened with a viſcid ſecretion, they preſerve the neceſſary ſoftneſs of the parts, prevent evaporation, reſiſt acrimony, enable plants to deſtroy their enemies, and aſſiſt the ſnail in performing its motions.

196 By their effluvia;

Both plants and animals, but particularly the former, are often protected by an odorous effluvia from their integuments. This effluvia is the finer part of their volatile oil, always inflammable, and ſo ſubtile, that the continual emiſſion of it from wood or flowers does not ſenſibly diminiſh their weight. To this fragrance it is owing, that the deadly nightſhade, the henbane, hounds tongue, and many others, are ſeen on almoſt every high road untouched by animals. The manchineelle-tree of the Weſt Indies emits ſo very dangerous vapours, that the natives poiſon their arrows with its juices, and thoſe have died who have ventured to ſleep under its ſhade. The lobelia longiflora of America produces a ſuffocating oppreſſion in the breaſt of thoſe who reſpire in its vicinity. The return of a periodical diſorder has been attributed to the exhalation of the rhus toxicodendron. Every one knows, ſays Chaptal, the effects of muſk and oriental ſaffron on certain perſons. Ingenhouſz mentions a young lady whoſe death was occaſioned by the ſmell of lilies; and Triller reports an inſtance of another who died in conſequence of the ſmell of violets. The ſelection of graſſes by different animals ſeems to be owing to the manner in which the volatile aroma affects their ſenſes. But of all the vegetable exhalations known, thoſe emitted by the bohun-upas, or poiſon-tree of Java, are the moſt remarkable. For many miles round no animal can breathe the air, no plant dares to peep from the ſoil, the fiſhes die in the poiſoned ſtream, and the birds that venture athwart the atmoſphere with deſpairing ſhrieks ſink down lifeleſs. Such often is the uſe of the fragrant oils in the vegetable economy. The ſhrubs and trees that are covered with thorns are in general a grateful food to animals. They generouſly avow their manner of attack, and ſcorn the dark aſſaſſination by poiſons.

Integumation.

197 By their colour;

The various colours of the integuments, as well as the aroma, is a ſpecies of defence. "Caterpillars which feed on leaves (ſays Darwin) are generally green; and earth-worms the colour of the earth which they inhabit. Butterflies which frequent flowers are coloured like them. Small birds which frequent hedges have greeniſh backs like the leaves, and light-coloured bellies like the ſky, and are hence leſs viſible to the hawk who paſſes under them or over them. Thoſe birds which are much amongſt flowers, as the goldfinch, are furniſhed with vivid colours. The lark, partridge, hare, are the colour of dry vegetables or earth on which they reſt; and frogs vary their colour with the mud of the ſtreams which they frequent (y), and thoſe which live on trees are green. Fiſh which are generally ſuſpended in the water, and ſwallows which are generally ſuſpended in the air, have their backs the colour of the diſtant ground, and their bellies of the ſky." The ſphinx-convolvuli, or unicorn-moth, reſembles in colour the flower on which it reſts; and among plants, the nectary and petals of the ophrys, and of ſome kinds of the delphinium, reſemble both in form and colour the inſects which plunder them, and thus ſometimes eſcape from their enemies by having the appearance of being pre-occupied. From colour being thus employed as a defence, many animals vary their colours with the ſeaſons and circumſtances; and thoſe which are of different colours in ſummer according to the places which they inhabit, do all in winter aſſume in common the colour of the ſnow.

198 By their change of colour.

But a change of colour is not the only change of the integuments. As the outmoſt are often inſenſible to ſtimulants, and for obvious reaſons poſſeſs little of the vital principle, in all caſes where they cannot be enlarged to admit an additional increaſe of growth, or where they are not furniſhed with neceſſary organs to repair thoſe injuries which they may ſuffer from diſeaſe or accident, the body is endowed by nature with a power to throw them off, and to produce others in their ſtead (z). For this reaſon we ſee the tree caſting annually its exterior bark, the lobſter his ſhell, the bird

199 Are changed themſelves.

(u) We have often inflated the oviducts of frogs, and dried them: and afterwards putting ſmall pieces of them into water, have ſeen them ſwoln in a few hours to a large ſize, and forming the tremella-noſtoc or ſtarfall.

(x) This ſnail is found in our gardens, and carries its ſhell, including the inteſtines, upon its back.

(y) The ſame is the caſe with many fiſhes that live in lakes.

(z) Several ſmall animals in changing their integuments change likewiſe the interior coat of the alimentary canal, which they void with the fæces.

Irritability. bird his feathers, the quadruped his hair, and sometimes his horns, the serpent his skin, and man himself renewing the scales of the epidermis. These changes

200 Toads eat the skin. usually take place once a-year, twice frequently with respect to serpents, and oftener in toads, who have been observed to devour the skin which they throw off. All the integuments of ova and seeds, being wholly the production of parental organs, neither are nor can be repaired.

Sect. VIII. *Irritability*,

201 Irritability. Is that property of the living fibre by which it acts in consequence of stimulants. Being one of the great causes of motion in living bodies, no property has excited more wonder, been the cause of more error, or exhibits such a number of striking phenomena to the senses. These effects, however, have arisen rather from the nature of the stimulants than from any thing mysterious in irritability. Many of the stimulants

202 The phenomena of irritability have led to strange conclusions. by which this property in bodies is displayed are often invisible, unknown, or unthought of; and men being conscious that a number of their motions proceed from a stimulant, that is, under the direction of a mental power, they readily conclude from a sort of analogy, that every motion in plant and insect that seems to answer a useful purpose, and is caused by some invisible stimulant, is the consequence of mind directing from within. They further suppose that irritability is in all cases the consequence of nerves, which are those organs which nature has employed in the animal kingdom to convey stimuli between body and mind. These singular conclusions have led to others that are less admissible even than themselves. It has been imagined that creatures the most stupid possess within them a principle of mind that is incapable of further improvement, but which notwithstanding is in many respects superior to reason, and a surer guide in whatever relates to self-preservation or that of the species: it enables the animal to predict without foresight, and to act rationally without intelligence. This wondrous principle has been called instinct: and in order to account for some of the singular phenomena of vegetables,

203 Some of these conclusions. a share of it has graciously been allowed to plants; which having become favourites of late, have been also presented with the privilege of sensation, permitted to fall in love, and to marry, and on some occasions to exercise the faculty of volition. Irritability.

At these concessions the metaphysician will naturally smile. He knows how many impose on themselves by the mere sound of their own words, as if by calling the snow black they were to discover a new property; which curious discovery would turn out at last to be only a gross ignorance of language, and the foolish misapplication of a syllable. He who has studied the philosophy of mind, and been accustomed to view objects through another medium than the magic colourings of passion and of fancy, readily perceives a something of absurdity in ascribing such wisdom to plants and insects. With respect to animals, these gentlemen do not recollect that voluntary actions are of two

204 Voluntary actions of two kinds, from design and propensity. kinds, as they proceed from design or propensity; that in performing one of these kinds the mind itself has an object in view, and is properly the source whence they originate; but that in the other the mind is merely a secondary agent, is acting under the influence of stimulants, is often not aware of the consequences, or although aware is often so infatuated as not to regard them, however fatal. It is generally well known

205 Whence propensities arise. to the naturalist, that not a few of these propensities arise from the form and structure of the body, from the manner in which the optic nerve is affected by colours, the olfactory by smells, the gustatory by tastes, and the auditory by sounds; from the different ways in which the sauces are affected by thirst, the stomach by hunger, and the genital parts by venereal orgasmus.

206 They act as stimulants through the medium of nerves. Besides these and other propensities which operate as stimulants in the system itself, the naturalist has found that light, heat, and moisture, in various degrees, from absolute darkness, coldness, and dryness, act as stimulants upon living bodies: he has experienced that electricity is a general agent, that several plants emit flashes (A), and that some animals even give shocks resembling the electric. He has made it probable that

(A) "In Sweden (says the author of the *Loves of the Plants*) a very curious phenomenon has been observed on certain flowers by M. Haggeren, lecturer on natural philosophy. One evening he perceived a faint flash of light dart from a marigold: surprised at such an uncommon appearance, he resolved to examine it with attention; and to be assured that it was no deception of the eye, he placed a man near him with orders to make a signal at the moment when he observed the light. They both saw it constantly at the same moment; the light was most brilliant on marigolds of an orange or flame colour, but scarcely visible on pale ones; the flash was frequently seen on the same flower two or three times in quick succession, but more commonly at intervals of several minutes; and when several flowers in the same place emitted their light together, it could be observed at a considerable distance. This phenomenon was remarked in the months of July and August at sunset, and for half an hour after when the atmosphere was clear, but after a rainy day or when the atmosphere was loaded with vapours nothing of it was seen. The following flowers emitted flashes more or less vivid in this order: The marigold, garden nasturtion, orange lily, African marigold; sometimes it was also observed on the sun-flowers; but bright, yellow, or flame colour, seemed in general necessary for the production of this light, for it was never seen on the flowers of any other colour. The flowers were carefully examined with a microscope without any insects or phosphoric worms being found. M. Haggeren, after having observed the flash from the orange-lily, the anthers of which are a considerable space distant from the petals, found that the light proceeded from the petals only; whence he concludes, that this electric light is caused by the pollen which, in flying off, is scattered upon the *petals (Observ. Physique par M Rozier*, vol. xxxiii. p. 111.)"—Addition to the note on *Tropæolum, the Loves of the Plants*. The author of this beautiful poem supposes, that the time of the twilight is sometimes extended by different bodies emitting the light which they had absorbed during the day.

Irritability. it produces all the wonders of cryſtallization; and that the cauſe of chemical affinity, and of all the phenomena diſplayed by the magnet, if not ſimply a modification, is at leaſt akin to it. In the male parts of plant and animal, he has ſeen both the fluid and the pollen that give the ſtimulus in generation, and are accompanied with ſo extraordinary changes in the ſyſtem. He has found that much of the vegetable economy, and that even the function of generation itſelf, as the developement of the fecundating powder, and its application to the female organ, is partly carried on by wind, heat, and other ſuch agents. He has reaſon to conjecture that many general agents in nature are yet unknown. By the help of chemiſtry, he has found out lately a conſiderable number which are called gaſes, which are of the very higheſt importance in both the animal and vegetable economy, and which, like the aromas of plants, or the cauſes of contagion, produce their effects without being viſible. It is only, too, of a late date that the celebrated profeſſor Galvani of Bologna has excited ſo much curioſity through Europe, by the diſcovery of a certain ſtimulus that reſides in the nerves, that paſſes along electric conductors, and which by a certain application of metals occaſions a vivid flaſh in the eye, convulſes the body of a living frog, and rouſes the detached limbs into action. The change of colour in the integuments according to different ſeaſons and circumſtances, though it anſwer a rational and uſeful purpoſe, proceeds from a cauſe that does not ſeem to be very well known. Even many agents which are not inviſible, nor yet unknown, exert their influence in a ſecret manner, ſo as not to be obvious to the ſenſes. It is generally known that many ſingular movements of plants are owing to heat, many to light, and ſeveral to moiſture. The barley-corn is often obſerved to creep on the ground by means of its awn, which dilates and contracts according to the different degrees of moiſture. The wild oat, employed as an hygrometer, moves through the barn, travels through the fields, nor ceaſes to be changing its ſituation till its beard fall off, or till it meet with a ſoil where it conveniently may ſtrike root. Upon a ſimilar principle of motion, the ingenious Edgeworth conſtructed an automaton which moved through a room which it inhabited. It is eaſily conceived how theſe ſingular effects, ariſing from cauſes that are unknown, inviſible, or unthought of, ſhould give birth to the notions of witchcraft and of inſtinct, and impreſs the fancy with an idea of ſomething reſembling ſenſation and volition in the vegetable kingdom. Theſe agents, whether inviſible, unknown, or unthought of, directed by regular and uniform laws under the great Author of nature, produce effects that indicate preſcience, wiſdom, and deſign, and cauſing a tranſient or permanent propenſity in the mental part, frequently controul by reſiſtleſs ſway the finite minds

207 Irritable principle affected by various ſtimulants.

208 Singular motions in plants.

that reſide in matter. Theſe minds, in a living body, have generally been found accompanied with ſome ſyſtem of nerves; and theſe nerves happening with equal facility and promptneſs to convey ſtimuli from the mind to the body and the body to the mind, the great difficulty has been to determine with reſpect to others when the action proceeds ſolely from deſign, ſolely from propenſity, or from deſign and propenſity together. The uniform conduct of the brute creation would ſeem to imply that their mind has little of inventive power; that it generally acts from the impulſe of propenſity; and that its manners are varied, not in conſequence of a change of ſentiments, but from the induction of new habits, and the application of new ſtimulants. Irritability.

209 Brutes act chiefly from propenſity.

It has been obſerved, that in all animals the vigour of mind has ſome relation to the quantity of brain, and to the perfection of its organization; and that the acuteneſs of the different ſenſes is generally proportioned to the quantity of nerve beſtowed on their organs (B). Man has a greater proportion of brain than any other animal; but many an animal has a much greater proportion of nerve beſtowed on different organs of ſenſe. Many animals have therefore acuter ſenſes than man; but man has a greater vigour of mind than any other animal on this globe.

210 Vigour of mind depends on the brain, the acuteneſs of the ſenſes on the ſtructure of their organs.

The brain of quadrupeds is ſomewhat ſimilar to that of man, but proportionally ſmaller, and not perhaps ſo well organized. Willis has obſerved, that among animals the ſtructure of the cerebrum is more variable than that of the cerebellum; that the former generally furniſhes nerves to the voluntary muſcles, and the latter with the medulla oblongata to the involuntary. He has likewiſe remarked, that the round prominences commonly called the nates and teſtes are large in the quadrupeds, which are active and vigorous, and in ſome meaſure able to procure their own ſubſiſtence at birth; that the tuber annulare is large in the quadrupeds that are diſtinguiſhed for their ſagacity; that wherever the tuber annulare is ſmall, the prominences are large, and wherever it is large the prominences are ſmall. From theſe obſervations he has concluded that the tuber annulare is the ſeat of genius, and the round prominences the ſeat of what has been called inſtinct (C).

211 The brain of quadrupeds

The brain of birds is ſeemingly the reverſe of the human brain; the cortical ſubſtance is the interior, and the ventricles are ſituated in the white part on the outſide. In the brain of the bird there are no circumvolutions like the inteſtines, no fomix, corpus calloſum, nor corpora ſtriata.

212 And birds.

The brain of fiſhes is in many reſpects ſimilar in its ſtructure to the brain of birds. It is very ſmall in proportion to their body, and is generally ſurrounded with an oily matter. In one genus of fiſhes, the gadus, Dr Monro found ſpheroidal bodies between the dura

213 The brain of fiſhes,

(B) The acuteneſs of the ſenſes depends upon the readineſs with which their organs are affected by ſtimuli. This readineſs depends on irritability. It is not neceſſarily connected with mind, nor ſhould it ever be confounded with perception, which in claſſical language ſignifies a property of the mental principle.

(C) Few perhaps who have diſſected different animals, and who, beſides a number of ſtructures, have ſeen a variety of tubercles and lobes exiſting in the brain, will be raſh in aſcribing to any one of them one particular office. The pineal gland was for ſome time thought the ſeat of the ſoul. It was afterwards found to be often

Irritability. dura and pia mater, and covering the greater part of the nerves like a coat of mail. The two ſenſes, ſeeing and hearing, in many fiſhes are often acute. By laying one ear on the water, and ſtriking the ſurface at ſome diſtance, this element is found to be a better conductor of ſound than even the air.

214 Of reptiles. The reptile tribes have very little brain, and like the fiſhes have no ganglions upon their nerves.

215 Of inſects. Moſt inſects have no brain at all, but a nervous cord that is full of ganglions, that runs from one extremity to the other, and is denominated the ſpinal marrow. This knotty cord, however, is not marrow; the inſect has nothing reſembling a ſpine; and the ſituation of the cord in the animal is often not along the back but the breaſt. In the ſilk-worm, and moſt other inſects, this cord is in contact with the alimentary canal; and the firſt ganglion, which is ſometimes called the brain, though not in the head, divides, in order to give a paſſage to the ſtomach, and again unites in a ſecond ganglion. Swammerdam found in a ſpecies of ſnail a brain with two lobes, in contact with the ſtomach, moveable by muſcles, and without a fixed place in the body.

216 A moveable brain in a ſpecies of ſnail.

217 Polypes. The polypes exhibit no appearance of brain or of nerve, as in other animals. Their ſkin, however, is obſerved to be full of a number of ſmall granulary bodies, which are connected by a glareous matter that reſembles a thread. Like rows of bead-ſtrings, they extend from one extremity to the other, and along the arms. Trembley learned from a number of experiments that they received their colour from the food, and therefore ſuppoſed them to be veſicles or glands. If not like the tuberous nerves of the inſects, they at leaſt are not very different in appearance from the nerves of the gadus that are covered with a number of ſpheroidal bodies like a coat of mail. Irritability.

218 Nerves act under other agents beſides mind. Some things would inſinuate that a nervous ſyſtem does not ſeem to be neceſſarily connected with mind. The ſtimuli of nerves may be brought into action by other cauſes beſides mind. Even many nerves are not ſubjected to the influence of mind; and the mind often by its own inattention may loſe the power which it originally poſſeſſed over nerves. Many perſons can move the muſcles of the ear, and others may have loſt that power through neglect. After Fontana had obſerved that the heart was a voluntary muſcle in a wheel polype, he learned to retard and accelerate the motions of his own at pleaſure. If ſome nerves, from a ſort of preſcription, thus ceaſe to be obedient to the power of mind, others by frequent ſervice and habit become ſo obedient as to convey their ſtimuli to the muſcles almoſt without the conſciouſneſs of mind. The motions excited by the ſtimuli of nerves are in many caſes exceedingly rapid. Theſe may be ſeen in the wings of moſt inſects, but are moſt noticed in dancers, tumblers, and apes, and all thoſe animals that are exhibited for feats of agility.

219 The great influence of the nerves. The motions which we ſee excited in the body by the ſtimuli of nerves have often been ſo vigorous and prompt, as to have torn the muſcle from the bone, and to have broken the bone itſelf. They often affect the organs of ſecretion, have often unhinged the fabric of the ſyſtem, occaſioned death, and accounted for the miracles that have been aſcribed to the power of fancy. The prompt motions of what have been named ſenſitive plants ſeem owing to a different ſpecies of ſtimulants acting on extremely irritable fibres (p).

In the animal kingdom all muſcles in the time of action

---

ten filled with ſtony concretions; and the celebrated Nuck, inſtead of aſſigning to it any prerogative, contented himſelf with writing its epitaph.

(p) In many inſtances the prompt motions of animals ſeem more owing to the irritability of their fibres than to what has been called the ſenſibility of their nerves. The poet was miſtaken when he ſuppoſed that the mangled inſect would feel as ſenſibly as a mangled giant. When the gad-fly fixes fairly on the hand, you may cut off its wings, its legs, its antennæ, and a part of the lower diviſion of its body, without diſturbing its gratification, or apparently occaſioning to it much trouble.

irritability; action are observed to discharge a quantity of their blood; and those muscles which are naturally white are the most irritable. In all living bodies, the irritable power will cease to obey the action of a stimulant if either long or violently applied. After exercise, therefore, the irritable fibre requires rest, after heat cold, after waking sleep, before it again becomes submissive to the action of the stimulant that overwhelmed it. This is the reason that in plants and animals there are certain exertions and functions of the system that can only be continued at intervals and seasons. The natural stimuli of involuntary muscles continue to act, and the muscles continue to obey through life.

210 What muscles are most irritable.

211 Effects of a stimulus when long continued.

212 Organs of sense intended to give distinct impressions.

The organs of sense were formed to mark the difference of stimulants; yet living bodies are affected by light without having eyes, by sounds without having ears, by odorous effluvia without having smell, and by sapid bodies without having taste. It is easily conceived how these objects, by their inherent properties or motion, may produce a confused sort of excitement in every highly irritable fibre. But the organs of sense are peculiarly fitted to receive accurate and distinct impressions from each of these objects; and these different impressions seem not to arise from any difference in the kind of nerves by which they are received. All the difference that has been observed arises from the structure of the organ itself, and from the manner in which the nerve is distributed through it. Other parts of the animal body, as the stomach, the fauces, and genital organs, are thus affected by particular stimulants; and many animals, and even vegetables, may be affected in various manners, and by various stimulants, of which neither our feelings nor our senses can give intimation of any thing analogous.

213 Different organs affected differently by the same stimulus.

214 The organs of sense.

With respect to the several organs of sense, some animals have many eyes without any motion, and some animals have few eyes with varieties of motion: The entrance to the ear in some animals is from the mouth, as happens in the frog; and the bones of the ear are without the cranium, as in some fishes. The sense of smelling is found in the nose: this sense is astonishing in dogs; and even sheep, in distinguishing their lambs, trust to it more than to seeing or hearing. The sense of taste is far from being general; and the sense of touch can hardly be said to reside peculiarly in any one organ.

Sect. IX. *Motion.*

215 Motion.

Irritability is one of the great sources of motion in all living bodies; and this power is brought into action immediately by nerves or some other stimulants.

216 Locomotion

Locomotion here is principally considered; for altho' the kinds of internal motion employed in secretion and the other functions be as remarkable, in the eye of the philosopher they have not so generally attracted the attention. Most animals are capable by nature of changing the place which their body occupies; for this reason the irritable fibres being formed into bundles, which are called *muscles*, are in most animals attached to bones, cartilages, or hard integuments, which they move as levers: these levers, with their muscles attached, are in most cases formed into wings, fins, and legs of various kinds, and are employed in performing the motions of flying, swimming, walking, leaping, and creeping. So very necessary, in the opinion of some of the ancients, was one or other of these instruments to progressive motion, that the movement of the serpent was often ascribed to a preternatural cause, was supposed to resemble the *incessus deorum*, and procured to the animal one of the highest and most honourable ranks among the emblematic kinds of divinities. Even Moses himself, who was unwilling to allow it the character of an agathodæmon or good genius, was yet so puzzled at its being able to move without feet, that he pronounces it a tool of the devil; and says that it was deprived of its feet by a curse from heaven for seducing mankind into idolatry. Notwithstanding, however, the surprise that has been occasioned by its singular movement, the motion of snails, though not so rapid, is in many respects as extraordinary: they adhere by a certain viscid secretion, on dry ground this secretion forms a pavement over which they glide; and they proceed by the action of muscles without bone, cartilage, or shell, to which these muscles can be attached.

Motion.

217 Performed by fins, wings, legs.

218 By the elasticity of spring of the body;

219 By muscles and a viscid secretion.

No animal walks without legs or flies without wings (E); but there are many that swim without fins, and that leap and creep without any legs. The rapidity of movement is not proportioned to the number of instruments that are employed: if the sprout-fish be observed to move slowly with one leg, the sea-urchin moves still slower with many thousands; the oyster moves by squirting out water; the scallop by the jerk of its shell, and when in the water it rises to the surface and sails before the wind.

220 Rapid motion depends not on the number of instruments employed.

221 Different ways of moving the body.

Many animals are formed by nature to fly, walk, leap, and swim: the fate of those is rather uncommon whose muscles or feet are by nature attached to their integuments; the lobster is obliged to throw off its shell, and the caterpillar all its feet with the skin, and in that situation to remain stationary till it receive new instruments of motion.

222 Instruments of locomotion changed.

Whoever has read the celebrated work *De Motu Animalium*, needs not to be told that, besides the organs which are here mentioned, the form, the structure, and even the specific gravity of the body, as depending on the nature of the bones and muscles, or as varied by air, vesicles, and bubbles, with a great variety of other circumstances, are necessary to explain the different phenomena of locomotion.

223 Many things necessary to explain locomotion.

As to vegetable motions, they evidently depend on external agents: The motion of the wild oat has been mentioned; the wings of seeds only fit them to be carried by the wind, their specific gravity to float in the water, and their legs or tentacula to adhere to bodies that are in motion; the singular motions which have been ascribed to sleeping, to waking, to sensation, and volition, in the vegetable kingdom, seem only the consequence of light, heat, moisture, and such stimulants, acting invisibly or with secret influence; the opening and closing of the meteoric flowers are always correspondent to the states of the atmosphere; and the opening and closing of the equinoctial and tropic flowers, to the light, the length, or shortness of the day.

224 Motions of vegetables.

The

(E) The fins of the flying fish enable it rather to spring than fly.

Habit.

234 Intention of locomotion.

The principal intentions of locomotion are to get food, to ſhun danger, to promote intercourſe, and diſperſe the ſpecies.

Sect. X. *Habit.*

235 Habit;

Habit here deviates a little from its uſual meaning. We employ it to ſignify that principle in living bodies by which they accommodate themſelves to circumſtances, aſſume as it were a different nature, and in many reſpects undergo a ſpecies of transformation.

236 Its effects on vegetables;

So very much do ſome individuals of the vegetable tribe accommodate themſelves to different ſituations, to ſoil, to climate, and the ſtate of cultivation, that thoſe naturaliſts who have not been accuſtomed to nice and accurate diſcriminations, have frequently miſtaken the variations of the ſame plant for ſo many ſpecies. Theſe variations may be daily ſeen by examining the plant as it grows on the mountains, in the valleys, in the garden, or in the fields; or by bringing it from a rude uncultivated ſtate, when it ſometimes lays aſide its formidable prickles, and changes the colour and ſtructure of its flowers.

237 On the conſtitution and integuments;

In the plant and animal, the delicacy and vigour of the conſtitution are oftener the effects of habit and circumſtance than original conformation. We have mentioned already the varying colour of the integuments, and the purpoſe which it ſerves in changing with the ſeaſons. We may here add, that animals covered with a down or hair have it thick or thin, long or ſhort, according to the different exigencies of climate.

238 On manners and propenſities;

Thoſe changes produced on their body are accompanied with others which are the cauſes of new taſtes, of new propenſities, and new manners. At the Cape of Good Hope the oſtrich inclines to ſit on her eggs day and night like any other bird; but in Senegal, where the heat is great, ſhe is ſomehow diſpoſed to leave them to the ſun during the day. In thoſe countries where proviſions can be found during the greateſt part of the year, the bee gradually loſes the propenſity of laying up ſtores for the ſeaſon of winter; and in "thoſe countries infeſted with monkeys, many birds (ſays an amuſing and inſtructive writer) which in other climates build in buſhes and the clefts of trees, ſuſpend their neſts upon ſlender twigs, and by this ingenious device elude the rapacity of their enemies."

239 On man.

Man, from imitation, is expoſed to a great number of habits peculiar to himſelf; and phyſical cauſes have ingeniouſly been aſſigned for the variety of his features and complexion.

240 The extent of its effects unknown.

Few experiments have yet been inſtituted with a view to ſhow how far this accommodating principle in nature may be extended in the different ſpecies of plants and animals. It is known, however, that the lamb and the dove can be made carnivorous; and that the hawk, laying aſide his ferocity, can be brought by art to live upon grain.

Habit.

Of all the effects of this ſingular principle, the moſt wonderful are thoſe which are ſeen to take place with reſpect to generation. The fact is far from being new to the naturaliſt, that certain animals, oviparous at one ſeaſon, are viviparous at another. This indicated much of accommodating power, though far inferior to what has been ſince witneſſed and diſplayed: for who from all this could ſuſpect, that any animal which uſually propagates by an intercourſe of ſexes, could in any circumſtance accommodate ſo far as to multiply its ſpecies another way. Bonnet of Geneva, however, has diſcovered, that the puceron or vine fretter, which generally propagates by an intercourſe of ſexes, is not only oviparous at one period and viviparous at another, but in all caſes where the union of the ſexes is not to be obtained, can eaſily accompliſh all the purpoſes of generation without it. Similar experiments have likewiſe proved, that many plants can bring to maturity a productive ſeed, though the male parts of the flower be deſtroyed before they can in the uſual way have any impregnating effect on the female. In this caſe the concluſions drawn have been ſomewhat new. From theſe experiments it has been inferred, that the ſexual ſyſtem is ill-founded, and that moſt of the learned naturaliſts of Europe are on this ſubject labouring at preſent under a miſtake. This reaſoning, however, is not ſatisfactory: for why, it might be aſked, in the vegetable kingdom more than in the animal, ſhould the mode of generation be neceſſarily uniform? Tho' ſome plants may, like ſome animals, propagate without ſexual diſtinctions, the concluſion is not logical that theſe diſtinctions are uſeleſs in all; and though ſome few may, in particular inſtances, propagate without that impregnation to which they were accuſtomed, will any one demonſtrate, that accommodating nature does not here as in the puceron adopt a new method to accompliſh her deſigns?

241 How far it accommodates with reſpect to generation.

In all living bodies, it frequently happens that ſeveral characteriſtic diſtinctions, as the colour, the features, and a number of diſeaſes that are originally the effects of circumſtance, do at laſt become ſo fixed in the ſyſtem, that they are afterwards tranſmitted to poſterity through ſome generations (F). With regard to animals theſe facts are well known; and as to vegetables, it has been obſerved by a pupil of Linnæus, that the apple-trees which are ſent from Britain to New England bloſſom at firſt too early for the climate, and

242 Its effects laſting and ſometimes propagated.

(F) Might not theſe facts reaſonably claim the attention of thoſe who mean to form matrimonial connections? How many might eaſily entail on their poſterity hale conſtitutions, regular features, beautiful forms, ſound minds, and tempers at once uniform and cheerful, who yet, from their ſordid deſire of wealth or their fond admiration of high rank, bequeath to them only ſcorbutic habits, deformed perſons, diſagreeable features, mean underſtandings, and forbidding tempers. Excepting the more extraordinary properties of body and mind, there are few that may not in ſome meaſure be tranſmitted to poſterity: but nature ſeems unwilling that what is very eminent ſhould ever be extended to a genus or a ſpecies; and therefore the ſons of Cicero and Cromwell are only two of a thouſand inſtances that might ſerve to prove, that neither extenſive nor eccentric geniuſes can be made hereditary: In the ſecond generation they often degenerate into minds that are weak, fatuous, or deranged; or into minds that are chiefly remarkable by their oddities and whims.

Habit.

and bear no fruit; and that it is only after some years that they conform to their situation: and this circumstance, by the way, explains why roots and seeds germinate sooner when brought from southern than when they are brought from northern latitudes. The very permanency of these effects has often been the cause of much confusion and error in philosophy: for the naturalist, mistaking the lasting though temporary qualities of habit for the real and essential qualities of species, has not unfrequently drawn conclusions from his experiments that have been contradicted by similar experiments in other circumstances. This is one of the obvious reasons why experiments exhibit so many inconsistencies and contradictions, and why we are amused with such a multitude of visionary theories about the properties of living bodies.

243 Renders the result of experiments delusive,

244 And medical prescriptions often dangerous.

From not attending to the numerous circumstances that induce habits, and to that general accommodating principle in living bodies, many medical prescriptions are found to be not only useless but mischievous; and many parents, by studying the health and comfort of their children, bring on habits that prove the sources of perpetual sickness or the certain presages of an early death.

245 Its origin;

The accommodating principle is one of the consequences of irritability. Its various effects arise from the actions of different stimulants on the irritable fibre; and the after-duration of these effects, from the modifications of the irritable fibre, become habitual from the frequently repeated action of the stimulants.

246 Its design.

The design of this accommodating principle is to fit both the plant and the animal for a more extensive and a more varied range of existence.

Sect. XI. *Transformation.*

247 Transformation

More remarkably striking than any of those changes to which the plant and animal are exposed, from the variations of habit or the change of integuments, are those alterations which they undergo from metamorphosis or transformation. It has indeed been asserted, that these alterations consist in throwing off certain temporary coverings or envelopes: but there is here a want of precision in the ideas, and consequently a want of accuracy in the expression. The same persons who make this assertion inform us, that caterpillars change their skin, and many of them even several times, previous to the period of their transformation. Transformation, therefore, and a change of integuments, by their own concessions, are different things. The truth is, transformation frequently takes place independent of any change of integuments; and there is often a change of the integuments without transformation or any appearance of a new form: but a new form or change of appearance is always implied in metamorphosis or transformation. This new form is sometimes occasioned by a change of shape, consistency, and colour; as when the lobes of a seed are converted into seminal leaves. It is sometimes occasioned by a change of proportions among the parts: the proportions of a fœtus, every one sees, are different from those of a full grown man; and the painter, merely by observing the proportions, represents a child, a dwarf, and a giant, on the same scale. It is sometimes occasioned by the addition of new organs; as when the emmet receives wings, and the plume of the seed is fed by new roots striking into the ground; or it is occasioned by a change of both the form and the organs, and their mode of operation, as happens remarkably in some insects: for though all living bodies, plants and animals without exception, undergo partial or general transformations, yet these changes are chiefly observable among insects. Many insects appear to consist of two distinct animal bodies one within the other: the exterior, a creature of an ugly form, residing in the water or under the earth, breathing by gills or sometimes by tracheæ projecting from the tail, possessing a voracious and groveling appetite, and having a system of sanguiferous vessels that circulates the blood towards the head. When all its parts decay and fall off, the creature inclosed succeeds in its stead: this often is an animal of a different form, generally lives in a different element, feeds on a different species of food, has different instruments of motion, different organs of sense, different organs of respiration, and differently situated; and being endowed with the parts of generation, inclines to gratify the sexual propensity, and produces an embryo which becomes like the first, and from which afterwards in process of time a creature is evolved similar to itself.

248 Not merely a change of temporary envelopes.

249 In what it consists, and different kinds of it.

Transformation.

250 Transformation of insects.

If the embryo or egg be deposited on a leaf, the leaf frequently is observed to bend, to wrap it in folds intended for the purpose, and to protect it from injuries and danger. If deposited in the body of an animal or plant, they accommodate themselves to its wants and necessities, and furnish a tumour which serves it for a nidus, and besides, like an uterus, supplies it with nourishment; and if deposited in the body of an insect, the creature provides for the future destination of its young charge with all the tender care of a parent, and then dies.

251 Accommodating principle in plants and animals.

These circumstances, added to the great variety of forms which insects assume, render it sometimes difficult to know who is the parent. We cannot, for instance, pronounce with certainty who is the true parent of the gordius, known by the name of the *feta equina*, or hair eel. A set of experiments, which we once began with a view to throw some light on the subject, were interrupted unfortunately by an accident, and we have not since had leisure to resume them. We learned only, from a number of observations, that certain black beetles about the end of the summer months have the strongest propensity to run into the water, where they soon die; and that one or two, and sometimes three or more, of those eels gradually drop from the beetle by the anus. Whether other insects provide for the gordius in this manner we have not yet been able to determine.

252 Difficult sometimes to know the parents of insects.

253 When transformation is most observable in some animals.

The transmutations of some animals are most observable in the uterus and egg. Some early transformations of the chick may be seen in the plate belonging to this article; and anatomy has often witnessed the change which happens at birth with respect to circulation, respiration, digestion, and the other functions.

If the reader wish to be much acquainted with the manners and transformations of insects, he will derive information and pleasure from consulting the plates and memoirs of Reaumur. If he wish to know their intimate structure, the laborious Swammerdam can introduce him to a new and amusing species of anatomy. This last author had before Reaumur defined and described

Transformation.

scribed the kinds of tranſmutations among inſects and ſome other animals. He has ſhown ſimilar tranſmutations in plants; and in plate 46 of his Book of Nature, has compared the frog and the clove July-flower under their ſix different forms.

254 Similar transformation in plants and animals.

In all living bodies poſſeſſed of mind, the changes of form, as well as the change of habit and of age, are uſually accompanied with new propenſities, appetites, and paſſions. It may therefore be inferred, that we ought not to look for the cauſe of temper in either the brain or the nervous ſyſtem; or to imagine, that the propenſities, appetites, and paſſions, are properties of mind: they ſeem only affections happening to mind in conſequence of ſtimuli and organic ſtructure.

255 Transformation accompanied with new propenſities, &c.

256 Is an evolution of parts by nutrition.

Microſcopic obſervations having demonſtrated, that all the forms of the plant and animal exiſted previouſly in the ſeed or embryo, transformation muſt be owing entirely to the evolution of the different parts by means of nutrition.

257 The deſign of transformation.

What nature intends by transformation, we pretend not to ſay; but by means of tranſformation different elements are peopled, the different ſeaſons variouſly adorned, and animated nature wonderfully diverſified without a multiplication of beings.

Sect. XII. *Generation.*

258 Generation.

Many of the cauſes which contribute to the formation of a living body have hitherto eluded human reſearch; may in all probability never be diſcovered; and perhaps are beyond human comprehenſion. Some philoſophers conſidering the extreme diviſibility of matter, and learning from the microſcope that transformation is but the developement of certain parts that previouſly exiſted, have thence imagined that generation is ſomewhat analogous; that all regularly organiſed bodies received their form at the beginning; that the firſt of every genus and ſpecies contained by involution the numerous millions of ſucceeding generations; and that the union of the two ſexes gives only a ſtimulus, and brings into view forms that had exiſted ſince the world began.

259 One hypotheſis, that all living bodies were formed at once, and brought into view by generation.

260 Objections to this hypotheſis.

This hypotheſis has attempted to explain a thing that is unknown by what muſt for ever remain incomprehenſible to the human mind in its preſent ſtate. It appeals abſurdly from obſervation to conjecture; and ſuppoſes that bodies which are originally brought into view, which are daily augmented, frequently repaired, and ſometimes renewed by organic action, do nevertheleſs in their firſt formation require an effort ſuperior to what omnipotent power is able to perform by ſecondary agents.

261 Does not explain the renewal of parts,

Had the ſupporters of this hypotheſis conſidered that many herbaceous plants produce new flowers when the firſt ſet are untimely cut off, that lobſters and many a ſpecies of inſect renew their limbs, and that certain polypes can raiſe ſo perfect vegetable forms as to puzzle the naturaliſt whether or not he ſhould claſs them under plants; they would not ſurely have preſcribed ſuch bounds to omniſcient wiſdom and almighty power, or declared with ſuch confidence what the Author of Nature, to ſpeak with the vulgar, muſt neceſſarily perform by his own hands, or what he may intruſt to ſecondary cauſes regulated by his laws.

Theſe philoſophers will find it difficult to account in a very ſatisfactory manner for monſtrous productions, and for thoſe changes of ſtructure and of form which for a while continue hereditary from the influence of habit. They object to others, that all the parts of a living body are mutually dependent on one another, and that they muſt neceſſarily have been coeval or exiſted at once. But though every attempt that has yet been made to aſcertain which of the vital organs are prior and which poſterior in a living body has proved unſucceſsful, it has not been demonſtrated that either themſelves or their functions are coeval. It may, on the contrary, be plainly demonſtrated from obſervation, that the lungs and the ſtomach do not begin to perform their functions ſo early as the heart and the vaſcular ſyſtem; that the heart and its ſyſtem perform their functions, even with ſome conſiderable changes, immediately after birth; that the vegetable tribes are without nerves; and that brain and nerves in the animal kingdom perform more and more of their functions as the ſyſtem approaches towards maturity. It has even been ſhown that bones will unite, and the limbs of an animal continue to be nouriſhed without nerves; that there is a principle of life in the blood; that the heart will act under other ſtimuli beſides that of nerves; and that ſound logic does by no means require us to ſuppoſe that the firſt actions of the fœtal heart, or the punctum ſaliens, are owing to the influence of ſtimuli from the brain, or that the brain muſt have exiſted when the heart firſt moved.

Generation

262 Nor the production of monſtrous forms.

263 Proceeds on queſtionable data.

Although the minuteneſs and tranſparency of the parts may prevent us from ſeeing the firſt gradual formation of the embryo, yet every obſervation corroborates the opinion that it is formed by ſecondary cauſes, and through the medium of organic powers.

264 Embryo formed by ſecondary cauſes.

It has been aſked, whether or not is the embryo formed by the joint operation of the two ſexes? or is it formed entirely by the one, and brought into action by a ſtimulus from the other? The former of theſe queſtions ſuppoſes that each of the ſexes has a feminal fluid; that ſome mixture takes place in the uterus, and produces an embryo, in the ſame manner that a neutral ſalt aſſumes a certain and determinate form. The notion implies ſome general and confuſed idea of chemical combination; but does not beſpeak a very clear head, profound reflection, or much acquaintance with the nature and properties of living bodies.

265 By one of the ſexes or both.

For a long time paſt the moſt rational phyſiologiſts have generally agreed that the embryo is formed gradually and ſlowly in one or other of the two ſexes, not by chemical combination and mixture, but a ſyſtem of organs, directed by laws and prompted by ſtimuli, with many of which we are yet unacquainted. From the great Hippocrates downwards to Aquapendens and Harvey, the credit of furniſhing the fœtal embryo was almoſt univerſally given to the females of thoſe animals which are named oviparous. Among the viviparous, appearances were ſuch, that the female was left to conteſt it with the male. At laſt the eclat of Leeuwenhoek's diſcoveries ſeemed to put an end to all doubts entertained upon the ſubject. He very plainly ſaw through his microſcope that very great profuſion of particles that move to and fro with amazing rapidity in the male ſemen. Upon this he embraced the doctrine of Hamme, who had ſeen them before, and ſuppoſed from their motions that theſe particles were not only animalcules, but the principles or

266 The opinion of Hippocrates Harvey, and their followers.

267 Of Hamme, Leeuwenhoek, and their followers.

Generation

rudiments of that animal in whom they were formed, and that they were depoſited in the uterus of the female only to be nouriſhed and augmented in ſize.

268 Objections to this laſt opinion.

What raiſed ſuſpicions againſt this theory were the numerous animalcules diſcoverable by the microſcope in other fluids, and that vaſt profuſion of young embryos in thoſe caſes where never more than one or two arrive at maturity. It was an objection to it, that ſome females had been impregnated where the hymen remained unbroken, and where the vulva had been ſhut ſo cloſely as to leave only a paſſage for the urine. The male ſemen in theſe inſtances could have reached only the mouth of the uterus. It was another*, that in all birds which have no intrant penis the male ſemen is never ſent farther than the mouth of the vulva, and that a ſingle act of the male impregnates the whole eggs of the ovarium. A third objection is the pollen of flowers, which is not applied immediately to the ſeed, but often to a diſtant part of the veſſel in which it is contained. A fourth may be taken from frogs and fiſhes, and all thoſe animals whoſe eggs are impregnated after emiſſion. And, laſtly, Haller had obſerved the pullet completely formed in thoſe eggs that were not fecundated.

* Vid. *Harv. de Partu.*

269 The former opinion better ſupported.

Suppoſing animalcules in every kind of prolific ſemen, yet it frequently happens that this ſemen undergoes a change before it can be applied to the embryo. The ſemen of the frog is diſſolved in water; and that which is injected diſappearing ſuddenly after coition, would ſeem to intimate, that in thoſe animals which have been examined it had met with a ſolvent ſomewhere in the uterus, and produced its effect after the change. It is now, we believe, pretty generally known, that the embryo does not commence its exiſtence in the cavity of the uterus. De Graaf obſerved it on its paſſage down the Fallopian tube; he ſaw the place where it firſt began in the teſticle of the female; and caſes have occurred where it has miſſed the Fallopian tube, where it has fallen into the abdomen, where the placenta has been formed, and the fœtus has grown among the viſcera of the lower belly.

270 More generally adopted.

From theſe facts it has been concluded, notwithſtanding ſome feeble objections, that the female teſticles are real ovaries containing eggs; that theſe eggs are brought into action by the ſtimulating power of the male ſemen, which is ſometimes thrown into the cavity of the uterus, ſometimes applied only to its mouth, and ſometimes ſprinkled over the egg after emiſſion.

271 Difference between oviparous and viviparous animals and plants.

The principal difference, therefore, that occurs between oviparous and viviparous animals, conſidered as ſuch, appears to be this: the former are accuſtomed to eject their embryo before it eſcapes from the membranes of the egg; the latter retain it long in the uterus until it acquires a conſiderable ſize, until the membranes can hold it no longer, and then eject it when the membranes are burſt. A plant is oviparous when it yields ſeed; viviparous when it produces a gem, a bud, a bulb, or an eyed root. The membranes of the ſeed being removed, an incipient embryo is ſeen through the microſcope.

Generation.

272 Some animals oviparous and viviparous.

Some animals, according to the ſeaſon, eject the embryo incloſed in its membranes, or retain it in the uterus till the membranes are broken. Theſe are the animals which are ſaid to be oviparous at one period and viviparous at another. The ſpider-flies retain their young till they be as large as the natural ſize of their own bodies, and have undergone all their transformations within the expanſile membranes of the egg, and an uterus as expanſile as the ſtomach of a ſerpent.

273 Union of the ſexes.

In moſt caſes generation requires a temporary union of two ſexes: but it has been ſaid, that in Senegal there is a ſpecies of ſhell-fiſh among whom this operation is the joint work of three individuals. In our own country, too, three frogs are frequently obſerved adhering together, though the labours of the third have generally been thought more officious than neceſſary. In ſome animals the ſexual union is almoſt inſtantaneous. It conſtitutes nearly the buſineſs of life in the laſt ſtage of the ephemeron; and the male both of the frog and toad often continues on the back of the female not for hours and for days only but for ſome weeks. Upon examination it has been found, that with his fore-feet he aſſiſts the female to protrude her eggs through the windings of the oviduct; and when they at laſt arrive at the anus, a ſpecies of the toad has been obſerved to draw them out with his hind legs. Theſe animals were probably the firſt of the maſculine gender who practiſed this art. But due honour has not been aſcribed to the diſcoverers. In former days, the generous and grateful ſpirit of the ancients made them ready to acknowledge their obligations to different animals for the arts of bleeding, clyſtering, and purging; but ſuch is the degeneracy of modern times, that many write only to claim the diſcoveries of others. On this account we ought not to wonder that many accoucheurs, in publiſhing encomiums on their own merit, have invidiouſly concealed the ſuperior pretenſions of the obſtetrical toad.

274 Different appearance of the two ſexes.

Among all living bodies the two ſexes are generally ſimilar; and the male ſex generally diſtinguiſhed by ſuperior ſtrength, beauty, and courage. The law, however, does not hold univerſally. The females of ſome carnivorous animals, who are left by the male to provide for their offſpring, are larger, ſtronger, and more ferocious than he. Among ſome inſects the male and female have no ſimilarity even in form. The male of the glow-worm is a beetle, which flies in the dark, and is attracted not by the form, but the brilliancy of his miſtreſs (G). The female gall inſect is a large maſs like a vegetable

(G) Such glowing beauty allures enemies as well as lovers. "In Jamaica, in ſome ſeaſons of the year, (ſays Dr Darwin), the fire-flies are ſeen in the evenings in great abundance. When they ſettle on the ground, the bull-frog greedily devours them; which ſeems to have given origin to a curious, though cruel, method of deſtroying theſe animals: If red-hot pieces of charcoal be thrown towards them in the duſk of the evening, they leap at them, and, haſtily ſwallowing them, are burnt to death." *Botanic Garden.* From this fact the romantic moraliſt and ſpiritualizer might derive ſome hints for amuſing declamation; and in their diſſuaſives might plauſibly demonſtrate, that in moſt caſes beauty is fatal to the object beloved, to the lover, and deſtroyer.

Generation.

vegetable excreſcence, without locomotion; the male a ſmall fly full of activity. The one is as unlike to the other as a Harpy to a Venus, and as diſproportioned in point of bulk as a horſe to an elephant.

275 Male and female parts of animals.

In many animals the diſtinctions of ſex are concealed in the body. When any of their parts are placed externally, or protruded occaſionally, the male parts are uſually prominent, and the female hollow, in order to receive them. In the acari, however, in many flies, and a few hornets, the caſe is reverſed; the female parts ſuffer erection, and the male parts are open and hollow for their reception.

276 Their ſituation.

The external ſituation of theſe parts is very much varied in different animals. In many worms it is near to the head. It is often upon the ſide of the ſnail; near to the breaſt in the female of the dragon-fly. It is at the extremity of the antennæ in the male ſpider. The vulva enters from the rectum in birds. Its common ſituation in moſt animals is well known. —The male penis, where there is one, is ſometimes found to enter the vulva, and ſometimes not: it is ſometimes imperforated, ſometimes forked, ſometimes double, ſometimes fleſhy, ſometimes bony, ſometimes ſtraight, ſometimes winding ſpirally like a ſcrew, ſometimes with a knob and ſometimes with a point at its extremity, according to the kinds and varieties of animals.

277 Androgynous animals.

Few individuals have more than one ſex. Many ſnails, however, are androgynous, and have two. In copulation they perform the office of two ſexes, and are mutually impregnated †. This circumſtance has often led the ſenſualiſt to wiſh that he were a ſnail. With equal reaſon the Epicure might wiſh to be one of thoſe worms that imbibe by abſorbents, and ſuck in nouriſhment by a thouſand mouths. The organs employed may be more in number, the continuance of their function may be much longer, and yet the gratification may be leſs. The diſcreet beauty can afford a million of pleaſures to her lover which no ſnail or ſenſualiſt enjoys, and which proſtitution can never yield.

† *Swammerd. Hiſt. of Inſects, p.* 1. ch. 9.

278 Male and female parts of vegetables.

The male and female parts of the vegetable are ſometimes both on the ſame flower, ſometimes on ſeparate flowers, and ſometimes even on different plants of the ſame ſpecies. Beſides the flower, another organ of generation is found in vegetables. This is the corona, from which the buds and branches proceed. It is a ſubſtance between the pith and the ligneous circles, and from which the diametral inſertments diverge.

279 Parts of generation change, and ſometimes diſappear.

The corona is moſt conſpicuous at the time when it ſends forth ſhoots. The flower comes forth only at the time when the ſeed is to be formed; and the teſticles and ovaries of thoſe animals which procreate only at ſtated periods are diminiſhed in ſize, and ſometimes diſappear, till the genial ſeaſon. Even ſome females, when they ceaſe to be prolific, as the pheaſant, for inſtance, aſſume many marks of the other ſex, as if their former ſex had been aſſumed only for a while, and to anſwer ſome temporary purpoſe.

In all animals the incipient embryos are perhaps neuters, and the ſex determined according to the predominancy of the male or female ſtimulus on the parts. It would not a little confirm this opinion, were the obſervation to be well founded, that certain bulls are very apt to beget males and others females, and that certain cows which have females always when they are young bring forth males when they grow old. The different proportions of males and females in different climates might alſo ſerve to illuſtrate this doctrine. It is no objection to it that the order of male and female births in the ſame family is often irregular. The proportional force of the two ſtimuli will naturally be different at different times. It may depend on the quantity or quality of the fluid ſecreted, upon the difference of ardour in the parties, on the fancy, the paſſions, the particular ſtate of the ſyſtem at the time, and a thouſand circumſtances, beſides the age, and the uſual or general habit of the body. We mean only to infer at preſent, that wherever a male or female is produced, the ſtimulus of that particular ſex, whatever was the cauſe, had during the time of coition and conception acquired the aſcendency over the parts that were to become ſexual in the embryo. We cannot ſo readily anſwer the queſtion, Why the offſpring ſhould poſſeſs the form and diſpoſitions of one parent, and the ſex of the other? In this caſe the different ſtimuli may have acted differently on different parts; in the caſe of hermaphrodites, which are very common in the horſe, the aſs, the cow, and the ſheep, the two parents ſeem to divide the form, the ſex, and the diſpoſitions, equally between them.

Generation.

280 Incipient embryos perhaps neuters.

281 Female orgaſmus.

The particular cauſe which excites the orgaſmus in the female organs is not aſcertained. That viſcous fluid which young laſcivious females eject when fond of the male, is chiefly a ſecretion from the glands of the vagina, the mouth of the uterus, and the neighbouring parts. In ſome reſpects it appears to be ſimilar to thoſe periodical diſcharges of females which frequently aſſume the erect poſture; and theſe diſcharges being uſually diſcontinued during the times of pregnancy and ſuckling, we muſt ſuppoſe that it is a portion of that fluid which nature has prepared for the uſe of the fœtus. Theſe diſcharges are always a proof that the female has arrived at the age of puberty; that her ovary is now performing its office; and that ſhe is diſpoſed to propagate her kind. Whatever be the cauſe of the female orgaſmus, it is often ſo ſtrong as to counteract the natural effects of the ſeminal fluid, and prevent impregnation. For this reaſon, few young and laſcivious females conceive immediately after their marriage; and after coition, therefore, in cattle, it is ſometimes a practice to beat the female, to plunge her in water, to weary her with running, and to uſe other means to prevent the return of the ſexual deſire.

282 Influence of fancy over the parts of generation.

In man, and ſome of the nobler animals, the influence of fancy over the organs of generation is unqueſtionably great; but the extent and mode of its agency is not defined. Thoſe who allow it ſo much power in impreſſing marks, and altering the form and colour of the fœtus, ſupport their opinion rather by the number than the ſtrength of their arguments. Many of the ſtories which they adduce as a ſort of proofs are evidently fabulous, and have brought the truth of the whole into queſtion. The reports, however, of the French commiſſioners who were appointed to examine the nature of animal magnetiſm, ought to deter the can-

Generation

did inquirer from drawing very haſty concluſions.—The queries of Fienus (H) concerning the powers of this mental faculty are important and curious, and might be of uſe in directing our reſearches; but they ought to be anſwered by accurate experiments, and not by acute metaphyſical reaſoning and hiſtorical anecdotes that are ill authenticated.

283 The mixture of ſpecies prevented, how.

To prevent a confuſion of genera and ſpecies, animals are generally reſtricted by propenſity to their own kind; and the ſeminal fluids, beſides, being various in various animals, they cannot indiſcriminately act as a ſtimulus on all female organs of generation. The changes of form induced by habit, which is owing itſelf to the influence of ſtimuli, will partly explain the manner in which the progeny is made to reſemble the male. As the irritability of different parts is of different kinds, the ſtimulus will have a different effect on different organs: and in theſe caſes where either genera or ſpecies are mixed, the parts which are moſt and leaſt affected by the ſtimulus of the male will be obvious in the ſhape and form of the offſpring.

284 Generation without ſexual diſtinctions in plants and animals.

We have hitherto ſpoken of generation as being performed by the temporary intercourſe of two ſexes; but the puceron is an inſtance where ſexual diſtinctions are not always neceſſary. Even where they exiſt they are daily diſpenſed with in the vegetable kingdom. Plants grow from the gem, the bulb, the leaf, or the root.—They propagate by ſlips, by ſuckers, and by layers, and ſome of them multiply by ſpontaneous ſeparation (1). In many animals the diſtinctions of ſex are totally unknown. It has been obſerved, that infuſory animalcules multiply their ſpecies by continual diviſions and ſubdiviſions of their own body; that ſome polypes, by ſpontaneous ſeparation, ſplit tranſverſely, ſome longitudinally, and that ſome ſend off ſhoots. When experiments have been made upon theſe animals, it has been diſcovered that the numerous and artificial diviſions of their body or their head produce entire animals. Trembley learned that they might be engrafted upon one another, and produce monſters as wild and extravagant as poet or fabuliſt has ever dreamed of. Generation.

285 Plants and ſome animals a congeries of living bodies.

It was noticed already that the alimentary canal of ſome animals diſtributed nouriſhment through the whole body without the intervention of circulating veſſels, and that the vital organs of vegetables were generally diffuſed through the whole ſyſtem. The caſe is the ſame in polypes as in plants. Every part is a miniature of the whole. It is found to have ſimilar organs of digeſtion, of reſpiration, of circulation, and of generation. In perfect animals all the parts are more dependent on one another: the vital organs have diſtinct ſituations, and their powers are concentrated in diſtinct places. The arm of a man has no heart; it has no lungs; it has no ſtomach, and no organs of generation; but the branch of a tree has as complete a ſyſtem of organs as the trunk itſelf, and is as independent of that body from which it grew as the graft is independent of the ſtock.

286 Difference between plants and the nobler animals.

The ſeveral parts of perfect animals all contribute to make one whole; the ſeveral parts of a plant or polype, when united together, form only a congeries of living bodies. Theſe facts contribute to explain the principal phenomena in this mode of propagation.

Sect. XIII. *Sleep.*

287 Sleep.

Sleep is rather an affection of mind than a property of body, and is therefore more naturally a ſubject of metaphyſics

---

(H) The ſmall work of Fienus to which we allude is intitled *De Viribus Imaginationis Tractatus.* The following queſtions ſerve to give an idea of its contents, and are named *Index Quæſtionum hujus Libri.*

Quæſtio. I. An anima habeat vim agendi in ullum corpus?
II. In quæ corpora agere poſſit, et qua actione?
III. Per quas potentias illos motus et actiones exerceat?
IV. An anima agat aliquid per potentiam imaginativam?
V. An phantaſia poſſit ullum corpus movere localiter?
VI. An poſſit alterare?
VII. An phantaſia poſſit vim ullam acquirere ab influxu cœlorum?
VIII. An ergo phantaſia nullam habeat vim agendi?
IX. Per quas potentias phantaſia corpora immutet?
X. Quid poſſit in corpus proprium, et *ſpecialiter*, an poſſit in eo creare morbos?
XI. An poſſit morbos creare?
XII. Quid poſſit in alienum externum?
XIII. Quid poſſit in alienum propinquum ſeu fœtum?
XIV. Quomodo et qua ratione fœtum immutet?
XV. Quomodo poſſit conformatricem dirigere?
XVI. Quænam imaginatio habeat illam ſignandi poteſtatem? quæ non?
XVII. Cur non omnis imaginatio quam animi paſſiones ſequuntur ſignat?
XVIII. An omnes animi paſſiones ſignant?
XIX. Quænam imaginatio ſignet, an tantum matris an etiam patris?
XX. An etiam brutorum imaginatio ſignet?
XXI. Quo tempore ſignet, an tantum graviditatis, an etiam conceptus?
XXII. Quantam permutationem poſſit in fœtum inducere, et quas ſignaturas poſſit cauſare?
XXIII. Cur phantaſia non ſemper imprimit in fœtum res imaginatas eodem modo, ſed ſæpe tam diverſis?
XXIV. Cur non eidem ſemper parti ſed diverſis notæ inducuntur?

(1) As the houſe leek and ſome graſſes.

Sleep.

metaphyſics than of phyſiology. This affection is often induced by fatigue and exerciſe; and ſeveral perſons, when they are weary and no longer able to move their limbs, ſay they are exhauſted. Though the word *exhauſted*, in this expreſſion, has ſeldom any preciſe meaning, it ſeems, however, to have been the means of ſuggeſting a theory with regard to ſleep. This theory ſuppoſes that ſleep is occaſioned by the exhauſtion of irritability in the living ſyſtem; but it ſeems to be founded on very limited and partial obſervations, or rather has been formed, like a great many others, prior to any obſervations at all, and afterwards tortured to account for facts which it does not comprehend. It does not account for the periodical returns of ſleep, for the almoſt unremitting drowſineſs of infants, and for that liſtleſs lethargic inaction ſo often attendant on old age. When no exhauſtion of irritability can well be ſuppoſed to have taken place, the propenſity to ſleep on many occaſions becomes irreſiſtible, from the effects of monotonous ſpeaking, from ſtillneſs, darkneſs, or from the ſameneſs of ſcenery around us; and when one ſtimulus, after long application, can rouſe no more (a plain proof that the irritable principle is by no means exhauſted), another ſtimulus that is leſs powerful in ordinary caſes is accompanied with excitement.

288 An affection of mind.

289 Favours nutrition.

Of theſe phenomena, we frankly confeſs that we can aſſign no phyſical cauſe that is ſatisfactory. It is eaſy, however, to ſee the intention which nature has in view by inducing ſleep. It has long been obſerved, that in all living bodies there is a continual waſte and repair, or, to ſpeak with more preciſion and accuracy, one proceſs of aſſimilation and another of diſſolution conſtantly taking place in all the different parts of the ſyſtem. It is alſo true that this aſſimilation, when the body is healthy, predominates in youth; that diſſolution prevails in old age; and that the two are nearly on a par during the vigour and meridian of life. Another fact which admits of demonſtration, is, that a gentle and moderate exertion of mind and body will promote both. And laſtly, it is certain that immoderate exertion in either reſpect, or any exertion that is not ſuited to our ſtrength, habits, or period of life, prevents aſſimilation, haſtens diſſolution; and that the means which nature employs to reſtore the balance is uſually by inducing a ſtate of ſleep.

290 Sleeping and waking each ſuited to different functions in the ſyſtem.

When the balance is reſtored, and all the parts are again repaired for diſcharging their office, man awakes; but his waking period is of ſhort duration. If appetite or paſſion do not engage him in ſome purſuit, if his mind be not occupied with ſome object, or if no ſtimuli be applied from without. This period ſeems chiefly intended for collecting food, and for being employed in thoſe exertions which promote reſpiration, digeſtion, abſorption, circulation, and ſecretion; while ſleep, after the food is collected, aſſiſts nutrition, and promotes aſſimilation throughout the ſyſtem. If what is the natural food of the ſpecies cannot be collected by the plant or animal in a ſhort time, the period of ſleep is proportionally reſtricted. If the food received be difficultly aſſimilated, the period of ſleep is proportionally extended. If the food be not prepared for aſſimilation, the ſleep is diſturbed. If it be difficultly prepared by the organs, the active exertions are more vigorous; if eaſily prepared, they are more feeble. If it be collected during the day, the ſleep is in the night; if collected in the night, the ſleep takes place during the day; and all living bodies are directed by nature to ſelect that time and ſpecies of food which is moſt ſuited to their nature, their habits, their circumſtances, and age.

Sleep.

291 Violent exertions of mind or body hurtful to the ſyſtem.

To favour nutrition, not only the body, but even the mind, muſt be allowed to indulge in reſt. The child ſleeps, and his mental faculties are under reſtraint, that thoſe functions employed in nutrition may not be diſturbed. The mental faculties are ſtill feeble in a more advanced period of life; and the moderate exertions of mind and body which are natural to youth are chiefly ſuch as favour the preparatory organs of the ſyſtem, and promote growth: but the active and vigorous exertions of manhood, conſidered with reſpect to mind or to body, ſoon cauſe diſſolution to preponderate in the ſcale, and old age becomes liſtleſs, inactive, and drowſy, and the mind returns to childhood or dotage, becauſe living bodies are known to accommodate themſelves to circumſtances and becauſe the prevailing diſſolution is retarded by the frequent returns of reſt and of ſleep, which favour ſo much the aſſimilating powers, counteract *re-abſorption*, and oppoſe decay.

292 Mental exertion counteracts nutrition.

During ſleep the irritable principle is more languid, and all the ſenſes are more obtuſe. The mind then is withdrawn ro its reſt, and does not attend to ſtimuli from without. The ſame happens when the mind is abſorbed in profound thought: but profound thought is hurtful to the ſyſtem. The mind then is engaged in purſuits peculiarly its own, and is leſs attentive to the calls of nature. In the time of ſleep it withdraws ſeemingly, not ſo much for its own ſake as that of the body, which then being freed from the interruption of voluntary motions, all thoſe organs which act ſpontaneouſly can more eaſily diſcharge their functions.

For the beſt of reaſons, the mind is not allowed to judge for itſelf when it is proper to eat, to drink, to ſleep, to wake, and to propagate the ſpecies. Theſe and the like are offices too important to be wholly intruſted with a being of ſo very limited intelligence. In all theſe caſes, it is therefore directed by certain propenſities reſulting from the body in conſequence of ſtimuli or organic ſtructure. Being often amuſed with thoughts and ideas on thoſe objects which are purely intellectual, as the notes of memory, the forms of fancy, and its own operations in the way of reaſoning; being inveſted with ſome little power in rouſing, calming, and regulating the paſſions, the deſires, and appetites; and having the command of all the voluntary movements of the body; it ſometimes neglects its charge of the ſyſtem, deſtroys it ſometimes by exceſſive indulgence, and ſometimes employs it in accompliſhing ends peculiarly its own. One ſhould imagine that the mental principle in the lower animals ſhould occaſion but little diſturbance to the ſyſtem; yet it has been obſerved that geeſe fatten ſooner in the dark than they do in light, where the mind is entertained with varieties of objects: and this circumſtance will partly explain why man does not fatten ſo regularly as the brute, and why caſtration, which prevents ſo much anxiety and paſſion and exhauſting efforts, aſſiſts growth and the organs of nutrition. The venereal ſtimulus, for this reaſon, is not ſtrongly felt at a very early period of youth, nor is very troubleſome in old age. In the former caſe it

293 Charge of the ſyſtem not contracted by the mind, therefore

Sleep.

would prevent the growth of the ſyſtem; in the latter it would haſten its diſſolution.

294 The ſyſtem accommodates with reſpect to ſleep.

The natural returns of waking and ſleeping may be altered by the preſence or abſence of ſtimuli, and are curiouſly affected by the influence of habit. Although the commencement of one of theſe periods happen to be changed, the commencement of the other will continue as before. If a perſon be accuſtomed to ſleep preciſely at nine in the evening, and to riſe again at ſix in the morning, though his ſleep in the evening may now and then be kept off till twelve, he will waken at ſix; and though continued by darkneſs, quietneſs, or ſuch like cauſes, till the day be advanced, it will recommence in the evening at nine. The ſtate of phyſiology is ſuch at preſent that we cannot aſſign any preciſe phyſical cauſe for the natural kinds of ſleeping and waking, or for their regular periods of return. As for the cauſes which occaſion morbid ſleeping and waking, we refer our readers to books on pathology.

295 Sleep of plants.

Plants too have been ſaid to ſleep. At the approach of night, many of them are obſerved to change their appearances very conſiderably, and ſometimes even to ſuch a degree as ſcarcely to be known for what they were before. Theſe changes happen principally to the leaves and the flowers. During the night, many leaves, according to the nature and genus of the plant, are ſeen to riſe up, to hang down, or to fold themſelves in various ways for the protection of the flowers, the buds, the fruits, or young ſtems; and many flowers, to eſcape a ſuperabundance of moiſture, to hang down their mouths towards the earth, or wrap themſelves up in their calixes. It was mentioned already, that theſe phenomena are owing to ſtimuli acting from without: we may add here, that moſt of the motions are performed at the joints where the leaves and petals articulate with the ſtem. A period of reſt is as neceſſary to plants as ſleep is to animals. The irritable principle cannot act long under the influence of the ſame ſtimulant, except at intervals; and the rapid growth obſervable in plants during the night, is a ſtrong proof that the organs employed in aſſimilation had been diſturbed in diſcharging their functions during the day, when expoſed to the actions of heat and light and of other ſtimulants.

Sect. XIV. *Death.*

296 Death.

Death is the ceſſation and total abſence of the living principle in organized bodies. It is ſometimes imitated by ſleep and ſwoons; and a ſtate of torpor in many inſtances can hardly be diſtinguiſhed from it. Several moſſes and a few animals, as the ears of blighted wheat, the ſeta equina, the wheel polype, and ſome ſnails as we learn from the Philoſophical Tranſactions, may be ſafely preſerved as dried preparations, not for months only but for years; and after irritability and ſenſation have been totally ſuſpended, will return to life upon the proper application of moiſture. A wheel polype was put by Fontana upon a bit of glaſs, and expoſed during the whole ſummer to the noonday ſun; another was expoſed in a ſimilar manner for a year and a half; and after they were like a piece of hardened glue, were reſtored to the uſe of all their functions by a few drops of water (κ). Wherever there is death, there muſt therefore be likewiſe a partial or general decompoſition of one or more of the vital organs. This decompoſition takes place naturally in ſome living bodies after a few hours, in ſome after a few days; the life of others is extended to weeks; ſome are vigorous for months or a ſeaſon. Man has often ſeen more than fourſcore; and the hardy oak ſurvives the ſhock of two or three centuries. Theſe obſervations conſpire to ſhow that there is a certain period of exiſtence allotted by nature to every ſpecies of living bodies. In the individual this period is ſometimes abridged, and may be ſometimes extended by circumſtances; but yet there is a bound which it cannot paſs, when the vital organs muſt be decompoſed, and the ſyſtem return to moulder with the duſt. The time of incubation and the time of geſtation are pretty much defined in every ſpecies, becauſe the circumſtances of the individual in theſe caſes are generally ſimilar; but after emerging from the fœtal ſtate, the individuals are partly entruſted to their own organs and the chances of life, which are much varied; and hence we account for the difference of their age.

Death.

297 In ſome inſtances not diſtinguiſhable from a ſtate of torpor.

298 A certain period of life allotted to the ſpecies.

299 Accommodates with reſpect to individuals.

Life in general ſeems to be proportioned to the ſpace occupied by that ſeries of functions which the ſpecies is evidently deſtined to perform: and here ſometimes the accommodating principle is ſingularly remarkable. As the period of decay is never ſeen to commence in the ſpecies till that of propagation be nearly elapſed, and as propagation in the lower tribes of plants and of animals is often the immediate harbinger of death; ſo many animals which have not propagated, indulged the propenſity, nor became uneaſy from the languor of deſire, continue vigorous longer than ordinary, as if it were waiting for an opportunity to multiply their kind. And in the vegetable kingdom, where no individual is ever the victim of deſire or paſſion, annuals, if prevented from flowering and ſeeding in their proper ſeaſon, will live double, and ſometimes triple, the uſual time, till theſe functions be

300 Life proportioned to the ſeries of functions to be performed.

(κ) Father Gumillo a Jeſuit, and the Indians of Peru, ſays Dr Fowler, are quoted by Fontana, on the authority of Bouguer, as ſpeaking of a large and venomous ſnake, which being dead and dried in the open air or in the ſmoke of a chimney, has the property of coming again to life on its being expoſed for ſome days to the ſun in ſtagnant and corrupted water. But, adds the Doctor, it would almoſt require the credulity of an Indian to credit the teſtimony of the Jeſuit. *Experiments and Obſervations relative to Animal Electricity, by Richard Fowler.*—With regard to this report, we ſhall only obſerve, that the ſnake would not readily return to life after it was dead: but if the Jeſuit meant only that it recovered after it was dried, and its ſeveral functions had been ſuſpended, we muſt ſay, that if his report be not ſufficiently authenticated, neither has it been ſufficiently diſproved.

Death. be somehow performed, and then die. But when all the organs are fully evolved and have discharged, or have continued for the usual time capable of discharging, those offices for which they were intended; dissolution commences, the assimilating organs begin gradually to lose their tone, and the reabsorbents carry off more from the different parts than what they receive in the way of nutrition: the irritable fibre then becomes rigid; the membranes and cartilages begin to ossify; the bones grow harder; the smaller vessels collapse and disappear; the parts no longer are obedient, as before, to the action of stimulants; and death ensues.

301 Symptoms of decay.

Some, in order to account for this event, imagine that the body receives at first a certain portion of irritability, and continues to live till that be exhausted: but this theory explains nothing; and without pretending to a great deal of foresight, we will venture to predict, that for all the irritability which it has, it will not be distinguished for its longevity.

Death. 302 An attempt to account for death.

With regard to the periods by which the life, the functions, and diseases of living bodies are so frequently regulated, and which periods may sometimes be varied but not evaded, the most prudent language that, perhaps, can be adopted in the present state of physiological science is this of the Divine, That the God who formed us hath numbered our days, determined our times, and prescribed the limits of our existence.

303 Physical causes not easily assigned for periodical phenomena in the system.

The following TABLE may be considered as in some respect a summary view of the foregoing Sections, and as a Supplement to the Table of D'Azyr.

1. RESPIRATION.

Some living bodies have respiratory organs (L)

- Diffused through the system.
- Confined to one place.
- Situated externally.
- Situated internally.
- In the course of circulation.
- Not in the course of circulation.
- Within or without the course of circulation at pleasure.
- Without tracheæ (M).
- With tracheæ ramified through the system where the respiratory organs are generally diffused.
- —— not ramified through the system where the respiratory organs are confined.
- —— formed by rings.
- —— by segments of rings on one side, and a membrane on the other.
- —— by continuous rings running spirally like a screw.
- —— admitting air by one entrance.
- —— by several entrances.
- —— wholly concealed in the body.
- —— partly projecting from the body.
- —— opening at the head.
- —— at the opposite extremity.
- —— upon one side.
- —— upon both sides.

2. DIGESTION.

Some living bodies have an alimentary canal

- Without teeth.
- With teeth in the mouth.
- —— in the stomach.
- —— stones or artificial teeth in the stomach.
- —— glands in the mouth for secreting a liquor to be mixed with the food.
- —— pouches in the mouth where the food is kept and moistened.
- —— a sac or bag where the food is kept and moistened.
- —— a membranous stomach.
- —— a muscular stomach.
- —— an intermediate stomach.
- Without a cœcum or blind gut.
- With a cœcum.
- —— two cœca.
- —— three cœca.
- —— four cœca.

These parts, as well as ruminating stomachs and their œsophagus, have antiperistaltic motions.

- —— one entrance or mouth.
- —— many entrances by absorbents.

Plants

(L) The gentlemen of the French Academy, who have been attentive to mark the number of lobes in the lungs and livers of different animals, have sufficiently demonstrated, by the facts which they relate, that many of those physiological conclusions which have been drawn from the number of lobes in these two viscera, are just as delusive as many of those which have been drawn from the number of lobes and the different tubercles found in the brain.

(M) Where the respiratory organs are situated externally.

3. Digestion.
- Plants have many alimentary canals (N).
- Some polypes have alimentary canals that branch through the body.
- The alimentary canals of plants, of some polypes, and worms, distribute the fluids without the aid of a circulating system.

5. Absorption. Performed
- By vessels beginning from the alimentary canal.
- ——————— from the cavities.
- ——————— from the surface.
- — veins in the penis and placenta.
- — reabsorbents originating from all the parts of the system.

4. Circulation. Some living bodies have
- No circulating system.
- A circulating system with one heart.
- ——————— a heart for distributing the blood through the respiratory organs, and an artery for distributing it through the system.
- ——————— one heart for the respiratory organs, and one for the system, both in one capsule.
- ——————— two hearts for the respiratory organs, and one for the system.
- ——————— a pulmonary heart, or a heart for the respiratory organs in the course of circulation.
- ——————— a pulmonary heart within or without the course of circulation pleasure.
- ——————— a heart situated in the breast.
- ——————————— near to the head.
- ——————————— in the opposite extremity.

5. Nutrition. The food is prepared
- By the alimentary canal.
- — the lacteals.
- — the respiratory organs.
- — the circulating system.
- — the cellular membrane.
- — glands.
- And by the several parts in which it becomes finally assimilated.

6. Secretion. Performed
- By vessels.
- — exhaling vessels.
- — excretory organs.
- — organic pores.
- — glands.
- And by all the parts of which the system is composed.

7. Integumation (O). Some living bodies have integuments
- Which are scaly.
- —— —— shelly.
- —— —— membranous.
- —— —— corneous.
- —— —— cretaceous.
- —— —— ligneous.
- —— —— covered with down.
- ——————— hair.
- ——————— prickles.
- ——————— feathers.
- ——————— a viscid matter.
- —— change their colour.
- —— —— their covering.
- —— are changed themselves.

8. Irri-

(N) The subterraneous bulbs, the swoln fleshy parts of the roots, and certain cups and vesicles which contain water, serve often as reservoirs of food to the plant, although for various reasons we have not ventured to call them stomachs. *Stomach* would be a vague and unmeaning word were it applied even to all those reservoirs of water or secreted fluids which we find in fishes, and by which some of these animals are preserved alive on the dry shore till the tide return.

(O) There seems to be a want of precision in classing bones with integuments, or integuments with bones, as is

8. Irritability. The irritable principle effected
- By ſtimulants inviſible.
- —— ——— unknown.
- —— ——— unthought of.
- — the nervous influence.
- — light.
- — heat.
- — moiſture.
- — electricity.
- — ſalts.
- — gaſes.
- — bodies that act mechanically.

9. Motion. Locomotion performed
- By legs.
- — wings.
- — fins.
- — the tail.
- — organs which fall not properly under theſe deſcriptions.
- — the ſpringineſs of the body or of ſome part of it.
- — contrivances which fit living bodies for being moved by foreign agents (p).

is done in D'Azyr's table. Comparatively ſpeaking, bones are confined to a few genera of living bodies, and are never ſubject to periodical changes like the integuments or cuticular coat of the alimentary canal in ſome animals.

For the ſake of perſpicuity, it could have been wiſhed that either anatomiſts or phyſiologiſts had defined bones in a manner different from what they have done, and as far as poſſible avoided thoſe looſe and inaccurate expreſſions which diſgrace ſcience; for ſome ſpeak of animals having their bones, by which they mean ſhells, on their outſide, and the muſcles within them. Some ſpeak of ſolid and compact bones that were once cartilages, membranes, nay a mere jelly; and ſome ſpeak of bones in general as the hardeſt, moſt ſolid, and moſt inflexible parts of the organized body. From all this we are led to infer, that integuments, if hard, ſolid, and inflexible, may be called bones; that the heart and blood-veſſels, if converted into a hard, ſolid, and inflexible ſubſtance, may be called bones; and that a jelly, a membrane, or a cartilage, if it can be ſuppoſed that in the courſe of nature they will become hard, ſolid, and inflexible, may likewiſe be called bones. But certainly if hardneſs, ſolidity, and inflexibility, be to conſtitute the characteriſtics of bones in a living body, however often we may be neceſſitated to include ſhells, wood, horns, and ſtony concretions, under that denomination, we can never with propriety ſpeak of bones that are cartilaginous, membranous, or even a mere jelly. Theſe expreſſions might be proper enough were oſſification conſidered merely as a natural or accidental circumſtance and were bones defined to be thoſe internal parts of an animal which are intended by nature to form what is meant by the ſkeleton in its uſual ſenſe. Theſe parts, we know, after paſſing through the forms of jellies, membranes, and cartilages, often become hard, ſolid, and inflexible, from oſſification; a ſpecies of induration which is natural to the parts which form the ſkeleton of ſome animals, an induration which occaſionally is extended to other parts, which ſometimes exhibits the appearance of cryſtallization, and in many reſpects is different from the manner in which the wood of vegetables and the ſhells of animals become hard.

Oſſification does not interfere ſo much as may be commonly imagined with the ſtructure of bones: the ſtructure of bodies may often be ſimilar, and yet their mode of induration be different. Bones have been obſerved to conſiſt of laminæ, or plates like ſhells, and cylindric bones of concentric circles like wood. The concentric circles of wood have been found to conſiſt of indurated membranes, which they receive ſucceſſively from the bark; and Swammerdam diſcovered that the ſhells of ſome fiſhes were compoſed of laminæ that conſiſted likewiſe of indurated membranes, or hardened cuticles, that had been ſucceſſively furniſhed by the body. It has thence been ſuppoſed that bones, though hardened in a different manner, are of a ſtructure nearly ſimilar to that of ſome ligneous bodies and ſhells, and that their laminæ in many inſtances conſiſt alſo of indurated membranes, ſupplied ſucceſſively by the perioſteum when it is preſent. When it is abſent, nature, which accommodates herſelf to circumſtances, can form the bone in another way, and afterwards cover her new productions with a perioſteum. For many excellent phyſiological obſervations on bones, we refer our readers to the *Oſteology* of the late Dr Monro, and particularly to the volume already publiſhed of Mr Bell's *Syſtem of Anatomy*.

(p) The pulp which ſurrounds ſeeds is often the means of their propagation. Animals ſwallow the ſeeds for the ſake of the pulp; and the ſeeds remaining indigeſtible, are carried to a diſtance, and diſcharged with the feces.

10. Habit — Accommodates with respect
- To respiration.
- — digestion.
- — absorption.
- — circulation.
- — nutrition.
- — secretion.
- — integumation.
- — irritability.
- — motion.
- — transformation.
- — generation.
- — sleep.
- — death.
- — form.
- — size.
- — climate.
- — propensity.
- — the healing of parts that are morbid.
- — the renewal of those that are broken off.

11. Transformation — Takes place
- By a change of proportion among the parts.
- ——— of their form.
- — throwing off old parts.
- — an addition of new ones of a different use, structure, and form.
- — a change of the whole form together.
- ——— —— of qualities, propensities, manners.

12. Generation. — Performed
- By the temporary union of two sexes.
- — the spontaneous separation of parts.
- — organs situated in the breast.
- ——————— in the side.
- ——————— near to the head.
- ——————— in the opposite extremity.
- — an intrant organ of the male and a recipient organ of the female.
- — an intrant organ of the female and a recipient organ of the male.
- — the stamina and pistils of flowers.
- — the seminal secretion of the male thrown into the organs of the female.
- ——————————— sprinkled at the entrance of the female organs.
- ——————————— thrown upon them from a distance.
- ——————————— transported to them by the winds.
- ——————————— sprinkled on the embryo after emission.
- ——————————— dissolved in a fluid secreted by the female before it can rightly perform its office.
- ——————————— dissolved in water.
- ——————————— dissolved perhaps sometimes in air, as in the case of dicœous plants, where it probably acts like an aroma.

13. Sleep. — Natural sleep is occasioned
- By quietness.
- — the absence of stimuli.
- — the sameness of stimuli when long continued.
- — deficient assimilation.
- — deficient irritability, which is owing sometimes to the weakness, inattention, or confined powers of the mental principle.

14. Death. — Happens naturally to some species of living bodies
- After hours.
- —— days.
- —— weeks.
- —— months.
- —— seasons.
- —— years.
- Not till after centuries.

All living bodies are much exhausted after performing the act of generation, and many of the inferior plants and animals begin immediately to sicken and decay.

We

We conclude by confeſſing, that concerning many uſes of the parts, and concerning different ſpecies of variety in the form, ſtructure, and poſition of the organs, much, after all, is ſtill reſerved for farther reading, for farther obſervation, and for future phyſiological arrangement.

Phytolacca || Piacenza.

Bryant's Flora Diæteticæ.

PHYTOLACCA, POKEWEED, or *American nightſhade*, in botany, is of the decandria icoſandria claſs of plants. It grows naturally in the province of Virginia in America. It hath a thick, fleſhy, perennial root, divided into ſeveral parts as large as middling parſneps. From this riſe many purpliſh, herbaceous ſtalks, about an inch thick, and ſix or ſeven feet long, which break into many branches, irregularly ſet with large, oval, ſharp-pointed leaves, ſupported on ſhort footſtalks. Theſe at firſt are of a freſh green colour, but as they grow old they turn reddiſh. At the joints and diviſions of the branches come forth long bunches of ſmall bluiſh-coloured flowers, conſiſting of five concave petals each, ſurrounding ten ſtamina and ten ſtyles. Theſe are ſucceeded by round depreſſed berries, having ten cells, each of which contains a ſingle ſmooth ſeed.

In Virginia and other parts of America the inhabitants boil the leaves, and eat them in the manner of ſpinach. They are ſaid to have an anodyne quality, and the juice of the root is violently cathartic. The ſtems when boiled are as good as aſparagus. The Portugueſe had formerly a trick of mixing the juice of the berries with their red wines, in order to give them a deeper colour; but as it was found to debaſe the flavour and to make the wine deleterious, the matter was repreſented to his Portugueſe Majeſty, who ordered all the ſtems to be cut down yearly before they produced flowers, thereby to prevent any further adulteration. The ſame practice was common in France till it was prohibited by an edict of Louis XVI. and his predeceſſor under pain of death. This plant has been ſaid to cure cancers; but the truth of this aſſertion has not been indiſputably proved, and does not appear very probable.

PHYTOLOGY, a diſcourſe concerning the kinds and virtues of plants. See BOTANY, and MATERIA *Medica*.

PHYTON, a general of the people of Rhegium againſt Dionyſius, the tyrant of Sicily. He was taken by the enemy, and tortured, and his ſon was thrown into the ſea. See SYRACUSE.

PIA MATER. See ANATOMY, n° 130. p. 756, &c.

PIABA, in ichthyology, is a ſmall freſh-water fiſh, caught in all the rivers and brooks in the Braſils, and in ſome other parts in America. It is about the bigneſs of the common minow; is well taſted, and much eſteemed by the natives.

PIABUCU, in ichthyology, is an American fiſh eaten in many places by the natives. It is ravenous, and ſo greedy of blood, that if a perſon goes into the water with a wound in any part of his body, the piabucu will make up to it to ſuck the blood. It ſeldom exceeds four inches in length.

PIACENZA is a city of Italy, in the duchy of Parma, in E. Long. 10. 25. N. Lat 45. It is a large handſome city, whoſe name is derived by ſome from its pleaſant ſituation, in a fruitful plain, on the Via Æmilia, about half a mile from the Po. It is the ſee of a biſhop ſuffragan of Bologna, and has a univerſity, but of no great fame. It is defended by a wall and a ſtrong citadel, and is reckoned about three miles in circumference, ſo that it is ſomewhat bigger than Parma. The houſes are low, but prettily built; the great ſtreet called the *Stradone* is in a direct line and of equal breadth, with a foot-way fenced with poſts on each ſide like London, and is about 3000 feet long. The houſes are generally built of brick, and ſome of them are prettily painted. The cathedral is an old ſtructure, but well adorned within. The duke of Parma, who is ſovereign of Piacenza, has a palace in the city built by Vignola. There are many excellent paintings in this place. There are two chapels painted, one with the hiſtory of St Catharine, and the other with a picture of Chriſt, as as alſo the altar of the church of St Auguſtin, all by Pordenone. In the ſame church there is a fine picture of the bleſſed virgin, St Peter, and St Paul, by Paolo Veroneſe. At the Capuchins there is a Francis by Guercino. There is a fountain ſaid to have been erected here by Julius Cæſar, and the equeſtrian ſtatues of the famous general Alexander I. duke of Parma and Placentia, and of his ſon Ranuccio, both in the great ſquare. In the palace of Scotti, there are a great many fine pictures by Lanfranco, who had been a page in their family, and among the reſt the rape of Helen, the taking of Troy, the bleſſed virgin, and St Francis. The trade of this city conſiſts chiefly in their cheeſe, as at Parma, theſe cities being ſurrounded with the richeſt paſture grounds in Italy; though the greateſt part of what we call the Parmeſan cheeſe is made in the duchy of Milan, and particularly at Lodi. See *Parmeſan* CHEESE — Without the walls, which are waſhed by the rivers Trebbia and Po, there is a large ſeminary or college, magnificently erected by cardinal Alberoni, a native of this city, but conſiderably hurt by the modern Goths in the laſt war. Towards the north of the city is the mouth of the river Trebbia, famous for the victory which Hannibal obtained over the Romans. Piacenza, Piaſtus.

PIASTUS, a native of Poland, was originally a wheelwright and the ſon of Coſſiſco, a citizen of Cruſwitz. He flouriſhed in the year 830, when on the extinction of the family of Popiel great diſputes aroſe about his ſucceſſor, and Cracow was afflicted with a ſevere famine. During this extremity, when the people were dropping down in the ſtreets, two angels in human forms, as the ſtory is told, took up their reſidence with Piaſtus, who was celebrated for his piety and extenſive charity. He had nothing left but a ſmall caſk of the common liquor of the country, and this he preſented to his new gueſts, who, charmed with his hoſpitality, promiſed him the crown of Poland. The faith of Piaſtus was equal to his other virtues: he implicitly believed the word of his gueſts, and piouſly followed their directions in every particular. He was ordered to diſtribute the liquor out of his little caſk to the multitude: he did ſo, and found that it was inexhauſtible. The people were aſtoniſhed; all cried out, "A *Mod. Univ. Hiſtory*, vol. xxi. p. 336, &c.

Piaſtus || Pibroch.

"A miracle!" and the electors determined to chuſe a perſon in whoſe favour Heaven had ſo viſibly declared: Piaſtus was accordingly taken from his ſhop, and raiſed to the ducal dignity.

Such is the relation of the canon of Cracow, which differs in many particulars from the account given by Guagnini, and ſeveral other hiſtorians. According to them, Piaſtus had prepared a ſmall collation, to entertain ſome friends who were aſſembled at the birth of a child. Two pilgrims, Paul and John, afterwards murdered at Rome, came about this time to Cracow. They begged charity at the door of the election hall, and were rudely repulſed; upon which they ſtumbled on the houſe of Piaſtus, and were kindly received. The miracle we have mentioned was wrought by them; and the two pilgrims, and not angels, were the inſtruments of the elevation of the hoſpitable wheelwright. Though we pay but little regard to the marvellous means by which Piaſtus aſcended the ducal throne of Poland, it would be preſumptuous entirely to omit a fact atteſted by all the writers upon this ſubject: it was proper, therefore, to take notice of it, and we leave the reſt to the reader's judgment.

Being now raiſed to the ſupreme dignity, he was not intoxicated with his proſperity. His natural charity, benevolence, and ſweetneſs of diſpoſition, remained: nothing was altered but his power of doing good. He was truly called the father of his people: the injured never returned unredreſſed, nor merit unrewarded. Piaſtus wiped the tear from the eyes of the widow; and was himſelf the guardian of the orphan, and the general patron of the poor and diſtreſſed. His excellent inclinations ſerved him in the room of great abilities; and the happineſs that his people enjoyed made them forget that their prince was not born a ſtateſman and a warrior. Several inteſtine commotions aroſe during his adminiſtration, all which he quelled by the mildneſs and clemency of his nature: his nobility were aſhamed of rebelling againſt a ſovereign who devoted his whole life to render his people happy. He removed the court from Cruſwitz, a city which he deteſted, becauſe it was the ſcene of Popiel's crimes and tragical end, and fixed his reſidence at Gneſna, where he died beloved, eſteemed, and even adored by his ſubjects.

It is in memory of this excellent prince, that all the natives of Poland, who have been ſince promoted to the ducal or regal dignity, were called Piaſtes, in contradiſtinction to the foreigners.

Piaſtus aſſociated his ſon Ziemovitus with him in the government before his death; a circumſtance of much benefit to the people.

PIAZZA, in building, popularly called *piache*, an Italian name for a portico, or covered walk, ſupported by arches.

The word literally ſignifies a broad open place or ſquare; whence it alſo became applied to the walks or porticoes around them.

PIBROCH, ſays Dr Beattie*, is a ſpecies of tune peculiar, I think, to the Highlands and Weſtern Iſles of Scotland. It is performed on a bagpipe, and differs totally from all other muſic. Its rythm is ſo irregular, and its notes, eſpecially in the quick movement, ſo mixed and huddled together, that a ſtranger finds it almoſt impoſſible to reconcile his ear to it, ſo as to perceive its modulation. Some of theſe pibroches, being intended to repreſent a battle, begin with a grave motion reſembling a march, then gradually quicken into the onſet; run off with noiſy confuſion and turbulent rapidity, to imitate the conflict and purſuit; then ſwell into a few flouriſhes of triumphant joy; and perhaps cloſe with the wild and ſlow wailings of a funeral proceſſion.

Pica || Picards.

PICA, in ornithology. See CORVUS, ſp. 9.

PICA *marina*, in ornithology. See HÆMATOPUS, and ALCA, n° 3.

PICA, in medicine, a depravation of appetite, which makes the patient long for what is unfit for food, or incapable of nouriſhing; as chalk, aſhes, coals, plaſterlime, &c. See MEDICINE, n° 371.

PICA, or *pye*, had formerly the ſame ſenſe as *ordinal*, meaning a table or directory, pointing out the order in which the devotional ſervices appointed for different occaſions were to be performed. Accordingly we are told it is derived from πιναξ, *a table*; and by others from *litera picta*, a great black letter at the beginning of ſome new order in the prayer. The term was uſed in a ſimilar ſenſe by officers of civil courts, who called their kalendars or alphabetical catalogues directing to the names and things contained in the rolls and records of their courts the *pyes*.

PICARD, a native of the Netherlands, who founded a ſect the profeſſors of which were called *Picards*. See PICARDS.

PICARD (John), an able mathematician, and one of the moſt learned aſtronomers of the 17th century, was born at Fleche, and became prieſt and prior of Rillie in Anjou. Going to Paris, he was in 1666 received into the Academy of Sciences in quality of aſtronomer. In 1671, he was ſent, by order of the king, to the caſtle of Uraniburg, built by Tycho Brahe in Denmark, to make aſtronomical obſervations there; and from thence he brought the original manuſcripts wrote by Tycho-Brahe, which are the more valuable as they differ in many places from the printed copies, and contain a book more than has yet appeared. He made important diſcoveries in aſtronomy; and was the firſt who travelled through ſeveral parts of France, to meaſure a degree of the meridian. His works are, 1. A treatiſe on levelling. 2. Fragments of dioptrics. 3. *Experimenta circa aquas effluentes*. 4. *De menſuris*. 5. *De menſura liquidorum & aridorum*. 6. A voyage to Uraniburg, or aſtronomical obſervations made in Denmark. 7. Aſtronomical obſervations made in ſeveral parts of France, &c. Theſe, and ſome other of his works, which are much eſteemed, are in the ſixth and ſeventh volumes of the Memoirs of the Academy of Sciences.

PICARDS, a religious ſect which aroſe in Bohemia in the 15th century.

Picard, the author of this ſect, from whom it derived its name, drew after him, as has been generally ſaid, a number of men and women, pretending he would reſtore them to the primitive ſtate of innocence wherein man was created: and accordingly he aſſumed the title of the *New Adam*. With this pretence he taught his followers to give themſelves up to all impurity; ſaying that therein conſiſted the liberty of the ſons of God; and that all thoſe not of their ſect were in bondage.

He

* *Eſſays by Dr Beattie*, 8vo edit. p. 422. note.

Picards. He firſt publiſhed his notions in Germany and the low countries, and perſuaded many people to go naked, and gave them the name of *Adamites*. After this he ſeized on an iſland in the river Lauſneez, ſome leagues from Thabor, the head quarters of Ziſca, where he fixed himſelf and his followers. His women were common, but none were allowed to enjoy them without his permiſſion: ſo that when any man deſired a particular woman, he carried her to Picard, who gave him leave in theſe words, *Go, increaſe, multiply, and fill the earth.*

At length, however, Ziſca, general of the Huſſites, (famous for his victories over the emperor Sigiſmund), hurt at their abominations, marched againſt them, made himſelf maſter of their iſland, and put them all to death except two; whom he ſpared, that he might learn their doctrine.

Such is the account which various writers, relying on the authorities of Æneas Sylvius and Varillas, have given of the Picards, who appear to have been a party of the Vaudois, that fled from perſecution in their own country, and ſought refuge in Bohemia. It is indeed doubtful whether a ſect of this denomination, chargeable with ſuch wild principles and ſuch licentious conduct, ever exiſted; and it is certainly aſtoniſhing that Mr Bayle, in his art. *Picards*, ſhould adopt the reproachful repreſentations of the writers juſt mentioned: for it appears probable at leaſt that the whole is a calumny invented and propagated in order to diſgrace the Picards, merely becauſe they deſerted the communion and proteſted againſt the errors of the church of Rome. Laſitius informs us, that Picard, together with 40 other perſons, beſides women and children, ſettled in Bohemia in the year 1418. Balbinus the Jeſuit, in his *Epitome Rerum Bohemicarum*, lib. ii. gives a ſimilar account, and charges on the Picards none of the extravagancies or crimes aſcribed to them by Sylvius. Schlecta, ſecretary of Ladiſlaus, king of Bohemia, in his letters to Eraſmus in which he gives a particular account of the Picards, ſays that they conſidered the pope, cardinals, and biſhops of Rome, as the true Antichriſts, and the adorers of the conſecrated elements in the euchariſt as downright idolaters; that they denied the corporal preſence of Chriſt in this ordinance; that they condemned the worſhip of ſaints, prayers for the dead, auricular confeſſion, the penance impoſed by prieſts, the feaſts and vigils obſerved in the Romiſh church; and that they confined themſelves to the obſervance of the ſabbath, and of the two great feaſts of Chriſtmas and Pentecoſt. From this account it would appear that they were no other than the Vaudois; and M. de Beauſobre has ſhown that they were both of the ſame ſect, though under different denominations. Beſides, it is certain that the Vaudois were ſettled in Bohemia in the year 1178, where ſome of them adopted the rites of the Greek, and others thoſe of the Latin church. The former were pretty generally adhered to till the middle of the 14th century, when the eſtabliſhment of the Latin rites cauſed great diſturbance. On the commencement of the national troubles in Bohemia, on account of the oppoſition to the papal power (ſee MORAVIANS), the Picards more publicly avowed and defended their religious opinions; and they formed a conſiderable body in an iſland by the river Launitz or Lauſneez, in the diſtrict of Bechin, and recurring to arms, were defeated by Ziſca. *Encyclop.* art. Picards.

Picardy ſi Piccolomini.

PICARDY, a province in France, is bounded on the north by Hainault, Artois, and the Straits of Calais; on the eaſt by Champaigne; on the ſouth by the Iſle of France; and on the weſt by Normandy and the Engliſh Channel (A). This province is long and narrow, being uſually compared to a bent arm; and in this figure is nearly 150 miles in length, but not above 40 in breadth, and in many places not above 20. It is generally a level country; and produces wine, fruit of all kinds, plenty of corn, and great quantities of hay: but wood being ſcarce, moſt of the inhabitants burn turf. They have, however, ſome pit-coal, but it is not ſo good as that of England. It was united to the crown of France in the year 1643; and is ſuppoſed to contain 533,000 inhabitants. *Payne's Geography*, vol. ii. p. 464.

Its principal rivers are the Somme, the Oiſe, the Canche, the Lanthie, the Lys, the Aa, the Scarpe, and the Deule.

The ſituation of this province on the ſea, its many navigable rivers and canals, with the induſtry of the inhabitants, render it the ſeat of a flouriſhing trade. In it are made beautiful ſilk ſtuffs, woollen ſtuffs, coarſe linen, lawn, and ſoap; it alſo carries on a large trade in corn and pit-coal. In the government of Calais and Boulogne are annually bred 5000 or 6000 colts, which being afterwards turned loſe in the paſtures of Normandy, are ſold for Norman horſes. The fiſheries on this coaſt are alſo very advantageous. This province is divided into Upper, Middle, and Lower Picardy; and is again ſubdivided into four deputy-governments. The principal town is Amiens.

PICART (Bernard), a celebrated engraver, ſon of Stephen Picart, alſo a famous engraver, was born at Paris in 1673. He learned the elements of his art from his father, and ſtudied architecture and perſpective under Sebaſtian le Clerc. As he embraced the reformed religion, he ſettled in Holland to enjoy the free exerciſe of it; where his genius produced thoſe maſterpieces which made him eſteemed the moſt ingenious artiſt of his age. A multitude of books are embelliſhed with plates of his engraving. He died in 1733.

PICCOLOMINI (Alexander), archbiſhop of Patras, and a native of Sienna, where he was born about the year 1508, was of an illuſtrious and ancient family, which came originally from Rome, but afterwards ſettled at Sienna. He compoſed with ſucceſs for the theatre; but he was not more diſtinguiſhed by his genius, than by the purity of his manners, and his regard to virtue. His charity was very great; and was chiefly exerted

(A) The origin of the name of this province does not date earlier than A. D. 1200. It was an academical joke; an epithet firſt applied to the quarrelſome humour of thoſe ſtudents in the univerſity of Paris who came from the frontier of France and Flanders, and hence to their country. *Valeſii Notitia Galliarum*, p. 447. *Longuerue, Deſcription de la France*, p. 52.

Piccolomini. exerted in relieving the neceſſities of men of letters. He has left behind him a number of works in Italian. The moſt remarkable of which are, 1. Various Dramatic Pieces, which laid the firſt foundation of his character as a writer. 2. A Treatiſe on the Sphere. 3. A Theory of the Planets. 4. A Tranſlation of Ariſtotle's Art of Rhetoric and Poetry, in 4to 5. A Syſtem of Morality, publiſhed at Venice, 1575, in 4to; tranſlated into French by Peter de Larivey in 4to; and printed at Paris, 1581. Theſe, with a variety of other works, prove his extenſive knowledge in natural philoſophy, mathematics, and theology. He was the firſt who made uſe of the Italian language in writing upon philoſophical ſubjects. He died at Sienna the 12th of March 1578, aged 70. A particular catalogue of his works may be ſeen in the Typographical Dictionary. There is one performance aſcribed to this author, intitled *Dialogo della bella Creanza delle Donne*, (printed at Milan, 1558, and at Venice, 1574, in 8vo.); which but ill ſuits the dignity of a prelate. It is filled with maxims which have an evident tendency to hurt the morals of young women. Piccolomini's name, indeed, is not in the title page; and it has all the appearance of being a juvenile production. It is very ſcarce; and the public would ſuſtain no loſs by its being entirely out of print. It was tranſlated into French by F. d'Amboiſe, and publiſhed at Lyons, in 16mo, under the title of *Inſtruction des jeunes dames*. It was afterwards reprinted in 1583, under that of *Dialogue & Devis des Demoiſelles*.

Piccolomini (Francis), of the ſame family with the foregoing, was born in 1520, and taught philoſophy with ſucceſs, for the ſpace of 22 years, in the moſt celebrated univerſities of Italy, and afterwards retired to Sienna, where he died, in 1604, at the age of 84. The city went into mourning on his death. His works are, 1. Some Commentaries upon Ariſtotle, printed at Mayence, 1608, in 4to. 2. *Univerſa Philoſophia de Moribus*, printed at Venice, 1583, in folio. He laboured to revive the doctrine of Plato, and endeavoured alſo to imitate the manners of that philoſopher. He had for his rival the famous James Zabarella, whom he excelled in facility of expreſſion and neatneſs of diſcourſe; but to whom he was much inferior in point of argument, becauſe he did not examine matters to the bottom as the other did; but preſſed too rapidly from one propoſition to another.

Piccolomini of *Aragon* (Octavius), duke of Amalfi, prince of the Empire, a general of the emperor's army, and knight of the order of the Golden Fleece, was born in 1599. He firſt bore arms among the Spaniſh troops in Italy. He afterwards ſerved in the army of Ferdinand II. who ſent him to the relief of Bohemia, and entruſted him with the command of the imperial troops in 1634. After having ſignalized himſelf at the battle of Nortlingue, he made Marſhal de Chatillon raiſe the ſiege of St Omer. He had the good fortune to gain a victory over Marquis de Feuquieres in 1639: nor did the loſs of the battle of Wolfenbuttel, in 1641, impair his glory. He died on the 10th of Auguſt 1656, being five years after, aged 57, without iſſue; and with the character of an able negociator and an active general. The celebrated Caprara was his nephew.

Piccolomini (James), whoſe proper name was *Ammanati*, took that of *Piccolomini* in honour of his patron Pius II. He was born in a village near Lucca in 1422. He became biſhop of Maſſa, afterwards of Freſcati: a cardinal in 1461, under the name of *Cardinal de Pavie*; and died in 1479, at the age of 57, of an indigeſtion of figs. He left 8000 piſtoles in the bankers hands, which Pope Sixtus IV. claimed; and of which he gave a part to the Hoſpital of the Holy Ghoſt. His works, which conſiſt of ſome Letters, and a Hiſtory of his own time, were printed at Milan, in 1521, in folio. His hiſtory, intitled *Commentaries*, commences the 18th of June 1464, and ends the 6th of December 1469. They may very properly be conſidered as a Sequel of Pope Pius II.'s Commentaries, which end with the year 1463.

Piccolomini, (Æneas Sylvius). See Pius II. Piccolomini II. Pickering.

PICENTIA, (Strabo, Pliny), the capital of the Picentini, whoſe territory, called *Ager Picentinus*, a ſmall diſtrict, lay on the Tuſcan Sea, from the *Promontorium Minervæ*, the ſouth boundary of Campania on the coaſt, to the river Silarus, the north boundary of Lucania, extending within-land as far as the Samnites and Hirpini, though the exact termination cannot be aſſigned. The Greeks commonly confound the *Picentini* and *Picentes*, but the Romans carefully diſtinguiſh them. The former, with no more than two towns that can be named, *Silernum* and *Picentia*; the ſituation of both doubtful: only Pliny ſays the latter ſtood within-land, at ſome diſtance from the ſea. Now thought to be *Bicenza*, (Holſtenius), in the Principato Citra of Naples.

PICENUM, (Cæſar, Pliny, Florus); Picenus Ager, (Cicero, Salluſt, Livy, Tacitus); *Ager Picentium*, (Varro): a territory of Italy, lying to the eaſt of Umbria, from the Apennine to the Adriatic; on the coaſt extending from the river Aeſis on the north, as far as the *Prætutiani* to the ſouth. In the upper or northern part of their territory the Umbri excluded them from the Apennine, as far as Camerinum, (Strabo); but in the lower or ſouthern part they extended from the Adriatic to the Apennine. A very fruitful territory, and very populous. *Picentes*, the people, (Cicero); from the ſingular, *Picens*, (Livy): different from the *Picentini*, on the Tuſcan ſea, though called ſo by the Greeks; but Ptolemy calls them *Piceni*, as does alſo Pliny. Their territory at this day is ſuppoſed to form the greateſt part of the March of Ancona, (Cluverius).

PICHFORD, in the county of Salop in England; on the ſouth-eaſt ſide of Shrewſbury, near Condover. It is noted for a ſpring of pitchy water (from whence ſome derive its name), on the top of which there always flows a ſort of liquid bitumen. Over moſt of the coal pits hereabouts there lies a ſtratum of blackiſh rock; of which, by boiling and grinding, they make pitch and tar, and alſo diſtil an oil from it.

PICHINCHA, a mountain in Peru. See Peru, n° 56.

PICKERING, in the north riding of Yorkſhire in England, 13 miles from Scarborough, and 225 from London, is a pretty large town belonging to the duchy of Lancaſter, on a hill among the wild mountains of Blakemore; having the foreſt of Pickering on the north, and Pickering-common on the ſouth. It is ſaid to have been built 270 years before Chriſt by Peridurus, a king of the Britons, who was buried here. It had once a caſtle, the ruins of which are ſtill to be

Pickery || Pico.

seen; to whose jurisdiction many of the neighbouring villages were subject: and the adjacent territory, commonly called Pickering-Lath, or the liberty or forest of Pickering, was given by Henry III. to his son Edmund earl of Lancaster. A court is kept here for all actions under 40s. arising within the honour of Pickering.

PICKERY, in Scots law, petty theft, or stealing things of small value.

PICKETS, in fortification, stakes sharp at one end, and sometimes shod with iron, used in laying out the ground, of about three feet long; but, when used for pinning the fascines of a battery, they are from three to five feet long.

Pickets, in artillery, are about five or six feet long, shod with iron, to pin the park lines, in laying out the boundaries of the park.

Pickets, in the camp, are also stakes of about six or eight inches long, to fasten the tent cords, in pitching the tents; also, of about four or five feet long, driven into the ground near the tents of the horsemen, to tie their horses to.

Picket, an out-guard posted before an army, to give notice of an enemy approaching.

Picket, a kind of punishment so called, where a soldier stands with one foot upon a sharp pointed stake; the time of his standing is limited according to the offence.

PICKLE, a brine or liquor, commonly composed of salt, vinegar, &c. sometimes with the addition of spices, wherein meat, fruit, and other things, are preserved and seasoned.

PICO, one of the Azore Islands, is so called from some lofty mountains on it; or rather from one very high mountain, terminating like Tenerisse in a peak, and reputed by some writers equal to it in height. This island lies about four leagues south-west from St George, twelve from Tercera, and about three leagues south-east of Fayal; in W. Long. 28. 21. and N. Lat. 38. 29. The mountain Pico, which gives name to the island, is filled with dismal dark caverns or volcanoes, which frequently vomit out flames, smoke, and ashes, to a great distance. At the foot of this mountain towards the east is a spring of fresh water, generally cold, but sometimes so heated with the subterraneous fire, as to rush forth in torrents with a kind of ebullition like boiling water; equalling that in heat, and sending forth a steam of sulphureous fetid vapours, liquefied stones, minerals, and flakes of earth all on fire, in such quantities, and with such a violence, as to have formed a kind of promontory vulgarly called *Mysterios*, on the declivity of the coast, and at the distance of 1200 paces from the fountain. Such at least is the account of Ortelius; though we do not find this last circumstance of the promontory confirmed by later observations. The circumference of Pico is computed at about 15 leagues: and its most remarkable places are Pico, Lagoas, Santa Cruce or Cruz, San Sebastian, Pesquin, San Rocko, Playa, and Magdalena; the inhabitants of which live wholly on the produce of the island, in great plenty and felicity. The cattle are various, numerous, and excellent in their several kinds: it is the same with the vine; and its juice, prepared into different wines, the best in the Azores. Besides cedar and other timber, they have a kind of wood which they call *teixo*, solid and hard as iron; and veined, when finely polished, like a rich scarlet tabby; which colour it has in great perfection. The longer it is kept, the more beautiful it grows: hence it is, that the teixo tree is felled only for the king's use or by his order; and is prohibited from being exported as a common article of trade.

Pico || Picrania.

Pico Marina, a sea fish common at Kongo in Africa, derives its name from the resemblance of its mouth to the beak of a wood-pecker. It is of a large size, and prodigious strength, has four fins on its back, three under its belly, and one on each side of its head; its tail is large and forked, by which it cuts the waves with surprising force and velocity. It is at war with every fish that swims, and with every thing it meets in its way, without being intimidated by the largest vessels; a surprising instance of which intrepidity, we are told by some missionaries, whose ship was attacked by one of them, near these coasts, in the dead of night. The violence of the shock which it gave to the vessel quickly awakened the captain and the rest of the people; who immediately ran to the ship's side, where they perceived, by moon light, this huge monster softened by its forehead to the vessel, and making the strongest efforts to disengage itself; upon which some of them tried to pierce him with their pikes, but he got off before they could accomplish their aim. On the next morning, upon visiting that side of the vessel, they found, about a foot below the surface of the water, a piece of its bony snout stuck fast into the wood, and two or three inches of it projecting outwards. They went presently after to visit the inside of the ship, and discovered about five or six inches more of the point of the horn which had penetrated through the plank.

Mod. Univ. History, vol. xii. p. 46. &c.

PICQUERING, a flying war, or skirmish, made by soldiers detached from two armies for pillage, or before a main battle begins.

PICQUET, or Picket. See Piquet.

PICRAMNIA, in botany: A genus of the pentandria order, belonging to the dioecia class of plants; and in the natural method ranking with those that are doubtful. The calyx is tripartite; the corolla has three petals; the stamina from three to five, awl-shaped, and seem to join together at the base; there are two styli, which are short and bent backwards; the berry is roundish, and contains two oblong seeds, and sometimes one seed only. There is only one species, viz. the antidesma, or murjoe bush. This shrub is frequent in copses and about the skirts of woods in Jamaica, rising about eight or nine feet from the ground. The leaves are of an oval form, pointed and placed in an alternate form along the branches; the flower spikes are long, pendulous, and slender; the florets small and white: the berries are numerous; at first red, then of a jet black colour; the pulp is soft, and of a purple complexion.—The whole plant is bitter, and especially the berry. The negroes make a decoction of them, and use it in weaknesses of the stomach and in venereal cases.

PICRANIA AMARA, or *Bitter Wood*, is a tall and beautiful timber tree, common in the woods of Jamaica. It is a new genus, belonging to the pentandria monogynia of Linnæus. The name is expressive of its sensible qualities.

Every part of this tree is intensely bitter; and even after the tree has been laid for floors many years, whoever

Picris || Picter.

ever rubs or ſcrapes the wood, feels a great degree of bitterneſs in their mouth or throat. Cabinet-work made of this wood is very uſeful, as no inſect will live near it.

This tree has a great affinity to the *Quaſſia Amara* of Linnæus; in lieu of which it is uſed as an antiſeptic in putrid fevers. When uſed, leſs of it will do than of the *Quaſſia Amara* of Surinam. See QUASSIA.

PICRIS, OX-TONGUE; a genus of the polygamia æqualis order, belonging to the ſyngeneſia claſs of plants. There are four ſpecies, of which the only remarkable one is the echioides, or common ox-tongue, growing ſpontaneouſly in corn-fields in Britain. It has undivided leaves embracing the ſtem, with yellow bloſſoms, which ſometimes cloſe ſoon after noon, at other times remain open till nine at night. It is an agreeable pot herb while young. The juice is milky, but not too acrid.

PICRIUM, in botany: A genus of the monogynia order, belonging to the tetrandria claſs of plants; and in the natural method ranking with thoſe that are doubtful. The calyx is monophyllous and quinquefid; the corolla monopetalous, and its tube is ſhort; the filaments are four in number, and hooded at the place of their inſertion; the ſtyle long and thick; the ſtigma bilamellated; the capſule is round, bivalved, and contains a number of ſmall ſeeds.—There are two ſpecies, viz. the *ſpicata* and *ramoſa*; both natives of Guaiana. Both ſpecies are bitter, and employed in dyſpepſy, and to promote the menſes: they are alſo recommended in viſceral obſtructions.

PICTET (Benedict), born at Geneva, in 1655, of a diſtinguiſhed family, proſecuted his ſtudies with great ſucceſs. After having travelled into Holland and England, he taught theology in his own country with an extraordinary reputation. The univerſity of Leyden, after the death of Spanheim, ſolicited him to come and fill his place; but he thought that his own country had the beſt right to his ſervices: and for that generoſity he received its thanks by the mouth of the members of council. A languiſhing diſorder, occaſioned by too much fatigue, haſtened his death; which happened on the 9th of June 1724, at the age of 69 years. This miniſter had much ſweetneſs and affability in his manner. The poor found in him a comforter and a father. He publiſhed a great number of works in Latin and French, which are much eſteemed in Proteſtant countries. The principal of theſe are, 1. A Syſtem of Chriſtian Theology in Latin, 3 vols. in 4to; the beſt edition of which is that of 1721. 2. Chriſtian Morality, printed at Geneva, 1710, 8 vols in 12mo. 3. The Hiſtory of the 11th and 12th centuries; intended as a ſequel to that of Sueur, printed in 1713, 2 vols. in 4to. The Continuator is held in higher eſtimation than the firſt author. 4. Several Controverſial Treatiſes. 5. A great number of tracts on morality and piety: among which we muſt diſtinguiſh "the Art of Living and dying well;" publiſhed at Geneva, 1705, in 12mo. 6. Some Letters. 7. Some Sermons, from 1697 to 1721; 4 vols. in 8vo. With a vaſt number of other books, the names of which it would be tedious to mention; but which, as Mr Senebier ſays, "all ſhow evident marks of piety and good ſenſe."

PICTET (John-Louis), a counſellor of Geneva, born in 1739, was of the ſame family. He was member of the Council of Two Hundred; Counſellor of State and Syndic; and died in 1781. He applied himſelf to the ſtudy of aſtronomy, and made ſeveral voyages into France and England for his improvement. Few men were ever bleſſed with a clearer or more enlightened underſtanding. He has left in manuſcript the "Journal of a Voyage which he made to Ruſſia and Siberia in 1768 and 1769, in order to obſerve the tranſit of Venus over the ſun's diſk:" A work very intereſting, from the lively deſcriptions which it gives both of men and of nature. Pictet || Picts.

PICTLAND. See PENTLAND.

PICTS, the name of one of thoſe nations who anciently poſſeſſed the north of Britain. It is generally believed that they were ſo called from their cuſtom of painting their bodies; an opinion which Camden ſupports with great erudition. (See Gough's edition, Vol. I. p. xci. of the preface). It is certainly liable, however, to conſiderable objections; for as this cuſtom prevailed among the other ancient inhabitants of Britain, who uſed the *glaſtum* of Pliny and the *vitrum* of Mela for the like purpoſe, it may be aſked, Why the name of *Picti* was confined by the Romans to only one tribe, when it was equally applicable to many others? Why ſhould they deſign them only by an epithet without ever annexing their proper name? Or why ſhould they impoſe a new name on this people only, when they give their proper name to every other tribe which they have occaſion to ſpeak of? As theſe queſtions cannot be anſwered in any ſatisfactory manner, it is plain we muſt look for ſome other derivation of the name. 1 Name.

The Highlanders of Scotland, who ſpeak the ancient language of Caledonia, expreſs the name of this once famous nation by the term *Pictich*; a name familiar to the ears of the moſt illiterate, who could never have derived it from the Roman authors. The word *Pictich* means *pilferers* or *plunderers*. The appellation was probably impoſed upon this people by their neighbours, or aſſumed by themſelves, ſome time after the reign of Caracalla, when the unguarded ſtate of the Roman province, on which this people bordered, gave them frequent opportunities of making incurſions thither, and committing depredations. Accordingly this name ſeems to have been unknown till the end of the 3d century. Eumenius the panegyriſt is the firſt Roman author who mentions this people under their new name of *Pictich*, or, with a Latin termination, *Picti*. When we ſay that this name may have been probably aſſumed for the reaſon juſt now mentioned, we muſt obſerve, that, in thoſe days of violence, the character of a robber was attended with no diſgrace. If he had the addreſs to form his ſchemes well, and to execute them ſucceſsfully, he was rather praiſed than blamed for his conduct; providing he made no encroachments on the property of his own tribe or any of its allies. We mean this as no peculiar ſtigma upon the Picts; for other nations of antiquity, in the like rude ſtate, thought and acted as they did. See *Thucydides*, lib. 3. p. 3. and *Virg. Æn.* 7. 745 et 749.

Concerning the origin of the Picts, authors are much divided. Boethius derives them from the Agathyrſi, 2 Origin. 7

Picts. thyrſi, Pomponius Lætus from the Germans, Bede from the Scythians, Camden(A) and Father Innes from the ancient Britons, Stillingfleet from a people inhabiting the Cimbrica Cherſoneſus, and Keating and O'Flaherty, on the authority of the Pſalter Caſhel, derive them from the Thracians. But the moſt probable opinion is, that they were the deſcendants of the old Caledonians. Several reaſons are urged in ſupport of this opinion by Dr Macpherſon; and the words of Eumenes, "Caledonum, aliorumque Pictorum, ſilvas," &c. plainly imply that the Picts and Caledonians were one and the ſame people.

As there has been much diſpute about the origin of the Picts, ſo there has been likewiſe about their language. There are many reaſons which make it plain that their tongue was the Gaelic or Celtic; and theſe reaſons are a further confirmation of their having been of Caledonian extract. Through the eaſt and north eaſt coaſts of Scotland (which were poſſeſſed by the Picts) we meet with an innumerable liſt of names of places, rivers, mountains, &c. which are manifeſtly Gaelic.

3 Language. From a very old regiſter of the priory of St Andrew's (Dalrymple's Collections, p. 122.) it appears, that in the days of Hungus, the laſt Pictiſh king of that name, St Andrew's was called *Mukroſs*; and that the town now called *Queensferry* had the name of *Ardchinneachan*. Both theſe words are plain Gaelic. The firſt ſignifies "the heath or promontory of boars;" and the latter, "the height or peninſula of Kenneth." In the liſt of Pictiſh kings publiſhed by Father Innes, moſt of the names are obviouſly Gaelic, and in many inſtances the ſame with the names in the liſt of Scottiſh or Caledonian kings publiſhed by the ſame author. Had Innes underſtood any thing of this language, he would not have ſuppoſed with Camden that the Picts ſpoke the Britiſh tongue. It was unlucky that the two words on which they built their conjecture (*Strath* and *Aber*) are as common in the Gaelic as they could have been in the Britiſh, and at this day make a part of the names of places in countries to which the Pictiſh empire never extended. The names of *Strathfillan* and *Lochaber* may ſerve as inſtances.

The venerable Bede, as much a ſtranger to the Celtic as either of the antiquaries juſt now mentioned, is equally unhappy in the ſpecimen which he gives of the Pictiſh language in the word *penuahel*, "the head of the wall." Allowing the commutation of the initial *p* into *c*, as in ſome other caſes, this word has ſtill the ſame meaning in Gaelic which Bede gives it in the Pictiſh. It is true, there might have been then, as well as now, a conſiderable difference between various dialects of the Celtic; and thus, perhaps, that pious author was led to diſcover five languages in Britain *agreeably to the five books of Moſes*: A conceit from which the good man derived a great deal of harmleſs ſatisfaction.

4 Territory. The Picts of the earlieſt ages, as appears from the joint teſtimony of all writers who have examined the ſubject, poſſeſſed only the eaſt and north-eaſt coaſt of Scotland. On one ſide, the ancient Drumalbin, or that ridge of mountains reaching from Lochlomond near Dumbarton to the frith of Taine, which ſeparates the county of Sutherland from a part of Roſs, was the boundary of the Pictiſh dominions. Accordingly we find in the life of Columba, that, in travelling to the palace of Brudius, king of the Picts, he travelled over Drumalbin, the *Dorſum Britanniæ* of Adamnan. On the other ſide, the territory of the Picts was bounded by the Roman province. After Britain was relinquiſhed by the emperor Honorius, they and the Saxons by turns were maſters of thoſe countries which lie between the frith of Edinburgh and the river Tweed. We learn from Bede, that the Saxons were maſters of Galloway when he finiſhed his Eccleſiaſtical Hiſtory. The Picts, however, made a conqueſt of that country ſoon after; ſo that, before the extinction of their monarchy, all the territories bounded on the one ſide by the Forth and Clyde, and on the other by the Tweed and Solway, fell into their hands.

5 Hiſtory. The hiſtory of the Picts, as well as of all the other ancient inhabitants of Britain, is extremely dark. The Iriſh hiſtorians give us a long liſt of Pictiſh kings, who reigned over Pictavia for the ſpace of eleven or thirteen centuries before the Chriſtian era. After them Innes, in his Critical Eſſay, gives us a liſt of above fifty, of whom no leſs than five held the ſceptre, each for a whole century. It is probable that theſe writers had confounded the hiſtory of the Picts with that of their anceſtors the old Caledonians. In any other view, their accounts of them are highly fabulous; and have been long ago confuted by Dr Macpherſon of Slate, an antiquary of much learning and reſearch. The Picts, as has been already obſerved, were probably not known by that name before the 2d or 3d century. Adamnan, abbot of Iona, is the firſt author that expreſsly mentions any Pictiſh king; and the oldeſt after him is Bede. We are informed by theſe two writers, that St Columba converted Brudius king of the Picts to the Chriſtian faith. Columba came into Britain in the year of the vulgar era 565. Before that period we have no general record to aſcertain ſo much as the name of any Pictiſh king. The hiſtory of *Druſt* or *Dreſt*, who is ſaid to have reigned over the Picts in the beginning of the fifth century, when St Ninian firſt preached the goſpel to that nation, has all the appearance of fiction (B). His having reigned a hundred years, and his putting an end to a hundred wars, are ſtories which exceed all the bounds of probability.

Brudius, the contemporary of Columba, is the firſt Pictiſh king mentioned by any writer of authority.

What figure his anceſtors made, or who were his ſucceſſors on the throne of Pictavia, cannot be aſcertained. Bede informs us, that, during the reign of one of them, the Picts killed Egfred king of Northumberland in battle, and deſtroyed the greateſt part of

(A) See *Gough's edition of Camden*, Vol. I. Preface, p. xc. and the *Ancient Univerſal Hiſtory*, Vol. XVII. p. 39, &c.

(B) According to Camden, this converſion happened about the year 630, in the ſouthern Pictiſh provinces; while the northern, which were ſeparated by fruitful mountains, were converted by Columba.

Picts. his army. The same author mentions another of their kings called *Naitan*, for whom he had a particular regard. It was to this *Naitan* that Ceolfrid, abbot of Wiremouth, wrote his famous letter concerning Easter and the Tonsure (c); a letter in which Bede himself is supposed to have had a principal hand. Roger Hoveden and Simon of Durham mention two other Pictish kings *Onnust* and *Kinoth*, the first of whom died in 761, and the latter flourished about the 774, and gave an asylum to Alfred of Northumberland, who was much about that time expelled his kingdom. The accounts given by the Scots historians of several other Pictish kings cannot be depended on; nor are the stories told by the British historians, Geoffroy of Monmouth and the author of the *Eulogium Britannicæ*, worthy of much greater credit.

In the ninth century the Pictish nation was totally subdued by the Scots in the reign of Kenneth Macalpin. Since that time their name has been lost in that of the conquerors, with whom they were incorporated after this conquest; however, they seem to have been treated by the Scottish kings with great lenity, so that for some ages after they commanded a great deal of respect. The prior of Hogulstead, an old English historian, relates, that they made a considerable figure in the army of David the Saint, in his disputes with Stephen king of England. In a battle fought in the year 1136, by the English on one side, and the Scots and Picts on the other, the latter insisted on their hereditary right of leading the van of the Scots army, and were indulged in that request by the king.

The principal seat of the Pictish kings was at Abernethy. Brudius, however, as appears from the accounts given by Adamnan, in his life of Columba, had a palace at Inverness, which was probably near the extremity of his territory in that quarter; for there is no good reason for believing, with Camden, that this king had any property in the Western Isles, or that he had made a gift of Iona to St Columba when he visited him in that place.

6 Manners. With respect to the manners and customs of the Picts, there is no reason to suppose they were any other than those of the old Caledonians and Scots, of which many particulars are related in the Greek and Roman writers who have occasion to speak of those nations.

Upon the decline of the Roman empire, cohorts of barbarians were raised, and Picts were invited into the service, by Honorius, when peace was every where restored, and were named *Honoriaci*. Those under Constantine opened the passes of the Pyrenean mountains, and let the barbarous nations into Spain. From this period we date the civilization of their manners, which happened after they had by themselves, and then with the Scots, ravaged this Roman province.

Picts Wall, in antiquity, a wall begun by the emperor Adrian, on the northern bounds of England, to prevent the incursions of the Picts and Scots. It was first made only of turf strengthened with palisadoes, till the emperor Severus, coming into Britain in person, built it with solid stone. This wall, part of which still remains, begun at the entrance of the Solway Frith in Cumberland, and running north-east extended to the German Ocean. See Adrian and Severus. Picts Wall

PICTURE, a piece of painting, or a subject represented in colours, on wood, canvas, paper, or the like. See Painting

PICTURESQUE beauty, says a late writer on that subject, refers to "such beautiful objects as are suited to the pencil." This epithet is chiefly applied to the works of nature, though it will often apply to works of art also. Those objects are most properly denominated picturesque which are disposed by the hand of nature with a mixture of *varied rudeness*, *simplicity*, and *grandeur*. A plain neat garden, with little variation in its plan, and no striking grandeur in its position, displays too much of art, design, and uniformity, to be called picturesque. "The ideas of *neat* and *smooth* (says Mr Gilpin), instead of being picturesque, in fact disqualify the object in which they reside from any pretensions to picturesque beauty. Nay, farther, we do not scruple to assert, that roughness forms the most essential point of difference between the beautiful and the picturesque: as it seems to be that particular quality which makes objects chiefly pleasing in painting. I use the general term *roughness*; but properly speaking roughness relates only to the surfaces of bodies: when we speak of their delineation, we use the word *ruggedness*. Both ideas, however, equally enter into the picturesque, and both are observable in the smaller as well as in the larger parts of nature; in the outline and bark of a tree, as in the rude summit and craggy sides of a mountain. Picturesque Beauty.

"Let us then examine our theory by an appeal to experience, and try how far these qualities enter into the idea of picturesque beauty, and how far they mark that difference among objects which is the ground of our inquiry.

"A piece of Palladian architecture may be elegant in the last degree; the proportion of its parts, the propriety of its ornaments, and the symmetry of the whole, may be highly pleasing; but if we introduce it in a picture, it immediately becomes a formal object, and ceases to please. Should we wish to give it picturesque beauty, we must use the mallet instead of the chissel; we must beat down one half of it, deface the other, and throw the mutilated members around in heaps; in short, from a smooth building we must turn it into a rough ruin. No painter who had the choice of the two objects would hesitate a moment.

"Again,

(c) We are told by some authors that Columba taught the Picts to celebrate Easter always on a Sunday between the 14th and 20th of March, and to observe a different method of tonsure from the Romans, leaving an imperfect appearance of a crown. This occasioned much dispute till Naitan brought his subjects at length to the Roman rule. In that age many of the Picts went on a pilgrimage to Rome, according to the custom of the times; and amongst the rest we find two persons mentioned in the antiquities of St Peter's church: *Asterius* count of the Picts, and *Syra* with his countrymen, performed their vow.

Picturesque Beauty.

"Again, why does an elegant piece of garden-ground make no figure on canvas? the shape is pleasing, the combination of the objects harmonious, and the winding of the walk in the very line of beauty. All this is true; but the smoothness of the whole, though right and as it should be in nature, offends in picture. Turn the lawn into a piece of broken ground, plant rugged oaks instead of flowering shrubs, break the edges of the walk, give it the rudeness of a road, mark it with wheel tracks, and scatter around a few stones and brushwood; in a word, instead of making the whole smooth, make it rough, and you make it also picturesque. All the other ingredients of beauty it already possessed." On the whole, picturesque composition consists in uniting in one whole, a variety of parts, and these parts can only be obtained from rough objects.

It is possible therefore to find picturesque objects among works of art, and it is possible to make objects so; but the grand scene of picturesque beauty is nature in all its original variety, and in all its irregular grandeur. "We seek it (says our author) among all the ingredients of landscape, trees, rocks, broken grounds, woods, rivers, lakes, plains, valleys, mountains, and distances. These objects in themselves produce infinite variety; no two rocks or trees are exactly the same; they are varied a second time by combination; and almost as much a third time by different lights and shades and other aerial effects. Sometimes we find among them the exhibition of a whole, but oftener we find only beautiful parts."

Sublimity or grandeur alone cannot make an object picturesque: for, as our author remarks, "however grand the mountain or the rock may be, it has no claim to this epithet, unless its form, its colour, or its accompaniments, have some degree of beauty. Nothing can be more sublime than the ocean; but wholly unaccompanied, it has little of the picturesque. When we talk therefore of a sublime object, we always understand that it is also beautiful; and we call it sublime or beautiful only as the ideas of sublimity or simple beauty prevail. But it is not only the form and the composition of the objects of landscape which the picturesque eye examines, it connects them with the atmosphere, and seeks for all those various effects which are produced from that vast and wonderful storehouse of nature. Nor is there in travelling a greater pleasure than when a scene of grandeur bursts unexpectedly upon the eye, accompanied with some accidental circumstance of the atmosphere which harmonizes with it, and gives it double value."

There are few places so barren as to afford no picturesque scene.

——— ——— ———Believe the muse,
She does not know that inauspicious spot
Where beauty is thus niggard of her store.
Believe the muse, through this terrestrial waste
The seeds of grace are sown, profusely sown,
Even where we least may hope.——

Mr Gilpin mentions the great military road between Newcastle and Carlisle as the most barren tract of country in England: and yet there, he says, there is "always something to amuse the eye. The interchangeable patches of heath and green-sward make an agreeable variety. Often too on these vast tracts of intersecting grounds we see beautiful lights, softening off along the sides of hills; and often we see them adorned with cattle, flocks of sheep, heath-cocks, grous, plover, and flights of other wild-fowl. A group of cattle standing in the shade on the edge of a dark hill, and relieved by a lighter distance beyond them, will often make a complete picture without any other accompaniment. In many other situations also we find them wonderfully pleasing, and capable of making pictures amidst all the deficiencies of landscape. Even a winding road itself is an object of beauty; while the richness of the heath on each side, with the little hillocks and crumbling earth, give many an excellent lesson for a store ground. When we have no opportunity of examining the grand scenery of nature, we have every where at least the means of observing with what a multiplicity of parts, and yet with what general simplicity, she covers every surface.

"But if we let the imagination loose, even scenes like these administer great amusement. The imagination can plant hills; can form rivers and lakes in valleys; can build castles and abbeys; and if it find no other amusement, can dilate itself in vast ideas of space."

Mr Gilpin, after describing such objects as may be called picturesque, proceeds to consider their sources of amusement. We cannot follow our ingenious author through the whole of this consideration, and shall therefore finish our article with a short quotation from the beginning of it. "We might begin (says he) in moral style, and consider the objects of nature in a higher light than merely as amusement. We might observe, that a search after beauty should naturally lead the mind to the great origin of all beauty; to the

——— ——— first good, first perfect, and first fair.

But though in theory this seems a natural climax, we insist the less upon it, as in fact we have scarce ground to hope that every admirer of picturesque beauty is an admirer also of the beauty of virtue; and that every lover of nature reflects, that

Nature is but a name for an *effect*,
Whose *cause* is God. ——— ———

If, however, the admirer of nature can turn his amusements to a higher purpose; if its great scenes can inspire him with religious awe, or its tranquil scenes with that complacency of mind which is so nearly allied to benevolence, it is certainly the better. *Apponat lucro.* It is so much into the bargain; for we dare not promise him more from picturesque travel than a rational and agreeable amusement. Yet even this may be of some use in an age teeming with licentious pleasure; and may in this light at least be considered as having a moral tendency."

Picturesque Beauty. Picuipinima.

PICUIPINIMA, in ornithology, is the name of a species of pigeon in Brasil. It is so very small as scarce to exceed the lark in size. Its head, neck, and wings, are of a pale lead colour, with a black semilunar mark at the extremity of each wing; but its long wing-feathers, which are seen when the wings are expanded in flying, are of a reddish-brown on one side, and blackish on the other, with black ends or tips; the tail is

Picumnus, Picus.

long, and is variegated with black, white, and brown; the belly is covered with white feathers, every one of which has a brown mark of the ſhape of a half moon at the end.

PICUMNUS and PILUMNUS, were two deities at Rome, who preſided over the auſpices required before the celebration of nuptials. Pilumnus was ſuppoſed to patronize children, as his name ſeems in ſome manner to indicate *quod pellat mala infantiæ*. The manuring of land was firſt invented by Picumnus, from which reaſon he is is called *Sterquilinius*. Pilumnus is alſo invoked as the god of bakers and millers, as he is ſaid to have firſt invented the art of grinding corn.

PICUS, the WOODPECKER, in ornithology, a genus belonging to the order of picæ. The beak is ſtraight, and conſiſts of many ſides, and like a wedge at the point; the noſtrils are covered with briſtly feathers; the tongue is round like a worm, very long, and ſharp at the point, which is beſet with briſtles bent backwards.

The grand characteriſtic, ſays Latham, of theſe birds is the tongue (which in no bird is ſimilar, the wryneck excepted, whoſe other characters, however, differ too widely to give it place in this claſs), the muſcles neceſſary to the motions of which are ſingular and worthy of notice; affording the animal means of darting it forwards the whole length, or drawing it within the mouth at will. See *Ray on the Creation*, p. 143. *Derham's Phyſic. Theol.* p. 342. Note e. *Will. Orn.* p. 136. t. 21.

The ſame intelligent ornithologiſt enumerates no leſs than 50 different ſpecies of woodpeckers, beſides varieties of ſome of them which amount to nine more. Each of theſe ſpecies our readers cannot expect us to deſcribe; we ſhall therefore content ourſelves with ſuch as appear to be moſt remarkable.

1. The picus martius, or greateſt black woodpecker, is about the ſize of a jackdaw, being about 17 inches long; the bill is nearly two inches and a half in length, of a dark aſh colour, and whitiſh on the ſides; the irides are pale yellow, and the eyelids are naked, according to Scopoli; the whole bird is black, except the crown of the head, which is vermilion; the firſt quill-feather is the ſhorteſt, and the two middle tail-feathers, which are longer than the others, make it appear a little rounded; the legs are of a lead colour, covered with feathers on the fore part for half their length.

Latham's Synopſis, vol. ii. p 552.

"The female differs from the male in having the hind head only red, and not the whole crown of the head; and the general colour of the plumage has a ſtrong caſt of brown in it. It has likewiſe been obſerved, that the red on the hind head has been wholly wanting; and indeed both male and female are apt much to vary in different ſubjects; ſome having a much greater proportion of red on the head than others. This ſpecies is found on the continent of Europe, but not in plenty except in Germany. It is not an inhabitant of Italy, and is very rarely ſeen in France. Friſch mentions it as a bird common to his parts; and it is found alſo in Sweden, Switzerland, and Denmark, but not in winter.

"It is ſaid to build in old aſh and poplar trees, making large and deep neſts; and Friſch obſerves, that they often ſo excavate a tree, that it is ſoon after blown down with the wind; and that under the hole of this bird may often be found a buſhel of duſt and bits of wood. The female lays two or three white eggs, the colour of which, as Willoughby obſerves, is peculiar to the whole of the woodpecker genus, or at leaſt all thoſe which have come under his inſpection."

Picus.

2. The picus principalis, or white-billed woodpecker, is ſomewhat bigger than the laſt, being equal in ſize to a crow. It is 16 inches long, and weighs about 20 ounces. The bill is white as ivory, three inches long, and channelled; the irides are yellow, and on the hind head is an erect pointed creſt, of a fine red colour, ſome of the feathers of which are two inches long; the head itſelf, and the body in general, are black; but the lower part of the back, rump, and upper tail-coverts, are white; from the eye there ariſes a ſtripe of white, which paſſes on each ſide of the neck down to the back; three or four of the prime quills are black, but the reſt are white; the tail is cuneiform, and of the ſame colour as the body; the legs and claws are alſo black.

"This ſpecies inhabits Carolina, Virginia, New Spain, and Braſil, and is called by the Spaniards *carpenter*, and not without reaſon, as this as well as moſt of the other ſpecies make a great noiſe with the bill againſt the trees in the woods, where they may be heard at a great diſtance, as if carpenters were at work, making, according to Cateſby, in an hour or two a buſhel of chips. He adds likewiſe, that the Canadian Indians make uſe of the bills of theſe birds for coronets, ſetting them round in a wreath with the points outwards; and that the northern Indians purchaſe them of the ſouthern at the rate of two and three buck-ſkins per bill. Kalm ſays they are found in New Jerſey, though very ſeldom, and only at certain ſeaſons."

3. The picus erythrocephalus, or red-headed woodpecker, is about eight inches three quarters long, and weighs two ounces. The bill is an inch and a quarter in length, of a lead colour, with a black tip; the irides are duſky; the head and the neck are of a moſt beautiful crimſon; the back and wings are black; the rump, breaſt, and belly, are white; the ten firſt quills are black, the eleventh black and white, and the others are white with black ſhafts; the tail is black and cuneiform; the legs and claws are of lead colour. The cock and hen are very nearly alike.

"This ſpecies inhabits Virginia, Carolina, Canada, and moſt of the parts of North America; but at the approach of winter it migrates more or leſs to the ſouthward, according to the ſeverity of the ſeaſon; and upon this circumſtance the people of North America foretel the rigour or clemency of the enſuing winter. Kalm obſerves that it is a very common bird, and is very deſtructive to the maize-fields and orchards, pecking through the ears of maize, and deſtroying great quantities of apples. In ſome years they are more numerous than in others, when they attack the orchards where the ſweet apples grow, which they eat ſo far that nothing remains but the mere pills. Some years ſince there was a premium of twopence per head paid from the public fund, in order to extirpate this pernicious bird; but this has been neglected much of late. They are ſaid likewiſe to be very fond of acorns. In Virginia and Carolina they ſtay the whole year, but

are

Picus. are not seen in such numbers in winter as in summer. During the winter they are very tame, and are frequently known to come into the houses in the same manner as the redbreast is wont to do in England. It is observed that this species is found chiefly in old trees; and the noise they make with their bills may be heard above a mile distant. It builds the earliest of all the woodpeckers, and generally pretty high from the ground. It is accounted by many people very good eating. Buffon is of opinion, that it is necessity alone that causes these birds to feed on vegetables of any kind, as it is contrary to the nature of the genus."

4. The picus pubescens, or little woodpecker, according to Catesby, weighs only about an ounce and an half. Brisson says, it is larger than the smallest of our European species, being about five inches and a half long. The bill is about eight lines long, and of a horn colour; the top of the head is black, and on each side above the eye is a white line; the hind head is red; the hind part of the neck, the back, and rump, are black, which is divided into two parts by a line of white passing down the middle to the rump; the scapulars, upper wing and tail coverts, are black; the greater wing coverts and quills are spotted with white; the under parts of the body are pale grey; the tail is black; the four middle feathers are plain, the rest are barred with white and black; and the legs and claws are black.

The female has no red on the hind head. Linnæus tells us, that the outer tail feather is white, marked with four black spots. This species inhabits Virginia and Carolina. According to Kalm, it abounds in New Jersey, where it is esteemed of all others the most dangerous to orchards, and is the most daring. As soon as it has pecked one hole in a tree, it makes another close to the first, in an horizontal direction, proceeding till it has made a circle of holes quite round the tree; and the apple trees in the orchards have often several of these rings of holes round the stem, insomuch that the tree frequently dries up and decays.

5. The yellow woodpecker is about nine inches long. The bill is of a yellowish white, and more than an inch long; the hind head is crested; the head itself, the neck, and whole body, are covered with dirty white feathers; from the lower jaw to the ears, on each side, there is a red stripe; the wing coverts are brown and edged with yellowish, and some of the greater ones are mixed with rufous on the inner web; the quills are brown or rufous; the tail is black; the legs and claws are grey.

"This species is common at Cayenne, and is called there *charpentier jaune*. It makes its nest in old trees which are rotten within; making with its bill a hole from without, at first horizontal, but declining downwards as soon as it has pierced through the sound part, till it is at last a foot and a half below the first opening. The female lays three white and nearly round eggs, and the young are hatched about the beginning of April. The male bears his share in the work with the female, and in her absence keeps centinel at the entrance of the hole. The note of this bird is a kind of whistle six times repeated, of which the two or three last are in a graver accent than the others. The female wants the red band on the side of the head which is seen in the male. Picus.

"Specimens vary; some are of that dirty white, as Brisson describes it, others of a light yellow; which last is the case in a specimen in the Leverian museum: this is 13 inches in length.

"In the place referred to above, we find a bird imperfectly described by Mr Fermin: he merely says, that it is a large species; that it has a fine red crest on the head; the neck, breast, and belly, of a citron colour; and the wings blueish above. He only adds, that it may be distinguished from others by the strokes of the bill, which it gives to the trees, and may be heard at a great distance."

6. The picus auratus, or gold-winged woodpecker, is about 11 inches long, and weighs about 5 ounces. The bill is an inch and a half long, and is somewhat bent, and is not square but roundish, ridged only on the top, the point being sharp; the upper parts of the head and neck are ash-coloured: the hind head is red; the sides of the head, throat, and fore part of the neck, are pale yellow; on each side of the head is a stripe of black, from the base of the lower jaw to the neck; the back, scapulars, and wing coverts, are of a grey brown colour, transversely striated with black lines; the rump is whitish; the breast, belly, and sides, are whitish yellow, and each feather is marked with a round black spot at the tip; on the middle of the breast there is a large crescent of black; the thighs, upper and under tail coverts, are black and white mixed; the quills are brown, with yellow shafts spotted with brown on the outer edge; the tail is blackish, being outwardly edged with grey; the outer feather is dotted with whitish on the margins; the shafts of all but the two middle feathers are yellow half way from the base; and the legs and claws are brown.

The female differs in having the crown and neck behind grey brown; the hind head of a less vivid red; and the greater quills not spotted on the edges. She also wants the black list on the throat, but otherwise like the male.

This species inhabits Virginia, Carolina, and Canada, and is plenty in New Jersey and about New York, where it is called by some *hitock* or *pint*, and by others *high-hole* (A). Both the first names have some relation to its

(A) "I have lately seen (says Latham) in the Leverian museum a bird which appears to be a mere variety, though brought from a far different country. This was much like the picus auratus in colour, but rather less in size. The bill exactly made like that bird, and brown; on each side of the jaw is a stripe of crimson like a whisker; the under part of the wings of a pale red colour, not unlike what is called *red lead*: and the shafts of the quills and tail, which in the other bird are yellow, in this are red; the plumage on the upper parts of the body is brown, beneath vinaceous, marked with round black spots; tail black, pointed, and each feather bifurcated at the tip, exactly like the American one. This was brought from the Cape of Good Hope. I have seen two specimens of this bird."

Picus. its note; and perhaps the latter, from the situation of the nest. It is almost continually on the ground, and is not observed to climb on the trees, like others of the genus. It lives chiefly on insects (B), and is commonly very fat, so as to be thought very palatable for the table. It stays all the year; and as it cannot at all times get insects, it must perhaps eat some kind of grass or plants in the fields. Its form and some of its qualities make it resemble the cuckow (C). Though it climbs not on trees, it flies to their tops and sits occasionally on the branches. Picus.

Forster, in the Philosophical Transactions, observes, that it is a bird of passage in the northern parts of America, visiting the neighbourhood of Albany Fort in April, and leaving it in September: that it lays from four to six eggs, in hollow trees, and feeds on worms and other insects. Called by the natives *su-thee-quannow*.

The following species are pretty well known in Britain

7. The viridis, or green woodpecker, weighs six ounces and a half; its length is 13 inches, the breadth 20 and a half; the bill is dusky, triangular, and near two inches long; the crown of the head is crimson, spotted with black; the eyes are surrounded with black, and the males have a rich crimson mark beneath the blackness; the back, neck, and lesser coverts of the wings, are green; the rump of a pale yellow; the whole of the under part of the body is of a very pale green, and the thighs and vent are marked with dusky lines; the legs and feet are of a cinereous green; the tail consists of ten stiff feathers, whose ends are generally broken, as the bird rests on them in climbing; their tips are black; the rest of each is alternately barred with dusky and deep green. These birds feed entirely on insects; and their principal action is that of climbing up and down the bodies or boughs of trees: for the first purpose they are provided with a long slender tongue, armed with a sharp bony end barbed on each side, which by the means of a curious apparatus of muscles they can exert at pleasure, darting it to a great length into the clifts of the bark, transfixing and drawing out the insects that lurk there. They make their nests in the hollows of trees: in order therefore to force their way to those cavities, their bills are formed strong, very hard, and wedge-like at the end; Dr Derham observes, that a neat ridge runs along the top, as if an artist had designed it for strength and beauty. Yet it has not power to penetrate a sound tree; their perforation of any tree is a warning to the owner to throw it down. Their legs are short, but strong; their thighs very muscular; their toes disposed two backward, two forward; the feathers of the tail are very stiff, sharp pointed, and bending downwards. The three first circumstances do admirably concur to enable them to run up and down the sides of trees with great security; and the strength of the tail supports them firmly when they continue long in one place, either where they find plenty of food, or while they are forming an access to the interior part of the timber. This form of the tail makes their flight very awkward, as it inclines their body down, and forces them to fly with short and frequent jerks when they would ascend, or even keep in a line. This species feeds oftener on the ground than any other of the genus: all of them make their nests in the hollows of trees; and lay five or six eggs, of a beautiful semitransparent white.

Willoughby says that the female lays five or six eggs; which Pennant (D) also observes; adding, that they are of a beautiful semitransparent white.

"These birds sometimes build in a hollow asp or other tree, 15 or 20 feet from the ground. The male and female take it by turns to bore through the living part of the wood, till they come to the rotten part, wherein, after being hollowed out to a proper depth, they lay their eggs (E), which are generally five and sometimes six (F) in number, greenish, with small black spots. The young ones climb up and down the trees before they can fly. It is worthy of remark to observe with what nicety the holes of the woodpecker are made, as perfectly round as if made by the assistance of a pair of compasses. Nuthatches, starlings, and bats, frequently build in these holes when deserted.

"Both Frisch and Klein mistake in saying that the females have not the red crown, for even the young ones in the nest have the appearance of it; and I have had them brought to me when they could scarcely fly, when the red was mixed with brown; but they do not become of a full red till after the first moult. They are said to be fond of bees in winter, making great havock among them. Salerne observes, that they are found in the markets in Italy, at Bologna; but this is not extraordinary, for the Italians eat all small birds almost without exception.

"In Sir A. Lever's museum there is a variety of this bird, of a straw-colour throughout, except the crown, which is faintly marked with red."

8. The major, or great spotted woodpecker, weighs two ounces three quarters; the length is nine inches; the breadth is 16. The bill is one and a quarter long, of a black horn colour. The irides are red. The forehead

(B) "In defect of insects I have been informed (says Mr Latham), that it feeds on the berries of the red cedar, and grows fat on them. This food has been both disgorged by the mouth, after being shot, as well as found in the stomach on dissection."

(C) "Linnæus, in his tenth edition of the *Systema Naturæ*, had ranked this with the cuckows; and Buffon, from its similarity to this genus, has placed it at the end of the woodpeckers of its class."

(D) *Br. Zool.* p. 242. where some pertinent observations on these birds may be found. Let the reader also consult *Ray on the Creation*, p. 143. and *Derham's Physico-theol.* p. 193, 339, 342.

(E) "This is sometimes so deep that they must feed their young quite in the dark; for I have been told by one, that he was obliged to thrust his whole arm to the shoulder down the hollow of a tree before he could reach the eggs."

(F) "I have seen six young ones together in one nest." *Will. Orn.* p. 136.

Picus. head is of a pale buff colour; the crown of the head a glofſy black; the hind-part marked with a rich deep crimſon ſpot. The cheeks are white; bounded beneath by a black line that paſſes from the corner of the mouth and ſurrounds the hind-part of the head. The neck is encircled with a black colour. The throat and breaſt are of a yellowiſh white; the vent feathers of a fine light crimſon. The back, rump, and coverts of the tail, and leſſer coverts of the wings, are black; the ſcapular feathers and coverts adjoining to them are white. The quill-feathers are black, elegantly marked on each web with round white ſpots. The four middle feathers of the tail are black, the next tipped with dirty yellow; the bottoms of the two outmoſt black; the upper parts a dirty white. The exterior feathers marked on each web with two black ſpots; the next with two on the inner web, and only one on the other. The legs are of a lead colour. The female wants that beautiful crimſon ſpot on the head; in other reſpects the colours of both agree. This ſpecies is much more uncommon than the preceding; and keeps altogether in the woods. This bird is pretty common in England, France, Germany, and other parts of Europe, frequenting the woods like the reſt of its genus, and is likewiſe met with in America. It is a very cunning bird; for when a perſon has ſeen one on a tree, he is almoſt ſure to loſe ſight of it, if the tree is large, and the obſerver not very attentive; for the moment it ſpies any one it will creep behind a branch, and there lie ſecure till the danger is over. The extreme facility with which birds of the woodpecker kind deſcend as well as aſcend the trees is worthy admiration, ſeeming to do both with equal eaſe to itſelf. We do not find any one who has noticed the colour of the eggs; but Buffon mentions having found a neſt with ſix young ones in an old decayed aſp tree, 30 feet from the ground.

9. The medius, or middle-ſized woodpecker, agrees with the preceding in colours and ſize, excepting that the crown of the head in this is of a rich crimſon; the crown of the head in the male of the former black; and the crimſon is in form of a bar on the hind part. Birds thus marked have been ſhot in Lancaſhire and other parts of England; but Mr Pennant is doubtful whether they are varieties, or diſtinct ſpecies. "Briſſon (ſays Latham), quotes many authors who have deſcribed this bird, but I am not clear in its being a diſtinct ſpecies. It is certainly much more ſcarce in England than any other. Buffon is reconciled to its being a variety only; but if ſo, this variety is regular, at leaſt, in all the ſpecimens which I have ſeen."

10. The minor, or leaſt ſpotted woodpecker, ſcarce weighs an ounce: the length is ſix inches; the breadth eleven. The forehead is of a dirty white: the crown of the head (in the male) of a beautiful crimſon: the cheeks and ſides of the neck are white, bounded by a bed of black beneath the former. The hind part of the head and neck, and the coverts of the wings, are black: the back is barred with black and white: the ſcapulars and quill feathers ſpotted with black and white: the four middle feathers of the tail are black; the others varied with black and white: the breaſt and belly are of a dirty white: the crown of the head (in the female) is white; the feet are of a lead colour. It has all the characters and actions of the greater kind, but is not ſo often met with. Salerne tells us that this bird is not found in France; but Buffon affirms that it inhabits moſt of the provinces there. It approaches near habitations in winter, and may be ſeen in orchards adjoining to houſes, which no doubt it does for the ſake of food, finding about the trunks of the trees both caterpillars and larvæ of inſects of all kinds. It builds in an hole of a tree, and often diſputes the right of poſſeſſion with the little colemouſe, which laſt, as it is much weaker of the two, muſt yield the victory. Willoughby ſays it is called in England by the name of *hickwall*. Linnæus, in his ſynonymes of this bird, quotes Haſſelquiſt for the ſame; but whoever will diligently read what this author ſays of the matter, will be convinced that the reference ſhould be to the greater rather than the leaſt of this genus. It is ſaid by him to inhabit the higher parts of Aſia. Picus

Mr Sonnerat mentions a bird found by him at Antigue, in the iſland of Panay, with the top of the head, and hind part of the neck, of a greyiſh black: on each ſide of the neck, two-thirds downwards, is a ſtripe of white, which begins juſt above the eye; and under this another of black from the eye to the ſhoulder. The upper part of the body is black and white. The under parts pale yellow, ſpotted with black. The tail is black above, and beneath barred with a dirty white and yellowiſh colour. The bill and legs blackiſh. The head had no red on it. Buffon ſuppoſes it to have been a female, and a variety only of our leaſt ſpotted woodpecker.

Picus (fab. hiſt.), a king of Latium, ſon of Saturn. He married Venilia, alſo called Canens, by whom he had Faunus. He was tenderly loved by the goddeſs Pomona, and he returned her affection. As he was one day hunting in the woods, he was met by Circe, who became deeply enamoured of him, and who changed him into a woodpecker, called by the name of *picus* among the Latins. His wife Venilia was ſo diſconſolate when ſhe was informed of his death, that ſhe pined away. Some ſuppoſe that Picus was the ſon of Pilumnus, and that he gave out propheeies to his ſubjects by means of a favourite woodpecker; from which circumſtance originated the fable of his being metamorphoſed into a bird.

Picus (John), earl of Mirandola, a prodigy of parts and learning, was the youngeſt child of John Francis Picus earl of Mirandola and Concordia; and was born in the year 1463. The progreſs that he made in letters was ſo extremely rapid, that it was matter of aſtoniſhment to ſee even a boy one of the firſt poets and orators of his age. He was the ſcholar of R. Jochanan, a German Jew, who confirmed his natural fondneſs for the cabaliſtical writings, inſomuch that he is reported to have declared, that thoſe who dived into them dived in the true head ſpring; whereas thoſe rivulets that had flowed thence into Greece were no better than corrupt and ſtagnated waters. After viſiting the moſt famous univerſities of France and Italy, he went to Rome; where, in 1486, before he was 24 years of age, he publiſhed 900 propoſitions in logic, mathematics, phyſics, divinity, cabaliſtic learning, and magic, drawn not only from Greek and Latin, but even from Jewiſh and Arabian writers: ſubjoining to his advertiſement, that, "if any philoſopher or divine would come to Rome to diſpute with

him

Picus
and
Pieces.

him upon any or all of them, he would defray the expences of his journey from the remoteſt corners of Italy." He enjoyed, however, the honour of this diſputatious challenge quietly, without danger to his credit: for envy procured ſome of his propoſitions to be charged with hereſy, and he was forbid to diſpute upon them. As a proof of the ignorance of his oppoſers, we are told that a theologian who had ſhown himſelf very zealous in cenſuring his book, being aſked what was the meaning of the word *cabbala?* anſwered, that he was a wicked man and a heretic, who had written againſt Jeſus Chriſt, and that thoſe who followed his opinion were called cabbaliſts. At the age of 28, he confined himſelf wholly to the ſtudy of the ſcriptures; and undertook to combat the Jews and Mahometans, as well as to confound judicial aſtrology; but in this intention his credit was alſo ſaved, though with the loſs of his life, by his dying in 1494, in his 32d year. He was called the *phœnix of his age*, and by Scaliger *Monſtrum ſine Vitio*. He compoſed a great number of works, which have often been printed both ſeparately and together. The following epitaph is upon his tomb:

Hic ſitus eſt Picus Mirandola, cætera norunt
Et Tagus et Ganges, forſan et Antipodes.

Picus (John Francis), prince of Mirandola, nephew of John Picus mentioned above, was born about the year 1469. He cultivated learning and the ſciences after the example of his uncle; but he had a principality and dominions to ſuperintend, which involved him in great troubles, and at laſt coſt him his life. He was twice driven from his principality, and twice reſtored; and at laſt, in 1533, was, together with his eldeſt ſon Albert, aſſaſſinated in his own caſtle by his nephew Galeoti. He was a great lover of letters; and ſuch of his works as were then compoſed were inſerted in the Straſburgh edition of his uncle's in 1504, and continued in future impreſſions, beſides ſome others which were never collected.

PIECE, in matters of money, ſignifies ſometimes the ſame thing with ſpecies; and ſometimes, by adding the value of the pieces, it is uſed to expreſs ſuch as have no other particular name. For the piece of eight, or piaſtre, ſee *Money-Table*.

Piece, is alſo a kind of money of account, or rather a manner of accounting uſed among the negroes on the coaſt of Angola in Africa, See *Money-Table*.

Piece, in heraldry, denotes an ordinary or charge. The honourable pieces of the ſhield are the chief, feſs, bend, pale, bar, croſs, ſaltier, chevron, and in general all thoſe which may take up one-third of the field, when alone, and in what manner ſoever it be. See Heraldry.

Pieces, in the military art, include all ſorts of great guns and mortars. Battering pieces are the larger ſort of guns uſed at ſieges for making the breaches; ſuch are the 24-pounder and culverine, the one carrying a 24 and the other an 18 pound ball. Field pieces are 12-pounders, demiculverines, 6-pounders, ſackers, minions, and 3-pounders, which march with the army, and encamp always behind the ſecond line, but in day of battle are in the front. A ſoldier's firelock is likewiſe called his *piece*.

PIEDMONT, a country of Italy, with the title of a principality, is bounded on the north by Savoy and Italy; on the weſt by France; on the ſouth by the Mediterranean and the republic of Genoa; and on the eaſt by the duchies of Montferrat and Milan; extending about 150 miles from north to ſouth, but much leſs from eaſt to weſt. It is called Piedmont, and in Latin *Piedmontium*, from its ſituation at the foot of the mountains, or Alps, which ſeparate France from Italy. This country is in ſome parts mountainous, but is everywhere very fruitful. The plains produce fine corn, and Montferrat and the Milaneſe yield great quantities of Turkey wheat, which commonly ſerves for bread, and with which the people of the middle rank mix rye; the pods are uſed for fuel, and the ſtalks being thick ſerve to mend the roads. The hills produce plenty of wine, which, like the Italian wines, is very luſcious when new, eſpecially the white. There is alſo a tartiſh red wine called *vino bruſco*, ſaid to be very wholeſome for fat people, and, on the other hand, the ſweet wine is recommended as a ſtomachic. The neighbourhood of Turin is famous for its fine fruits, and many long walks of cheſnut and mulberry trees, which produce both pleaſure and profit. Marons, or large cheſnuts, are a favourite dainty among the common people. Theſe are put into an oven, and, when thoroughly hot, and cooled in red wine, are dried a ſecond time in the oven, and afterwards eaten cold. Truffles grow here in ſuch abundance, that Piedmont has obtained the name of the *truffle country*. Some are black, others white marbled with red. Their price is rated according to their ſize. Sometimes they are found of 12 or 14 pounds weight; and many country people earn from 60 to 70 dollars a-year merely by digging for them. The trade in cattle is ſaid to bring into Piedmont no leſs than three millions of livres per annum. The cultivation of ſilk is alſo a profitable article, the Piedmonteſe ſilk being, on account of its fineneſs and ſtrength, eſteemed the beſt in Italy. The Piedmonteſe gentry breed vaſt numbers of ſilk-worms under the care of their tenants, who have the eggs and mulberry leaves delivered to them, and in return they give half the ſilk to their maſters. This principality comprehends eleven ſmall provinces: Piedmont proper, the valleys between France and Italy, the valley of Saluza, the county of Nice, the marquiſate of Suſa, the ducby of Aoſt, the Canaveſe, the lordſhip of Vetſail, the county of Aſt, and the Langes. It was formerly a part of Lombardy, but now belongs to the king of Sardinia, and lies at the foot of the Alps, which ſeparate France from Italy. It contains many high mountains, among which there are rich and fruitful valleys, as pleaſant and populous as any part of Italy. In the mountains are mines of ſeveral kinds, and the foreſts afford a great deal of curious game, among which the *tumor* is an uſeful animal. "The mules (ſays Mr Watkins) are very fine in this country; but the inhabitants have other beaſts, or rather monſters, which they find very ſerviceable, though vicious and obſtinate. Theſe are produced by a cow and an aſs, or mare and bull, and called *jumarres* or *gimerri* (A). I cannot ſay that I have ever ſeen any of them, but I am told they are very common."

Piedmont

The

(A) Theſe equivocal animals, however, if we may ſo term them, are ſo generally mentioned by travellers in

Piedmont. The Piedmonteſe have more ſenſe than the Savoyards, but then they are not ſo ſincere. Some authors repreſent them as lively, artful, and witty, the inhabitants of the mountain of Aoſta excepted, who are farther diſtinguiſhed by large wens, as even their horſes, dogs, and other animals. Mr Baretti, however, in his *Account of Italy*, vol. ii. p. 116. gives the following account of them. "One of the chief qualities (ſays he), which diſtinguiſh the Piedmonteſe from all other Italians, is their want of cheerfulneſs. Piedmont never produced a ſingle good poet, as far as the records of the country can go, whereas there is no other province of Italy but what can boaſt of ſome poet ancient or modern; and yet the Piedmonteſe are not deficient in ſeveral branches of learning, and ſome of them have ſucceeded tolerably well in civil law, phyſic, and the mathematics. It is likewiſe obſerved of this people, that none of them ever attained to any degree of excellence in the polite arts, and it is but lately that they can boaſt of a painter, Cavaliero Bomente; a ſtatuary, Signor Lodetto; and ſome architects, Conte Alfieri, Signor Borra, and others, who yet, to ſay the truth, are far inferior to numberleſs artiſts produced by the other provinces of Italy. They have, on the other hand, greatly advanced when conſidered as ſoldiers; though their troops have never been very numerous, every body converſant in hiſtory knows the brave ſtand they made for ſome centuries paſt againſt the French, Spaniards, and Germans, whenever they have been invaded by theſe nations. The ſkill of the Piedmonteſe in fortification is likewiſe very great, and their Bertolas and Pintos have ſhown as much genius as the Vaubans and Cohorns, in rendering impregnable ſeveral places which inferior engineers would only have made ſecure."

Payne's Geog. vol. II.

The chief trade of this principality conſiſts in hemp and ſilk. Indeed, ſo great is their trade in raw ſilk, that the Engliſh alone have purchaſed to the value of 200,000 lb. in a year. The ſilk worm thrives ſo well, that many peaſants make above (B) 100 lb. of ſilk annually; and it is not only abundant, but univerſally known to be ſtronger and finer than any in Italy. The land owners divide the profit with their tenants. The Piedmonteſe workmen, however, are ſaid to want expertneſs, though they finiſh their work equally well with thoſe of other nations. The high duty and land-carriage on mules likewiſe tend to leſſen the value of this trade. They have beſides corn, rice, wine, fruits, flax, and cattle.

In the valleys of Lucerne, Peyrouſe, and St Martin, which have always belonged to Piedmont, live the celebrated Waldenſes or Vaudois, a name which ſignifies *people of the valleys*. Theſe have rendered themſelves famous in hiſtory for their diſſent from the Romiſh church long before the time of Luther and Calvin, and for the perſecutions they have ſuffered on that account; but ſince the year 1730 they have not been openly moleſted for their religion, but, in order to ſuppreſs them by degrees, a popiſh church has been built in every pariſh. They are heavily taxed, and labour under great oppreſſions. The number of people in theſe valleys ſcarce at preſent exceeds 10,000, of which 1000 are Catholics. The chief river of Piedmont is the Po, which flows out of Mount Viſo. The river Seſia, the Doria, Baltea, the ancient Druſia, the Tenaro, and ſeveral others, run into it. The Var, anciently called the Varus, riſes in the county of Nice, and after watering it emptics itſelf into the Mediterranean. The language of the Piedmonteſe is a mixture of French and Italian. In this country are about 50 earldoms, 15 marquiſates, a multitude of lordſhips, and 20 abbeys. Though the country be entirely popiſh, except ſome valleys inhabited by the Waldenſes, the king reſerves to himſelf the greateſt part of the power in church affairs, which in many other places is given up to the pope, and the conſtitution *unigenitus* is here univerſally oppoſed. Towards the end of the laſt century, the French king perſuaded the duke of Savoy to drive them out of the country; in conſequence of which 200,000 of them retired to Germany, England, and Holland, and yet they are not all extirpated, though, as we have obſerved, they are obliged to have a Roman Catholic church in every pariſh.

Turin, the general reſidence of the king of Sardinia, to whom this principality belongs, is the chief city. See TURIN. The number of inhabitants, Mr Watkins ſays, in Piedmont and Savoy, amount to 2,695,727 ſouls, of which Turin contains about 77,000.

PIENES, a ſmall iſland of Japan, over againſt the harbour of Saccai, is famed not only for the beauty of its walks, to which crowds of people reſort from the city, but for a deity worſhipped there, to which vaſt numbers of perſons devote themſelves. They go from his temple to the ſea ſide, where they enter into a boat provided for the purpoſe; then, launching into the deep, they throw themſelves overboard, loaded with ſtones, and ſink to the bottom. The temple of that deity, which is called Canon, is very large and lofty, and ſo are many others in the city itſelf; one in particular, dedicated to the gods of other countries, is thought the fineſt in the whole empire.

Pienes, Piepoudre.

PIEPOUDRE *(Court of)*, the loweſt, and at the ſame time the moſt expeditious, court of juſtice known to the law of England. It is called PIEPOUDRE, *(curia pedis pulverizati)*, from the duſty feet of the ſuitors; or, according to Sir Edward Coke, becauſe juſtice is there done as ſpeedily as duſt can fall from the foot: Upon the ſame principle that juſtice among the Jews was adminiſtered in the gate of the city, that the proceedings might be the more ſpeedy, as well as public. But the etymology given us by a learned modern writer is much more ingenious and ſatisfactory; it being derived, according to him, from *pied*

this part of Europe, that we have no doubt of their exiſtence, nor of their being found hardy and ſerviceable as labourers.

(B) Each pound is valued in Piedmont at 18 s. The little village of La Tour, in the valley of Lucerne, makes above 50,000 lb. annually, and the exports every year to the ſingle city of Lyons amount to more than 160,000 l. Sterling.

Pier
||
Pierino.

puldreaux, "a pedlar," in old French, and therefore signifying the court of such petty chapmen as resort to fairs or markets. It is a court of record, incident to every fair and market; of which the steward of him who owns or has the toll of the market is the judge. It was instituted to administer justice for all commercial injuries done in that very fair or market, and not in any preceding one. So that the injury must be done, complained of, heard, and determined, within the compass of one and the same day, unless the fair continues longer. The court hath cognizance of all matters of contract that can possibly arise within the precinct of that fair or market; and the plaintiff must make oath that the cause of an action arose there. From this court a writ of error lies, in the nature of an appeal, to the courts at Westminster. The reason of its institution seems to have been, to do justice expeditiously among the variety of persons that resort from distant places to a fair or market; since it is probable, that no other inferior court might be able to serve its process, or execute its judgments, on both or perhaps either of the parties; and therefore, unless this court had been erected, the complaint must necessarily have resorted even in the first instance to some superior judicature.

PIER, in building, denotes a mass of stone, &c. opposed by way of fortress to the force of the sea, or a great river, for the security of ships that lie at harbour in any haven.

Piers of a Bridge. See Bridge.

PIERCEA. See Rivinia.

PIERIA (anc. geog.), a district of Macedonia, contained between the mouths of the rivers Ludias and Peneus; extended by Strabo beyond the Ludias, to the river Axios on the north, and on the south no farther than the Aliacmon, along the west side of the Sinus Thermaicus.—Another *Pieria* of Syria, the north part of Seleucia, or the *Antiochena*, situated on the Sinus Issicus, and lying next Cilicia to the north-west.

PIERIDES, in fabulous history, the daughters of Pierus a Macedonian prince, presuming to dispute with the muses for the prize of poetry, were turned into magpies. The name of *Pierides* was also given to the muses, from mount Pieris in Thessaly, which was consecrated to them; or, according to others, from Pierus, a Thessalian poet, who was the first who sacrificed to them. See Pieris.

PIERINO del Vaga, an eminent Italian painter, born of poor parents in Tuscany, about the year 1500. He was placed apprentice with a grocer in Florence, and got some instructions from the painters to whom he was sent with colours and pencils; but a painter named *Vaga* taking him to Rome, he was called *Del Vaga*, from living with him, his real name being *Buonacorsi*. He studied anatomy with the sciences necessary for his profession; and had somewhat of every thing that was good in his compositions. After Raphael's death, he joined with Julio Romano and Francisco Penni to finish the works in the Vatican which were left imperfect by their common master; and to confirm their friendship married Penni's sister. He gained the highest reputation by his performances in the palace of prince Doria at Genoa: but the multiplicity of his business, and the vivacity of his imagination, drained his spirits in the flower of his age; for he died in the year 1547. Of all Raphael's disciples, Pierino kept the character of his master longest, *i.e.* his exterior character and manner of designing; for he fell very short of the fineness of Raphael's thinking. He had a particular genius for the decoration of places according to their customs. His invention in that kind of painting was full of ingenuity; grace and order are everywhere to be met with, and his dispositions, which are ordinary in his pictures, are wonderful in his ornaments: some of these he has made little; and some great, and placed them both with so much art, that they set off one another by comparison and contrast. His figures are disposed and designed according to Raphael's gusto; and if Raphael gave him at first some slight sketches of ornaments, as he did to Giovanni d'Udine, he executed them to admiration. The tapestries of the seven planets, in seven pieces, which Pierino designed for Diana de Poitiers, and which were, when De Piles wrote, with Monsieur the first president at Paris, shows sufficiently what he was, and that the above character does not exceed the truth.

Pieris,
Pierre.

PIERIS (anc. geog.), a mountain which is thought to have given name to Pieria of Macedonia; taking its name from Pierus a poet, who was the first that sacrificed to the Muses, thence called *Pierides*, if credit may be given to an ancient scholiast on Juvenal.

PIERRE d'AUTOMNE is a French name, translated from the Chinese, of a medicinal stone, celebrated in the east for curing all disorders of the lungs. Many imagine it had its name of the autumn-stone from its being only to be made at that season of the year; but it may certainly be made equally at all times. The Chinese chemists refer the various parts of the body to the several seasons of the year, and thus they refer the lungs to autumn. This is evident in their writings, and thus the stone for diseases of the lungs came to be called *autumn stone*. It is prepared as follows: They put 30 pints of the urine of a strong and healthy young man into a large iron pot, and set it over a gentle fire. When it begins to boil, they add to it, drop by drop, about a large tea-cup full of rape oil. They then leave it on the fire till the whole is evaporated to a thick substance like black mud. It is then taken out of the pot, and laid on a flat iron to dry, so that it may be powdered very fine. This powder is moistened with fresh oil, and the mass is put into a double crucible, surrounded with coals, where it stands till it be thoroughly dried again. This is again powdered, and put into a china vessel, which being covered with silk cloth and a double paper, they pour on it boiling water, which makes its way, drop by drop, through these coverings, till so much is got in as is sufficient to reduce it to a paste. This paste is well mixed together in the vessel it is kept in, and this is put into a vessel of water, and the whole set over the fire. The matter thus becomes again dried in *balneo mariæ*, and is then finished. *Observ. sur les Cout. de l'Asie*, p. 258.

Pierre (St), is a large river in North America, scarcely inferior to the Rhine or the Danube, and navigable almost to its source. Together with many other large streams, it falls into the great river Mississippi.

Pierre (St), or *St Peter's*, the capital of Martinico, was built in 1665, in order to overawe the mutineers

Pierre
ll
Piety.

neers of the island who rebelled against its proprietors, the second West India company, who were at the same time the proprietors of all the French Antilles. It is situated on the western side of the island. The town extends along the shore, and a battery that commands the road is erected on the west side, which is washed by the river Royolan, or St Peter. The town is divided into three wards; the middle, which is properly St Peter's, begins at the fort, and runs westward to the battery of St Nicholas. Under the walls of the second ward ships at anchor ride more securely than under the fort, on which account this ward is called the *Anchorage*. The third ward, called the *Gallery*, extends along the sea side from Fort St Peter to the Jesuits' River, and is the most populous part of the city. The houses of St Peter's ward are neat, commodious, and elegant, particularly those of the governor of the island, the intendant, and the other officers. The parish church of St Peter is a magnificent stone building which belonged to the Jesuits, with a noble front of the Doric order. The church of the Anchorage, which belongs to the Jacobine friars, is likewise of stone. It is a place of considerable trade, and is built with tolerable regularity. The houses are mostly constructed of a grey pumice-stone or lava, which is found on the strand; and the high-street is, according to Dr Ifert, above an English mile in length. It is supposed to contain about 2000 houses, and 30,000 inhabitants, including negroes. St Pierre, with the whole of the flourishing island of Martinico, was taken from the French in the month of March 1794, by the British land and sea forces under the command of Sir Charles Grey and Sir John Jervis, and will now, we presume, continue annexed to the British crown: 125 vessels loaded with the produce of the island, and of great value, were captured, 71 of which were in the harbour of St Pierre.

PIETISTS, a religious sect sprung up among the Protestants of Germany, seeming to be a kind of mean between the Quakers of England and the Quietists of the Romish church. They despise all sorts of ecclesiastical polity, all school theology, and all forms and ceremonies, and give themselves up to contemplation and the mystic theology. Many gross errors are charged on the Pietists, in a book intitled *Manipulus Observationum Antipietisticarum*; but they have much of the air of polemical exaggeration, and are certainly not at all just. Indeed there are Pietists of various kinds: Some running into gross illusions, and carrying their errors to the overturning of a great part of the Christian doctrine, while others are only visionaries; and others are very honest and good, though perhaps misguided, people. They have been disgusted with the coldness and formality of other churches, and have thence become charmed with the fervent piety of the Pietists, and attached to their party, without giving into the grossest of their errors. See *Mosheim's Eccl. History*, vol. iv. p. 454.

PIETISTS, otherwise called the *Brethren and Sisters of the Pious and Christian Schools*, a society formed in the year 1678 by Nicholas Barre, and obliged by their engagements to devote themselves to the education of poor children of both sexes.

PIETOLA, anciently called *Andes*, is a place within two Italian miles of Mantua, famous for being the birth-place of Virgil.

PIETY, is a virtue which denotes veneration for the Deity, and love and tenderness to our friends. This distinguished virtue, like many others, received among the Romans divine honours, and was made one of their gods. Aelius Glabrio first erected a temple to this divinity, which he did upon the spot on which a woman had fed with her own milk her aged father, who had been imprisoned by order of the senate, and deprived of all aliments. The story is well known, and is given at length in authors which are in the hands of every school-boy. See *Cicero de div.* 1. and *Valerius Maximus*, 5. c. 4. and our article *Filial Piety*, p. 238. col. 2d. Piety.

If piety was thus practised and thus honoured in Heathen antiquity, it surely ought not to be less so among Christians, to whom its nature is better defined, and to the practice of which they have motives of greater cogency. A learned and elegant writer has said that the want of piety arises from the want of sensibility; and his observations and arguments are so just and so well expressed, that we cannot do better than transcribe them.

"It appears to me (says Dr Knox), that the mind of man, when it is free from natural defects and acquired corruption, feels no less a tendency to the indulgence of devotion than to virtuous love, or to any other of the more refined and elevated affections. But debauchery and excess contribute greatly to destroy all the susceptible delicacy with which nature usually furnishes the heart; and, in the general extinction of our better qualities, it is no wonder that so pure a sentiment as that of piety should be one of the first to expire.

"It is certain that the understanding may be improved in a knowledge of the world, and in the arts of succeeding in it, while the heart, or whatever constitutes the seat of the moral and sentimental feelings, is gradually receding from its proper and original perfection. Indeed experience seems to evince, that it is hardly possible to arrive at the character of a complete man of the world, without losing many of the most valuable sentiments of uncorrupted nature. A complete man of the world is an artificial being; he has discarded many of the native and laudable tendencies of his mind, and adopted a new system of objects and propensities of his own creation. These are commonly gross, coarse, sordid, selfish, and sensual. All, or either of these attributes, tend directly to blunt the sense of every thing liberal, enlarged, disinterested; of every thing which participates more of an intellectual than of a sensual nature. When the heart is tied down to the earth by lust and avarice, it is not extraordinary that the eye should be seldom lifted up to heaven. To the man who spends his Sunday (because he thinks the day fit for little else) in the counting-house, in travelling, in the tavern, or in the brothel, those who go to church appear as fools, and the business they go upon as nonsense. He is callous to the feelings of devotion; but he is tremblingly alive to all that gratifies his senses or promotes his interest.

"It has been remarked of those writers who have attacked Christianity, and represented all religious merely as diversified modes of superstition, that they were indeed, for the most part, men of a metaphysical and a disputatious turn of mind, but usually little distinguished for benignity and generosity. There was,

Piety. amidst all their pretensions to logical sagacity, a cloudiness of ideas, and a coldness of heart, which rendered them very unfit judges on a question in which the heart is chiefly interested; in which the language of nature is more expressive and convincing, than all the dreary subtleties of the dismal metaphysicians. Even the reasoning faculty, on which we so greatly value ourselves, may be perverted by excessive refinement; and there is an abstruse, but vain and foolish philosophy, which philosophizes us out of the noblest parts of our noble nature. One of those parts of us is our instinctive sense of religion, of which not one of those brutes which the philosophers most admire, and to whose rank they wish to reduce us, is found in the slightest degree to participate.

"Such philosophers may be called, in a double sense, the enemies of mankind. They not only endeavour to entice man from his duty, but to rob him of a most exalted and natural pleasure. Such, surely, is the pleasure of devotion. For when the soul rises above this little orb, and pours its adoration at the throne of celestial Majesty, the holy fervour which it feels is itself a rapturous delight. Neither is this a declamatory representation, but a truth felt and acknowledged by all the sons of men; except those who have been defective in sensibility, or who hoped to gratify the pride or the malignity of their hearts by singular and pernicious speculation.

"Indeed all disputations, controversial and metaphysical writings on the subject of religion, are unfavourable to genuine piety. We do not find that the most renowned polemics in the church militant were at all more attentive than others to the common offices of religion, or that they were actuated by any peculiar degree of devotion. The truth is, their religion centered in their heads, whereas its natural religion is the heart. The heart! confined, alas! in colleges or libraries, unacquainted with all the tender charities of husband, father, brother, friend; some of them have almost forgotten that they possess a heart. It has long ceased to beat with the pulsations of love and sympathy, and has been engrossed by pride on conquering an adversary in the syllogistic combat, or by impotent anger on a defeat. With such habits, and so defective a system of feelings, can we expect that a doctor of the Sorbonne, or the disputing professor of divinity, should ever feel the pure flame of piety that glowed in the bosoms of Mrs Rowe, Mrs Talbot, or Mr Nelson?

"It is however certain, that a devotional taste and habit are very desirable in themselves, exclusive of their effects in meliorating the morals and disposition, and promoting present and future felicity. They add dignity, pleasure, and security to any age: but to old age they are the most becoming grace, the most substantial support, and the sweetest comfort. In order to preserve them, it will be necessary to preserve our sensibility; and nothing will contribute so much to this purpose as a life of temperance, innocence, and simplicity."

Of piety, as it denotes love and tenderness to our friends, there have been many distinguished instances both in ancient and modern times. See *Filial Piety*, *Fraternal* and *Parental Affection*, &c.

The following example of filial piety in China, taken from P. Du Halde's description of that country, will not we trust be disagreeable to our readers. "In the commencement of the dynasty of the Tang, Lou-tao-tsong, who was disaffected to the government, being accused of a fault, which touched his life, obtained leave from those who had him in custody, to perform the duties of the Tao to one of his deceased friends. He managed matters so well, that giving his keepers the slip, he fled to the house of Lou Nan kin, with whom he had a friendship, and there hid himself. Lou Nan-kin, notwithstanding the strict search that was made, and the severity of the court against those who conceal prisoners that have escaped, would not betray his friend. However, the thing coming to be discovered, Lou Nan-kin was imprisoned; and they were just on the point of proceeding against him, when his younger brother presenting himself before the judge, *It is I, Sir*, said he, *who have hidden the prisoner; it is I who ought to die, and not my elder brother.*" The eldest maintained on the contrary, that his younger brother accused himself wrongfully, and was not at all culpable. The judge, who was a person of great sagacity, sifted both parties so effectually, that he not only discovered that the younger brother was innocent, but even made him confess it himself: *It is true, Sir*, said the younger all in tears, *I have accused myself falsely; but I have very strong reasons for so doing. My mother has been dead for some time, and her corps is not yet buried; I have a sister also who is marriageable, but is not yet disposed of: these things which my brother is capable of managing, I am not, and therefore desire to die in his stead. Vouchsafe to admit my testimony.* The commissioner gave an account of the whole affair to the court, and the emperor at his solicitation pardoned the criminal."

Piety. || Piganiol.

PIG, in zoology. See Sus.

Guinea-Pig. See Mus.

Pig of lead, the eighth part of a fother, amounting to 250 pounds weight.

PIGANIOL DE LA FORCE (John Aymar de), a native of Auvergne, of a noble family, applied himself with ardour to the study of geography, and of the history of France. With the view of improving himself in this study, he travelled into different provinces; and, in the course of his travels, made some important observations on the natural history, the commerce, the civil and ecclesiastical government of each province. These observations were of great use to him in compiling the works he has left behind him, of which the chief are, 1. An Historical and Geographical Description of France; the largest edition of which is that of 1753, in 15 vol. 12mo. It is the best work which has hitherto appeared upon that subject, though it contains a great number of inaccuracies and even errors. 2. A Description of Paris, in 10 vol. 12mo; a work equally entertaining and instructive, and much more complete than the description given by Germain Brice: besides, it is written with an elegant simplicity. He published an abridgment of it in 2 vol. 12mo. 3. A Description of the Castle and Park of Versailles, Marly, &c. in 2 vol. 12mo: it is very amusing, and pretty well executed. Piganiol had also a concern with Abbé Nadal in the Journal of Trevoux. He died at Paris in February 1753, at the age of 80 years. This learned man was as much to be respected for his manners as for his talents. To a profound and varied knowledge

Pigeon. knowledge he united great probity and honour, and all the politeneſs of a courtier.

PIGEON, in ornithology. See COLUMBA.

PIGEON-Houſe is a houſe erected full of holes within for the keeping, breeding, &c. of pigeons, otherwiſe called a *dove cote*.

Any lord of manor may build a pigeon-houſe on his land, but a tenant cannot do it without the lord's licence. When perſons ſhoot at or kill pigeons within a certain diſtance of the pigeon-houſe, they are liable to pay a forfeiture.

In order to erect a pigeon-houſe to advantage, it will be neceſſary, in the firſt place, to pitch upon a convenient ſituation; of which none is more proper than the middle of a ſpacious court-yard, becauſe pigeons are naturally of a timorous diſpoſition, and the leaſt noiſe they hear frightens them. With regard to the ſize of the pigeon-houſe, it muſt depend entirely upon the number of birds intended to be kept; but it is better to have it too large than too little; and as to its form, the round ſhould be preferred to the ſquare ones; becauſe rats cannot ſo eaſily come at them in the former as in the latter. It is alſo much more commodious; becauſe you may, by means of a ladder turning upon an axis, eaſily viſit all the neſts in the houſe, without the leaſt difficulty; which cannot ſo eaſily be done in a ſquare houſe. In order to hinder rats from climbing up the outſide of the pigeon-houſe, the wall ſhould be covered with tin plates to a certain height, about a foot and a half will be ſufficient; but they ſhould project out three or four inches at the top, to prevent their clambering any higher.

The pigeon-houſe ſhould be placed at no great diſtance from water, that the pigeons may carry it to their young ones; and their carrying it in their bills will warm it, and render it more wholeſome in cold weather. The boards that cover the pigeon-houſe ſhould be well joined together, ſo that no rain may penetrate through it: and the whole building ſhould be covered with hard plaſter, and white-waſhed within and without, white being the moſt pleaſing colour to pigeons. There muſt be no window, or other opening in the pigeon-houſe to the eaſtward; theſe ſhould always face the ſouth, for pigeons are very fond of the ſun, eſpecially in winter.

The neſts or covers in a pigeon-houſe ſhould conſiſt of ſquare holes made in the walls of a ſize ſufficient to admit the cock and hen to ſtand in them. The firſt range of theſe neſts ſhould not be leſs than four feet from the ground, that the wall underneath being ſmooth, the rats may not be able to reach them. Theſe neſts ſhould be placed in quincunx order, and not directly over one another. Nor muſt they be continued any higher than within three feet of the top of the wall: and the upper row ſhould be covered with a board projecting a conſiderable diſtance from the wall, for fear the rats ſhould find means to climb the outſide of the houſe.

M. Duhamel thinks that pigeons neither feed upon the green corn, nor have bills ſtrong enough to ſearch for its ſeeds in the earth; but only pick up the grains that are not covered, which would infallibly become the prey of other animals, or be dried up by the ſun. "From the time of the ſprouting of the corn, ſays he, pigeons live chiefly upon the ſeeds of wild uncultivated plants, and therefore leſſen conſiderably the quantity of weeds that would otherwiſe ſpring up; as will appear from a juſt eſtimate of the quantity of grain neceſſary to feed all the pigeons of a well ſtocked dove-houſe." But Mr Worlidge and Mr Liſle allege facts in ſupport of the contrary opinion. The latter relates, that a farmer in his neighbourhood aſſured him he had known an acre ſowed with peas, and rain coming on ſo that they could not be harrowed in, every pea was fetched away in half a day's time by pigeons: and the former ſays, "It is to be obſerved, that where the flight of pigeons falls, there they fill themſelves and away, and return again where they firſt roſe, and ſo proceed over a whole piece of ground, if they like it. Although you cannot perceive any grain above the ground, they know how to find it. I have ſeen them lie ſo much upon a piece of about two or three acres ſown with peas, that they devoured at leaſt three parts in four of the ſeed, which, I am ſure, could not be all above the ſurface of the ground. That their ſmelling is their principal director, I have obſerved; having ſown a ſmall plat of peas in my garden, near a pigeon-houſe, and covered them ſo well that not a pea appeared above ground. In a few days, a parcel of pigeons were hard at work in diſcovering this hidden treaſure; and in a few days more I had not above two or three peas left out of about two quarts that were planted; for what they could not find before, they found when the buds appeared, notwithſtanding they were hoed in, and well covered. Their ſmelling alone directed them, as I ſuppoſed, becauſe they followed the ranges exactly. The injury they do at harveſt on the peas, vetches, &c. is ſuch that we may rank them among the greateſt enemies the poor huſbandman meets withal; and the greater, becauſe he may not erect a pigeon-houſe, whereby to have a ſhare of his own ſpoils; none but the rich being allowed this privilege, and ſo ſevere a law being alſo made to protect theſe winged thieves, that a man cannot encounter them, even in defence of his own property. You have therefore no remedy againſt them, but to affright them away by noiſes or ſuch like. You may, indeed, ſhoot at them; but you muſt not kill them; or you may, if you can, take them in a net, cut off their tails, and let them go; by which means you will impound them: for when they are in their houſes, they cannot bolt or fly out of the tops of them, but by the ſtrength of their tails; after the thus weakening of which, they remain priſoners at home."

Pigeon.

Mr Worlidge's impounding the pigeons reminds us of a humorous ſtory of a gentleman who, upon a neighbouring farmer's complaining to him, that his pigeons were a great nuiſance to his land, and did ſad miſchief to his corn, replied jokingly, Pound them, if you catch them treſpaſſing. The farmer, improving the hint, ſteeped a parcel of peas in an infuſion of *cocculus indicus*, or ſome other intoxicating drug, and ſtrewed them upon his grounds. The pigeons ſwallowed them, and ſoon remained motionleſs on the field: upon which the farmer threw a net over them, incloſed them in it, and carried them to an empty barn, from whence he ſent the gentleman word that he had followed his directions with regard to the pounding of his pigeons, and deſired him to come and releaſe them.

Carrier-PIGEON. See *CARRIER-Pigeon* and COLUMBA.

Pigeon. PIGEON (Peter Charles Francis), curate of St Peter du Regard, in the diocese of Bayeux, was one of the priests lately belonging to the king's house at Winchester. He was born in Lower Normandy, of honest and virtuous parents, and of a decent fortune. His inclinations early led him to embrace the ecclesiastical state, from which neither the solicitations of his friends, nor the prospect of a more ample fortune on the death of his elder brother, could withdraw him. Several of his schoolfellows and masters, who are now resident in the king's house at Winchester, bear the most ample testimony to his assiduity, regularity, piety, and the sweetness of his disposition, during the whole course of his education. The sweetness of temper, in particular, was so remarkable, and so clearly depicted on his countenance, as to have gained him the esteem and affection of such of the inhabitants of Winchester as by any means had become acquainted with him. He was seven years employed in quality of vicar, or, as we should call it, *curate*, of a large parish in the diocese of Seez, where his virtues and talents had ample scope for exertion. His practice was to rise at five o'clock every morning, and to spend the whole time till noon (the usual time of dining for persons in his station) in prayer and study. The rest of the day, till evening, he devoted to visiting the sick, and other exterior duties of his function. In 1789, the year of the French Revolution, M. Pigeon was promoted to a curacy, or rather a rectory, in the diocese of Bayeux, called the *parish of St Peter du Regard*, near the town of Condè sur Noereau. It was easy for him to gain the good-will and the protection of his parishioners; but a Jacobin club in the above-mentioned town seemed to have no other subject to deliberate upon than the various ways of harassing and persecuting M. Pigeon and certain other priests in the neighbourhood, who had from motives of conscience refused the famous civic oath. It would be tedious to relate the many cruelties which were at different times exercised upon him, and the imminent danger of losing his life to which he was exposed, by the blows that were inflicted on him, by his being thrown into water, and being obliged to wander in woods and other solitary places, without any food or place to lay his head, in order to avoid his persecutors. We may form some judgment of the spirit of his persecutors from the following circumstance. Being disappointed on a particular occasion in the search they were making after M. Pigeon, with the view of amusing themselves with his sufferings, they made themselves amends by seizing his mother, a respectable lady of 74 years of age, and his two sisters, whom they placed upon asses with their faces turned backwards, obliging them in derision to hold the tails of these animals. Thus they were conducted in pain and ignominy throughout the whole town of Condè, for no other alleged crime except being the nearest relations of M. Pigeon. At length the decree for transporting all the ecclesiastics arrived; and this gentleman, with several others, after having been stripped of all their money, was shipped from Port Beffin, and landed at Portsmouth, where he was shortly after received into the establishment at Foxton, and, upon that being dissolved in order to make room for prisoners of war, into the king's house at Winchester. Being of a studious turn, he was accustomed, as many of his brethren also were, to betake himself to the neighbouring lanes and thickets for the sake of greater solitude. With this view having about ten o'clock in the morning, Aug. 28. 1793, retired to a certain little valley, on the north-east side of a place called *Oram's Arbour*, the same place where the county elections for Hampshire are held, he was there found, between three and four o'clock in the afternoon, murdered, with the upper part of his skull absolutely broken from the lower part, and a large hedge-stake, covered with blood, lying by him, as were the papers on which he had been transcribing a manuscript sermon, with the hearing of which he had been much edified, and the sermon itself which he was copying, together with his pen, imbrued in blood. His watch was carried away, though part of the chain, which had by some means been broken, was left behind. He was writing the word *paradise*, the last letters of which remained unwritten when the fatal blow was given him, which appears evidently to have been discharged upon him from a gap in a hedge which was immediately behind him. At first the suspicion of this cruel murder fell upon the French democrats, who, to the number of 200, are prisoners of war, at the neighbouring town of Alresford, as one of that number, who had broken his parole, had, about three weeks before, been taken up in Winchester, and both there and at Alresford had repeatedly threatened to murder his uncle, a priest, whom he understood to be then at Winchester, not without fervent wishes of having it in his power to murder the whole establishment, consisting of more than 600 persons. However, as no French prisoner was seen that day in the neighbourhood of Winchester, as none of them were known to have left Alresford, it is evidently reasonable to acquiesce in the verdict of the coroner; namely, that the murder was committed by a person or persons unknown. The most noble marquis of Buckingham, whose munificence and kindness to those conscientious exiles, the emigrant French clergy, can only be conceived by those who have been witnesses of the same, with the truly respectable corps of the Buckinghamshire militia, then quartered at Winchester, joined in paying the last mark of respect to the unfortunate deceased, by attending his funeral, which was performed at the Roman Catholic burying-ground, called *St James's*, near the said city, on Saturday, August 29. He was just 38 years of age when he was murdered.

Pigeon || Pigue.

PIGMENTS, preparations used by painters, dyers, &c. to impart colours to bodies, or to imitate particular colours. See COLOUR-*Making*, and DYEING.

PIGNEROL is a town of Italy in the province of Piedmont, in E. Long. 7. 15. Lat 44. 45. situated on the river Chizon, 10 miles south-west of Turin, at the foot of the Alps, and the confines of Dauphiny. The town is small, but populous, and extremely well fortified by the king of Sardinia, since the treaty of Utrecht. It is defended by a citadel, on the top of the mountain, near which is the castle of Perouse, which was built at the entrance of the valley of that name.

PIGNUT, or *Earthnut*. See BUNIUM.

PIGUS, in ichthyology, is the name of a species of leather-mouthed fish, very much resembling the nature of the common carp; being of the same shape and size, and its eyes, fins, and fleshy palate, exactly the same; from the gills to the tail there is a crooked dotted line; the

Pi-hahiroth || Pike.

the back and ſides are bluiſh, and the belly reddiſh. It is covered with large ſcales; from the middle of each of which there riſes a fine, pellucid, prickle, which is very ſharp. It is an excellent fiſh for the table, being perhaps preferable to the carp: and it is in ſeaſon in the months of March and April. It is caught in lakes in ſome parts of Italy, and is mentioned by Pliny, tho' without a name. Artedi ſays it is a ſpecies of cyprinus, and he calls it the *cyprinus*, called *piclo* and *pigus*.

PI-HAHIROTH, (Moſes); underſtood to be a mouth or narrow paſs between two mountains, called *Chiroth*, or *Eiroth*, and lying not far from the bottom of the weſtern coaſt of the Arabian gulf; before which mouth the children of Iſrael encamped, juſt before their entering the Red Sea, (Wells).

PISSKER, in ichthyology, is a fiſh of the muſtela kind, commonly called the *foſſile muſtela*, or *foſſile fiſh*. They are generally found as long as an ordinary man's hand is broad, and as thick as one's finger; but they ſometimes grow much longer: the back is of grey with a number of ſpots and tranſverſe ſtreaks, partly black and partly blue; the belly is yellow, and ſpotted with red, white, and black; the white are the larger, the others look as if they were made with the point of a needle; and there is on each of the ſides a longitudinal black and white line. There are ſome fleſhy excreſcences at the mouth, which are expanded in ſwimming; and when out of the water, they are contracted. Theſe fiſhes run into caverns of the earth, in the ſides of rivers, in marſhy places, and penetrate a great way, and are often dug up at a diſtance from waters. Often, when the waters of brooks and rivers ſwell beyond their banks, and again cover them, they make their way out of the earth into the water; and when it deſerts them, they are often left in vaſt numbers upon the ground, and become a prey to ſwine. It is thought to be much of the ſame kind with the fiſgum fiſh; and it is indeed poſſible that the pæcilia of Schoneſeldt is the ſame.

PIKE, in ichthyology. See Esox.

The pike never ſwims in ſhoals as moſt other fiſh do, but always lies alone; and is ſo bold and ravenous, that he will ſeize upon almoſt any thing leſs than himſelf. Of the ravenous nature of this fiſh we ſhall give the following inſtances. At Rycott in Oxfordſhire, in the year 1749, in a moat ſurrounding the earl of Abingdon's ſeat, there was a jack or pike of ſuch a monſtrous ſize, that it had deſtroyed young ſwans feathers and all. An old cobb ſwan having hatched five young, one after another was loſt till four were gone. At length an under gardener ſaw the fiſh ſeize the fifth. The old one fought him with her beak, and with the aſſiſtance of the gardener, releaſed it although he had got it under water. In the year 1765 a large pike was caught in the river Ouze, which weighed upwards of 28 pounds, and was ſold for a guinea. On gutting the fiſh, a watch with a black ribbon and two ſteel ſeals were found in its ſtomach, which, by the maker's name, &c. was found to belong to a perſon who had been drowned about ſix weeks before. This fiſh breeds but once in a year, which is in March. It is found in almoſt all freſh waters; but is very different in goodneſs, according to the nature of the places where it lives. The fineſt pike are thoſe which feed in clear rivers; thoſe in ponds and meres are inferior to theſe, and the worſt of all are thoſe of the fen ditches. They are very plentiful in theſe laſt places, where the water is foul and coloured; and their food, ſuch as frogs and the like, very plentiful, but very coarſe; ſo that they grow large, but are yellowiſh and high bellied, and differ greatly from thoſe which live in the clearer waters. Pike.

The fiſhermen have two principal ways of catching the pike; by the ledger, and by the walking-bait.

The ledger-bait is fixed in one certain place, and may continue while the angler is at ſent. This muſt be a live bait, a fiſh or frog: and among fiſh, the dace, roach, and gudgeon, are the beſt; of frogs, the only caution is to chooſe the largeſt and yelloweſt that can be met with. If the bait be a fiſh, the hook is to be ſtuck through the upper lip, and the line muſt be 14 yards at leaſt in length; the other end of this is to be tied to a bough of a tree, or to a ſtick driven into the ground near the pike's haunt, and all the line wound round a forked ſtick, except about half a yard. The bait will by this means keep playing ſo much under water, and the pike will ſoon lay hold of it.

If the bait be a frog, then the arming wire of the hook ſhould be put in at the mouth, and out at the ſide; and with a needle and ſome ſtrong ſilk, the hinder-leg of one ſide is to be faſtened by one ſtitch to the wire-arming of the hook. The pike will ſoon ſeize this, and muſt have line enough to give him leave to get to his haunt and poach the bait.

The trolling for pike is a pleaſant method alſo of taking them: in this a dead bait ſerves, and none is ſo proper as a gudgeon.

This is to be pulled about in the water till the pike ſeizes it; and then it is to have line enough, and time to ſwallow it: the hook is ſmall for this ſport, and has a ſmooth piece of lead fixed at its end to ſink the bait; and the line is very long, and runs through a ring at the end of the rod, which muſt not be too ſlender at top.

The art of feeding pike, ſo as to make them very fat, is the giving them eels; and without this it is not to be done under a very long time; otherwiſe perch, while ſmall, and their prickly fins tender, are the beſt food for them. Bream put into a pike-pond are a very proper food: they will breed freely, and their young ones make excellent food for the pike, who will take care that they ſhall not increaſe over much. The numerous ſhoals of roaches and ruds, which are continually changing place, and often in floods get into the pike's quarters, are food for them for a long time.

Pike, when uſed to be fed by hand, will come up to the very ſhore, and take the food that is given them out of the fingers of the feeder. It is wonderful to ſee with what courage they will do this, after a while practiſing; and it is a very diverting ſight when there are ſeveral of them nearly of the ſame ſize, to ſee what ſtriving and fighting there will be for the beſt bits when they are thrown in. The moſt convenient place is near the mouth of the pond, and where there is about half a yard depth of water; for, by that means, the offal of the feedings will all lie in one place, and the deep water will ſerve for a place to retire into and reſt in, and will be always clean and in order.

Carp will be fed in the ſame manner as pike; and though by nature a fiſh as remarkably ſhy and timo-

Pike, Pila.

rous as the pike is bold and fearleſs, yet by cuſtom they will come to take their food out of the perſon's hand; and will, like the pike, quarrel among one another for the niceſt bits.

PIKE, in war, an offenſive weapon, conſiſting of a wooden ſhaft, 12 or 14 feet long, with a flat ſteel head, pointed, called the *ſpear*. This weapon was long in uſe among the infantry; but now the bayonet, which is fixed on the muzzle of the firelock, is ſubſtituted in its ſtead. It is ſtill uſed by ſome of the officers of infantry, under the name of *ſponton*. The Macedonian phalanx was a battalion of pikemen. See PHALANX.

PILA MARINA, or the *ſea-ball*, in natural hiſtory, is the name of a ſubſtance very common on the ſhores of the Mediterranean, and elſewhere. It is generally found in the form of a ball about the ſize of the balls of horſe-dung, and compoſed of a variety of fibrillæ irregularly complicated. Various conjectures have been given of its origin by different authors. John Bauhine tells us, that it conſiſts of ſmall hairy fibres and ſtraws, ſuch as are found about the ſea plant called *alga vitriariorum*; but he does not aſcertain what plant it owes its origin to. Imperatus imagined it conſiſted of the exuviæ both of vegetable and animal bodies. Mercatus is doubtful whether it be a congeries of the fibrillæ of plants, wound up into a ball by the motion of the ſea water, or whether it be not the workmanſhip of ſome ſort of beetle living about the ſea ſhore, and analogous to our common dung beetle's ball, which it elaborates from dung for the reception of its progeny. Schreckius ſays it is compoſed of the filaments of ſome plant of the reed kind: and Welchius ſuppoſes it is compoſed of the pappous part of the flowers of the reed. Maurice Hoffman thinks it the excrement of the hippopotamus; and others think it that of the phoca or ſea calf. Klein, who had thoroughly and minutely examined the bodies themſelves, and alſo what authors had conjectured concerning them, thinks that they are wholly owing to, and entirely compoſed of, the capilliments which the leaves, growing to the woody ſtalk of the *alga vitriariorum*, have when they wither and decay. Theſe leaves, in their natural ſtate, are as thick as a wheat ſtraw, and they are placed ſo thick about the tops and extremities of the ſtalks, that they enfold, embrace, and lie over one another; and from the middle of theſe cluſters of leaves, and indeed from the woody ſubſtance of the plant itſelf, there ariſe ſeveral other very long, flat, ſmooth, and brittle leaves. Theſe are uſually four from each tuft of the other leaves; and they have ever a common vagina, which is membranaceous and very thin. This is the ſtyle of the plant, and the *pila marina* appears to be a cluſter of the fibres of the leaves of this plant, which cover the whole ſtalk, divided into their conſtituent fibres; and by the motion of the waves firſt broken and worn into ſhort ſhreds, and afterwards wound up together into a roundiſh or longiſh ball.

PILA, was a ball made in a different manner according to the different games in which it was to be uſed. Playing at ball was very common amongſt the Romans of the firſt diſtinction, and was looked upon as a manly exerciſe, which contributed both to amuſement and health. The pila was of four ſorts: 1ſt, *Follis* or *balloon*; 2d, *Pila Trigonalis*; 3d, *Pila Paganica*; 4th, *Harpaſtum*. All theſe come under the general name of pila. For the manner of playing with each of them, ſee the articles FOLLIS, TRIGONALIS.

Pilaſter, Pilate.

PILASTER, in architecture. See there, n° 50, &c.

PILATE, or PONTIUS PILATE, was governor of Judea when our Lord was crucified. Of his family or country we know but little, though it is believed that he was of Rome, or at leaſt of Italy. He was ſent to govern Judea in the room of Gratus, in the year 26 or 27 of the vulgar era, and governed this province for ten years, from the 12th or 13th year of Tiberius to the 22d or 23d. He is repreſented both by Philo and Joſephus as a man of an impetuous and obſtinate temper, and as a judge who uſed to ſell juſtice, and to pronounce any ſentence that was deſired, provided he was paid for it. The ſame authors make mention of his rapines, his injuries, his murders, the tormenta that he inflicted upon the innocent, and the perſons he put to death without any form of proceſs. Philo, in particular, deſcribes him as a man that exerciſed an exceſſive cruelty during the whole time of his government, who diſturbed the repoſe of Judea, and gave occaſion to the troubles and revolt that followed after. St Luke (xiii. 1, 2, &c.) acquaints us, that Pilate had mingled the blood of the Galileans with their ſacrifices; and that the matter having been related to Jeſus Chriſt, he ſaid, "Think you that theſe Galileans were greater ſinners than other Galileans becauſe they ſuffered this calamity. I tell you nay; and if you do not repent, you ſhall all periſh in like manner. It is unknown upon what occaſion Pilate cauſed theſe Galileans to be ſlain in the temple while they were ſacrificing; for this is the meaning of that expreſſion of mingling their blood with their ſacrifices. Some think they were diſciples of Judas the Gaulonite, who taught that the Jews ought not to pay tribute to foreign princes; and that Pilate had put ſome of them to death even in the temple; but there is no proof of this fact. Others think that theſe Galileans were Samaritans, whom Pilate cut to pieces in the village of Tirataba †, as they were preparing to go up to mount Gerizim, where a certain impoſtor had promiſed to diſcover treaſures to them; but this event did not happen before the year 35 of the common era, and conſequently two years after the death of Jeſus Chriſt. At the time of our Saviour's paſſion, Pilate made ſome endeavours to deliver him out of the hands of the Jews. He knew they had delivered him up, and purſued his life with ſo much violence, only out of malice and envy (Matt. xxvii. 18.) His wife alſo, who had been diſturbed the night before with frightful dreams, ſent to tell him ſhe deſired him not to meddle in the affair of that juſt perſon (ib. 19.) He attempted to appeaſe the wrath of the Jews, and to give them ſome ſatisfaction, by whipping Jeſus Chriſt (John xix. 1. Matth. xxvii. 26.) He tried to take him out of their hands, by propoſing to deliver him or Barabbas, on the day of the feſtival of the paſſover. Laſtly, he had a mind to diſcharge himſelf from pronouncing judgment againſt him, by ſending him to Herod king of Galilee (Luke xxiii. 7, 8.) When he ſaw all this would not ſatisfy the Jews, and that they even threatened him in ſome manner, ſaying he could be no friend to the emperor if he let him go (John xix. 12, 15.), he cauſed water to be brought, waſhed his hands before all

† *Joſeph. Ant.* lib. 18. c. 5.

Pilate. all the people, and publicly declared himſelf innocent of the blood of that juſt perſon (Matt. xxvii. 23, 24.); yet at the ſame time he delivered him up to his ſoldiers, that they might crucify him. This was enough to juſtify Jeſus Chriſt, as Calmet obſerves, and to ſhow that he held him as innocent; but it was not enough to vindicate the conſcience and integrity of a judge, whoſe duty it was as well to aſſert the cauſe of oppreſſed innocence as to puniſh the guilty and criminal. He ordered to be put over our Saviour's croſs, as it were, an abſtract of his ſentence, and the motive of his condemnation (John xix. 19.), *Jeſus of Nazareth, king of the Jews*, which was written in Latin, Greek, and Hebrew. Some of the Jews found fault with it, and remonſtrated to Pilate that he ought to have written *Jeſus of Nazareth, who pretended to be king of the Jews*. But Pilate could not be prevailed with to alter it, and gave them this peremptory anſwer, *That what he had written he had written*.

Towards evening, he was applied to for leave to take down the bodies from the croſs, that they might not continue there the following day, which was the paſſover and the ſabbath-day (John xix. 31.) This he allowed, and granted the body of Jeſus to Joſeph of Arimathea, that he might pay his laſt duties to it, (ib. 33.) Laſtly, when the prieſts, who had ſolicited the death of our Saviour, came to deſire him to ſet a watch about the ſepulchre, for fear his diſciples ſhould ſteal him away by night, he anſwered them, that they had a guard, and might place them there themſelves (Matt. xxvii. 65.) This is the ſubſtance of what the goſpel tells us concerning Pilate.

Juſtin Martyr, Tertullian, Euſebius, and after them ſeveral others both ancient and modern, aſſure us, that it was formerly the cuſtom for Roman magiſtrates to prepare copies of all verbal proceſſes and judicial acts which they paſſed in their ſeveral provinces, and to ſend them to the emperor. And Pilate, in compliance to this cuſtom, having ſent word to Tiberius of what had paſſed relating to Jeſus Chriſt, the emperor wrote an account of it to the ſenate, in a manner that gave reaſon to judge that he thought favourably of the religion of Jeſus Chriſt, and ſhowed that he ſhould be willing they would decree divine honours to him. But the ſenate was not of the ſame opinion, and ſo the matter was dropped. It appears by what Juſtin ſays of theſe acts, that the miracles of Jeſus Chriſt were mentioned there, and even that the ſoldiers had divided his garments among them. Euſebius inſinuates that they ſpoke of his reſurrection and aſcenſion. Tertullian and Juſtin refer to theſe acts with ſo much confidence as would make one believe they had them in their hands. However, neither Euſebius nor St Jerome, who were both inquiſitive, underſtanding perſons, nor any other author that wrote afterwards, ſeem to have ſeen them, at leaſt not the true and original acts; for as to what we have now in great number, they are not authentic, being neither ancient nor uniform. There are alſo ſome pretended letters of Pilate to Tiberius, giving a hiſtory of our Saviour, but they are univerſally allowed to be ſpurious.

Pilate being a man that, by his exceſſive cruelties and rapine, had diſturbed the peace of Judea during the whole time of his government, was at length depoſed by Vitellius the proconſul of Syria, in the 36th year of Jeſus Chriſt, and ſent to Rome to give an account of his conduct to the emperor. But though Tiberius died before Pilate arrived at Rome, yet his ſucceſſor Caligula baniſhed him to Vienne in Gaul, where he was reduced to ſuch extremity that he killed himſelf with his own hands. The evangeliſts call him governor, though in reality he was no more than procurator of Judea, not only becauſe governor was a name of general uſe, but becauſe Pilate in effect acted as one, by taking upon him to judge in criminal matters; as his predeceſſors had done, and other procurators in the ſmall provinces of the empire where there was no proconſul, conſtantly did. See *Calmet's Dictionary*, *Echard's Eccleſiaſtical Hiſtory*, and *Beauſobre's Annot.*

Pilatre, Pilchard.

With regard to Pilate's wife, the general tradition is, that ſhe was named Claudia Procula or Proſcula; and in relation to her dream, ſome are of opinion that as ſhe had intelligence of our Lord's apprehenſion, and knew by his character that he was a righteous perſon, her imagination, being ſtruck with theſe ideas, did naturally produce the dream we read of; but others think that this dream was ſent providentially upon her, for the clearer manifeſtation of our Lord's innocence.

PILATRE DU ROSIER (Francis), was born at Metz the 30th of March 1756. He was firſt apprentice to an apothecary there, and afterwards went to Paris in queſt of farther improvement. He applied himſelf to the ſtudy of natural hiſtory and of natural philoſophy, and had already acquired ſome reputation, when the diſcovery of M. de Montgolfier had juſt aſtoniſhed the learned world. On the 25th of October 1783, he attempted an aerial voyage with the Marquis of Arlande. He performed ſeveral other excurſions in this way with brilliant ſucceſs, in the preſence of the royal family of France, of the king of Sweden, and of Prince Henry of Pruſſia. He then reſolved to paſs into England by means of his aerial vehicle, and for that purpoſe he repaired to Boulogne, whence he roſe about 7 o'clock in the morning of the 15th June 1785; but in half an hour after he ſet out, the balloon took fire, and the aeronaut, with his companion M. Romaine, were cruſhed to death by the fall of that machine, which was more ingenious, perhaps, than uſeful*. Pilatre's ſocial virtues and courage, which were very diſtinguiſhed, heightened the regret of his friends for his loſs. His merit as a chemiſt, and his experiments as an aeronaut, procured him ſome pecuniary reward, and ſome public appointments. He had a penſion from the King, was intendant of Monſieur's cabinets of natural philoſophy, chemiſtry, and natural hiſtory, profeſſor of natural philoſophy, a member of ſeveral academies, and principal director of Monſieur's muſeum.

* See *Aerostation*, N° 34.

PILCHARD, in ichthyology, a fiſh which has a general likeneſs to the herring, but differs in ſome particulars very eſſential. The body of the pilchard is leſs compreſſed than that of the herring, being thicker and rounder: the noſe is ſhorter in proportion, and turns up; the under jaw is ſhorter. The back is more elevated; the belly leſs ſharp. The dorſal fin of the pilchard is placed exactly in the centre of gravity, ſo that when taken up by it, the body preſerves an equilibrium, whereas that of the herring dips at the head. The ſcales of the pilchard adhere very cloſely, whereas thoſe of the herring very eaſily drop off. The pil-

Pilchard, Pile.

chard is in general leſs than the herring; but it is fatter, or more full of oil.

The pilchard appears in vaſt ſhoals off the Corniſh coaſts about the middle of July, diſappearing the beginning of winter, yet ſometimes a few return again after Chriſtmas. Their winter retreat is the ſame with that of the herring, and their motives for migrating the ſame †. They affect, during ſummer, a warmer latitude; for they are not found in any quantities on any of our coaſts except thoſe of Cornwall, that is to ſay, from Fowey harbour to the Scilly iſles, between which places the ſhoals keep ſhifting for ſome weeks. The approach of the pilchard is known by much the ſame ſigns as thoſe that indicate the arrival of the herring. Perſons, called in Cornwall *huers*, are placed on the cliffs, to point to the boats ſtationed off the land the courſe of the fiſh. By the 1ſt of James I. c. 23, fiſhermen are empowered to go on the grounds of others to hue, without being liable to actions of treſpaſs, which before occaſioned frequent law-ſuits.

† See *Clupea*.

The emoluments that accrue to the inhabitants of that county are great, and are beſt expreſſed in the words of Dr W. Borlaſe, in his *Account of the Pilchard Fiſhery*. "It employs a great number of men on the ſea, training them thereby to naval affairs; employs men, women, and children, at land, in ſalting, preſſing, waſhing, and cleaning, in making boats, nets, ropes, caſks, and all the trades depending on their conſtruction and ſale. The poor is fed with the offals of the captures; the land with the refuſe of the fiſh and ſalt; the merchant finds the gains of commiſſion and honeſt commerce; the fiſherman, the gains of the fiſh. Ships are often freighted hither with ſalt, and into foreign countries with the fiſh, carrying off at the ſame time part of our tin. The uſual number of hogſheads of fiſh exported each year, for ten years, from 1747 to 1756 incluſive, from the four ports of Fowey, Falmouth, Penzance, and St Ives, in all amounts to 29,794; ſince it appears that Fowey has exported yearly 1732 hogſheads; Falmouth, 14,631 hogſheads and two-thirds; Penzance and Mounts-Bay, 12,149 hogſheads and one-third; St Ives, 1282 hogſheads. Every hogſhead for ten years laſt paſt, together with the bounty allowed for each when exported, and the oil made out of each, has amounted, one year with another at an average, to the price of L. 1:13:3; ſo that the caſh paid for pilchards exported has, at a medium, annually amounted to the ſum of L. 49,532, 10s." The numbers that are taken at one ſhooting out of the nets is amazingly great. Mr Pennant ſays, that Dr Borlaſe aſſured him, that on the 5th of October 1767, there were at one time incloſed in St Ives's Bay 7000 hogsheads, each hogſhead containing 35,000 fiſh, in all 245,000,000.

PILE, in heraldry, an ordinary in form of a wedge, contracting from the chief, and terminating in a point towards the bottom of the ſhield.

Pile.

Pile, among the Greeks and Romans, was a pyramid built of wood, whereon were laid the bodies of the deceaſed to be burnt. It was partly in the form of an altar, and differed in height according to the quality of the perſon to be conſumed. Probably it might originally be conſidered as an altar, on which the dead were conſumed as a burnt-offering to the infernal deities. The trees made uſe of in the erection of a funeral pile were ſuch as abounded in pitch or roſin, as being moſt combuſtible; if they uſed any other wood, it was ſplit that it might the more eaſily catch fire. Round the pile were placed cypreſs boughs to hinder the noiſome ſmell. See Funeral.

Pile, in building, is uſed for a large ſtake rammed into the ground in the bottom of rivers, or in marſhy land, for a foundation to build upon.

Pile is alſo uſed among architects for a maſs of building.

Pile, in coinage, denotes a kind of puncheon, which, in the old way of coining with the hammer, contained the arms or other figure and inſcription to be ſtruck on the coin. See Coinage.

Accordingly we ſtill call the arms-ſide of a piece of money the *pile*, and the head the *croſs*; becauſe in ancient coin, a croſs uſually took the place of the head in ours.

Pile-Engine, a very curious machine invented by Mr Vauloue for driving the piles of Weſtminſter-bridge. It is repreſented Plate CCCXCIII. A is a great upright ſhaft or axle, on which are the great wheel B, and the drum C, turned by horſes joined to the bars S, S. The wheel B turns the trundle X, on the top of whoſe axis is the fly O, which ſerves to regulate the motion, and alſo to act againſt the horſes, and to keep them from falling when the heavy ram Q is diſcharged to drive the pile P down into the mud in the bottom of the river. The drum C is looſe upon the ſhaft A, but is locked to the wheel B by the bolt Y. On this drum the great rope HH is wound; one end of the rope being fixed to the drum, and the other to the follower G, to which it is conveyed over the pulleys I and K. In the follower G is contained the tongs F, that takes hold of the ram Q by the ſtaple R, for drawing it up. D is a ſpiral or fuſy fixed to the drum, on which is wound the ſmall rope T that goes over the pulley U, under the pulley V, and is faſtened to the top of the frame at 7. To the pulley-block V is hung the counterpoiſe W, which hinders the follower T from accelerating as it goes down to take hold of the ram; for as the follower tends to acquire velocity in its deſcent, the line T winds downwards upon the fuſy, on a larger and larger radius, by which means the counterpoiſe W acts ſtronger and ſtronger againſt it; and ſo allows it to come down with only a moderate and uniform velocity. The bolt Y locks the drum to the great wheel, being puſhed upward by the ſmall lever 2, which goes through a mortiſe in the ſhaft A, turns upon a pin in the bar 3, fixed to the great wheel B, and has a weight 4, which always tends to puſh up the bolt Y through the wheel into the drum. L is the great lever turning on the axis *m*, and reſting upon the forcing bar 5, 5, which goes through a hollow in the ſhaft A, and bears up the little lever 2.

By the horſes going round, the great rope H is wound about the drum C, and the ram Q is drawn up by the tongs F in the follower G, until the tongs come between the inclined planes E; which, by ſhutting the tongs at the top, opens it at the foot, and diſcharges the ram which falls down between the guides *b b* upon the pile P, and drives it by a few ſtrokes as far into the mud as it will go; after which, the top part is ſawed off cloſe to the mud by an engine for that purpoſe.

Immediately

Pile. Immediately after the ram is discharged, the piece 6 upon the follower G takes hold of the ropes *a a*, which raise the end of the lever L, and cause its end N to descend and press down the forcing bar 5 upon the little lever 2, which, by pulling down the bolt Y, unlocks the drum C from the great wheel B; and then the follower being at liberty, comes down by its own weight to the ram; and the lower ends of the tongs slip over the staple R, and the weight of their heads causes them to fall outward, and shut upon it. Then the weight 4 pushes up the bolt Y into the drum, which locks it to the great wheel, and so the ram is drawn up as before.

As the follower comes down, it causes the drum to turn backward, and unwinds the rope from it, whilst the horses, great wheel, trundle, and fly, go on with an uninterrupted motion; and as the drum is turning backward, the counterpoise W is drawn up, and its rope T wound upon the spiral susy D.

There are several holes in the under side of the drum, and the bolt Y always takes the first one that it finds when the drum stops by the falling of the follower upon the ram; until which stoppage the bolt has not time to slip into any of the holes.

This engine was placed upon a barge on the water, and so was easily conveyed to any place desired. The ram was a ton weight; and the guides *b b*, by which it was let fall, were 30 feet high.

A new machine for driving piles has been invented lately by Mr S. Bunce of Kirby street, Hatten street, London. It will drive a greater number of piles in a given time than any other; and can be constructed more simply to work by horses than Mr Vauloué's engine above described.

Plate CCCXCIII. Fig. 1 and 2 represent a side and front section of the machine. The chief parts are A, fig. 1, which are two endless ropes, or chains connected by cross pieces of iron B (see fig. 2) corresponding with two cross grooves cut diametrically opposite in the wheel C (fig. 1.), into which they are received; and by which means the rope or chain A is carried round. FHK is a side-view of a strong wooden frame moveable on the axis H. D is a wheel, over which the chain passes and turns within at the top of the frame. It moves occasionally from F to G upon the centre H, and is kept in the position F by the weight I fixed to the end K. Fig. 3. L is the iron ram, which is connected with the cross pieces by the hook M. N is a cylindrical piece of wood suspended at the hook at O, which by sliding freely upon the bar that connects the hook to the ram, always brings the hook upright upon the chain when at the bottom of the machine, in the position of GP. See fig. 1.

When the man at S turns the usual crane-work, the ram being connected to the chain, and passing between the guides, is drawn up in a perpendicular direction; and when it is near the top of the machine, the projecting bar Q of the hook strikes against a cross piece of wood at R (fig. 1.); and consequently discharges the ram, whilst the weight I of the moveable frame instantly draws the upper wheel into the position shown at F, and keeps the chain free of the ram in its descent. The hook, while descending, is prevented from catching the chain by the wooden piece N. For that piece being specifically lighter than the iron weight below, and moving with a less degree of velocity cannot come in contact with the iron till it is at the bottom and the ram stops. It then falls and again connects the hook with the chain, which draws up the ram, as before.

Pile || Pilgrimage.

Mr Bunce has made a model of this machine, which performs perfectly well; and he observes, that, as the motion of the wheel C is uninterrupted, there appears to be the least possible time lost in the operation.

Pile-Worms, are a kind of worms found in the piles of the sea-dikes in Holland. They are of very various sizes; for some of the young ones are not above an inch or two in length, while others have been found thirteen or fourteen inches long. The heads of these creatures are covered with two hard shells or hemicrania; which together form a figure resembling an augre; and with which they bore the wood. The best remedy against them is, to perforate the pile with many small holes about an inch asunder; then it must be done over with a varnish in the hottest sun; and, while the varnish is hot, brick-dust must be strewed over it: and this being several times repeated, the pile will be covered with a strong crust absolutely impenetrable to all insects.

PILES, in medicine, the same with hæmorrhoids. See MEDICINE, n° 240, &c.

PILEUS, in Roman antiquity, was the ordinary cap or hat worn at public shows and sacrifices, and by the freedmen. It was one of the common rewards assigned to such gladiators as were slaves, in token of their obtaining freedom.

PILEWORT (*Ranunculus ficaria*, Lin.), the root. This is a very small plant, found in moist meadows and by hedge sides. The roots consist of slender fibres with some little tubercles among them, which are supposed to resemble the hæmorrhoids. From thence it has been concluded, that this root must needs be of wonderful efficacy for the cure of that distemper: to the taste, it is little other than mucilaginous; and although still retained in several of the foreign pharmacopœias, it is hardly in use in this country.

PILGRIM, one who travels through foreign countries to visit holy places, and to pay his devotion to the relicks of dead saints. See PILGRIMAGE.

The word is formed from the Flemish *pelgrim*, or Italian *pelegrino*, which signifies the same; and those originally from the Latin *peregrinus*, a "stranger or traveller."

PILGRIMAGE, a kind of religious discipline, which consists in taking a journey to some holy place in order to adore the relicks of some deceased saint. Pilgrimages began to be made about the middle ages of the church; but they were most in vogue after the end of the 11th century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account. The places most visited were Jerusalem, Rome, Compostella (A), and Tours; but the greatest numbers now resort to Loretto, in order to visit the chamber of the

(A) It deserves to be remarked here, that in the year 1428, under the reign of Henry VI. abundance of pi-

Pilgrimage.

bleſſed virgin, in which ſhe was born, and brought up her ſon Jeſus till he was 12 years of age. For the pilgrimage of the followers of Mahomet, ſee MAHOMETANISM, p. 465.

In every country where popery was eſtabliſhed, pilgrimages were common; and in thoſe countries which are ſtill popiſh, they continue. In England, the ſhrine of St Thomas à Becket was the chief reſort of the pious; and in Scotland, St Andrew's; where, as tradition informs us, was depoſited a leg of the holy apoſtle. In Ireland they ſtill continue; for, from the beginning of May till the middle of Auguſt every year, crowds of popiſh penitents from all parts of that country reſort to an iſland near the centre of *Lough-ſin*, or *White Lake*, in the county of Donnegal, to the amount of 3000 or 4000. Theſe are moſtly of the poorer ſort, and many of them are proxies for thoſe who are richer; ſome of which, however, together with ſome of the prieſts and biſhops on occaſion, make their appearance there. When the pilgrim comes within ſight of the holy lake, he muſt uncover his hands and feet, and thus walk to the water-ſide, and is taken to the iſland for ſixpence. Here there are two chapels and 15 other houſes; to which are added confeſſionals, ſo contrived, that the prieſt cannot ſee the perſon confeſſing. The penance varies according to the circumſtances of the penitent; during the continuance of which (which is ſometimes three, ſix, or nine days) he ſubſiſts on oatmeal, ſometimes made into bread. He traverſes ſharp ſtones on his bare knees or feet, and goes through a variety of other forms, paying ſixpence at every different confeſſion. When all is over, the prieſt bores a gimblet-hole through the pilgrim's ſtaff near the top, in which he faſtens a croſs peg; gives him as many holy pebbles out of the lake as he cares to carry away, for amulets to be preſented to his friends, and ſo diſmiſſes him, an object of veneration to all other papiſts not thus initiated; who no ſooner ſee the pilgrim's croſs in his hands, than they kneel down to get his bleſſing.

There are, however, other parts of Ireland ſacred to extraordinary worſhip and pilgrimage; and the number of holy wells, and miraculous cures, &c. produced by them, is very great. That ſuch things ſhould exiſt in this enlightened age, and in a Proteſtant country, is indeed ſtrange; but our wonder ceaſes, when we reflect that it is among the loweſt, and perhaps the worſt of the people. They who carry external religion to an extreme, and place that confidence in ceremony which belongs only to the ſpirit of it, are ſeldom diſtinguiſhed either for their wiſdom or their virtue. We do not deny, however, that they who carry matters to the other extreme, may be equally deſtitute of real knowledge and genuine morality.

Dr Johnſon, in his *Raſſelas*, gives us ſome obſervations on pilgrimage, which are ſo much to the purpoſe, that we think we cannot do better than lay them before our readers. "Pilgrimage (ſaid Imlac, into whoſe mouth the obſervations are put), like many other acts of piety, may be reaſonable or ſuperſtitious according to the principles upon which it is performed. Long journeys in ſearch of truth are not commanded. Truth, ſuch as is neceſſary to the regulation of life, is always found where it is honeſtly ſought: change of place is no natural cauſe of the increaſe of piety, for it inevitably produces diſſipation of mind. Yet ſince men go every day to view the fields where great actions have been performed, and return with ſtronger impreſſions of the event, curioſity of the ſame kind may naturally diſpoſe us to view that country whence our religion had its beginning: and I believe no man ſurveys thoſe awful ſcenes without ſome confirmation of holy reſolutions. That the Supreme Being may be more eaſily propitiated in one place than in another, is the dream of idle ſuperſtition; but that ſome places may operate upon our own minds in an uncommon manner, is an opinion which hourly experience will juſtify. He who ſuppoſes that his vices may be more ſucceſsfully combated in Paleſtine, will, perhaps, find himſelf miſtaken; yet he may go thither without folly: he who thinks they will be more freely pardoned, diſhonours at once his reaſon and religion."

Pilgrimage, Pilkington.

PILKINGTON (Lætitia), a famous poetical genius, the daughter of Dr Van Lewin, a phyſician of Dublin, where ſhe was born in 1712. She was married very young to the Rev. Matthew Pilkington, a poet alſo of no inconſiderable merit; and theſe two wits, as is often the caſe, lived very unhappily together. They were at length totally ſeparated, on the huſband accidentally diſcovering a gentleman in her bedchamber at two o'clock in the morning; a circumſtance which ſhe accounted for in a very unſatisfactory manner. The ſtory is told at large in her Memoirs; where ſhe ſays, "Lovers of learning, I am ſure, will pardon me, as I ſolemnly declare it was the attractive charms of a new book, which the gentleman would not lend me, but conſented to ſtay till I read it through, that was the ſole motive of my detaining him." As there are not wanting ſome who form objections to marrying learned wives, the chance of ſuch literary aſſignations may perhaps be added to the liſt of them. After this unlucky adventure, Mrs Pilkington came to London; and having recourſe to her pen for ſubſiſtence, through the means of Colley Cibber, ſhe lived ſome time on the contributions of the great. She was however thrown into the Marſhalſea for debt; and being ſet at liberty, opened a pamphlet ſhop. She raiſed at length a handſome ſubſcription for her Memoirs; which are written with great ſprightlineſs and wit, containing ſeveral entertaining anecdotes of dean Swift with whom ſhe was intimate, as well as many pretty little

---

cences were granted from the crown of England to captains of Engliſh ſhips, for carrying numbers of devout perſons to the ſhrine of St James of Compoſtella in Spain; provided, however, that thoſe pilgrims ſhould firſt take an oath not to take any thing prejudicial to England, nor to reveal any of its ſecrets, nor to carry out with them any more gold or ſilver than what would be ſufficient for their reaſonable expences. In this year there went out thither from England, on the ſaid pilgrimage, the following number of perſons. From London 280, Briſtol 200, Weymouth 122, Dartmouth 90, Yarmouth 60, Jerſey 60, Plymouth 40, Exeter 30, Poole 24, Ipſwich 20, in all 926 perſons.

Pill
ll
Pillars.

little pieces of her poetry. This ingenious but unhappy woman is said at last to have killed herself with drinking at Dublin, in 1750.

PILL, in pharmacy, a form of medicine resembling a little ball, to be swallowed whole; invented for such as cannot take bitter and ill-tasted medicinal draughts; as also to keep in readiness for occasional use without decaying. See PHARMACY-*Index*.

PILLAR, in architecture. See ARCHITECTURE.

PILLAR, in the manege, is the centre of the ring, or manege-ground, round which a horse turns, whether there be a pillar in it or not. Besides this, there are pillars on the circumference or sides of the manege-ground, placed at certain distances, by two and two, from whence they are called the *two pillars*, to distinguish them from that of the centre. The use of the pillar in the centre is for regulating the extent of ground, that the manege upon the volts may be performed with method and justness, and that they may work in a square, by rule and measure, upon the four lines of the voits; and also to break unruly high-mettled horses, without endangering the rider. The two pillars are placed at the distance of two or three paces one from the other; and the horse is put between those, to teach him to rise before and yerk out behind, and put himself upon raised airs, &c. either by the aids or chastisements.

Pompey's PILLAR. See ALEXANDRIA, p. 393.

PILLARS, in antiquarian topography, are large single stones set up perpendicularly. Those of them which are found in this country have been the work of the Druids; but as they are the most simple of all monuments, they are unquestionably more ancient than druidism itself. They were placed as memorials recording different events; such as remarkable instances of God's mercies, contracts, singular victories, boundaries, and sometimes sepulchres. Various instances of these monuments erected by the patriarchs occur in the Old Testament: such was that raised by Jacob at Lug, afterwards by him named *Bethel*; such also was the pillar placed by him over the grave of Rachel. They were likewise marks of execrations and magical talismans.

These stones, from having long been considered as objects of veneration, at length were by the ignorant and superstitious idolatrously worshipped; wherefore, after the introduction of Christianity, some had crosses cut on them, which was considered as snatching them from the service of the devil. Vulgar superstition of a later date has led the common people to consider them as persons transformed into stone for the punishment of some crime, generally that of sabbath-breaking; but this tale is not confined to single stones, but is told also of whole circles: witness the monuments called the *hurlers* in Cornwall, and *Rollrick stones* in Warwickshire. The first are by the vulgar supposed to have been once men, and thus transformed as a punishment for playing on the Lord's day at a game called *hurling*; the latter, a pagan king and his army.

At Wilton, where the earl of Pembroke has a very magnificent house, there is a pillar of one piece of white Egyptian granite, which was brought from the temple of Venus Genetrix at Rome, near 14 feet high and 22 inches diameter, with an inscription to Astarte or Venus.

PILLORY (*collistrigium*, "collum stringens;" *pilloria*, from the French *pilleur*, i. e. *depeculator*, or *pelori*; derived from the Greek πυλη, *janua*, a "door," because one standing on the pillory puts his head as it were through a door, and ορασω, *video*), is an engine made of wood to punish offenders, by exposing them to public view, and rendering them infamous. There is a *statute of the pillory*, 51 Hen. III. And by statute it is appointed for bakers, forestallers, and those who use false weights, perjury, forgery, &c. 3 *Inst.* 219. Lords of leets are to have a pillory and tumbrel, or it will be the cause of forfeiture of the leet; and a village may be bound by prescription to provide a pillory, &c. 2 *Hawk.* P. C. 73.

Pillory,
Pilot.

PILOT, the officer who superintends the navigation, either upon the sea-coast or on the main ocean. It is, however, more particularly applied by our mariners to the person charged with the direction of a ship's course on or near the sea-coast, and into the roads, bays, rivers, havens, &c. within his respective district.

Pilots of ships, taking upon them to conduct any ship from Dover, &c. to any place up the river Thames, are to be first examined and approved by the master and wardens of the society of Trinity House, &c. or shall forfeit 10 l for the first offence, 20 l. for the second, and 40 l. for every other offence; one moiety to the informer, the other to the master and wardens; but any master or mate of a ship may pilot his own vessel up the river: and if any ship be lost through the negligence of any pilot, he shall be for ever after disabled to act as a pilot. 3 Geo. I. c. 13. Also the lord-warden of the cinque ports may make rules for the government of pilots, and order a sufficient number to ply at sea to conduct ships up to the Thames: 7 Geo. I. c. 21. No person shall act as a pilot on the Thames, &c. (except in collier ships) without a licence from the master and wardens of Trinity House at Deptford, on pain of forfeiting 20 l. And pilots are to be subject to the government of that corporation; and pay ancient dues, not exceeding 1 s. in the pound, out of wages, for the use of the poor thereof. Stat. 5 Geo. II. c. 20.

By the former laws of France, no person could be received as pilot till he had made several voyages and passed a strict examination; and after that, on his return in long voyages, he was obliged to lodge a copy of his journal in the admiralty; and if a pilot occasioned the loss of a ship, he had to pay 100 livres fine, and to be for ever deprived of the exercise of pilotage; and if he did it designedly, be punished with death. *Lex Mercat.* 70. 71.

The laws of Oleron ordain, That if any pilot designedly misguide a ship, that it may be cast away, he shall be put to a rigorous death, and hung in chains: and if the lord of a place, where a ship be thus lost, abet such villains in order to have a share of the wreck, he shall be apprehended, and all his goods forfeited for the satisfaction of the persons suffering; and his person shall be fastened to a stake in the midst of his own mansion, which, being fired on the four corners, shall be burned to the ground, and he with it. *Leg. Ol.* c. 25. And if the fault of a pilot be so notorious, that the ship's crew see an apparent wreck, they may lead him to the hatches, and strike off his head; but the common law denies this hasty execution: an ignorant

pilot

Pilot. pilot is ſentenced to paſs thrice under the ſhip's keel by the laws of Denmark. *Lex Mercat.* 70.

The regulations with regard to pilots in the royal navy are as follow: "The commanders of the king's ſhips, in order to give all reaſonable encouragement to ſo uſeful a body of men as pilots, and to remove all their objections to his Majeſty's ſervice, are ſtrictly charged to treat them with good uſage, and an equal reſpect with warrant-officers.

"The purſer of the ſhip is always to have a ſet of bed ling provided on board for the pilots; and the captain is to order the boatſwain to ſupply them with hammocks, and a convenient place to lie in, near their duty, and apart from the common men; which bedding and hammocks are to be returned when the pilots leave the ſhip.

"A pilot, when conducting one of his Majeſty's ſhips in pilot-water, ſhall have the ſole charge and command of the ſhip, and may give orders for ſteering, ſetting, trimming, or furling the ſails; tacking the ſhip; or whatever concerns the navigation: and the captain is to take care that all the officers and crew obey his orders. But the captain is diligently to obſerve the conduct of the pilot; and if he judges him to behave ſo ill as to bring the ſhip into danger, he may remove him from the command and charge of the ſhip, and take ſuch methods for her preſervation as ſhall be judged neceſſary; remarking upon the log book, the exact hour and time when the pilot was removed from his office, and the reaſons aſſigned for it.

"Captains of the king's ſhips, employing pilots in foreign parts of his majeſty's dominions, ſhall, after performance of the ſervice, give a certificate thereof to the pilot, which being produced to the proper naval officer, he ſhall cauſe the ſame to be immediately paid; but if there be no naval-officer there, the captain of his majeſty's ſhip ſhall pay him, and ſend the proper vouchers, with his bill, to the navy-board, in order to be paid as bills of exchange.

"Captains of his Majeſty's ſhips, employing foreign pilots to carry the ſhips they command into or out of foreign ports, ſhall pay them the rates due by the eſtabliſhment or cuſtom of the country, before they diſcharge them; whoſe receipts being duly vouched, and ſent, with a certificate of the ſervice performed, to the navy-board, they ſhall cauſe them to be paid with the ſame exactneſs as they do bills of exchange." *Regulations and Inſtructions of the Sea-ſervice*, &c.

Plate CCCXCII. *Pilot-Fiſh*, or *Gaſteroſteus Ductor*, in ichthyology, is a ſpecies of the gaſteroſteus, and is found in the Mediterranean and in the Atlantic ocean, chiefly towards the equator. Cateſby, who gives a figure of it in its natural ſize, together with a ſhort deſcription, calls it *perca marina ſetteria*, or rudder-fiſh. One of them, which Gronovius deſcribes, was about four inches in length, and its greateſt breadth little more than an inch: the head is about a third of the body, and covered, excepting the ſpace between the ſnout and the eye, with ſcales ſcarcely perceptible, and covering one another like tiles; the iris of the eye is a ſilver grey; the jaws are of equal ſize, and furniſhed as well as the palate with ſmall teeth diſpoſed in groups; there is alſo a longitudinal row of teeth on the tongue. The trunk of the pilot-fiſh is oblong, a little rounded, but it appears quadrangular towards the tail, becauſe at this place the lines are thicker, and form a kind of membranaceous projection. The back fin is long, and furniſhed with ſeven radii; on the fore-part of this fin are three moveable prickles very ſhort; the fins on the breaſt have each of them 20 radii, forked at their extremity; the abdominal fins have ſix; that of the anus has 17 branches, of which the firſt is longeſt; this fin is preceded by a ſmall moveable prickle; that of the tail is thick, large, and forked. The pilot-fiſh is of a browniſh colour, changing into gold; a tranſverſal black belt croſſes the head; a ſecond paſſes over the body at the place of the breaſt; a third near the moveable prickles of the back; three others near the region of the anus; and a ſeventh at the tail. Pilot, Pilten.

Seafaring people obſerve, that this fiſh frequently accompanies their veſſels; and as they ſee it generally towards the fore part of the ſhip, they imagined that it was guiding and tracing out the courſe of the veſſel, and hence it received the name of *pilot-fiſh*.

Oſbec tells us, that they are ſhaped like thoſe mackerels which have a tranſverſal line acroſs the body. "Sailors (continues he) give them the name of *pilots*, becauſe they cloſely follow the dog-fiſh, ſwimming in great ſhoals round it on all ſides. It is thought that they point out ſome prey to the dog-fiſh; and indeed that fiſh is very unwieldy. They are not only not touched, but alſo preſerved by it againſt all their enemies. Pſalm cvi. ver. 2. 'Who can utter the mighty acts of the Lord? Who can ſhow forth all his praiſe?' This ſcarce and remarkable fiſh I had an opportunity of deſcribing: it is *Scomber cæruleo-albus cingulis tranſverſis nigris ſex, dorſo monopterygio.* See the *Memoirs of the Swediſh Academy of Sciences for the year* 1755, vol. xvi. p. 71. of the Swediſh edition."

It likewiſe follows the ſhark, apparently for the purpoſe of devouring the remains of its prey. It is pretended that it acts as its pilot. The manner in which it attends the ſhark, according to M. Daubenton, may have given riſe to this name. It is ſaid to ſwim at the height of a foot and a half from the ſnout of this voracious animal, to follow and imitate all its movements, and to ſeize with addreſs every part of its prey which the ſhark allows to eſcape, and which is light enough to buoy up towards the ſurface of the water. When the ſhark, which has its mouth below, turns to ſeize any fiſh, the pilot fiſh ſtarts away; but as ſoon as the ſhark recovers his ordinary ſituation, it returns to its former place. Barbut informs us, that theſe fiſhes propagate their ſpecies like the ſhark. He adds, that in the gulph of Guinea thoſe fiſhes follow ſhips for the ſake of the offals and human excrements; and hence the Dutch give them the name of *dung-fiſh*. It is remarkable, that though ſo ſmall they can keep pace with ſhips in their ſwifteſt courſe.

PILTEN, a diviſion of Courland, which lies in Courland properly ſo called, derives its name from the ancient caſtle or palace of Pilten, built by Valdemar II. king of Denmark about the year 1220, when he founded a biſhop's ſee in this country for the more effectual converſion of its Pagan inhabitants. This diſtrict afterwards ſucceſſively belonged to the Germans, then again to the king of Denmark, the duke of Courland, and to Poland; and by virtue of the inſtrument of regency drawn up for this diſtrict in the year 1717, the government is lodged in ſeven Poliſh ſenators or coun-

Pilum, Pimento.

counſellors, from whom an appeal lies to the king. The biſhop of Samogitia alſo ſtyles himſelf biſhop of Pilten.

The moſt remarkable part of this diſtrict is the promontory of Domeſneſs, which projects northward into the gulf of Livonia. From this cape a ſand-bank runs four German miles farther into the ſea, half of which lies under water, and cannot be diſcerned. To the eaſt of this promontory is an unfathomable abyſs, which is never obſerved to be agitated. For the ſafety of veſſels bound to Livonia, two ſquare beacons have been erected on the coaſt, near Domeſneſs church, oppoſite to the ſand bank, and facing each other. One of theſe is twelve fathoms high, and the other eight; and a large fire is kept burning on them from the firſt of Auguſt to the firſt of January. When the mariners ſee theſe fires appear as one in a direct line, they may conclude that they are clear of the extremity of the ſand bank, and conſequently out of danger; but if they ſee both beacons, they are in danger of running upon it. The diſtrict of Pilten contains ſeven pariſhes, but no towns worthy of notice. The inhabitants are chiefly of the Lutheran perſuaſion.

PILUM, a miſſive weapon uſed by the Roman ſoldiers, and in a charge darted upon the enemy. Its point, we are told by Polybius, was ſo long and ſmall, that after the firſt diſcharge it was generally ſo bent as to be rendered uſeleſs. The legionary ſoldiers made uſe of the pilum, and each man carried two. The pilum underwent many alterations and improvements, inſomuch that it is impoſſible with any preciſion to deſcribe it. Julius Scaliger laboured much to give an accurate account of it, and would have eſteemed ſucceſs on this head amongſt the greateſt bleſſings of his life. This weapon appears, however, to have been ſometimes round, but moſt commonly ſquare, to have been two cubits long in the ſtaff, and to have had an iron point of the ſame length hooked and jagged at the end. Marius made a material improvement in it; for during the Cimbrian war, he ſo contrived it, that when it ſtuck in the enemies ſhield it ſhould bend down in an angle in the part where the wood was connected with the iron, and thus become uſeleſs to the perſon who received it.

PIMENTO, or, as Mr Edward writes, PIEMENTO, in botany, or JAMAICA PEPPER, or *Allſpice*, a ſpecies of the myrtus. See MYRTUS.

"The pimento trees grow ſpontaneouſly, and in great abundance, in many parts of Jamaica, but more particularly on hilly ſituations near the ſea, on the northern ſide of that iſland; where they form the moſt delicious groves that can poſſibly be imagined; filling the air with fragrance, and giving reality, tho' in a very diſtant part of the globe, to our great poet's deſcription of thoſe balmy gales which convey to the delighted voyager

'Sabean odours from the ſpicy ſhore
'Of Araby the bleſt.
'Chear'd with the grateful ſmell, old ocean ſmiles.'

"This tree is purely a child of nature, and ſeems to mock all the labours of man in his endeavours to extend or improve its growth: not one attempt in fifty to propagate the young plants, or to raiſe them from the ſeeds, in parts of the country where it is not found growing ſpontaneouſly, having ſucceeded. The uſual method of forming a new pimento plantation (in Jamaica it is called a *walk*) is nothing more than to appropriate a piece of woodland, in the neighbourhood of a plantation already exiſting, or in a country where the ſcattered trees are found in a native ſtate, the woods of which being fallen, the trees are ſuffered to remain on the ground till they become rotten and periſh. In the courſe of twelve months after the firſt ſeaſon, abundance of young pimento plants will be found growing vigorouſly in all parts of the land, being without doubt produced from ripe berries ſcattered there by the birds, while the fallen trees, &c. afford them both ſhelter and ſhade. At the end of two years it will be proper to give the land a thorough cleanſing, leaving ſuch only of the pimento trees as have a good appearance, which will then ſoon form ſuch groves as thoſe I have deſcribed, and, except perhaps for the firſt four or five years, require very little attention afterwards.

"Soon after the trees are in bloſſom, the berries become fit for gathering; the fruit not being ſuffered to ripen on the tree, as the pulp in that ſtate, being moiſt and glutinous, is difficult to cure, and when dry becomes black and taſteleſs. It is impoſſible, however, to prevent ſome of the ripe berries from mixing with the reſt; but if the proportion of them be great, the price of the commodity is conſiderably injured.

"It is gathered by the hand; one labourer on the tree, employed in gathering the ſmall branches, will give employment to three below (who are generally women and children) in picking the berries; and an induſtrious picker will fill a bag of 70lbs. in the day.

"The returns from a pimento walk in a favourable ſeaſon are prodigious. A ſingle tree has been known to yield 150 lbs. of the raw fruit, or one cwt. of the dried ſpice; there being commonly a loſs in weight of one third in curing; but this, like many other of the minor productions, is exceedingly uncertain, and perhaps a very plenteous crop occurs but once in five years."

Pimento, Pimpinella.

PIMPINELLA, BURNET SAXIFRAGE; a genus of the digynia order, belonging to the pentandria claſs of plants. There are ſeven ſpecies; the moſt remarkable of which are, 1. The major, or greater burnet ſaxifrage, growing naturally in chalky woods, and on the ſides of the banks near hedges, in ſeveral parts of England. The lower leaves of this ſort are winged; the lobes are deeply ſawed on their edges, and ſit cloſe to the midrib, of a dark green. The ſtalks are more than a foot high, dividing into four or five branches. The lower part of the ſtalk is garniſhed with winged leaves, ſhaped like thoſe at the bottom, but ſmaller: thoſe upon the branches are ſhort and trifid; the branches are terminated by ſmall umbels of white flowers, which are compoſed of ſmaller umbels or rays. The flowers have five heart ſhaped petals, which turn inward, and are ſucceeded by two narrow, oblong, channelled ſeeds. 2. The aniſum, or common aniſe, is an annual plant, which grows naturally in Egypt; but is cultivated in Malta and Spain, from whence the ſeeds are annually imported into Britain. The lower leaves of this plant are divided into three lobes, which are deeply cut on their edges; the ſtalk riſes a foot and a half high, dividing into ſeveral ſlender branches, garniſhed with

Pimpinella
||
Pin.

narrow leaves, cut into three or four narrow ſegments, terminated by pretty large looſe umbels, compoſed of ſmaller umbels or rays, which ſtand on pretty long footſtalks. The flowers are ſmall, and of a yelloviſh white; the ſeeds are oblong and ſwelling.—The former ſpecies requires no culture; the latter is too tender to be cultivated for profit in this country. However, the ſeeds will come up if ſown in the beginning of April upon a warm border. When they come up, they ſhould be thinned, and kept clear of weeds, which is all the culture they require.

Uſes. Both theſe ſpecies are uſed in medicine. The roots of pimpinella have a grateful, warm, very pungent taſte, which is entirely extracted by rectified ſpirit: in diſtillation the menſtruum ariſes, leaving all that it had taken up from the root united into a pungent aromatic reſin. This root promiſes, from its ſenſible qualities, to be a medicine of conſiderable utility, though little regarded in common practice: the only officinal compoſition in which it is an ingredient is the *pulvis ari compoſitus*. Stahl, Hoffman, and other German phyſicians, are extremely fond of it; and recommend it as an excellent ſtomachic, reſolvent, detergent, diuretic, diaphoretic, and alexipharmac. They frequently gave it, and not without ſucceſs, in ſcorbutic and cutaneous diſorders, foulneſs of the blood and juices, tumors and obſtructions of the glands, and diſeaſes proceeding from a deficiency of the fluid ſecretions in general. Boerhaave directs the uſe of this medicine in aſthmatic and hydropic caſes, where the ſtrongeſt reſolvents are indicated: the form he prefers is a watery infuſion; but the ſpirituous tincture poſſeſſes the virtues of the root in much greater perfection.

Aniſeeds have an aromatic ſmell, and a pleaſant warm taſte, accompanied with a degree of ſweetneſs. Water extracts very little of their flavour; rectified ſpirit the whole.

Theſe ſeeds are in the number of the four greater hot ſeeds: their principal uſe is in cold flatulent diſorders, where tenacious phlegm abounds, and in the gripes to which young children are ſubject. Frederic Hoffman ſtrongly recommmends them in weakneſs of the ſtomach, diarrhœas, and for ſtrengthening the tone of the viſcera in general; and thinks they well deſerve the appellation given them by Helmont, *inteſtinorum ſolamen*. The ſmaller kind of aniſeeds brought from Spain are preferred.

PIMPLE, in medicine, a ſmall puſtule ariſing on the face. By mixing equal quantities of the juice of houſe-leek, *ſedum minus*, paſſed through paper, and of ſpirit of wine rectified by itſelf, a white coagulum of a very volatile nature is formed, which Dr Bughart commends for curing pimples of the face; and ſays, that the thin liquor ſeparated from it with ſugarcandy is an excellent remedy for thick viſcid phlegm in the breaſt.

PIN, in commerce, a little neceſſary inſtrument made of braſs-wire, chiefly uſed by women in adjuſting their dreſs.

In the year 1543, by ſtatute 34 and 35 of Henry VIII. cap. vi. it was enacted, "That no perſon ſhall put to ſale any pinnes but only ſuch as ſhall be double-headed, and have the heads ſoldered faſt to the ſhank of the pins, well-ſmoothed, the ſhank well-ſhapen, the points well and round filed, cauted, and ſharpened." From the above extract it ſhould appear that the art of pin-making was but of late invention, probably introduced from France; and that our manufactories ſince that period have wonderfully improved. Pin.

Though pins are apparently ſimple, their manufacture is, however, not a little curious and complex. We ſhall therefore give our readers an account of it from Ellis's *Campagna* of London.

"When the braſs-wire, of which the pins are formed, is firſt received at the manufactory, it is generally too thick for the purpoſe of being cut into pins. The firſt operation therefore is that of winding it off from one wheel to another with great velocity, and cauſing it to paſs between the two, through a circle in a piece of iron of ſmaller diameter: the wire being thus reduced to its proper dimenſions, is ſtraitened by drawing it between iron pins, fixed in a board in a zig-zag manner, but ſo as to leave a ſtraight line between them: afterwards it is cut into lengths of three or four yards, and then into ſmaller ones, every length being ſufficient to make ſix pins; each end of theſe is ground to a point, which was performed when I viewed the manufactory by boys who ſat each with two ſmall grinding ſtones before him, turned by a wheel. Taking up a handful, he applies the ends to the coarſeſt of the two ſtones, being careful at the ſame time to keep each piece moving round between his fingers, ſo that the points may not become flat: he then gives them a ſmoother and ſharper point, by applying them to the other ſtone, and by that means a lad of 12 or 14 years of age is enabled to point about 16,000 pins in an hour. When the wire is thus pointed, a pin is taken off from each end, and this is repeated till it is cut into ſix pieces. The next operation is that of forming the heads, or, as they term it, *head-ſpinning*; which is done by means of a ſpinning-wheel, one piece of wire being thus with aſtoniſhing rapidity wound round another, and the interior one being drawn out, leaves a hollow tube between the circumvolutions: it is then cut with ſheers; every two circumvolutions or turns of the wire forming one head; theſe are ſoftened by throwing them into iron pans, and placing them in a furnace till they are red-hot. As ſoon as they are cold, they are diſtributed to children, who ſit with anvils and hammers before them, which they work with their feet, by means of a lathe, and taking up one of the lengths, they thruſt the blunt end into a quantity of the heads which lie before them, and catching one at the extremity, they apply them immediately to the anvil and hammer, and by a motion or two of the foot, the point and the head are fixed together in much leſs time than it can be deſcribed, and with a dexterity only to be acquired by practice; the ſpectator being in continual apprehenſion for the ſafety of their fingers ends. The pin is now finiſhed as to its form, but ſtill it is merely braſs; it is therefore thrown into a copper, containing a ſolution of tin and the leys of wine. Here it remains for ſome time; and when taken out aſſumes a white though dull appearance: in order therefore to give it a poliſh, it is put into a tub containing a quantity of bran, which is ſet in motion by turning a ſhaft that runs through its centre, and thus by means of friction it becomes perfectly bright. The

Pinacia || Pindar.

pin being complete, nothing remains but to separate it from the bran, which is performed by a mode exactly similar to the winnowing of corn; the bran flying off and leaving the pin behind fit for immediate sale. I was the more pleased with this manufactory, as it appeared to afford employment to a number of children of both sexes, who are thus not only prevented from acquiring the habits of idleness and vice, but are on the contrary initiated in their early years in those of a beneficial and virtuous industry." See NEEDLES.

PINACIA, among the Athenians, were tablets of brass inscribed with the names of all those citizens in each tribe who were duly qualified and willing to be judges of the court of Areopagus. These tablets were cast into a vessel provided for the purpose, and the same number of beans, an hundred being white and all the rest black, were thrown into another. Then the names of the candidates and the beans were drawn out one by one, and they whose names were drawn out together with the white beans were elected judges or senators. In Solon's time there were only four tribes, each of which chose 100 senators; but the number of tribes afterwards increasing, the number of senators or judges increased to so many hundreds more.

PINANG, the Chinese name of the *Areca Catechu*, Lin. See ARECA.

PINCHBECK. See ZINC.

PINDAR, the prince of lyric poets, was born at Thebes, about 520 years B. C. He received his first musical instructions from his father, who was a flute-player by profession; after which, according to Suidas, he was placed under Myrtis, a lady of distinguished abilities in lyric poetry. It was during this period that he became acquainted with the poetess Corinna, who was likewise a student under Myrtis. Plutarch tells us, that Pindar profited from the lessons which Corinna, more advanced in her studies, gave him at this school. It is very natural to suppose, that the first poetical effusions of a genius so full of fire and imagination as that of Pindar would be wild and luxuriant; and Lucian has preserved six verses, said to have been the exordium of his first essay; in which he crowded almost all the subjects for song which ancient history and mythology then furnished. Upon communicating this attempt to Corinna, she told him smiling, that he should sow with the hand, and not empty his whole sack at once. Pindar, however, soon quitted the leading strings of these ladies, his poetical nurses, and became the disciple of Simonides, now arrived at extreme old age: after which he soon surpassed all his masters, and acquired great reputation over all Greece: but, like a true prophet, he was less honoured in his own country than elsewhere; for at Thebes he was frequently pronounced to be vanquished, in the musical and poetical contests, by candidates of inferior merit.

The custom of having these public trials of skill in all the great cities of Greece was now so prevalent, that but little fame was to be acquired by a musician or poet any other way than by entering the lists; and we find, that both Myrtis and Corinna publicly disputed the prize with him at Thebes. He obtained a victory over Myrtis, but was vanquished five different times by Corinna. The judges, upon occasions like these, have been frequently accused of partiality or ignorance, not only by the vanquished, but by posterity: and if the merit of Pindar was pronounced inferior to that of Corinna five several times, it was, says Pausanias, because the judges were more sensible to the charms of beauty than to those of music and poetry (A). Was it not strange, said the Scythian Anacharsis, that the Grecian artists were never judged by artists, their peers? Pindar.

Pindar, before he quitted Thebes, had the vexation to see his Dithyrambics traduced, abused, and turned into ridicule, by the comic poets of his time; and Athenæus tells us, that he was severely censured by his brother lyrics, for being a lipogrammatist, and composing an ode from which he had excommunicated the letter S. Whether these censures proceeded from envy or contempt cannot now be determined; but they were certainly useful to Pindar, and it was necessary that he should be lashed for such puerilities. Thebes seems to have been the purgatory of our young bard: when he quitted that city, as his judgement was matured, he avoided most of the errors for which he had been chastised, and suddenly became the wonder and delight of all Greece. Every hero, prince, and potentate, desirous of lasting fame, courted the muse of Pindar.

He seems frequently to have been present at the four great festivals, of the Olympian, Pythian, Nemean, and Isthmian games, as may be inferred from several circumstances and expressions in the odes which he composed for the victors in them all. Those at Olympia, who were ambitious of having their atchievements celebrated by Pindar, applied to him for an ode, which was first sung in the Prytaneum or town-hall of Olympia, where there was a banqueting room, set apart for the entertainment of the conquerors. Here the ode was rehearsed by a chorus, accompanied by instruments. It was afterwards performed in the same manner at the triumphal entry of the victor into his own country, in processions, or at the sacrifices that were made with great pomp and solemnity on the occasion.

Pindar, in his second Isthmian ode, has apologized for the mercenary custom among poets, of receiving money for their compositions. "The world (says he) is grown interested, and thinks in general with the Spartan philosopher Aristodemus, that *money only makes the man:* a truth which this sage himself experienced, having with his riches lost all his friends." It is supposed that Pindar here alludes to the avarice of Simonides, who first allowed his muse to sell her favours to the highest bidder.

(A) Pausanias says, that Corinna was one of the most beautiful women of her time, as he judged by a picture of her which he saw at Tanagris at the place where the public exercises were performed. She was represented with her head ornamented by a tiband as a memorial of the victories she had obtained over Pindar at Thebes.

Pindar.

There is no great poet in antiquity whoſe moral character has been leſs cenſured than that of Pindar. Plutarch has preſerved a ſingle verſe of his *Epicedium* or *Dirge* that was ſung at his funeral; which, ſhort and ſimple as it is, implies great praiſe: *This man was pleaſing to ſtrangers, and dear to his fellow-citizens.* His works abound with precepts of the pureſt morality: and it does not appear that he ever traduced even his enemies; comforting himſelf, for their malignity, by a maxim which he inſerted in his firſt *Pythic*, and which afterwards became proverbial, *That it is better to be envied than pitied.*

Pauſanias ſays, that the character of poet was truly conſecrated, in the perſon of Pindar, by the god of verſe himſelf; who was pleaſed, by an expreſs oracle, to order the inhabitants of Delphos to ſet apart for Pindar one half of the firſt fruit offerings brought by the religious to his ſhrine, and to allow him a conſpicuous place in his temple, where in an iron chair he uſed to ſit and ſing his hymns in honour of that god. This chair was remaining in the time of Pauſanias, ſeveral centuries after, and ſhown to him as a relick not unworthy of the ſanctity and magnificence of that place.

But though Pindar's muſe was penſioned at Delphos, and well paid by princes and potentates elſewhere, ſhe ſeems, however, ſometimes to have ſung the ſpontaneous ſtrains of pure friendſhip. Of this kind were, probably, the verſes beſtowed upon the muſician Midas, of Agrigentum in Sicily, who had twice obtained the palm of victory by his performance on the flute at the Pythic games (B). It is in his 12th Pythic ode that Pindar celebrates the victory of Midas *over all Greece, upon that inſtrument which Minerva herſelf had invented* (C).

Fabricius tells us, that Pindar lived to the age of 90; and, according to the chronology of Dr Blair, he died 435 years B. C. aged 86. His fellow-citizens erected a monument to him in the Hippodrome at Thebes, which was ſtill ſubſiſting in the time of Pauſanias; and his renown was ſo great after his death, that his poſterity derived very conſiderable honours and privileges from it. When Alexander the Great attacked the city of Thebes, he gave expreſs orders to his ſoldiers to ſpare the houſe and family of Pindar. The Lacedemonians had done the ſame before this period; for when they ravaged Bœotia and burned the capital, the following words were written upon the door of the poet: *Forbear to burn this houſe, it was the dwelling of Pindar.* Reſpect for the memory of this great poet continued ſo long, that, even in Plutarch's time, the beſt part of the ſacred victim at the Theoxenian feſtival was appropriated to his deſcendants.

PINDARIC ODE, in poetry, an ode formed in imitation of the manner of Pindar. See POETRY, n° 136, &c. Pindaric || Pinea.

PINDUS (anc. geog.), not a ſingle mountain, but a chain of mountains, inhabited by different people of Epirus and Theſſaly; ſeparating Macedonia, Theſſaly, and Epirus: An extenſive chain, having Macedonia to the north, the Perrhœbi to the weſt, the Dolopes to the ſouth, and the mountain itſelf of Theſſaly (Strabo).

PINDUS, a Doric city of Ætolia, ſituated on the cognominal river, which falls into the Cephiſſus (Strabo).

PINE, in botany. See PINUS.

Pine-Apple. See BROMELIA.

PINEA, or PIGNE, in commerce, is a term uſed in Peru and Chili, for a kind of light, porous maſſes, or lumps, formed of a mixture of mercury and ſilver-duſt from the mines. The ore, or mineral, of ſilver, when dug out of the veins of the mine, is firſt broken and then ground in mills for the purpoſe, driven by water with iron peſtles, each of 200 pounds weight. The mineral, when thus pulverized, is next ſifted, and then worked up with water into a paſte; which, when half dry, is cut into pieces, called *cuerpos*, a foot long, weighing each about two thouſand five hundred pounds.

Each piece or cuerpo is again kneaded up with ſea-ſalt, which, diſſolving, incorporates with it. They then add mercury, from 10 to 20 pounds for each cuerpo, kneading the paſte afreſh until the mercury be incorporated therewith. This office, which is exceedingly dangerous on account of the noxious qualities of the mercury, is always made the lot of the poor Indians. This amalgamation is continued for eight or nine days; and ſome add lime, lead, or tin ore, &c. to forward it; and, in ſome mines, they are obliged to uſe fire. To try whether or no the mixture and amalgamation be ſufficient, they waſh a piece in water; and if the mercury be white, it is a proof that it has had its effect; if black, it muſt be ſtill farther worked. When finiſhed, it is ſent to the lavatories, which are large baſons that empty ſucceſſively into one another. The paſte, &c. being laid in the uppermoſt of theſe, the earth is then waſhed from it into the reſt by a rivulet turned upon it; an Indian, all the while, ſtirring it with his feet, and two other Indians doing the like in the other baſons. When the water runs quite clear out of the baſons, the mercury and ſilver are found at bottom incorporated. This matter they call *pella*, and of this they form the pineas, by expreſſing as much of the mercury as they can; firſt, by putting it in woollen bags, and preſſing and beating it ſtrongly; then, by ſtamping it in a kind of wooden mould, of an octagonal form, at bottom whereof is a braſs plate pierced

(B) This Midas is a very different perſonage from his long-eared majeſty of Phrygia, whoſe deciſion in favour of Pan had given ſuch offence to Apollo; as is manifeſt, indeed, from his having been cotemporary with Pindar.

(C) The moſt extraordinary part of this muſician's performance that can be gathered from the ſcholiaſt upon Pindar, was his finiſhing the ſolo, without a reed or mouth-piece, which broke accidentally while he was playing. The legendary account given by the poet in this ode, of the occaſion upon which the flute was invented by Minerva, is diverting: "It was (ſays he) to imitate the howling of the Gorgons, and the hiſſing of their ſnakes, which the goddeſs had heard when the head of Meduſa (one of theſe three anti-graces) was cut off by Perſeus."

Pineal Gland, Pineau

pierced full of little holes. The matter, when taken out of the mould, is laid on a trivet, under which is a large veſſel full of water; and the whole being covered with an earthen head, a fire is made around it.

The mercury ſtill remains in the maſs and is thus reduced into fumes, and, at length condenſing, it is precipitated into the water, leaving behind it a maſs of ſilver grains of different figures, which, only joining or touching at the extremes, render the matter very porous and light. This, therefore, is the pinea, or pigne, which the workmen endeavour to ſell ſecretly to veſſels trading to the South ſea; and from which thoſe, who have ventured to engage in ſo dangerous a commerce, have made ſuch vaſt gains. Indeed the traders herein muſt be very careful; for the Spaniſh miners are arrant knaves, and to make the pignes weigh the more, they often fill the middle with ſand or iron.

PINEAL GLAND. See ANATOMY.

PINEAU (Severin du), who died at Paris in 1619, was a native of Chartres, and firſt ſurgeon to the king of France. He was very ſkilful in lithotomy; and has left behind him, 1. A Diſcourſe concerning the Extraction of the Stone in the Bladder, publiſhed in 1610 in 8vo. 2. A treatiſe *De Virginitatis Notis*, printed at Leyden 1641, in 12mo. This laſt performance, however uſeful it may be to men of ſcience, we would not venture to recommend to the peruſal of young people, on account of ſome particulars which it was perhaps unneceſſary to expoſe to the eyes of the public.

PINEAU (Gabriel du), was born at Angers in 1573, where he followed the profeſſion of a lawyer with a reputation above his years. He went afterwards to Paris, and pled with eclat before the parliament and great council. Upon his return to Angers, he became a counſellor in the preſidial court. He was conſulted by all the neighbouring provinces, and had an active hand in all the great affairs of his time. Mary de Medicis conferred upon him the office of maſter of requeſts, and in her diſgrace wiſhed to ſupport herſelf by his credit and counſels; but Du Pineau, always attentive to what he owed on the one hand to the mother of his king, and on the other to the king himſelf, never ceaſed to inſpire that princeſs with ſentiments of peace.

In 1632 Louis XIII. by way of reward, appointed him mayor and captain-general of the city of Angers; a ſituation in which he merited the flattering title of *Father of the People*. He had no reſpect of perſons; for he was equally acceſſible to the poor and the great. This worthy citizen died the 15th of October 1644, at the age of 71. His houſe was a kind of academy, where regular conferences were held, and attended by young officers, advocates, and other literary characters. In thoſe conferences every one freely ſtated the difficulties which occurred to him upon ſubjects either of law or hiſtory; and when Pineau ſpoke, all was made clear; but he was always the laſt in delivering his ſentiments, becauſe he perceived that too much deference was paid to his opinion. His writings are, 1. Latin notes, in addition to thoſe of Du Moulin, upon the canon law, and printed along with the works of that eminent lawyer by the care of Francis Pinſon. 2. Commentaries, obſervations, and conſultations, upon ſeveral important queſtions reſpecting the laws both of Anjou and of France, with ſome diſſertations upon different ſubjects, &c. reprinted in 1725 in 2 vol. fol. by the care of Livoniere, who has enriched them with very uſeful remarks. The editor ſays, that "Du Pineau is a little inferior to the celebrated Du Moulin on the civil law, but that he is more accurate than the other upon the canon law."—Menage made theſe two verſes upon his death:

Pineda, Pinelli.

Pinellus periit, Themidis pius ille ſacerdos,
In proprio judex limine perpetuus.

PINEDA (John), who was born at Seville of a noble family, entered into the ſociety of Jeſuits in 1572. He taught philoſophy and divinity in ſeveral colleges; and devoted his time to the ſtudy of the Holy Scriptures. That he might render that ſtudy the eaſier, he made himſelf maſter of the oriental languages. We have of his writings, 1. Two volumes of Commentaries upon the book of Job, in folio. 2. Two upon Eccleſiaſtes. 3. A General Hiſtory of the Church, in Spaniſh, 4 vol. in folio. 4. A Hiſtory of Ferdinand III. in the ſame language, in folio. He died in 1637, much regretted by the members of his ſociety, and by the public in general.

PINELLI (John Vincent), born at Naples, was ſon of Count Pinelli, a noble Genoeſe, who had ſettled in that city, and had acquired a handſome fortune in the way of trade. After receiving a liberal education he quitted the place of his nativity, and repaired to Padua, where he took up his reſidence at the age of 24. Being a great lover of ſcience, he gave a preference to that city on account of its famous univerſity, which brought to it a number of learned men. He had an excellent library, which conſiſted of a choice collection of books and manuſcripts, and which he continued to enrich till the hour of his death. His literary correſpondence, not only in Italy, but through the moſt of Europe, procured him all the new works which were worthy of a place in his collection. The authors themſelves were often forward to pay their reſpects to him. In many cities of Italy he had perſons employed to ſearch, at leaſt once a month, the ſtalls of thoſe artificers who make uſe of old parchments, ſuch as lute-makers, ſievewrights, and others; and by this means he had the good fortune often to ſave from deſtruction ſome valuable fragments. His paſſion for knowledge embraced all the ſciences; but hiſtory, medals, antiquities, natural hiſtory, and particularly botany, were his favourite ſtudies. He was conſulted from all quarters, and the extent of his acquaintance with the learned world was very great. He correſponded with Juſtice Lipſius, Joſeph Scaliger, Signonius, Poſſevin, Peter Pithou, and a great many others, who have all paid the higheſt compliments to his erudition. Inſenſible to all the pleaſures of life, and acquainted only with thoſe of the mind, he had a great diſlike to plays, entertainments, ſhows, and every thing which moſt excites the curioſity of other men. During the ſpace of 43 years that he lived at Padua, he was never known to be out of the city but twice; once on occaſion of a plague which infeſted it; and afterwards on a voyage to Naples, which he made at the earneſt ſolicitation of his friends. In ſhort, Pinelli was generous, ſympathizing, and compaſſionate, particularly to men of letters, whoſe wants he often anticipated. His zeal

Pinet
ll
Pinguicula.

for the progreſs and advancement of ſcience rendered him very communicative of his knowledge and of his books; but this was always done with judgment and diſcretion. He died in 1601, aged 68, without having publiſhed any work. Paul Gualdo, who has written Pinelli's life, does not ſpecify the number of volumes of which his rich library conſiſted: he only informs us, that when it was tranſported by ſea to Naples, it was packed up in 130 cheſts, of which 14 contained manuſcripts; but it did not go wholly to his heirs. The ſenate of Venice cauſed their ſeal to be ſet upon the manuſcripts, and took away whatever concerned the affairs of the republic, to the number of 200 pieces.—"I compare (ſays Preſident de Thou) Pinelli to Titus Pomponius; for, as that illuſtrious Roman was called *Attick*, Pinelli alſo bore the title of *Venetian*, on account of the great affection which the republic of Venice had for him.

PINET (Antony du), lord of Noroy, lived in the 16th century, and was a native of Beſançon. He was ſtrongly attached to the Proteſtant religion, and a bitter enemy to the church of Rome. His book, intitled *La Conformité des Egliſes Reformés de France*, and *de l'Egliſe primitive*, printed at Lyons, 1564, in 8vo; and the notes which he added to the French tranſlation of the Fees of the Pope's Chancery, which was printed at Lyons, in 8vo, 1564, and reprinted at Amſterdam in 1700, in 12mo, plainly diſcover his ſentiments. He publiſhed the laſt mentioned performance under this title: *Taxe des parties caſuelles de la boutique du Pape*, in Latin and French, with ſome notes taken from decrees, councils, and canons, in order to aſcertain the diſcipline anciently obſerved in the church. In the epiſtle dedicatory, he aſſumes the tone of a declared enemy to the court of Rome. He apologizes for having preſented this book "to a ſociety ſo holy as yours (the Proteſtants), in which are heard only hymns, pſalms, and praiſes, to the Lord our God: but it is proper to ſhow to the villain his villany, and the fool his folly, leſt one ſhould be thought to reſemble them" We ſee by this ſpecimen, that Pinet had no more politeneſs in his ſtyle than in his manners. His tranſlation of Pliny's Natural Hiſtory, printed at Lyons, in 2 vol. folio, 1566, and at Paris, 1608, was formerly much read. Though there are a good many errors in it, it is yet very uſeful at preſent, eſpecially for thoſe who underſtand Pliny's Latin, on account of the tranſlator's reſearches, and a great number of marginal notes. Pinet alſo publiſhed Plans of the principal fortreſſes in the world at Lyons, 1564, in folio

Groſier's General Deſcription of China, vol. i. p. 92.

PING-LEANG FOU, a city of China in the Province of Chen-ſi. It is one of the moſt conſiderable cities of the weſtern part of the province, and is ſituated on the river Kin-ho. The air here is mild; and the agreeable views which the ſurrounding mountains preſent, added to the ſtreams which water the country, render it a very delightful reſidence. It has under its juriſdiction three cities of the ſecond claſs and ſeven of the third. In this diſtrict is a valley ſo deep and narrow, that it is almoſt impervious to the light: a large highway, paved with ſquare ſtones, runs through it.

PINGUICULA, Butterwort; a genus of the monogynia order, belonging to the diandria claſs of plants. There are four ſpecies; of which the moſt remarkable is the vulgaris, or common butterwort, growing commonly on bogs or low moiſt grounds in England and Scotland. Its leaves are covered with ſoft, upright pellucid prickles, ſecreting a glutinous liquor. The flowers are pale red, purple, or deep violet colour, and hairy within. If the freſh gathered leaves of this plant are put into the ſtrainer through which warm milk from the cow is poured, and the milk ſet by for a day or two to become aceſcent, it acquires a conſiſtency and tenacity, and neither whey nor cream ſeparate from it. In this ſtate it is an extremely grateful food, and as ſuch is uſed by the inhabitants of the north of Sweden. There is no further occaſion to have recourſe to the leaves; for half a ſpoonful of this prepared milk, mixed with freſh warm milk, will convert it to its own nature, and this again will change another quantity of freſh milk, and ſo on without end. The juice of the leaves kills lice; and the common people uſe it to cure the cracks or chops in cows udders. The plant is generally ſuppoſed injurious to ſheep, by occaſioning in them that diſeaſe called the *rot*. But from experiments made on purpoſe, and conducted with accuracy, it appears, that neither ſheep, cows, goats, horſes, or ſwine, will feed upon this plant.

Pinguicula.
Pinguin.

Wherever this plant, called alſo *Yorkſhire ſanicle*, is found, it is a certain indication of a boggy ſoil. From the idea that the country people have of its noxious operation on ſheep, this plant has been called the *white rot*; ſince as they imagine it gives them the rot whenever they eat it, which they will not do but from great neceſſity.

The Laplanders, like the Swedes with the milk of cows, receive that of the rein-deer upon the freſh leaves of this plant, which they immediately ſtrain off and ſet aſide till it becomes ſomewhat aceſcent; and the whole acquires in a day or two the conſiſtence of cream without ſeparating the ſerum, and thus becomes an agreeable food. When thus prepared, a ſmall quantity of the ſame has the property of rennet in producing the like change on freſh milk.

PINGUIN, or Penguin, in ornithology, a genus of birds of the order of palmipedes; diſtinguiſhed by Mr Latham by the following characters. The bill is ſtrong, ſtrait, more or leſs bending towards the point, and furrowed on the ſides; the noſtrils are linear, and placed in the furrows; the tongue is covered with ſtrong ſpines, pointing backwards; the wings are ſmall, very like fins, and covered with no longer feathers than the reſt of the body, and are uſeleſs in flight; the body is clothed with thick ſhort feathers, having broad ſhafts, and placed as compactly as the ſcales of fiſhes; the legs are ſhort, thick, and placed very near the vent; the toes are four, and are all placed forwards, the interior are looſe, and the reſt are webbed; the tail is very ſtiff, conſiſting of broad ſhafts ſcarcely webbed.

It is agreed that Pinguins are inhabitants of ſouthern latitudes only; being, as far as is yet known, found only on the coaſts of South America from Port Deſire to the Straits of Magellan; and Frezier ſays they are found on the weſtern ſhore as high as Conception. In Africa they ſeem to be unknown, except on a ſmall iſle near the Cape of Good Hope, which takes its name from them. They are found in vaſt numbers on land during the breeding ſeaſon; for they ſeldom come on ſhore but at that time: they form burrows under

Pinguin. ground like rabbits; and the iſles they frequent are perfectly undermined by them.

Their attitude on land is quite erect, and on that account they have been compared by ſome to pygmies, by others to children with white bibs. They are very tame, and may be driven like a flock of ſheep. In water they are remarkably active, and ſwim with vaſt ſtrength, aſſiſted by their wings, which ſerve inſtead of fins. Their food in general is fiſh; not but that they will eat graſs like geeſe.

Mr Latham remarks, that this genus appears to hold the ſame place in the ſouthern diviſion of the earth that the awks do in the northern; and that, however authors may differ in opinion on this head, they ought not to be confounded with one another. The pinguin is never ſeen but in the temperate and frigid zones ſouth of the equator, while the awk only appears on the parallel latitudes north of the equator; for neither of theſe genera have yet been obſerved within the tropics. Forſter, in his voyage (vol. i. page 92.), ſays, he ſaw one for the firſt time in lat. 48. ſouth, nor are they ever met with nearer than 40 degrees ſouth. *Id. Introd. Diſc. on Pinguins, Comment. Got.* vol. 3d.

The wings of the pinguin are ſcarcely any thing elſe than mere fins, while the awk has real wings and gills, though they be but ſmall. The former has four toes on each foot, the latter only three. While ſwimming, the pinguin ſinks wholly above the breaſt, the head and neck only appearing out of the water; while the awk, like moſt other birds, ſwims on the ſurface. There are ſeveral other peculiarities which ſerve to diſtinguiſh the two genera, but what we have mentioned are doubtleſs ſufficient.

"The bodies of the pinguin tribe (ſays our author) are commonly ſo well and cloſely covered with feathers that no wet can penetrate; and as they are in general exceſſively fat, theſe circumſtances, united ſecure them from cold. They have often been found above 700 leagues from land; and frequently on the mountains of ice, on which they ſeem to aſcend without difficulty, as the ſoles of their feet are very rough and fitted to the purpoſe." Mr Latham enumerates nine different ſpecies of this genus, beſides two varieties of the black-footed pinguin or diomedea.

Latham's Synopſis.

1. The firſt, which is a very beautiful ſpecies, our author calls the *creſted* pinguin. The birds of this ſpecies are 23 inches long; the bill is three inches long, and of a red colour, with a dark furrow running along on each ſide to the tip; the upper mandible is curved at the end, the under is obtuſe; the irides are of a dull red; the head, neck, back, and ſides are black. Over each eye there is a ſtripe of pale yellow feathers, which lengthens into a creſt behind, nearly four inches long; the feathers on each ſide of the head, above this ſtripe, are longer than the reſt, and ſtand upward, while thoſe of the creſt are decumbent, but can be erected on each ſide at pleaſure; the wings, or rather fins, are black on the outſide, edged with white; on the inſide they are white; the breaſt and all the under parts are alſo white; the legs are orange, and the claws are duſky. The female has a ſtreak of pale yellow over the eye, but it is not prolonged into a creſt behind as in the male.

This ſpecies inhabits Falkland's Iſlands, and was likewiſe met with in Kerguelen's Land, or Iſle of Deſolation, as well as at Van Diemen's Land, and New Holland, particularly in Adventure Bay. They are called *hopping pinguins* and *jumping jacks*, from their action of leaping quite out of the water, on meeting with the leaſt obſtacle, for three or four feet at leaſt; and indeed, without any ſeeming cauſe they often do the ſame, appearing chiefly to advance by that means. This ſpecies ſeems to have a greater air of livelineſs in its countenance than others, yet is in fact a very ſtupid bird, ſo much ſo as to ſuffer itſelf to be knocked on the head with a ſtick when on land. Forſter ſays he found them difficult to kill, and when provoked, he adds, they ran at the ſailors in flocks, and pecked their legs, and ſpoiled their clothes. When angered too they erect their creſts in a beautiful manner. Theſe birds make their neſts among thoſe of the pelican tribe, living in tolerable harmony with them; and lay ſeldom more than one egg, which is white, and larger than that of a duck. They are moſtly ſeen by themſelves, ſeldom mixing with other pinguins, and often met with in great numbers on the outer ſhores, where they have been bred. They are frequently ſo regardleſs as to ſuffer themſelves to be taken by the hand. The females of this ſpecies lay their eggs in burrows, which they eaſily form of themſelves with their bills, throwing out the dirt with their feet. In theſe holes the eggs are depoſited on the bare earth. The general time of ſitting is in October; but ſome of the ſpecies, eſpecially in the colder parts, do not ſit till December, or even January. How long they ſit is not known.

Pinguin.

2. The ſecond ſpecies mentioned by Latham is the *patagonian*. It is diſtinguiſhed by this name not only becauſe it is found on that coaſt, but alſo becauſe it exceeds in bulk the common pinguins as much as the natives are ſaid to do the common race of men. It was firſt diſcovered by Captain Macbride, who brought one of them from Falkland Iſlands off the Straits of Magellan. The length of the ſtuffed ſkin of this particular bird meaſured four feet three inches, and the bulk of the body ſeemed to exceed that of a ſwan. The bill was four inches and a half long, ſlender, ſtraight, bending on the end of the upper mandible, with no noſtrils. The tongue half the length of the bill, and ſingularly armed with ſtrong ſharp ſpikes pointing backwards. The plumage is moſt remarkable, the feathers lying over one another with the compactneſs of the ſcales of a fiſh; their texture equally extraordinary; the ſhafts broad and very thin; the vanes unwebbed; the head, throat, and hind part of the neck, are of a deep brown colour; from each ſide of the head to the middle of the fore part of the neck are two lines of bright yellow, broad above, narrow beneath, and uniting half way down; from thence the ſame colour widens towards the breaſt, fading away till it is loſt in pure white, of which colour is the whole under ſide of the body, a duſky line dividing it from the colour of the upper part. The whole back is of a very deep aſh-colour, almoſt duſky; but the end of each feather is marked with a blue ſpot, thoſe about the junction of the wings larger and paler than the others. The wings are in this ſpecies, as in all the others, extremely ſhort in reſpect to the ſize of the bird; hang down, and have the appearance of fins, whoſe office they perform; their length is only 14 inches; on the outſide they are duſky, and covered

Plate CCCXCVI

Pinguin. vered with ſcale-like feathers, or at beſt, with ſuch whoſe ſhafts are ſo broad and flat as ſcarce to be diſtinguiſhed from ſcales; thoſe on the ridge of the wings conſiſting entirely of ſhaft; the larger, or quill feathers, have ſome very ſhort webs. The tail conſiſts of 30 brown feathers, or rather thin ſhafts, reſembling ſplit whale-bone; flat on the upper ſide, concave on the under, and the webs ſhort, unconnected, and briſtly. From the knees to the end of the claws ſix inches, covered with ſtrong pentangular black ſcales; the fore toe ſcarce an inch long, and the others ſo remarkably ſhort, as to evince the neceſſity of that ſtrength of the tail, which ſeems intended as a ſupport to the bird in its erect attitude; in the ſame manner as that of the woodpecker is when it clings to the ſides of trees: between the toes is a ſtrong ſemilunar membrane, continued up even part of the claws; the middle claw is near an inch long, and the inner edge very ſharp and thin; the interior toe is ſmall, and placed very high. The ſkin is extremely tough and thick; which, with the cloſeneſs of the feathers, guards it effectually in the element wherein it is ſo converſant.

This ſpecies, which was, as we have ſeen, firſt met with in Falkland Iſlands, has ſince been ſeen in Kerguelen's Land, New Georgia, and New Guinea. M. Bougainville caught one, which ſoon became ſo tame as to follow and know the perſon who had care of it: it fed on fleſh, fiſh, and bread; but after a time grew lean, pined away, and died. The chief food, when at large, is thought to be fiſh; the remains of which, as well as crabs, ſhell-fiſh, and moluſcæ, were found in the ſtomach. This ſpecies is the fatteſt of the tribe; and therefore moſt ſo in January when they moult. They are ſuppoſed to lay and ſit in October. They are met with in the moſt deſerted places. Their fleſh is black, though not very unpalatable. This has been conſidered as a ſolitary ſpecies, but has now and then been met with in conſiderable flocks. They are found in the ſame places as the papuan pinguins, and not unfrequently mixed with them; but in general ſhow a diſpoſition of aſſociating with their own ſpecies.

3. The third ſpecies is denominated *papuan*. It is about 2½ feet long, being a little bigger than that which is called the *Cape Pinguin*. This ſpecies inhabits the Iſle of Papos, or New Guinea; and has been met with at Falkland Iſles and Kerguelen's Land; it is often found among the patagonian pinguins.

4. The antarctic pinguin is about 25 inches long, and weighs about 11¼ pounds. The bill is upwards of 2¾ inches long; the upper parts of the body are black, the under are gloſſy white; beneath the chin there is a narrow ſtreak of a blackiſh colour, paſſing backward towards the hind head, a little bent about the region of the ears; the wings are much the ſame as in the other ſpecies; the tail is cuneiform; the feathers, or rather briſtles, of which it is compoſed are black and in number 32; the legs are of a fleſh colour, and the ſoles of the feet are black.

"This ſpecies (ſays Latham) inhabits the ſouth ſea, from 48 degrees to the antarctic circle; and is frequently found on the ice mountains and iſlands, on which it aſcends; it is a pretty numerous ſpecies. Our laſt voyagers found them in plenty in the Iſle of Deſolation. And it was obſerved, that in an iſland they touched at, not greatly diſtant, the rocks were almoſt covered with pinguins and ſhags; the firſt moſt probably of this ſort." Pinguin.

5. For the black-footed pinguin, or diomedea demerſa, ſee DIOMEDEA.

6. The magellanic ſpecies is about the ſize of the antarctic pinguin. They are about 2 feet and ſometimes 2½ feet long, and weigh 11 pounds. The bill is black, having a tranſverſe band acroſs near its tip; the head and neck are black, except a few markings here and there; the upper parts of the body and wings are of the ſame colour; the under parts of both are white from the breaſt, except a narrow band of black paſſing at a little diſtance within the white on the breaſt, and downwards on each ſide, beneath the wings quite to the thighs; the legs are of a reddiſh colour, irregularly ſpotted on the thighs; and the claws are black. This ſpecies, which is very numerous, inhabits the Straits of Magellan, Staten Land, Terra del Fuego, and Falkland iſlands. Far from being timid, theſe birds will often attack a man and peck his legs. As food they are not at all unpalatable. They often mix with ſea-wolves among the ruſhes, burrowing in holes like a fox. They ſwim with prodigious ſwiftneſs. They lay their eggs in collective bodies, reſorting in incredible numbers to certain ſpots, which their long reſidence has freed from graſs, and to which were given the name of towns.—Penroſe obſerves, that they compoſed their neſts of mud, a foot in height, and placed as near one another as may be. It is poſſible that they may have different ways of neſting, according to the places they inhabit; or perhaps the manners of this may be blended with thoſe of another. "Here, (ſays he, *i. e.* in the places they frequent), during the breeding ſeaſon, we were preſented with a ſight which conveyed a moſt dreary, and I may ſay awful, idea of the deſertion of theſe iſlands by the human ſpecies:—a general ſtillneſs prevailed in theſe towns; and whenever we took our walks among them, in order to provide ourſelves with eggs, we were regarded indeed with ſide-long glances, but we carried no terror with us.

"The eggs are rather larger than thoſe of a gooſe, and laid in pairs. When we took them once, and ſometimes twice in a ſeaſon, they were as often replaced by the birds; but prudence would not permit us to plunder too far, leſt a future ſupply in the next year's brood might be prevented." They lay ſome time in November, driving away the albatroſſes, which have hatched their young in turn before them. The eggs were thought palatable food, and were preſerved good for three or four months.

7. The collared pinguin is a very little leſs than the papuan, being 18 inches long. The bill, which is black, is ſimilar to that of the patagonian pinguin; the irides are black; the eye is ſurrounded with a bare ſkin of a blood colour, of an oval ſhape, and three times as large as the eye itſelf; the head, throat, hind part of the neck, and ſides, back, wings, and tail, are all black; the fore part of the neck, breaſt, belly, and thighs, are white, extending round the neck, where the white begins, like a collar, except that it does not quite meet at the back part; the legs are black.

This ſpecies inhabits New Guinea. It was alſo ſeen by Dr Foſter near Kerguelen's Land; and again on two iſles adjoining to the iſland of South Georgia.

8. For

Pinion || Pinna.

8. For the red-footed pinguin, or phaeton demerſus, ſee PHAETON.

9. The *ſmall*, or, as Latham calls it, the *little pinguin*, is about the ſize of a teal, being 15 inches long. The bill, which is of a duſky colour, is about 1¼ long, and ſhaped like that of the phaeton demerſus: the upper parts of the bird from the head to the tail appear to be of a cinereous blue colour, of which colour are the ends of the feathers; the baſe of them, however, is brown black, and the ſhafts of each of the ſame colour; the under parts from chin to vent are white; the wings are duſky above and white beneath; the tail, which is exceedingly ſhort, conſiſts of 16 ſtiff feathers, which are ſcarcely perceptible; the legs are of a dull red colour; the webs are duſky, and the claws are black.

This ſpecies is pretty commonly found among the rocks on the ſouthern parts of New Zealand, but they are moſt frequent at Duſky Bay. They make deep burrows on the ſides of the hills, in which they lay their eggs: theſe holes are ſo thick in ſome parts, that a perſon is ſcarcely able to walk three or four ſteps without falling into one of them up to the knees. The inhabitants of Queen Charlotte's Sound kill them with ſticks, and, after ſkinning them, eſteem the fleſh as good food. They are known at New Zealand by the name of *korora*.—"Theſe birds (ſays Latham), I have found to vary both in ſize and colour: ſome are much ſmaller than others, quite black above, and meaſure only 13 inches in length; others are rather larger, and of a plain lead-colour on the upper parts, and the wings black, though all are white, or nearly ſo, beneath. The legs in theſe two laſt are marked with black at the ends of the toes; and the claws are black."

PINION, in mechanics, an arbor, or ſpindle, in the body whereof are ſeveral notches, which catch the teeth of a wheel that ſerves to turn it round, or it is a leſſer wheel that plays in the teeth of a larger.

PINK, a name given to a ſhip with a very narrow ſtern; whence all veſſels, however ſmall, whoſe ſterns are faſhioned in this manner, are called *pink ſterned*.

PINK, in botany. See DIANTHUS.

Plate CCXCII.

PINNA, in zoology; a genus belonging to the order of vermes teſtacea. See MYTILUS, n° 6. The animal is a ſlug. The ſhell is bivalve, fragile, and furniſhed with a beard; gapes at one end; the valves hinge without a tooth. They inhabit the coaſts of Provence, Italy, and the Indian ocean. The largeſt and moſt remarkable ſpecies inhabits the Mediterranean. It is blind, as are all of the genus; but furniſhed with very ſtrong calcareous valves. The ſcuttle-fiſh (*ſepia*), an inhabitant of the ſame ſea, is a deadly foe to this animal: as ſoon as the pinna opens its ſhell, he ruſhes upon her like a lion; and would always devour her, but for another animal whom ſhe protects within her ſhell, and from whom in return ſhe receives very important ſervices. It is an animal of the crab kind (ſee CANCER, n° 15.), naked like the hermit, and very quick-ſighted. This cancer or crab the pinna receives into her covering; and when ſhe opens her valves in queſt of food, lets him out to look for prey. During this the ſcuttle fiſh approaches; the crab returns with the utmoſt ſpeed and anxiety to his hoſteſs, who being thus warned of the danger ſhuts her doors, and keeps out the enemy. That very ſagacious obſerver Dr Haſſelquiſt, in his voyage towards Paleſtine, beheld this curious phenomenon, which tho' well known to the ancients had eſcaped the moderns. Ariſtotle (*Hiſt.* lib. 5. c. 15.) relates, that the pinna kept a guard to watch for her: That there grew to the mouth of the pinna a ſmall animal, having claws, and ſerving as a caterer, which was like a crab, and was called the *pinnophylax*. Pliny (lib. 9. 51.) ſays, the ſmalleſt of all the kinds is called the *pinnoteres*, and therefore liable to injury; this has the prudence to hide itſelf in the ſhells of oyſters. Again, lib. 9. 66. he ſays, the pinna is of the genus of ſhell fiſh; it is produced in muddy waters, always erect, nor ever without a companion, which ſome call the *pinnoteres*, others the *pinnophylax*. This ſometimes is a ſmall ſquill, ſometimes a crab, that follows the pinna for the ſake of food. The pinna, upon opening its ſhell, expoſes itſelf as a prey to the ſmalleſt kind of fiſhes; for they immediately aſſault her, and, growing bolder upon finding no reſiſtance, venture in. The guard watching its time gives notice by a bite; upon which the pinna, cloſing its ſhell, ſhuts in, kills, and gives part of whatever happens to be there to its companion.

Pinna.

The pinna and the crab together dwell,
For mutual ſuccour, in one common ſhell.
They both to gain a livelihood combine;
That takes the prey, when this has given the ſign.
From hence this crab, above his fellows fam'd,
By ancient Greeks was *pinnoteres* nam'd.—OPPIAN.

The pinnæ marinæ differ leſs from muſcles in the ſize of their ſhells than in the fineneſs and number of certain brown threads which attach them to the rocks, hold them in a fixed ſituation, ſecure them from the rolling of the waves, eſpecially in tempeſts, and aſſiſt them in laying hold of ſlime. See MYTILUS, p. 611. note (B). Theſe threads, ſays Rondelet, are as fine, compared with thoſe of muſcles, as the fineſt flax is compared with tow. M. de Reaumur ſays, that theſe threads are nearly as fine and beautiful as ſilk from the ſilk-worm, and hence he calls them the *ſilk-worms of the ſea*. Stuffs, and ſeveral kinds of beautiful manufacture, are made of theſe threads at Palermo; in many places they are the chief object of fiſhing, and become a ſilk proper for many purpoſes. It requires a conſiderable number of the pinnæ marinæ for one pair of ſtockings. Nothing can equal the delicacy of this ſingular thread. It is ſo fine, that a pair of ſtockings made of it can be eaſily contained in a ſnuff-box of an ordinary ſize. In 1754, a pair of gloves or ſtockings of theſe materials was preſented to Pope Benedict XIV. which, notwithſtanding their extreme fineneſs, ſecured the leg both from cold and heat. A robe of the ſame ſingular materials was the gift of the Roman emperor to the Satraps of Armenia. See *Procopius de Edif.* lib. 3. c. 1. A great many manufacturers are employed in manufacturing theſe threads into various ſtuffs at Palermo and other places.

The men who are employed in fiſhing up the pinna marina, inform us, that it is neceſſary to break the tuft of threads. They are fiſhed up at Toulon, from the depth of 15, 20, and ſometimes more than 30, feet, with an inſtrument called a cramp. This is a kind of fork of iron, of which the prongs are perpendicular with reſpect to the handle. Each of them is

Pinna || Pint.

about eight feet in length, and there is a space between them of about six inches; the length of the handle is in proportion to the depth of the water; the pinnæ are seized, separated from the rock, and raised to the surface by means of this instrument. The tuft of silk issues directly from the body of the animal; it comes from the shell at the place where it opens, about four or five inches from the summit or point in the large pinnæ.

M de Reaumur, *Mem. de l'Acad. des Sciences*, 1711, page 216, and 1717, page 177, considers the pinna as the most proper of all shell-fish to elucidate the formation of pearls. It produces many of them of different colours, as grey or lead-coloured, red, and some of a blackish colour, and in the form of a pear.

M. d'Argenville distinguishes three kinds of the pinnæ: 1*st*, The large kind, which are red within, and which have reddish mother-of-pearl, similar to the substance of the shell itself. There are of those shells which weigh near 15 pounds. This is the *ostura* of the Venetians.

2*d*, The smaller kind. Some of these are slender, *papyraceous*, of the colour of horn, a little shaded with pale red.

3*d*, The kind called *perna*. These are adorned with points in the channels of their shell; but what is very singular, the edges of the shell are thicker at the openings than at the joining of the valves.

The animal which lodges in the pinna marina rarely shows itself, because the valves are seldom opened. Its head is below, its largest extremity opposite; it is kept in the shell by four vigorous muscles, placed at the extremities of the valves; the shell has no hinges, but a flat and blackish ligament, which is equal in length to one-half of the shell. See PINNOTERUS and PEARL.

PINNACE, a small vessel navigated with oars and sails, and having generally two masts, which are rigged like those of a schooner.

PINNACE is also a boat usually rowed with eight oars. See the article BOAT.

PINNACLE, in architecture, the top or roof of an house, terminating in a point. This kind of roof among the ancients was appropriated to temples; their ordinary roofs were all flat, or made in the platform way.

PINNATED LEAVES, in botany. See BOTANY, p. 445. n° 232.

PINNATIFID, do. p. 442. n° 103.

PINNOTERUS, or PINNOPHYLAX, is a kind of crab-fish, furnished with very good eyes. It is said to be the companion of the pinna marina. They live and lodge together in the same shell, which belongs to the latter. When it has occasion to eat, it opens its valves, and sends out its faithful purveyor to procure food. If during their labour the pinnoterus perceives the polypus, it immediately returns to warn its blind friend of the danger, when, by shutting its valves, it escapes the rage of its enemy; but when the pinnoterus loads itself with booty without molestation, it makes a gentle noise at the opening of the shell, and when admitted the two friends feast on the fruits of its industry. See PINNA, &c.

PINT *(pinta)*, a vessel, or measure, used in estimating the quantity of liquids, and even sometimes of dry things.—Budæus derives the word from the Greek πινδξ; others from the German *pint*, a little measure of wine; Nicod from the Greek πινω, "to drink."

Pinnades || Pirus.

The *English pint* is twofold; the one for wine-measure, the other for beer and ale-measure. See MEASURE.

PINTADA, a species of PROCELLARIA.

PINTLES, certain pints or hooks fastened upon the back part of the rudder, with their points downwards, in order to enter into, and rest upon, the *goosings*, fixed in the stern-post, to hang the rudder. See HELM.

PINTOR (Peter), born at Valentia in Spain, in the year 1420, was physician to Alexander VI. whom he followed to Rome, where he practised with great success. He has left behind him two performances of considerable merit, 1. *Aggregator Sententiarum Doctorum de Curatione in Pestilentia*, printed at Rome 1499, in folio. 2. *De Morbo Fœdo & Occulto his Temporibus Affligenti*, &c. printed at Rome, 1500, in 4to, black letter; a book extremely scarce, unknown to Luisini and Astruc, and which traces the venereal disease to the year 1496. Pintor died at Rome in 1503, aged 83 years.

PINTURICCIO (Bernardino), a celebrated Italian painter, born at Perusia in 1454. He was the disciple of Peter Perugino, under whom he became so good an artist, that he employed him on many occasions as his assistant. He principally painted history and grotesque; but he also excelled in portraits, among which those of pope Pius II. and Innocent VIII. of Giulia Farnese, Cæsar Borgia, and queen Isabella of Spain, are particularly distinguished. The most memorable performance of Pinturiccio is the history of Pius II. painted in ten compartments in the history of Siena; in which undertaking, Raphael, then a young man, and bred under the same master, assisted him so far as to sketch out cartoons of many parts of the composition. The story of his death is worth relating, especially as it illustrates his character. The last work he was engaged in was a *Nativity* for the monastery of St Francis at Siena: the monks accommodated him with a chamber to work in, which they cleared of all the furniture, except one old trunk or chest that appeared too rotten to move; but Pinturiccio, naturally positive and peevish, insisting on its being taken away, the monks, willing to gratify him, complied. It was no sooner stirred than one of the planks bursting, out tumbled 500 pieces of gold, which had been secreted there for many years. The monks were overjoyed at finding this treasure, and the painter proportionably mortified at losing his chance of the discovery by his indiscreet obstinacy: it affected his spirits so much that he survived but a few months, and it was generally considered as the cause of his death.

PINUS, the PINE-TREE; a genus of the monodelphia order, belonging to the monœcia class of plants. The pine-tree was well known to the ancients, and has been described and celebrated both by their philosophers and poets. Pliny enumerates no less than six species of trees of this genus; and it is mentioned by Virgil both in his Eclogues, his Georgics, and his Æneid; by Horace in his Odes; by Ovid in his Metamorphoses; by Statius; and by Catullus, &c. Macrobius relates a pleasant anecdote concerning the cones

of

Pinus. of pine-trees, which in common language were called *poma pinea*, "pine-apples." There lived in the Auguſtan age one Vatinius, who by ſome means had irritated the Roman people ſo much that they pelted him with ſtones. When he entertained them with gladiators, to ſave himſelf from ſuch treatment for the future, he procured an edict from the ediles, that no perſon ſhould throw any thing but apples in the amphitheatre. It accidentally happened that at this time Caſcellius, eminent for his wit as well as knowledge of the law, was conſulted on the queſtion, whether a pine-apple (the cone of the pine) was legally included in the term *pomum*, "an apple?" It is an apple (ſaid he) if you intend to fling it at Vatinius *. A deciſion by which the edict in his favour did not much mend his ſituation: for Martial repreſents it dangerous to come under this tree, becauſe the cones in his time were of ſo great a ſize and weight, probably enlarged by cultivation for ages.

* Saturn. lib. 2. cap. 6.

Nuces Pineæ.

Poma ſumus Cybeles: procul hinc diſcede, viator,
Ne cadat in miſerum noſtra ruina caput †.

† Lib. 13. Ep. 25.

There are generally reckoned 14 ſpecies of this genus; of which the moſt remarkable are theſe following:

1. The *pinea*, *pin-aſter*, or wild pine, grows naturally on the mountains in Italy and the ſouth of France. It grows to the ſize of a large tree; the branches extend to a conſiderable diſtance; and while the trees are young, they are fully garniſhed with leaves, eſpecially where they are not ſo cloſe as to exclude the air from thoſe within; but as they advance in age, the branches appear naked, and all thoſe which are ſituated below become unſightly in a few years; for which reaſon they are now much leſs in eſteem than formerly.

2. The *pinus pinea*, or ſtone pine, is a tall evergreen tree, native of Italy and Spain. It delights in a ſandy loam, though like moſt others it will grow well in almoſt any land. Reflecting the uſes of this ſpecies, Hanbury tells us that "the kernels are eatable, and by many preferred to almonds. In Italy they are ſerved up at table in their deſerts. —They are exceeding wholeſome, being good for coughs, colds, conſumptions, &c. on which account only this tree deſerves to be propagated." Hanbury continues: "It may be very proper here to take notice of a very great and dangerous miſtake Mr Miller has committed, by ſaying, under this article of ſtone-pine, that ſeeds kept in the cones will be good and grow if they are ſown ten or twelve years after the cones have been gathered from the trees; whereas the ſeeds of this ſort, whether kept in the cones or taken out, are never good after the firſt year; and though ſometimes a few plants will come up from the ſeeds that are kept in the cones for two years before, yet this is but ſeldom; neither muſt a tenth part of a crop be expected. This caution is the more neceſſary, as ſeveral gentlemen who had cones, upon reading Mr Miller's book, and finding the ſeeds would take no damage when kept there, deferred the work for a ſeaſon or two, when they thought they ſhould have more conveniency either of men or ground for their purpoſe; and were afterwards wholly diſappointed, no plants appearing, the ſeeds being by that time ſpoiled and worth nothing."

3. The *rubra*, commonly called the *Scots fir* or *pine*. Pinus. It is common throughout Scotland, whence its name; though it is alſo found in moſt of the other countries of Europe. M. du Hamel, of the Royal Academy of Sciences, mentions his having received ſome ſeeds of it from St Domingo in the Weſt Indies; and thence concludes, that it grows indifferently in the temperate, frigid, and torrid zones. The wood of this tree is the red or yellow deal, which is the moſt durable of any of the kinds yet known. The leaves of this tree are much ſhorter and broader than thoſe of the former ſort, of a greyiſh colour, growing two out of one ſheath; the cones are ſmall, pyramidal, and end in narrow points; they are of a light colour, and the ſeeds are ſmall.

4. The *pinus picea*, or yew-leaved fir, is a tall evergreen and a native of Scotland, Sweden, and Germany. This ſpecies includes the ſilver fir and the balm of Gilead fir. The firſt of theſe is a noble upright tree. Mr Marſham ſays, "The talleſt trees I have ſeen were ſpruce and ſilver firs in the valleys in Switzerland. I ſaw ſeveral firs in the dockyards in Venice 40 yards long; and one of 39 yards was 18 in the diameter at the ſmall end. I was told they came from Switzerland."

The branches are not very numerous, and the bark is ſmooth and delicate. The leaves grow ſingly on the branches, and their ends are ſlightly indented. Their upper ſurface is of a fine ſtrong green colour, and their under has an ornament of two white lines running lengthwiſe on each ſide the midrib; on account of which ſilvery look this ſort is called the *ſilver fir*. The cones are large, and grow erect; and, when the warm weather comes on, they ſoon ſhed their ſeeds; which ſhould be a caution to all who wiſh to raiſe this plant, to gather the cones before that happens. *Treatiſe on Planting and Ornamental Gardening.*

The balm of Gilead fir has of all the ſorts been moſt coveted, on account of the great fragrance of its leaves; though this is not its only good property: for it is a very beautiful tree, naturally of an upright growth, and the branches are ſo ornamented with their balmy leaves, as to exceed any of the other ſorts in beauty. The leaves, which are very cloſely ſet on the branches, are broad; and their ends are indented. Their upper ſurface, when healthy, is of a fine dark green colour, and their under has white lines on each ſide the midrib lengthwiſe, nearly like thoſe of the ſilver fir. Theſe leaves when bruiſed are very finely ſcented; and the buds, which ſwell in the autumn for the next year's ſhoot, are very ornamental all winter, being turgid, and of a fine brown colour: and from theſe alſo exudes a kind of fine turpentine, of the ſame kind of (though heightened) fragrancy. The tree being wounded in any part, emits plenty of this turpentine; and Hanbury ſays, "it is ſuppoſed by many to be the ſort from whence the balm of Gilead is taken, which occaſions this tree being ſo called. But this is a miſtake; for the true balm of Gilead is taken from a kind of terebinthus: though I am informed, that what has been collected from this tree has been ſent over to England from America (where it grows naturally), and often ſold in the ſhops for the true ſort."

The ſilver fir is very hardy, and will grow in any ſoil or ſituation, but always makes the greateſt proceſs in rich loamy earth. The balm of Gilead fir muſt be planted in deep, rich, good earth; nor will it live long in

Pinus. in any other. The ſoil may be a black mould, or of a ſandy nature, if it be deep enough, and if the roots have room enough to ſtrike freely.

5. The *pinus abies*, or European ſpruce fir, a native of the northern parts of Europe and of Aſia, includes the Norway ſpruce and long-coned Corniſh fir. The former of theſe is a tree of as much beauty while growing as its timber is valuable when propagated on that account. Its growth is naturally like the ſilver, upright: and the height it will aſpire to may be eaſily conceived, when we ſay that the white deal, ſo much coveted by the joiners, &c. is the wood of this tree; and it may perhaps ſatisfy the curious reader to know, that from this fir pitch is drawn. The leaves are of a dark green colour; they ſtand ſingly on the branches, but the younger ſhoots are very cloſely garniſhed with them. They are very narrow; their ends are pointed; and they are poſſeſſed of ſuch beauties as to excite admiration. The cones are eight or ten inches long, and hang downwards. *Ibid.*

The better the ſoil is, the faſter will the ſpruce fir grow, though it will thrive very well in moſt of our Engliſh lands. In ſtrong loamy earth it makes a ſurpriſing progreſs; and it delights in freſh land of all ſorts, which never has been worn out by ploughing, &c. though it be ever ſo poor. The long-coned Corniſh fir differs ſcarcely in any reſpect from the Norway ſpruce, except that the leaves and the cones are larger.

6. The *pinus Canadenſis*, American or Newfoundland ſpruce fir, a native of Canada, Pennſylvania, and other parts of North America, includes three varieties. The white Newfoundland ſpruce, the red Newfoundland ſpruce, and the black Newfoundland ſpruce. Theſe, however, differ ſo little, that one deſcription is common to them all. They are of a genteel upright growth, though they do not ſhoot ſo freely or grow ſo faſt with us as the Norway ſpruce. The leaves are of the ſame green, and garniſh the branches in the ſame beautiful manner as thoſe of that ſpecies; only they are narrower, ſhorter, and ſtand cloſer. The greateſt difference is obſervable in the cones; for theſe are no more than about an inch in length, and the ſcales are cloſely placed. In the cones, indeed, conſiſts the difference of theſe three ſorts: thoſe of the white ſpecies are of a very light brown colour; thoſe of the red ſpecies more of a nut-brown or reddiſh colour; and thoſe of the black ſpecies of a dark or blackiſh colour. Beſides this, there is ſcarcely any material difference; though it is obſervable, that this trifling variation ſeems to be pretty conſtant in the plants raiſed from the like ſeeds. Theſe ſorts will often flower, and produce cones when only about five or ſix feet high; and indeed look then very beautiful: but this is a ſign of weakneſs in the plant, which it does not often fairly get over.

7. The *pinus balſamea*, or hemlock fir, a native of Virginia and Canada, poſſeſſes as little beauty as any of the fir tribe; though, being rather ſcarce in proportion, it is deemed valuable. It is called by ſome the *yew-leaved fir*, from the reſemblance of the leaves to thoſe of the yew-tree. It is a tree of low growth, with but few branches; and theſe are long and ſlender, and ſpread abroad without order. The leaves do not garniſh the branches ſo plentifully as thoſe of any other ſort of fir. The cones are very ſmall and rounded; they are about half an inch long; and the ſcales are looſely arranged. We receive theſe cones from America, by which we raiſe the plants; though this caution ſhould be given to the planter, that this tree is fond of moiſt rich ground, and in ſuch a kind of ſoil will make the greateſt progreſs. Pinus.

8. The *pinus orientalis*, or oriental fir, a native of the Eaſt, is a low but elegant tree. The leaves are very ſhort, and nearly ſquare. The fruit is exceeding ſmall, and hangs downward; and the whole tree makes an agreeable variety with the other kinds.

9. The *ſtrobus*, Lord Weymouth's pine, or North American white pine. This grows ſometimes to the height of 100 feet and upwards, and is highly valued on account of its beauty. The bark of the tree is very ſmooth and delicate, eſpecially when young; the leaves are long and ſlender, five growing out of one ſheath; the branches are pretty cloſely garniſhed with them, and thus make a fine appearance. The cones are long, ſlender, and very looſe, opening with the firſt warmth of the ſpring; ſo that if they are not gathered in winter, the ſcales open and let out the ſeeds. The wood of this ſort is eſteemed for making maſts for ſhips. In Queen Anne's time there was a law made for the preſervation of theſe trees, and for the encouragement of their growth in America. Within theſe laſt 50 years they have been propagated in Britain in conſiderable plenty.

With reſpect to the culture of this ſpecies, Mr Hanbury, after ſome more general directions, continues thus, "I have known gentlemen, who, in attempting to raiſe theſe trees, have ſeen the young plants go off without perceiving the cauſe; and the more watering and pains they have taken, have found the plants perſiſt in this way more and more, to their great mortification and aſtoniſhment. In the ſpring following theſe plants ſhould be pricked out in beds half a foot aſunder each way; and here they may ſtand two years, when they may be either finally planted out, or removed into the nurſery, at the diſtance of one foot aſunder, and two feet in the rows. If care has been taken of them in the nurſery, they may be removed at a conſiderable height with great aſſurance of ſucceſs: for it is much eaſier to make this pine grow than any of the other ſorts: ſo that where they are wanted for ornament in parks, open places, &c. a ſhow of them may be made in a little time.

"The ſoil the Weymouth pine delights in moſt is a ſandy loam; but it likes other ſoils of an inferior nature: and although it is not generally to be planted on all lands like the Scotch fir, yet I have ſeen it luxuriant and healthy, making ſtrong ſhoots, on blue and red clays, and other ſorts of ſtrong ground. On ſtony and and flaty ground, likewiſe, I have ſeen ſome very fine trees; ſo that I believe whoever is deſirous of having plantations of this pine, need not be curious in the choice of his ground."

10. The *pinus tæda*, or ſwamp-pine, is a tall evergreen tree, a native of the ſwamps of Virginia and Canada. There are ſeveral varieties of this genus which Hanbury enumerates and deſcribes: ſuch as, 1ſt, The three-leaved American ſwamp-pine. 2d, The two-leaved American pine. 3d, The yellow American pine, the yellow tough pine, and the tough pine of the plains;

Pinus. among which there is but little variety. 4th, The baſtard pine. 5th, The frankincenſe pine. And , (The dwarf pine.

" There are many (continues our author) other ſorts of American pines, which we receive from thence with the like cant names of thoſe of the above, which I have choſen to retain, as they will probably be continued to be ſent over; and that the gardener receiving them as ſuch may beſt know what to do with them. In many of thoſe ſorts I ſee at preſent no material difference; ſo am induced to think they are the ſame, ſent over with different names. Some of the ſorts above-mentioned differ in very few reſpects; but I have choſen to mention them, as a perſon may be ſupplied with the ſeeds from Pennſylvania, Jerſey, Virginia, Carolina, &c. where they all grow naturally: and having once obtained the ſeeds, and from them plants, they will become pleaſing objects of his niceſt obſervations."

11. The *pinus cedrus*, ranked by Tournefort and others under larix, famous for its duration, is that popularly called by us the *cedar of Lebanon*, by the ancients *cedrus magna* or the *great cedar;* alſo *cedrelate*, κεδρελατη; and ſometimes the Phœnician or Syrian cedar, from the country where it grows in its greateſt perfection. It is a coniferous evergreen, of the bigger ſort, bearing large roundiſh cones of ſmooth ſcales, ſtanding erect, the leaves being ſmall, narrow, and thick ſet.—They ſometimes counterfeit cedar, by dying wood of a reddiſh hue: but the ſmell diſcovers the cheat, that of true cedar being very aromatic. In ſome places, the wood of the cajou-tree paſſes under the name of cedar, on account of its reddiſh colour and its aromatic ſmell, which ſomewhat reſemble that of ſantal. Cedar-wood is reputed almoſt immortal and incorruptible; a prerogative which it owes chiefly to its bitter taſte, which the worms cannot endure. For this reaſon it was that the ancients uſed cedar tablets to write upon, eſpecially for things of importance, as appears from that expreſſion of Perſius, *Et cedra digna locutus*. A juice was alſo drawn from cedar, with which they ſmeared their books and writings, or other mattera, to preſerve them from rotting; which is alluded to by Horace: by means of which it was, that Numa's books, written on papyrus, were preſerved entire to the year 535, as we are informed by Pliny.

Solomon's temple, as well as his palace, were both of this wood. That prince gave king Hiram ſeveral cities for the cedars he had furniſhed him on theſe occaſions. Cortes is ſaid to have erected a palace at Mexico, in which were 7000 beams of cedar, moſt of them 120 feet long, and twelve in circumference, as we are informed by Herrera. Some tell us of a cedar felled in Cyprus 130 feet long, and 18 in diameter. It was uſed for the main-maſt in the galley of king Demetrius. Le Bruyn aſſures us, that the two biggeſt he ſaw on mount Lebanon, meaſured, one of them 57 palms, and the other 47, in circumference. In the temple of Apollo at Utica, there were cedar trees near 2000 years old; which yet were nothing to that beam in an oratory of Diana at Seguntum in Spain, ſaid to have been brought thither 200 years before the deſtruction of Troy. Cedar is of ſo dry a nature, that it will not endure to be faſtened with iron nails, from which it uſually ſhrinks; ſo that they commonly faſten it with pins of the ſame wood. Pinus.

" The ſtatue (ſays Hanbury) of the great goddeſs at Epheſus was made of this material; and, if this tree abounded with us in great plenty, it might have a principal ſhare in our moſt ſuperb edifices. The effluvia conſtantly emitted from its wood are ſaid to purify the air, and make rooms wholeſome. Chapels and places ſet apart for religious duties, being wainſcotted with this wood, inſpire the worſhippers with a more ſolemn awe. It is not obnoxious to worms; and emits an oil which will preſerve cloth or books from worms or corruption. The ſaw-duſt will preſerve human bodies from putrefaction; and is therefore ſaid to be plentifully uſed in the rites of embalming, where practiſed."

It is remarkable that this tree is not to be found as a native in any other part of the world than mount Libanus, as far as hath yet been diſcovered. What we find mentioned in Scripture of the lofty cedars can be nowiſe applicable to the common growth of this tree; ſince, from the experience we have of thoſe now growing in England, as alſo from the teſtimony of ſeveral travellers who have viſited thoſe few remaining trees on mount Libanus, they are not inclined to grow very lofty, but on the contrary extend their branches very far; to which the alluſion made by the Pſalmiſt agrees very well, when he is deſcribing the flouriſhing ſtate of a people, and ſays, " They ſhall ſpread their branches like the cedar-tree."

Rauwolf, in his Travels, ſays, there were not at that time (i. e. anno 1574) upon mount Libanus more than 26 trees remaining, 24 of which ſtood in a circle; and the other two, which ſtood at a ſmall diſtance, had their branches almoſt conſumed with age; nor could he find any younger tree coming up to ſucceed them, though he looked about diligently for ſome. Theſe trees (he ſays) were growing at the foot of a ſmall hill, on the top of the mountains, and amongſt the ſnow. Theſe having very large branches, commonly bend the tree to one ſide, but are extended to a great length, and in ſo delicate and pleaſant order, as if they were trimmed and made even with great diligence, by which they are eaſily diſtinguiſhed, at a great diſtance, from fir-trees. The leaves (continues he) are very like to thoſe of the larch tree, growing cloſe together in little branches upon ſmall brown ſhoots.

Maundrel, in his Travels, ſays, there were but 16 large trees remaining when he viſited the mountain, ſome of which were of a prodigious bulk, but that there were many more young ones of a ſmaller ſize: he meaſured one of the largeſt, and found it to be 12 yards ſix inches in girth, and yet ſound, and 37 yards in the ſpread of its boughs. At about five or ſix yards from the ground it was divided into five limbs, each of which was equal to a great tree. What Maundrel hath related was confirmed by a gentleman who was there in the year 1720, with this difference only, viz. in the dimenſions of the branches of the largeſt tree, which he meaſured, and found to be 22 yards diameter. Now, whether Mr Maundrel meant 37 yards in circumference of the ſpreading branches, or the diameter of them, cannot be determined by his

Pinus. words; yet either of them well agrees with this laſt account.

12. There is another ſpecies, viz. the *larch-tree*, which the old botaniſts ranked under larix, with deciduous leaves, and oval obtuſe cones. It grows naturally upon the Alps and Apennines, and of late has been very much propagated in Britain. It is of quick growth, and the trunk riſes to 50 feet or more; the branches are ſlender, their ends generally hanging downward, and are garniſhed with long narrow leaves which ariſe in cluſters from one point, ſpreading open above like the hairs of a painter's bruſh: they are of a light green, and fall away in autumn. In the month of April the male flowers appear, which are diſpoſed in form of ſmall cones; the female flowers are collected into oval obtuſe cones, which in ſome ſpecies have bright purple tops, and in others they are white: theſe differences are accidental; the cones are about an inch long, obtuſe at their points; the ſcales are ſmooth, and lie over each other: under each ſcale there are generally lodged two ſeeds, which have wings. There are other two varieties of this tree, one of which is a native of America, and the other of Siberia. The cones of the American kind which have been brought to Britain ſeem in general to be larger than thoſe of the common ſort.

"Many encomiums (ſays Hanbury when ſpeaking of this ſpecies) have been beſtowed on the timber of the larch: and we find ſuch a favourable account of it in ancient authors, as ſhould induce us to think it would be proper for almoſt any uſe. Evelyn recites a ſtory of Witſen, a Dutch writer, that a ſhip built of this timber and cypreſs had been found in the Numidian ſea, twelve fathoms under water, found and entire, and reduced to ſuch a hardneſs as to reſiſt the ſharpeſt tool, after it had lain ſubmerged above 1400 years. Certain it is this is an excellent wood for ſhip and houſe-building. At Venice this wood is frequently uſed in building their houſes, as well as in Switzerland, where theſe trees abound: ſo that, without all doubt, the larch excels for maſts for ſhips, or beams for houſes, doors, windows, &c. particularly as it is ſaid to reſiſt the worm.

"In Switzerland (A) their houſes are covered with boards of this wood cut out a foot ſquare; and, as it emits a reſinous ſubſtance, it ſo diffuſes itſelf into every joint and crevice, and becomes ſo compact and cloſe, as well as ſo hardened by the air, as to render the covering proof againſt all weather. But as ſuch covering for houſes would cauſe great devaſtation in caſe of fire, the buildings are confined to a limited diſtance by an order of police from the magiſtrates. The wood, when firſt laid on the houſes, is ſaid to be very white; but this colour, in two or three years is changed, by means of the ſun and reſin, to a black, which appears like a ſmooth ſhining varniſh."

Of the common larch there are ſeveral varieties. The flowers which the commoneſt ſort exhibits early in the ſpring are of a delicate red colour; another ſort produces white flowers at the ſame ſeaſon, and theſe have a delightful effect among thoſe of the red ſort; whilſt another, called the *Black Newfoundland larix*, increaſes the variety, though by an aſpect little differing from the others. There are alſo larches with greeniſh flowers, pale red, &c. all of which are accidental varieties from ſeeds. Theſe varieties are eaſily diſtinguiſhed, even when out of blow: the young ſhoots of the white flowering larch are of the lighteſt green, and the cones when ripe are nearly white. The red flowering larch has its ſhoots of a reddiſh caſt, and the cones are of a brown colour; whilſt the cones and ſhoots of the black Newfoundland larch are in the ſame manner proportionally tinged. The cones, which are a very great ornament to ſeveral ſorts of the pines, are very little to theſe. Their chief beauty conſiſts in the manner of their growth, the nature and beauty of their pencilled leaves and fair flowers; for the cones that ſucceed them are ſmall, of a whitiſh, a reddiſh, or a blackiſh brown colour, and make no figure. Pinus.

The pinus cedrus and pinus larix are propagated by ſowing in March on a bed of light earth expoſed to the morning ſun. The ſeed muſt be covered half an inch thick with fine light earth, and the beds watered at times when the weather is dry. In about ſix weeks the plants will appear; they muſt at this time be carefully guarded from the birds, ſhaded from the ſun and winds, and kept very clear of weeds. In the latter end of April the following year, they may be removed into beds of freſh earth, placing them at ten inches diſtance every way. They are to be kept here two years, and ſuch of them as ſeem to bend muſt be tied up to a ſtake to keep them upright. They may afterwards be planted in the places where they are to remain. They thrive well on the ſides of barren hills, and make a very pretty figure there.

Reſpecting the uſes of this tree, Dr Pallas, in his *Flora Roſſica*, informs us, that if it is burnt, and the wood conſumed, the internal part of the wood diſtils copiouſly a drying reddiſh gum, a little leſs glutinous than gum arabic, ſomewhat of a reſinous taſte, but wholly ſoluble in water. At the inſtigation of M. Kinder, this gum has lately been ſold in the Ruſſian ſhops under the name of *gummi Orenburgenſis*, but which our author thinks ſhould be called *gummi uralienſe* or *laricis*. It is eat by the Woguli as a dainty, and is ſaid to be nutritious and antiſcorbutic. Some manna was gathered from the green leaves, but it could never be conſerved. The Ruſſians uſe the boletus laricinus as an emetic in intermittents, and to check the leucorrhœa. At Baſchir and Siberia the inhabitants ſprinkle the dry powder on the wounds of oxen and horſes, as a detergent and anthelmintic.

The

(A) "Between Bex and Bevieux (ſays Coxe in his *Travels in Switzerland*), I obſerved the larch in great plenty. Painters, from the time of Pliny to that of Raphael, truſted their works to this wood, which the Roman naturaliſt ſtiles *immortale lignum*. The wood is reckoned excellent for all works which are to lie under water: and the boatmen on the lake of Geneva prefer it for building their veſſels. In theſe parts I ſaw moſt beautiful woods of cheſnut. Haller ſays that they extend ſome leagues: he alſo informs us, that they are found in other parts of Switzerland, and even in deſert places in ſome of the tranſalpine parts. Accident muſt have brought them thither, as it appears from Pliny that theſe trees were firſt introduced into Europe from Sardis."

Pinus. The nuts of the pinus cembra, the ſame author aſſerts, are eat as luxuries in Ruſſia, and are even exported with the ſame view. The unripe cones give a very fragrant oil, termed balſamic. The inhabitants of Siberia uſe the tender tops, and even the bark rubbed off in the ſpring, as an antiſcorbutic. The kernels of the nuts of the amygdalus nana give a very pleaſing flavour to brandy; and, when preſſed, afford a bitter oil in large quantities. The way of deſtroying the bitter is by diſtilling it in the ſun with ſpirit of wine, and it then becomes ſweet and extremely agreeable.

From the larch-tree is extracted what we erroneouſly call *Venice turpentine*. This ſubſtance, or natural balſam, flows at firſt without inciſion; when it has done dropping, the poor people who wait in the fir woods make inciſions at about two or three feet from the ground into the trunks of the trees, into which they fix narrow troughs about 20 inches long. The end of theſe troughs is hollowed like a ladle; and in the middle is a ſmall hole bored for the turpentine to run into the receiver which is placed below it. As the gummy ſubſtance runs from the trees, it paſſes along the ſloping gutter or trough to the ladle, and from thence runs through the holes into the receiver. The people who gather it viſit the trees morning and evening from the end of May to September, to collect the turpentine out of the receivers. When it flows out of the tree, Venice turpentine is clear like water, and of a yelloviſh white; but, as it grows older, it thickens and becomes of a citron colour. It is procured in the greateſt abundance in the neighbourhood of Lyons, and in the valley of St Martin near St Lucern in Switzerland.

Though we have already noticed the manner of cultivating ſome of the particular ſpecies of this genus, and have alſo remarked the uſes of ſome of them, we ſhall finiſh the article with a few general obſervations on the culture and uſes of the whole.

Culture. All the ſorts of pines are propagated by ſeeds produced in hard woody cones. The way to get the ſeeds out of theſe cones is to lay them before a gentle fire, which will cauſe the cells to open, and then the ſeeds may be eaſily taken out. If the cones are kept entire, the ſeeds will remain good for ſome years; ſo that the ſureſt way of preſerving them is to let them remain in the cones till the time for ſowing the ſeeds. If the cones are kept in a warm place in ſummer, they will open and emit the ſeeds; but if they are not expoſed to the heat, they will remain cloſe for a long time. The beſt ſeaſon for ſowing the pines is about the end of March. When the ſeeds are ſown, the place ſhould be covered with nets to keep off the birds; otherwiſe, when the plants begin to appear with the huſk of the ſeed on the top of them, the birds will peck off the tops, and thus deſtroy them.

Uſes. From the firſt ſpecies is extracted the common turpentine, much uſed by farriers, and from which is drawn the oil of that name. The proceſs of making pitch, tar, reſin, and turpentine, from theſe trees is very familiar. In the ſpring time, when the ſap is moſt free in running, they pare off the bark of the pine tree, to make the ſap run down into a hole which they cut at the bottom to receive it. In the way, as it runs down, it leaves a white matter like cream, but a little thicker. This is very different from all the kinds of reſin and turpentine in uſe, and it is generally ſold to be uſed in the making of flambeaux inſtead of white bees wax. The matter that is received in the hole at the bottom is taken up with ladles, and put in a large baſket. A great part of this immediately runs through, and this is the common turpentine. This is received into ſtone or earthen pots, and is ready for ſale. The thicker matter, which remains in the baſket, they put into a common alembic, adding a large quantity of water. They diſtil this as long as any oil is ſeen ſwimming upon the water. This oil they ſeparate from the ſurface in large quantities, and this is the common oil or ſpirit of turpentine. The remaining matter at the bottom of the ſtill is common yellow reſin. When they have thus obtained all that they can from the ſap of the tree, they cut it down, and, hewing the wood into billets, they fill a pit dug in the earth with theſe billets, and, ſetting them on fire, there runs from them, while they are burning, a black thick matter. This naturally falls to the bottom of the pit, and this is the tar. The top of the pit is covered with tiles, to keep in the heat; and there is at the bottom a little hole, out at which the tar runs like oil. If this hole be made too large, it ſets the whole quantity of the tar on fire, but, if ſmall enough, it runs quietly out. Pinus.

The tar, being thus made, is put up in barrels; and if it be to be made into pitch, they put it into large boiling veſſels, without adding any thing to it. It is then ſuffered to boil a while, and being then let out, is found when cold to be what we call pitch.

A decoction of the nuts or ſeeds of the firſt ſpecies in milk, or of the extremities of the branches pulled in ſpring, is ſaid, with a proper regimen, to cure the moſt inveterate ſcurvy. The wood of this ſpecies is not valued; but that of the Scots pine is ſuperior to any of the reſt. It is obſervable of the Scots pine, that when planted in bogs, or in a moiſt ſoil, though the plants make great progreſs, yet the wood is white, ſoft, and little eſteemed; but when planted in a dry ſoil, though the growth of the trees is there very ſlow, yet the wood is proportionably better. Few trees have been applied to more uſes than this. The talleſt and ſtraighteſt are formed by nature for maſts to our navy. The timber is reſinous, durable, and applicable to numberleſs domeſtic purpoſes, ſuch as flooring and wainſcotting of rooms, making of beds, cheſts, tables, boxes, &c. From the trunk and branches of this, as well as moſt others of the pine tribe, tar and pitch is obtained. By inciſion, barras, Burgundy pitch, and turpentine, are acquired and prepared. The reſinous roots are dug out of the ground in many parts of the Highlands, and, being divided into ſmall ſplinters, are uſed by the inhabitants to burn inſtead of candles.—At Loch-Broom, in Roſs-ſhire, the fiſhermen make ropes of the inner bark; but hard neceſſity has taught the inhabitants of Sweden, Lapland, and Kamtſchatka, to convert the ſame into bread. To effect this, they, in the ſpring ſeaſon, make choice of the talleſt and faireſt trees; then ſtripping off carefully the outer bark, they collect the ſoft, white, ſucculent interior bark, and dry it in the ſhade. When they have occaſion to uſe it, they firſt toaſt it at the fire, then grind, and afterwards

Pioneers || Pipe

ter ſteeping the flour in warm water to take off the reſinous taſte, they make it into thin cakes, which are baked for uſe. On this ſtrange food the poor inhabitants are ſometimes conſtrained to live for a whole year; and, we are told, through cuſtom, become at laſt even fond of it. Linnæus remarks, that this ſame bark-bread will fatten ſwine; and humanity obliges us to wiſh, that men might never be reduced to the neceſſity of robbing them of ſuch a food. The interior bark, of which the above mentioned bread is made, the Swediſh boys frequently peel off the trees in the ſpring, and eat raw with greedy appetite. From the cones of this tree is prepared a diuretic oil, like the oil of turpentine, and a reſinous extract, which has ſimilar virtues with the balſam of Peru. An infuſion or tea of the buds is highly commended as an antiſcorbutic. The farina, or yellow powder, of the male-flowers, is ſometimes in the ſpring carried away by the winds, in ſuch quantities, where the trees abound, as to alarm the ignorant with the notion of its raining brimſtone. The tree lives to a great age; Linnæus affirms to 400 years.

PIONEERS, in the art of war, are ſuch as are commanded in from the country, to march with an army for mending the ways, for working on intrenchments and fortifications, and for making mines and approaches. The ſoldiers are likewiſe employed for all theſe purpoſes. Moſt of the foreign regiments of artillery have half a company of pioneers, well inſtructed in that important branch of duty. Our regiments of infantry and cavalry have three or four pioneers each, provided with aprons, hatchets, ſaws, ſpades, and pick-axes. Each pioneer muſt have an ax, a ſaw, and an apron; a cap with a leather crown, and a black bears-ſkin front, on which is to be the king's creſt in white, on a red ground; and the number of the regiment is to be on the back part of it.

PIP, or Pep, a diſeaſe among poultry, conſiſting of a white thin ſkin, or film, that grows under the tip of the tongue, and hinders their feeding. It uſually ariſes from want of water, or from the drinking puddle-water, or eating filthy meat. It is cured by pulling off the film with the fingers, and rubbing the tongue with ſalt. Hawks are particularly liable to this diſeaſe, eſpecially from feeding on ſtinking fleſh.

PIPE, in building, &c. a canal, or conduit, for the conveyance of water and other liquids. Pipes for water, water-engines, &c. are uſually of lead, iron, earth, or wood: the latter are uſually made of oak or elder. Thoſe of iron are caſt in forges; their uſual length is about two feet and a half: ſeveral of theſe are commonly faſtened together by means of four ſcrews at each end, with leather or old hat between them, to ſtop the water. Thoſe of earth are made by the potters; theſe are fitted into one another, one end being always made wider than the other. To join them the cloſer, and prevent their breaking, they are covered with tow and pitch: their length is uſually about that of the iron pipes. The wooden pipes are trees bored with large iron augres, of different ſizes, beginning with a leſs, and then proceeding with a larger ſucceſſively; the firſt being pointed, the reſt being formed like ſpoons, increaſing in diameter, from one to ſix inches or more: they are fitted into the extremities of each other (as repreſented fig. 2.), and are ſold by the foot.

Pipe.

Plate CCCXCIII.

Wooden pipes are bored as follows. The machine repreſented fig. 1. is put in motion by the wheel A, which is moved by a current of water; upon the axle of this wheel is a cog-wheel B, which cauſes the lanterns C, D, to turn horizontally, whoſe common axis is conſequently in a perpendicular direction. The lantern D turns at the ſame time two cog-wheels, E and F: the firſt, E, which is vertical, turns the augre which bores the wood; and the ſecond, F, which is horizontal, cauſes the carriage bearing the piece to advance by means of the arms H, I, which takes hold of the notches in the wheel K. The firſt, H, by means of the notches, draws the wheel towards F; and the other, I, puſhes the under-poſt of the wheel in an oppoſite direction; both which motions tend to draw the carriage towards F, and conſequently cauſe the augre to pierce the wood. The augre being from 9 to 12 feet in length, and of a proportionable bigneſs, it will be neceſſary to have two pieces, as L, L, to ſupport its weight, and cauſe it to enter the piece to be bored with the ſame uniformity.

For the conſtruction of leaden pipes, ſee the article Plumbery.

Air-Pipes. See *Air-Pipes.*

Pipes of an Organ. See Organ.

Bag-Pipe. See *Bag-Pipe.*

Horn-Pipe. See Hornpipe.

Tobacco-Pipe, a machine uſed in the ſmoking of tobacco, conſiſting of a long tube, made of earth or clay, having at one end a little caſe, or furnace, called the *bowl*, for the reception of the tobacco, the fumes whereof are drawn by the mouth through the other end. Tobacco pipes are made of various faſhions; long, ſhort, plain, worked, white, varniſhed, unvarniſhed, and of various colours, &c. The Turks uſe pipes three or four feet long, made of ruſhes, or of wood bored, at the end whereof they fix a kind of a pot of baked earth, which ſerves as a bowl, and which they take off after ſmoking.

Pipe, alſo denotes a veſſel or meaſure for wine, and things meaſured by wine-meaſure. See Barrel and Measure.

Pipe, in mining, is where the ore runs forwards endwiſe in a hole, and doth not ſink downwards or in a vein.

Pipe, *Pipa*, in law, is a roll in the exchequer, called alſo the *great roll*. See the next article.

Pipe-Office, is an office wherein a perſon called the *clerk of the pipe*, makes out leaſes of crown-lands, by warrant from the lord-treaſurer, or commiſſioners of the treaſury, or chancellor of the exchequer. The clerk of the pipe makes out alſo all accounts of ſheriffs, &c. and gives the accountants their *quietus eſt*. To this office are brought all accounts which paſs the remembrancer's office, and remain there, that if any ſtated debt be due from any perſon, the ſame may be drawn down into the great roll of the pipe: upon which the comptroller iſſues out a writ, called the *ſummons of the pipe*, for recovery thereof; and if there be no goods or chattels, the clerk then draws down the debts to the lord treaſurer's remembrancer, to write eſtreats againſt their lands. All tallies which vouch the

Pipe, Piper.

the payment of any ſum contained in ſuch accounts are examined and allowed by the chief ſecondary of the pipe. Beſides the chief clerk in this office, there are eight attorneys or ſworn clerks, and a comptroller.

Pipe Fiſh, in ichthyology. See SYNGNATHUS.

Sea-Pipes, in zoology, are univalve ſhells, of an oblong figure, terminating in a point, ſometimes a little bending, and ſometimes ſtraight. Sea ears, figures of which we have given along with the ſea-pipes, are alſo univalve flat ſhells, reſembling in ſhape the ear of a man. In ſea ears it is not uncommon to find ſmall pearls, the ſeeds of which are often found in the middle of their cavities, which are of the fineſt naker or mother-of-pearl colour. There are ridges on both ſides; thoſe without form a kind of volute or ſpire, terminating in an eye. In theſe ſhells there is a row of round holes, ſix of which generally go quite through.

There is a ſhell of this kind, which is longer in proportion to its width, and much leſs common, for it is never found in our ſeas. There is yet another, very fine and thin, of a dirty grey colour, neither nakered nor perforated as the others are; the inner rim is ſpiral, and at ſome diſtance from the outer.

The ſea-pipes are diſtinguiſhed from ſea-worms by having their pipes ſingle; whereas the others form an aſſemblage of pipes joined together. The ſea worms, from the number and junction of their parts, are multivalves. The ſhells of pipes called *dentales* and *antales* are diſtinguiſhed from each other only by their ſize, the antales being much the leaſt. The *ſea pencil*, or *watering ſpout*, is the moſt remarkable ſhell of this tribe, and muſt be conſidered as having a ſpecific character either by its form, which is ſtraight, or the ſingularity of its ſuperior extremity, which is perforated like the ſpout of a watering pot.

In Plate CCCXCII. the ſhell, fig. 1. pierced with many holes, is found with its natural covering in our ſeas. It is finely nakered within, and in the middle of its hollow or cavity contains many ſmall pearls. Fig. 2. is placed on its upper ſide to ſhow its ſpots, which are red upon a ground of the pureſt white; the ridges are prominent; the rim and the eye are irregular and notched. Fig. 4. the ſingularity of this ſhell conſiſts in its being neither nakered nor perforated, and in turning very much up near the eye of its ſpire or contour. Fig. 5. is a pencil or watering ſpout; at the head is a kind of ruff, and within it is formed like the end of a watering ſpout, perforated with many holes, which, when the fiſh is alive, are filled with very fine threads, like the hairs of a painter's pencil. Fig. 6. are called dentals from their reſemblance of elephants teeth; the point or apex is white, and the other extremity green. They are both ribbed and nakered, and are diſtinguiſhed from each other only by ſome excreſcences which appear on the uppermoſt. Fig. 7. are two ſmall ſhells of the dental figure, called for diſtinction antales. They are perfectly ſmooth; one is white, and the other reddiſh.

PIPER, in ichthyology. See TRIGLA.

Piper.

PIPER, *Pepper*; a genus of the trigynia order, belonging to the diandria claſs of plants. There are 20 ſpecies, of which the moſt remarkable is the ſiriboa, with oval, heart-ſhaped, nerved leaves, and reflexed ſpikes. This is the plant which produces the pepper ſo much uſed in food. It is a ſhrub whoſe root is ſmall, fibrous, and flexible; it riſes into a ſtem, which requires a tree or a prop to ſupport it. Its wood has the ſame ſort of knots as the vine; and when it is dry, it exactly reſembles the vine-branch. The leaves, which have a ſtrong ſmell and a pungent taſte, are of an oval ſhape; but they diminiſh towards the extremity, and terminate in a point. From the flower-buds, which are white, and are ſometimes placed in the middle and ſometimes at the extremity of the branches, are produced ſmall berries reſembling thoſe of the currant-tree. Each of theſe contains between 20 and 30 corns of pepper; they are commonly gathered in October, and expoſed to the ſun ſeven or eight days. The fruit, which was green at firſt, and afterwards red, when ſtripped of its covering aſſumes the appearance it has when we ſee it. The largeſt, heavieſt, and leaſt ſhrivelled, is the beſt.

The pepper plant flouriſhes in the iſlands of Java, Sumatra (A), and Ceylon, and more particularly on the Malabar coaſt. It is not ſown, but planted; and great nicety is required in the choice of the ſhoots. It produces no fruit till the end of three years; but bears ſo plentifully the three ſucceeding years, that ſome plants yield between ſix and ſeven pounds of pepper. The bark then begins to ſhrink; and the ſhrub declines ſo faſt, that in 12 years time it ceaſes bearing.

The culture of pepper is not difficult: it is ſufficient to plant it in a rich ſoil, and carefully to pull up the weeds that grow in great abundance round its roots, eſpecially the three firſt years. As the ſun is highly neceſſary to the growth of the pepper-plant, when it is ready to bear, the trees that ſupport it muſt be lopped to prevent their ſhade from injuring the fruit. When the ſeaſon is over, it is proper to crop the head of the plant. Without this precaution, there would be too much wood, and little fruit.

The pepper exported from Malabar, which was formerly entirely in the hands of the Portugueſe, and is at preſent divided between the Dutch, Britiſh, and French, amounts to about 10,000,000 weight. Betel, or betle, is a ſpecies of this genus. See BETEL. It is a creeping and climbing plant like the ivy; and its leaves a good deal reſemble thoſe of the citron, though they are longer and narrower at the extremity. It grows in all parts of India, but thrives beſt in moiſt places. The natives cultivate it as we do the vine, placing props for it to run and climb upon; and it is a common practice to plant it againſt the tree which bears the areca-nut.

At all times of the day, and even in the night, the Indians chew the leaves of the betel, the bitterneſs of which is corrected by the areca that is wrapped up in them. There is conſtantly mixed with it the chinam, a kind of burnt lime made of ſhells. The rich frequently

(A) See a copious account of the mode of cultivating pepper in Sumatra, in Mr Marſden's *Hiſtory of Sumatra*, or in the *New Annual Regiſter* for 1783, p. 147.

Piper, Pipra.

fy add perfumes, either to gratify their vanity or their lenfuality.

It would be thought a breach of politeneſs among the Indians to take leave for any long time, without preſenting each other with a purſe of betel. It is a pledge of friendſhip that relieves the pain of abſence. No one dares to ſpeak to a ſuperior unleſs his mouth is perfumed with betel; it would even be rude to neglect this precaution with an equal. The women of gallantry are the moſt laviſh in the uſe of betel, as being a powerful incentive to love. Betel is taken after meals; it is chewed during a viſit; it is offered when you meet, and when you ſeparate; in ſhort, nothing is to be done without betel. If it is prejudicial to the teeth, it aſſiſts and ſtrengthens the ſtomach. At leaſt, it is a general faſhion that prevails throughout India.

London Medical Journal, vol. viii part iii. p. 270, &c

The *piper amalago*, or black pepper, and the *piper inequale*, or long pepper of Jamaica, with ſome other ſpecies, are indigenous, and known by the names of *joint wood*, or *peppery elders*. The firſt bears a ſmall ſpike, on which are attached a number of ſmall ſeeds of the ſize of muſtard. The whole of the plant has the exact taſte of the Eaſt India black pepper. The long pepper buſh grows taller than the amalago. The leaves are broad, ſmooth, and ſhining. The fruit is ſimilar to the long pepper of the ſhops, but ſmaller. The common people in Jamaica ſeaſon their meſſes with the black pepper. To preſerve both, the fruit may be ſlightly ſcalded when green, then dried, and wrapped in paper. Perhaps hereafter they may be deemed worthy of attention.

PIPRA, in ornithology; a genus of birds of the order of *paſſeres*. Latham gives it the name of *manakin*, and ſo does Buffon, who informs us that it was beſtowed upon them by the Dutch ſettlers in Surinam. Latham deſcribes 25 different ſpecies, and five varieties. The general character of the genus is, that the bill is ſhort, ſtrong, hard, and ſlightly incurvated, and the noſtrils are naked. The middle toe is connected to the outer as far as the third joint: this character, however, is not altogether univerſal, ſome of the ſpecies differing in this particular. The tail is ſhort. This genus has a conſiderable reſemblance to the genus *parus*, or titmouſe. They are ſuppoſed to inhabit South America only; but this is not true, for Mr Latham aſſures us that he has ſeen many of thoſe ſpecies which he has deſcribed which came from other parts, but which nevertheleſs certainly belong to this genus.—Buffon differs widely in his arrangement from Mr Latham, and only enumerates ſix diſtinct ſpecies. Without particularizing thoſe differences, however, we ſhall give from Buffon the following elegant account of the genus in general: "The natural habits common to them all were not known, and the obſervations which have been made are ſtill inſufficient to admit an exact detail. We ſhall only relate the remarks communicated to us by Sonini of Manoncour, who ſaw many of theſe birds in their native climates. They inhabit the immenſe foreſts in the warm parts of America, and never emerge from their receſſes to viſit the cleared grounds or the vicinity of the plantations. They fly with conſiderable ſwiftneſs, but always at a ſmall height, and to ſhort diſtances; they never perch on the ſummits of trees, but on the middle branches; they feed upon ſmall wild fruits, and alſo eat inſects. They generally occur in ſmall bodies of eight or ten of the ſame ſpecies, and ſometimes intermingled with other flocks of the ſame genus, or even of a different genus, ſuch as the Cayenne warblers, &c. It is commonly in the morning that they are found thus aſſembled, and then ſeem to be joyous, and warble their delicate little notes. The freſhneſs of the air ſeems to inſpire the ſong, for they are ſilent during the burning heat of the day, and diſperſe and retire to the ſhade of the thickeſt parts of the foreſt. This habit is obſerved, indeed, in many kinds of birds, and even in thoſe of the woods of France, where they collect to ſing in the morning and evening; but the manakins never aſſemble in the evening, and continue together only from ſun-riſe to nine or ten o'clock in the forenoon, and remain ſeparate during the reſt of the day and the ſucceeding night. In general they prefer a cool humid ſituation, though they never frequent marſhes or the margins of lakes." Pipra.

1. The *pipra rupicola*, or creſted manakin, is about the ſize of a ſmall pigeon, being about 10 or 12 inches long. The bill is about an inch and a quarter long, and of a yellowiſh colour. The head is furniſhed with a double round creſt; the general colour of the plumage is orange, inclining to ſaffron; the wing coverts are looſe and fringed; the quills are partly white and partly brown; the tail feathers are in number 12; the baſe half of the ten middle ones is of an orange colour, from thence to the ends they are brown; the outer feathers are brown, and the baſe half of the inner web is orange; all of them are ſimilarly fringed; the upper tail coverts are very long, looſely webbed, and ſquare at the ends; the legs and claws are yellow. The female is altogether brown, except the under wing coverts, which are of a ruſous orange; the creſt is neither ſo complete nor rounded as that of the male. Both males and females are at firſt grey, or of a very pale yellow, inclining to brown. The male does not acquire the orange colour till the ſecond year, neither does the female the full brown.

"This beautiful ſpecies (ſays Latham), inhabits various parts of Surinam, Cayenne, and Guiana, in rocky ſituations; but is nowhere ſo frequent as in the mountain Luca, near the river Oyapoc, and in the mountain Couronaye, near the river Aprouack, where they build in the cavernous hollows, and the darkeſt receſſes. They lay two round white eggs, the ſize of thoſe of a pigeon, and make the neſt of a few dry bits of ſticks. They are in general very ſhy, but have been frequently tamed, inſomuch as to run at large among the poultry. It is ſaid that the female, after ſhe has laid eggs for ſome years, and ceaſes ſo to do more, becomes at the enſuing moult of the ſame colour as the male, and may be miſtaken for him; in this imitating the females of various kinds of poultry, ſuch as the peacock, pheaſant, &c. (See Pavo, &c.) A moſt complete pair is in the Leverian Muſeum." Our author deſcribes a variety of this ſpecies, which he calls the *Peruvian manakin*. It is longer than the preceding, eſpecially in the tail, and the upper coverts of it are not truncated at the ends; the wing coverts are not fringed, as in the rock manakin, and the creſt is not ſo well defined as in that bird; the general colour of the plumage inclines much to red; the ſecond

Pipra, Piquet.

cond coverts and rump are of an aſh colour; the wings and tail are black; the bill and legs are as in the laſt deſcribed. It is an inhabitant of Peru, from whence its name.

2. The next and laſt ſpecies which we ſhall deſcribe (for it would be impoſſible to enumerate them all), Mr Latham calls the *tuneful manakin*. Its length is four inches; the bill is duſky, the forehead yellow, and the crown and nape blue; the chin, ſides of the head below the eyes, and the throat, are black; the upper part of the back, the wings, and the tail, are duſky black; the tail is very ſhort; the lower part of the back and rump, the breaſt, belly, vent, and thighs, are orange coloured; the legs are duſky. It is a native of St Domingo, where it has gained the name of *organiſte* from its note, forming the complete octave in the moſt agreeable manner, one note ſucceſſively after another. It is ſaid not to be uncommon, but not eaſy to be ſhot, as, like the creeper, it perpetually ſhifts to the oppoſite part of the branch from the ſpectator's eye, ſo as to elude his vigilance. It is moſt likely the very bird mentioned by Du Pratz, above quoted, whoſe notes, he ſays, are ſo varied and ſweet, and which warbles ſo tenderly, that thoſe who have heard it value much leſs the ſong of the nightingale. It is ſaid to ſing for near two hours without ſcarce taking breath, and after a reſpite of about the ſame time begins again. Du Pratz, who himſelf has heard it, ſays that it ſung perched on an oak, near the houſe he was then in.

PIQUET, or PICKET, a celebrated game at cards, much in uſe throughout the polite world.

It is played between two perſons, with only 32 cards; all the duces, threes, fours, fives, and ſixes, being ſet aſide.

In reckoning at this game, every card goes for the number it bears, as a ten for ten; only all court cards go for ten, and the ace for eleven: and the uſual game is one hundred up. In playing, the ace wins the king, the king the queen, and ſo down.

Twelve cards are dealt round, uſually by two and two; which done, the remainder are laid in the middle: if one of the gameſters finds he has not a court-card in his hand, he is to declare he has *carte-blanche*, and tell how many cards he will lay out, and deſire the other to diſcard, that he may ſhow his game, and ſatisfy his antagoniſt that the carte-blanche is real; for which he reckons ten.

Each perſon diſcards, *i. e.* lays aſide a certain number of his cards, and takes in a like number from the ſtock. The firſt of the eight cards may take three, four, or five; the dealer all the remainder, if he pleaſes.

After diſcarding, the eldeſt hand examines what ſuit he has moſt cards of; and reckoning how many points he has in that ſuit, if the other have not ſo many in that or any other ſuit, he tells one for every ten of that ſuit. He who thus reckons moſt is ſaid to win the point.

The point being over, each examines what *ſequences* he has of the ſame ſuit, viz. how many tierces, or ſequences of three, quartes or fours, quintes or fives, ſixiemes, or ſix's, &c. For a tierce they reckon three points, for a quarte four, for a quinte 15, for a ſixieme 16, &c. And the ſeveral ſequences are diſtinguiſhed in dignity by the cards they begin from: thus ace king, and queen, are called *tierce major*; king, queen, and knave, *tierce to a king*; knave, ten, and nine, *tierce to a knave*, &c. and the beſt tierce, quarte, or quinte, *i. e.* that which takes its deſcent from the beſt card, prevails, ſo as to make all the others in that hand good, and deſtroy all thoſe in the other hand. In like manner, a quarte in one hand ſets aſide a tierce in the other. Piquet.

The ſequences over, they proceed to examine how many aces, kings, queens, knaves, and tens, each holds; reckoning for every three of any ſort, three: but here too, as in ſequences, he that with the ſame number of threes has one that is higher than any the other has, *e. gr.* three aces, has all his others made good hereby, and his adverſary's all ſet aſide. But four of any ſort, which is called a *quatorze*, always ſets aſide three.

All the game in hand being thus reckoned, the eldeſt proceeds to play, reckoning one for every card he plays above a nine, and the other follows him in the ſuit; and the higheſt card of the ſuit wins the trick. Note, unleſs a trick be won with a card above a nine (except the laſt trick), nothing is reckoned for it; though the trick ſerves afterwards towards winning the cards; and that he who plays laſt does not reckon for his cards unleſs he wins the trick.

The cards being played out, he that has moſt tricks reckons ten for winning the cards. If they have tricks alike, neither reckons any thing. The deal being finiſhed, and each having marked up his game, they proceed to deal again as before, cutting afreſh each time for the deal.

If both parties be within a few points of being up, the carte blanche is the firſt thing that reckons, then the point, then the ſequences, then the quatorzes or threes, then the tenth cards.

He that can reckon 30 in hand by carte-blanche, points, quintes, &c. without playing, ere the other has reckoned any thing, reckons 90 for them; and this is called a *repique*. If he reckons above 30, he reckons ſo many above 90. If he can make up 30, part in hand and part play, ere the other has told any thing, he reckons for them 60. And this is called a *pique*. Whence the name of the game. He that wins all the tricks, inſtead of ten, which is his right for winning the cards, reckons 40. And this is called a *capot*.

Mr de Moivre, who has made this game the object of mathematical inveſtigations, has propoſed and ſolved the following problems: 1. To find at piquet the probability which the dealer has for taking one ace or more in three cards, he having none in his hand. He concludes from his computation, that it is 27 to 28 that the dealer takes one ace or more. 2. To find at piquet the probability which the eldeſt has of taking an ace or more in five cards, he having no ace in his hand. Anſwer; 232 to 91, or 5 to 2, nearly. 3. To find at piquet the probability which the eldeſt hand has of taking an ace and a king in five cards, he having none in his hand. Anſwer; the odds againſt the eldeſt hand taking an ace and a king are 331 to 315, or 21 to 20 nearly. 4. To find at piquet the probability of having 12 cards dealt to, without king, queen, or knave, which caſe is commonly called *cartes-blanches*. Anſwer; the odds againſt cartes blanches are 1791 to 1 nearly.

Pira. nearly. 5. To find how many different ſets, eſſentially different from one another, one may have at piquet before taking in. Anſwer; 28,967,278. This number falls ſhort of the ſum of all the diſtinct combinations, whereby 12 cards may be taken out of 32, this number being 225,792,840; but it muſt be conſidered that in that number ſeveral ſets of the ſame import, but differing in ſuit, might be taken, which would not introduce an eſſential difference among the ſets. The ſame author gives alſo ſome obſervations on this game, which he had from an experienced player. See *Doctrine of Chances*, p. 179, &c. M. de Monmort has treated of piquet in his *Analyſe des Jeux de Hazard*, p. 162.

PIRA, is a name by which a variety of foreign fiſhes are diſtinguiſhed. The *pira-aca* is a little horned fiſh of the Weſt Indies, called by Cluſius and others the *monoceros* or *unicorn-fiſh*. The *pira acangata* is the name of a Braſilian fiſh, which reſembles the perch both in ſize and ſhape. It ſeldom exceeds four or five inches in length; its mouth is ſmall; its tail forked. On the back it has only one long fin, which is ſupported by rigid and prickly ſpines. This fin it can depreſs at pleaſure, and ſink within a cavity made for it in the back. Its ſcales are of a ſilvery white colour; it is wholeſome and well taſted. *Pira-bebe* is the name of the milvus, or kite-fiſh. *Pira-coaba* is an American fiſh of the truttaceous kind, of a very delicate flavour. It grows to the length of 12 inches; its noſe is pointed, and its mouth large, but without teeth; the upper jaw is longer than the under one, and hangs over like a cartilaginous prominence; its eyes are very large, and its tail is forked; under each of the gill fins there is a beard made of ſix white filaments, and covered with ſilvery ſcales. *Pira jurumenbeca* is a Braſilian fiſh, otherwiſe called *bocca molle*. It lives in the muddy bottom of the American ſeas, and is a long bodied not flatted fiſh. It grows to a great ſize, being found nine, and ſometimes even ten or eleven, feet long, and two feet and a half thick. It has one long fin on the back, the anterior part of which is thin and pellucid. There is alſo a cavity on the back, as in the pira acangata, into which the fin can be depreſſed at pleaſure; the tail is not forked, and the ſcales are all of a ſilvery colour and brightneſs. The fiſh is very well taſted; the *pira pixanga* is another Braſilian fiſh of the turdus or wraſſe kind, and called by ſome the *gatviſh*. It is generally about four or five inches long; its mouth is pretty large, and furniſhed with very ſmall and very ſharp teeth; its head is ſmall, but its eyes are large and prominent, the pupil being of a fine turquoiſe colour, and the iris yellow and red in a variety of ſhades. The coverings of the gills end in a triangular figure, and are terminated by a ſhort ſpine or prickle; its ſcales are very ſmall, and ſo evenly arranged, and cloſely laid on the fleſh, that it is very ſmooth to the touch; its tail is rounded at the end; its whole body, head, tail, and fins, are of a pale yellow colour, variegated all over with very beautiful blood-coloured ſpots; theſe are round, and of the bigneſs of hemp-ſeed on the back and ſides, and ſomething larger on the belly; the fins are all ſpotted in the ſame manner, and are all marked with an edge of red It is caught among the rocks, and about the ſhores, and is a very well taſted fiſh. *Piranba* is an American fiſh, more generally known by the name *piraya*. *Piraquiba*, or *Ipiraquiba*, is the name of a fiſh originally Braſilian, which ſome writers apply to the *remora* or *ſucking fiſh*. Piræus

PIRÆUS PORTUS, (anc. geog.), a celebrated port to the weſt of Athens, conſiſting, naturally of three harbours or baſons, (Thucydides); which lay neglected, till Themiſtocles put the Athenians on making it a commodious port, (Nepos); the Phalerus, a ſmall port, and not far from the city, being what they uſed before that time, (Pauſanias, Nepos). Piræeus was originally a village of Attica, (Pauſanias); an iſland, (Strabo); and though diſtant 40 ſtadia from Athens, was joined to it by two long walls, (Thucydides), and itſelf locked or walled round, (Nepos): A very commodious and ſafe harbour. The whole of its compaſs was 60 ſtadia, including the Munichia. Not far from the Piræus ſtood the ſepulchre of Themiſtocles; whither his friends conveyed his bones from Magneſia, into the Hither Aſia, (Cicero, Plutarch, Pauſanias). The entrance of the Piræus is narrow, and formed by two rocky points, one belonging to the promontory of Eetion, the other to that of Alcimus. Within were three ſtations for ſhipping; Kantharus, ſo named from a hero; Aphrodiſium, from a temple of Venus; and Zea, the reſort of veſſels laden with grain. By it was a demos or borough town of the ſame name before the time of Themiſtocles, who recommended the exchanging its triple harbour for the ſingle one of Phalerum, both as more capacious and as better ſituated for navigators. The wall was begun by him when archon, in the ſecond year of the 75th Olympiad, 477 years before Chriſt; and afterwards he urged the Athenians to complete it as the importance of the place deſerved. This whole fortification was of hewn ſtone, without cement or other material, except lead and iron, which were uſed to hold together the exterior ranges or facings. It was ſo wide that the loaded carts could paſs on it in different directions, and it was 40 cubits high, which was about half what he had deſigned. Chandler's Travels in Greece, p. 19. &c.

The Piræus, as Athens flouriſhed, became the common emporium of all Greece. Hippodamus an architect, celebrated, beſides other monuments of his genius, as the inventor of many improvements in houſe building, was employed to lay out the ground. Five porticoes, which uniting formed the *Long Portico*, were erected by the ports. Here was an *agora* or market-place, and, farther from the ſea, another called *Hippodamia*. By the veſſels were dwellings for the mariners. A theatre was opened, temples were raiſed, and the Piræus, which ſurpaſſed the city in utility, began to equal it in dignity. The cavities and windings of Munychia, natural and artificial, were filled with houſes; and the whole ſettlement, comprehending Phalerum and the ports of the Piræus, with the arſenals, the ſtorehouſes, the famous armoury of which Philo was the architect, and the ſheds for 300, and afterwards 400, triremes, reſembled the city of Rhodes, which had been planned by the ſame Hippodamus. The ports, on the commencement of the Peloponneſian war, were ſecured with chains. Centinels were ſtationed, and the Piræus was carefully guarded.

The Piræus was reduced with great difficulty by Sylla, who demoliſhed the walls, and ſet fire to the armoury and arſenals. In the civil war it was in a defenceleſs condition. Calenus, lieutenant to Cæſar,

Piræus, Piracy.

ſeized it, inveſted Athens, and ravaged the territory. Strabo, who lived under the emperors Auguſtus and Tiberius, obſerves, that the many wars had deſtroyed the long walls, with the fortreſs of Munychia, and had contracted the Piræus into a ſmall ſettlement by the ports and the temple of Jupiter Saviour. This fabric was then adorned with wonderful pictures, the works of illuſtrious artiſts, and on the outſide with ſtatues. In the ſecond century, beſides houſes for triremes, the temple of Jupiter and Minerva remained, with their images in braſs, and a temple of Venus, a portico, and the tomb of Themiſtocles.

The port of the Piræus has been named *Porto Lione*, from the marble lion ſeen in the chart, and alſo *Porto Draco*. The lion has been deſcribed as a piece of admirable ſculpture, 20 feet high, and as repoſing on its hinder parts. It was pierced, and, as ſome have conjectured, had belonged to a fountain. Near Athens, in the way to Eleuſis, was another, the poſture couchant; probably its companion. Both theſe were removed to Venice by the famous general Moroſini, and are to be ſeen there before the arſenal. At the mouth of the port are two ruined piers. A few veſſels, moſtly ſmall craft, frequent it. Some low land at the head ſeems an incroachment on the water. The buildings are a mean cuſtomhouſe, with a few ſheds; and by the ſhore on the eaſt ſide, a warehouſe belonging to the French; and a Greek monaſtery dedicated to St Spiridion. On the oppoſite ſide is a rocky ridge, on which are remnants of the ancient wall, and of a gateway towards Athens. By the water-edge are veſtiges of building; and going from the cuſtomhouſe to the city on the right hand, traces of a ſmall theatre in the ſide of the hill of Munychia.

PIRACY, the crime of robbery and depredation upon the high ſeas.

By the ancient common law, piracy, if committed by a ſubject, was held to be a ſpecies of treaſon, being contrary to his natural allegiance; and by an alien, to be felony only: but now, ſince the ſtatute of treaſons, 25 Edw. III. c. 2. it is held to be only felony in a ſubject. Formerly it was only cognizable by the admiralty courts, which proceed by the rules of the civil law. But, it being inconſiſtent with the liberties of the nation, that any man's life ſhould be taken away, unleſs by the judgment of his peers, or the common law of the land, the ſtatute 28 Hen. VIII. c. 15. eſtabliſhed a new juriſdiction for this purpoſe; which proceeds according to the courſe of the common law.

The offence of piracy, by common law, conſiſts in committing thoſe acts of robbery and depredation upon the high ſeas, which, if committed upon land, would have amounted to felony there. But, by ſtatute, ſome other offences are made piracy alſo: as, by ſtatute 11 and 12 W. III. c. 7. if any natural-born ſubject commits any act of hoſtility upon the high ſeas, againſt others of his majeſty's ſubjects, under colour of a commiſſion from any foreign power; this, though it would only be an act of war in an alien, ſhall be conſtrued piracy in a ſubject. And farther, any commander, or other ſeafaring perſon, betraying his truſt, and running away with any ſhip, boat, ordnance, ammunition, or goods; or yielding them up voluntarily to a pirate; or conſpiring to do theſe acts; or any perſon aſſaulting the commander of a veſſel, to hinder him from fighting in defence of his ſhip; or confining him, or cauſing or endeavouring to cauſe a revolt on board; ſhall, for each of theſe offences, be adjudged a pirate, felon, and robber, and ſhall ſuffer death, whether he be principal, or merely acceſſory by ſetting forth ſuch pirates, or abetting them before the fact, or receiving or concealing them or their goods after it. And the ſtatute 4 Geo. I. c. 11. expreſsly excludes the principals from the benefit of clergy. By the ſtatute 8 Geo. I. c. 24. the trading with known pirates, or furniſhing them with ammunition, or fitting out any veſſel for that purpoſe, or in anywiſe conſulting, combining, confederating, or correſponding with them; or the forcibly boarding any merchant veſſel, though without ſeizing or carrying her off, and deſtroying or throwing any of the goods overboard; ſhall be deemed piracy: and ſuch acceſſories to piracy as are deſcribed by the ſtatute of king William are declared to be principal pirates; and all pirates convicted by virtue of this act are made felons without benefit of clergy. By the ſame ſtatutes alſo, (to encourage the defence of merchant-veſſels againſt pirates), the commanders or ſeamen wounded, and the widows of ſuch ſeamen as are ſlain, in any piratical engagement, ſhall be entitled to a bounty to be divided among them, not exceeding one fiftieth part of the value of the cargo on board: and ſuch wounded ſeamen ſhall be intitled to the penſion of Greenwich hoſpital; which no other ſeamen are, except only ſuch as have ſerved in a ſhip of war. And if the commander ſhall behave cowardly, by not defending the ſhip, if ſhe carries guns or arms; or ſhall diſcharge the mariners from fighting, ſo that the ſhip falls into the hands of pirates; ſuch commander ſhall forfeit all his wages, and ſuffer ſix months impriſonment. Laſtly, by ſtatute 18 Geo. II. c. 30. any natural born ſubject or denizen, who in time of war ſhall commit hoſtilities at ſea againſt any of his fellow-ſubjects, or ſhall aſſiſt an enemy on that element, is liable to be tried and convicted as a pirate.

Piracy, Pirate.

PIRATE, (πειρατης, Gr.); a ſea-robber, or an armed ſhip that roams the ſeas without any legal commiſſion, and ſeizes or plunders every veſſel ſhe meets indiſcriminately, whether friends or enemies.

The colours uſually diſplayed by pirates are ſaid to be a black field, with a death's head, a battle-axe, and hour-glaſs. The laſt inſtrument is generally ſuppoſed to determine the time allowed to the priſoners, whom they take, to conſider whether they will join the pirates in their felonious combination, or be put to death, which is often perpetrated in the moſt cruel manner.

Amongſt the moſt celebrated pirates of the north is recorded Alvilda, daughter of a king of the Goths named *Sypardus*. She embraced this occupation to deliver herſelf from the violence impoſed on her inclination, by a marriage with Alf, ſon of Sigarus king of Denmark. She dreſſed herſelf as a man; and compoſed her band of rowers, and the reſt of her crew, of a number of young women attired in the ſame manner. Amongſt the firſt of her cruizes, ſhe touched at a place where a company of pirates bewailed the

Pirene ‖ Piron.

death of their captain. The ſtrangers were captivated with the agreeable manners of Alvilda, and choſe her for their chief. By this reinforcement ſhe became ſo formidable upon the ſea, that prince Alf came to engage her. She ſuſtained his attacks for a conſiderable time: but, in a vigorous action, Alf boarded her veſſel, and having killed the greateſt part of her crew, ſeized the captain, namely herſelf; whom nevertheleſs he knew not, becauſe the princeſs had a caſque which covered her viſage. Being maſter of her perſon, he removed the caſque; and in ſpite of her diſguiſe, inſtantly recognized her, and offered her his hand in wedlock.

PIRENE, (Pliny); a fountain ſacred to the muſes, ſpringing below the top of the Acrocorinthus, a high and ſteep mountain which hangs over Corinth. Its waters were agreeable to drink, (Pauſanias); extremely clear, (Strabo); very light, (Athenæus); and pale, (Perſius): having relation either to the grief of Pirene, mother of Cenchreas, from whoſe tears this fountain aroſe, (Pauſanias); or to the paleneſs brought on by the too eager purſuits of the muſes.

PIROMALLI (Paul), a dominican of Calabria, was ſent a miſſionary into the eaſt. He remained a long time in Armenia, where he had the happineſs to bring back to the church many ſchiſmatics and Eutycheans, and the patriarch himſelf, who had before thrown every obſtacle in his way. He afterwards paſſed into Georgia and Perſia, then into Poland, in quality of Pope Urban VIII.'s nuncio, in order to appeaſe the diſturbances which had been occaſioned there by the diſputes of the Armenians, who were very numerous in that country. Piromalli reunited them in the profeſſion of the ſame faith, and obſervance of the ſame ceremonies. In his return to Italy, he was taken by ſome Corſairs who carried him priſoner to Tunis. As ſoon as he was ranſomed, he went to Rome, and gave an account of his miſſion to the pope, who conferred upon him ſome ſignal marks of his eſteem. His holineſs entruſted him with the reviſal of an Armenian Bible, and ſent him again into the eaſt, where he was promoted, in 1655, to the biſhopric of Naſſivan. After having governed that church for nine years, he returned to Italy, and took the charge of the church of Baſignano, where he died three years after in 1667. His charity, his zeal, and other virtues did honour to the Epiſcopal office. There are extant of his writings, 1. Some works of Controverſy and Theology. 2. Two Dictionaries; the one a Latin-Perſian, and the other an Armenian-Latin. 3. An Armenian Grammar. 4. A Directory, which is of great uſe in correcting Armenian books. All theſe works equally diſtinguiſh him for virtue and for learning.

PIRON (Alexis), whoſe father was an apothecary, was born at Dijon the 9th of July 1689, where he paſſed more than 30 years in the idle and deſtructive diſſipation too common to young men. He was at length obliged to quit the place of his nativity, in order to avoid the reproaches of his fellow citizens, on account of an ode which he had written, and which gave great offence. His relations not being able to give him much aſſiſtance, he ſupported himſelf at Paris by means of his pen, the ſtrokes of which were as beautiful and fair as thoſe of an engraver. He lived in the houſe of M. de Belliſle as his ſecretary, and afterwards with a financier, who did not know that he had a man of genius under his roof. His reputation as a writer commenced with ſome pieces which he publiſhed for the entertainment of the populace, and which ſhowed ſtrong marks of original invention; but what fully eſtabliſhed his character in this way was his comedy intitled *Metromany*, which was the beſt that had appeared in France ſince Regnard's Gameſter. This performance, in five acts, well conducted, replete with genius, wit, and humour, was acted with the greateſt ſucceſs upon the French ſtage in 1738. The author met with every attention in the capital which was due to a man of real genius, and whoſe flaſhes of wit were inexhauſtible. We ſhall inſert a few anecdotes of him, which will ſerve to ſhow his character and turn of mind. In Burgundy the inhabitants of Beaune are called the *Aſſes of Beaune*. Piron often indulged his ſatirical diſpoſition at their expence. One day as he was taking a walk in the neighbourhood of that city, he diverted himſelf with cutting down all the thiſtles which he met with. When a friend aſked him his reaſon for doing ſo, he replied, *J'ai à me plaindre des Beaunois; je leur coupe les vivres*, i. e. "I am ſorry indeed for the Beaunians; for I am cutting down their food." Being told again that theſe people would certainly be revenged of him,

Allez, (ſays he) *Allez: je ne crains point leur impuiſſant courroux;*
Et, quand je ſerois ſeul, je les batterois tous.

"Get you gone, get you gone: I fear not their feeble revenge; for tho' alone, I ſhould beat them all." Going into a theatre one time where a play was acting, he aſked what it was? The Cheats of Scapin, gravely replied a young Beaunian. "Ah! Sir, (ſays Piron, after thanking him), I took it to be the Cheats of Oreſtes." In the time of the play, ſome body addreſſes the company with "Silence there, gentlemen, we don't hear." "It is not at leaſt (cried Piron) for want of ears." A biſhop one day aſked Piron, during the diſputes about Janſeniſm, "Did you read my mandate, Mr Piron?" "No, my lord; and you——The converſation turning very warm, the biſhop reminded him of the diſtance which birth and rank had put between them. "Sir (ſays Piron), I have plainly the ſuperiority over you at this moment; for I am in the right, and you are in the wrong."—Voltaire's Semiramis did not meet with a very favourable reception the firſt time it was acted. The author finding Piron behind the ſcenes, aſked him what he thought of his performance? "I think (replied he) you would have been pleaſed that I had been the author of it." The performer of the character Ferdinand Cortez (the title of one of Piron's Tragedies) having requeſted ſome corrections to be made on the play the firſt time it was acted, Piron fired at the word *corrections*. The player, who was deputed to wait upon the author with this requeſt, cited the example of Voltaire, who corrected ſome of his pieces in order to gratify the taſte of the public. "The caſes are widely different (replied Piron); Voltaire works in chequer-work, and I caſt in braſs." If this anſwer be not very modeſt, we muſt allow that it does not want wit. He thought himſelf, if not ſuperior, at leaſt equal to Voltaire. Some perſon congratulating him on having compoſed the beſt comedy of this age, he anſwered, with more frankneſs than modeſty, "Add too, and the beſt tragedy." The following verſes are well known, in which he ſays:

Piron.

En

Piron, Pisa.

En deux mots voulez-vous diſtinguer & connoître
Le rimeur Dijonnois & le Pariſien?
Le premier ne fut rien, & ne voulut rien etre;
L'autre voulut tout etre, & ne fut preſque rien.

We ſee by theſe different traits that Piron had a ſufficient ſtock of ſelf-conceit. What helped to increaſe it, and make him fancy himſelf ſuperior to the moſt celebrated of his contemporaries, was, that his company, on account of his original humour, of which he had an uncommon ſhare, was more courted than that of Voltaire, who was otherwiſe too lively, too captious, and crabbed. But thoſe who have favoured us with an account of his many witticiſms in converſation, would have done more honour to his memory if they had paſſed over ſuch as were either indecent or inſipid. A thing often pleaſes over a glaſs of wine, which will not give the ſame ſatisfaction when it is repeated, eſpecially if, in repeating it, you want to make it appear of ſome importance. Be that as it may, Piron's miſchievous ingenuity was partly the cauſe which excluded him from the French Academy.—"I could not (ſaid he) make thirty-nine people think as I do, and I could ſtill leſs think as thirty-nine do." He called that celebrated ſociety very unjuſtly *les invalides du bel eſprit*, "the invalids of wit;" and yet he often endeavoured to be one of thoſe invalids. His death was haſtened by a fall which he got a little before. He died the 21ſt of January 1773, at the age of 83. He had prepared for himſelf the following epitaph, in the way of an epigram:

Ci gît Piron, qui ne fut rien,
Pas même académicien.

"Here lies Piron, who was nothing, not even an academician."

His wife Maria Thereſa Quenandon, who died in 1751, he deſcribes as a ſweet and moſt agreeable companion. They lived together for ſeveral years; and no huſband ever diſcharged his duty with more fidelity and attention.

A collection of his works appeared in 1776, in 7 vol. 8vo, and 9 vol. 12mo. The principal pieces are, The School of Fathers; a comedy acted in 1728 under the title of Ungrateful Sons. Calliſthenes; a tragedy, the ſubject of which is taken from Juſtin. The Myſterious Lover, a comedy. Guſtavus and Ferdinand Cortez, two tragedies; ſome ſcenes of which diſcover an original genius, but the verſification neither pleaſes the ear nor affects the heart. Metromany, a comedy. The Courſes of Tempe, an ingenious paſtoral, in which the manners both of the town and country are pleaſantly drawn. Some odes, poems, fables, and epigrams. In this laſt kind of poetry he was very ſucceſsful, and he may be placed after Marot and Rouſſeau. There was no occaſion for loading the public with 7 vols of his works; the half of that number might have ſufficed. For, excepting Metromany, Guſtavus, the Courſes of Tempe, ſome odes, about 20 epigrams, three or four fables, and ſome epiſtles, the reſt are but indifferent, and have no claim to any extraordinary merit.

PISA, a large town of Tuſcany in Italy, ſituated on the river Arno, 52 miles from Florence. It was a famous republic, till ſubdued, firſt by the duke of Milan, and then by the Florentines in the year 1406. Before it loſt its freedom, it is ſaid to have contained near 150,000 inhabitants, but now it has not above 16,000 or 17,000. It was founded, we are told by the Piſans of Peloponneſus, and afterwards became one of the 12 municipia of Tuſcany. Its neighbourhood to Leghorn, which is now the chief port in the Mediterranean, though formerly of little or no note for trade, has contributed greatly to the decay of Piſa, which, however, begins to lift up its head again, under the auſpices of the preſent grand duke, who has made it his winter reſidence. Between Piſa and Leghorn is a canal 16 Italian miles in length.—Its territory is very fruitful; abounding in corn, wine, and fruit, and fine cattle. The houſes are well built, and the ſtreets even, broad, and well paved; but in many places over-run with graſs. The univerſity is well endowed, and has able profeſſors, but is not in a very flouriſhing condition. The exchange is a ſtately ſtructure, but little frequented. The grand duke's galleys are built, and commonly ſtationed here. This city is alſo the principal reſidence of the order of St Stephen, and the ſee of an archbiſhop. The cathedral, a large Gothic pile, contains a great number of excellent paintings and other curioſities. This church is dedicated to St Mary; is very advantageouſly ſituated in the middle of a large piazza, and built out of a great heap of wrought marble, ſuch as pillars, pedeſtals, capitals, cornices, and architraves, part of the ſpoils which the Piſans took in their eaſtern expeditions, when the republic was in a flouriſhing condition. The roof is ſupported by 76 high marble pillars of different colours, and finely gilt. Both the church and the cupola are covered with lead. The choir is painted by good hands, and the floor is Moſaic work. The brazen doors are curiouſly wrought with the hiſtory of the Old and New Teſtament, by Bonanno, an ancient ſtatuary. The chapel of St Rainerius is richly adorned with gilt metals, columns of porphyry, and fine paintings. In the middle of the nave of the church you ſee two brazen tombs, raiſed upon pillars. The marble pulpit was carved by John Piſano, and the choir by Julian da Majana. Joining thereto is the altar, over which is preſerved a hollow globe or veſſel of marble, wherein they kept the ſacrament for the new baptized, according to the opinion of Father Mabillon. In the ſquare before the church, you ſee a pillar upon which is the meaſure of the ancient Roman talent. In the ſame ſquare with the dome, ſtands the baptiſtry, a round fabric ſupported by ſtately pillars, and remarkable for a very extraordinary echo.

Pisa.

On the north ſide of the cathedral is the burying-place, called *Campo Santo*, being covered with earth brought from the Holy Land. This burying place is incloſed with a broad portico, well painted, and paved with grave ſtones. Here are a great many ancient tombs, among the reſt that of Beatrix, mother of the counteſs Mathilda, with marble baſſo relievos, which the Piſans brought from Greece, where you ſee the hunt of Meleager, which aſſiſted Nicholas of Piſa in the reſtoration of ſculpture. The walls of the Campo Santo are painted by the beſt maſters of their times. Giotto has drawn ſix hiſtorical pieces of Job; and Andrea Orgagna has given a fine piece of the laſt judgment. Under the portico there is a decree of the city, ordering the inhabitants to wear mourning a year for the death of Cæſar. Near the church you ſee a ſteeple in the form of a cylinder, to which you aſcend

by

Pisa || Piscidia.

by 153 steps; it inclines 15 feet on one side, which some ascribe to art, but others to the sinking of the foundation. Its inclination is so great that a plumb-line let fall from the top touches the ground at the distance of almost 15 feet from the bottom. It was built by John of Inspruck and Bonanno of Pisa, in 1174. Near this steeple is a fine hospital, dependent on that of St Maria Nuova in Florence.

The steeple of the church of the Augustinians is also very fine, being an octagon, adorned with pillars, and built by Nicholas of Pisa. In the great market-place there is a statue of Plenty, by Pierino da Vinci. In the church of St Matthew, the painting of the ceiling by the brothers Melani, natives of this city, is an admired performance. The church of the knights of St Stephen, decorated with the trophies taken from the Saracens, is all of marble, with marble steps, and a front adorned with marble statues. In the square there is a statue of Cosmo I. upon a very fine pedestal. Contiguous to the church is the convent or palace of the knights, which is worth seeing, as also the churches Della Madonna and Della Spina; the last of which was built by a beggar, whose figure you may see on the outside of the wall. It is pretended that one of the thorns of the crown which was placed on our Saviour's head is preserved here. Belonging to the university there is a great number of colleges, the chief of which is the Sapienza, where the professors read their public lectures; next to which are the colleges Puteano, Ferdinando, Ricci, and others. Besides the public palace, and that of the grand duke, there are several others with marble fronts, the finest of which is that of Lanfranchi, which, with the rest along the banks of the Arno, makes a very fine appearance. There is here a good dock, where they build the galleys, which are conveyed by the Arno to Leghorn. They have a famous aqueduct in this town, consisting of 5000 arches, which conveys the water from the hills at five miles distance. This water is esteemed the best in Italy, and is carried in flasks to Florence and Leghorn. The neighbouring country produces great store of corn and wine, but the latter is not much esteemed. They have very good butter in this neighbourhood, which is a scarce commodity in Italy. The city for its defence has a moat, walls, a castle, fort, and citadel; the last of which is a modern work. The Arno is of a considerable breadth here, and has three bridges over it, one of them of marble: two leagues below the town it falls into the sea. The physic-garden is very spacious, contains a great number of plants, and is decorated with water-works: over the door leading into it are these words, *Hic Argus sed non Briareus esto:* i. e. Employ the eyes of Argus, but not the hands of Briareus. The air is said to be unwholesome here in summer, on account of the neighbouring morasses. Many buffaloes are bred in the neighbouring country, and their flesh is commonly eaten. Between Pisa and Lucca are hot baths. E. Long. 10. 17. N. Lat. 43. 43.

PISCARY, in our ancient statutes, the liberty of fishing in another man's waters.

PISCES, in astronomy, the 12th sign or constellation of the zodiac.

PISCIDIA, a genus of the decandria order, belonging to the diadelphia class of plants. There are two species, *viz.* 1. The erythrina, or dog-wood tree. This grows plentifully in Jamaica, where it rises to the height of 25 feet or more; the stem is almost as large as a man's body, covered with a light-coloured smooth bark, and sending out several branches at the top without order; the leaves are about two inches long, winged, with oval lobes. The flowers are of the butterfly kind, and of a dirty white colour; they are succeeded by oblong pods, with four longitudinal wings, and jointed between the cells which contain the seeds. 2. The Carthaginiensis, with oblong oval leaves, is also a native of the West Indies. It differs from the former only in the shape and consistence of the leaves, which are more oblong and stiffer; but in other respects they are very similar. Both species are easily propagated by seeds; but require artificial heat to preserve them in this country.—The negroes in the West Indies make use of the bark of the first species to intoxicate fish. When any number of gentlemen have an inclination to divert themselves with fishing, or, more properly speaking, with fish-hunting, they send each of them a negro-slave to the woods, in order to fetch some of the bark of the dog-wood tree. This bark is next morning pounded very small with stones, put into old sacks, carried into rocky parts of the sea, steeped till thoroughly soaked with salt-water, and then well squeezed by the negroes to express the juice. This juice immediately colours the sea with a reddish hue; and, being of a poisonous nature, will in an hour's time make the fishes, such as groopers, rock-fish, old wives, Welchmen, &c. so drunk or intoxicated, as to swim on the surface of the water, quite heedless of the danger: the gentlemen then send in their negroes, who pursue, both swimming and diving, the poor inebriated fishes, till they catch them with their hands; their masters in mean time standing by, on high rocks, to see the pastime.

Piscidia || Pisistratus.

It is remarkable, that though this poison kills millions of the small fry, it has never been known to impart any bad quality to the fish which have been caught in consequence of the intoxication.

The wood of this tree, although pretty hard, is only fit for fuel; and even for this purpose the negroes very seldom, if ever, employ it, on account of its singular quality just mentioned. The bark is rough, brown, and thick; the tree sends forth a considerable number of branches, and is well clothed with leaves, which resemble those of the pea, are thick, cottony, and of a deep green. The bark used for the above-mentioned purpose is chiefly that of the roots.

PISCINA, in antiquity, a large bason in a public place or square, where the Roman youth learned to swim; and which was surrounded with a high wall, to prevent filth from being thrown into it.—This word is also used for a lavatory among the Turks, placed in the middle court of a mosque or temple, where the Mussulmen wash themselves before they offer their prayers.

PISISTRATUS, an Athenian who early distinguished himself by his valour in the field, and by his address and eloquence at home. After he had rendered himself the favourite of the populace by his liberality and by the intrepidity with which he had fought their battles, particularly near Salamis, he resolved to make himself master of his country. Every thing seemed

Bibliotheca Classica by Lempriere.

Pifiſtratus. ed favourable to his ambitious views; but Solon alone, who was then at the head of affairs, and who had lately enforced his celebrated laws, oppoſed him, and diſcovered his duplicity and artful behaviour before the public aſſembly. Piſiſtratus was not diſheartened by the meaſures of his relation Solon, but he had recourſe to artifice. In returning from his country-houſe, he cut himſelf in various places; and after he had expoſed his mangled body to the eyes of the populace, deplored his misfortunes, and accuſed his enemies of attempts upon his life, becauſe he was the friend of the people, the guardian of the poor, and the reliever of the oppreſſed, he claimed a choſen body of 50 men from the populace to defend his perſon in future from the malevolence and the cruelty of his enemies. The unſuſpecting people unanimouſly granted his requeſt, though Solon oppoſed it with all his influence; and Piſiſtratus had no ſooner received an armed band on whoſe fidelity and attachment he could rely, than he ſeized the citadel of Athens, and made himſelf abſolute. The people too late perceived their credulity; yet, though the tyrant was popular, two of the citizens, Megacles and Lycurgus, conſpired together againſt him, and by their means he was forcibly ejected from the city. His houſe and all his effects were expoſed to ſale; but there was found in Athens only one man who would buy them. The private diſſenſions of the friends of liberty proved favourable to the expelled tyrant; and Megacles, who was jealous of Lycurgus, ſecretly promiſed to reſtore Piſiſtratus to all his rights and privileges in Athens, if he would marry his daughter. Piſiſtratus conſented; and by the aſſiſtance of his father-in-law, he was ſoon enabled to expel Lycurgus, and to re-eſtabliſh himſelf. By means of a woman called *Phya*, whoſe ſhape was tall, whoſe features were noble and commanding, he impoſed upon the people, and created himſelf adherents even among his enemies. Phya was conducted through the ſtreets of the city, and ſhowing herſelf ſubſervient to the artifice of Piſiſtratus, ſhe was announced as Minerva, the goddeſs of wiſdom, and the patroneſs of Athens, who was come down from Heaven to re-eſtabliſh her favourite Piſiſtratus in a power which was ſanctioned by the will of Heaven, and favoured by the affection of the people. In the midſt of his triumph, however, Piſiſtratus found himſelf unſupported; and ſome time after, when he repudiated the daughter of Megacles, he found that not only the citizens, but even his very troops, were alienated from him by the influence, the intrigues, and the bribery of his father-in-law. He fled from Athens where he no longer could maintain his power, and retired to Eubœa. Eleven years after he was drawn from his obſcure retreat, by means of his ſon Hippias, and he was a third time received by the people of Athens as their maſter and ſovereign. Upon this he ſacrificed to his reſentment the friends of Megacles, but he did not loſe ſight of the public good, and while he ſought the aggrandizement of his family, he did not neglect the dignity and the honour of the Athenian name. He died about 528 years before the Chriſtian era, after he had enjoyed the ſovereign power at Athens for 33 years, and he was ſucceeded by his ſon Hipparchus. Piſiſtratus claims our admiration for his juſtice, his liberality, and his moderation. If he was dreaded and deteſted as a tyrant, the Athenians loved and reſpected his private virtues and his patriotiſm as a fellow-citizen; and the opprobrium which generally falls on his head may be attributed not to the ſeverity of his adminiſtration, but to the republican principles of the Athenians, who hated and exclaimed againſt the moderation and equity of the mildeſt ſovereign, while they flattered the pride and gratified the guilty deſires of the moſt tyrannical of their fellow ſubjects. Piſiſtratus often refuſed to puniſh the inſolence of his enemies; and when he had one day been virulently accuſed of murder, rather than inflict immediate puniſhment upon the man who had criminated him, he went to the areopagus, and there convinced the Athenians that the accuſations of his enemies were groundleſs, and that his life was irreproachable. It is to his labours that we are indebted for the preſervation of the poems of Homer; and he was the firſt, according to Cicero, who introduced them at Athens in the order in which they now ſtand. He alſo eſtabliſhed a public library at Athens; and the valuable books which he had diligently collected were carried into Perſia when Xerxes made himſelf maſter of the capital of Attica. Hipparchus and Hippias the ſons of Piſiſtratus, who have received the name of *Piſiſtratidæ*, rendered themſelves as illuſtrious as their father; but the flames of liberty were too powerful to be extinguiſhed. The Piſiſtratidæ governed with great moderation, but the name of tyrant or ſovereign was inſupportable to the Athenians. Two of the moſt reſpectable of the citizens, called *Harmodius* and *Ariſtogiton*, conſpired againſt them, and Hipparchus was diſpatched in a public aſſembly. This murder was not, however, attended with any advantages; and though the two leaders of the conſpiracy, who have been celebrated through every age for their patriotiſm, were ſupported by the people, yet Hippias quelled the tumult by his uncommon firmneſs and prudence, and for a while preſerved that peace in Athens which his father had often been unable to command. This was not long to continue. Hippias was at laſt expelled by the united efforts of the Athenians and of their allies, and he left Attica, when he found himſelf unable to maintain his power and independence. The reſt of the family of Piſiſtratus followed him in his baniſhment; and after they had refuſed to accept the liberal offers of the princes of Theſſaly, and the king of Macedonia, who wiſhed them to ſettle in their reſpective territories, the Piſiſtratidæ retired to Sigæum, which their father had in the ſummit of his power conquered and bequeathed to his poſterity. After the baniſhment of the Piſiſtratidæ, the Athenians became more than commonly jealous of their liberty, and often ſacrificed the moſt powerful of their citizens, apprehenſive of the influence which popularity and a well-directed liberality might gain among a fickle and unſettled populace. The Piſiſtratidæ were baniſhed from Athens about 18 years after the death of Piſiſtratus. Piſiſtratus, Piſmires.

PISMIRES, are a kind of inſects very common in Africa; of which there is ſo great a variety, and ſuch innumerable ſwarms, that they deſtroy not only the fruits of the ground but even men and beaſts in ſo little a time as one ſingle night; and would, without all doubt, prove more fatally deſtructive to the inhabitants, were they not ſo happily deſtroyed by a proportionable number of monkeys, who greedily ferret and devour them.

Piſo. them. For a further account of theſe, and ſome other grievous plagues with which the far greater part of the vaſt continent of Africa is afflicted, particularly that moſt horrid viſitation of locuſts, which ſeldom fail a year of laying waſte ſome of the provinces, ſee GRYLLUS, p. 161.

PISO (Lucius Calpurnius), ſurnamed *Frugi* on account of his frugality, was deſcended of the illuſtrious family of the Piſos, which gave ſo many great men to the Roman republic. He was tribune of the people in the year 149 before Chriſt, and afterwards conſul. During his tribuneſhip, he publiſhed a law againſt the crime of conceſſion or extortion, intitled *Lex Calpurnia de pecuniis repetundis*. He happily ended the war in Sicily. To reward the ſervices of one of his ſons, who had diſtinguiſhed himſelf in that expedition, he left him by his will a golden crown, weighing 20 pounds. Piſo joined to the qualities of a good citizen the talents of a lawyer, an orator, and hiſtorian.

PISO (Caius Calpurnius), a Roman conſul in the year 67 before Chriſt, was author of the law which forbid canvaſſing for public offices, intitled *Lex Calpurnia de ambitu*. He diſplayed all the firmneſs worthy of a conſul in one of the moſt ſtormy periods of the republic. The Roman people, deceived by the flattery of Marcus Palicanus, a turbulent and ſeditious fellow, were on the eve of loading themſelves with the greateſt diſgrace, by putting the ſupreme authority into the hands of this man, who deſerved puniſhment rather than honours. The tribunes of the people, by their harangues, inflamed the blind fury of the multitude, already ſufficiently mutinous of themſelves. In this ſituation, Piſo mounted the roſtrum, and being aſked if he would declare Palicanus conſul, in caſe the ſuffrages of the people ſhould concur in the nomination, he inſtantly replied, that "he did not think the republic was yet involved in ſuch darkneſs and deſpair as to be capable of committing ſo infamous an action." Being afterwards ſtrongly and repeatedly called upon to ſay, "what he would do, if the thing ſhould happen?" his anſwer was, "No, I would not name him." By this firm and laconic anſwer he deprived Palicanus of the dignity to which he aſpired. Piſo, according to Cicero, was not poſſeſſed of a quick conception, but he thought maturely, and with judgment, and, by a proper firmneſs, he appeared to be an abler man than he really was.

PISO (Cneius Calpurnius), was conſul in the reign of Auguſtus, and governor of Syria under Tiberius, whoſe confident he was. It is ſaid, that by the order of this emperor he cauſed Germanicus to be poiſoned. Being accuſed of that crime, and ſeeing himſelf abandoned by every body, he laid violent hands on himſelf in the 20th year of our Lord. He was a man of inſupportable pride and exceſſive violence. Some inſtances of his wicked cruelty have been handed down to us. Having given orders in the heat of his paſſion to conduct to puniſhment a ſoldier, as guilty of the death of one of his companions, becauſe he had gone out of the camp with him and returned without him, no prayers or intreaty could prevail with Piſo to ſuſpend the execution of this ſentence until the affair ſhould be properly inveſtigated. The ſoldier was led without the entrenchments, and had already preſented his head to receive the fatal ſtroke, when his companion whom he was accuſed of having killed made his appearance again. Whereupon the centurion, whoſe office it was to ſee the ſentence executed, ordered the executioner to put up his ſword into the ſcabbard. Thoſe two companions, after embracing each other, are conducted to Piſo, amidſt the acclamations of the whole army, and a prodigious crowd of people. Piſo, foaming with rage, aſcends his tribune, and pronounces the ſame ſentence of death againſt the whole three, without excepting the centurion who had brought back the condemned ſoldier, in theſe terms: "You I order to be put to death becauſe you have been already condemned; you, becauſe you have been the cauſe of the condemnation of your comrade; and you, becauſe having got orders to put that ſoldier to death, you have not obeyed your prince." Piſſaſphaltum.

PISSASPHALTUM, EARTH-PITCH; a fluid, opaque, mineral body, of a thick conſiſtence, ſtrong ſmell, readily inflammable, but leaving a reſiduum of greyiſh aſhes after burning. It ariſes out of the cracks of the rocks, in ſeveral places in the iſland of Sumatra, and ſome other places in the Eaſt Indies, where it is much eſteemed in paralytic diſorders. There is a remarkable mine of it in the iſland of Bua, (ſee BUA), of which the following curious deſcription is given us by the Abbé Fortis. "The iſland is divided into two promontories between the north and weſt, croſſing over the top of the latter, which is not half a mile broad, and deſcending in a right line towards the ſea, one is conducted to a hole well known to the inhabitants. This hole extends not much above 12 feet, and from its bottom above 25 feet perpendicular, ariſe the marble ſtrata which ſuſtain the irregular maſſes that ſurround the top of the mountain

"The place ſeemed to me (continues our author), ſo worthy of obſervation, that I cauſed a drawing of it to be taken. The hole AAA is dug out of an irregular ſtratum of argillaceous ſandy earth, in ſome parts whitiſh, and in others of a greeniſh colour; part of it is half petrified, and full of numiſmales of the largeſt kind, lenticulares, and fragments, with here and there a ſmall branch of madreporites, and frequently of thoſe other foſſil bodies called by Geſner *cornua ammonis candida, minima*, &c. The maſs B is fallen from the height of the rock, and lies iſolated. The excavation, made by ſome poor man in the ſofter matter, reaches a little below the extremity CC of the ſtratum DD. This is ſeparated by the line EE from the ſtratum FF, which is of hard common marble, with marine bodies without flints. The upper part *aa* is of hard lenticular ſtone, interſperſed with flints full of lenticulares. The maſs H does not diſcover the diviſions of its ſtrata on the outſide, and tranſpires very ſmall drops of piſſaſphaltum, ſcarcely diſcernible; but the tears III of the ſame matter, which flow from the fiſſures and chinks of the whitiſh ſtratum DD, are very obſervable. They come out moſt abundantly when the ſun falls on the marble rock in the heat of the day. This piſſaſphaltum is of the moſt perfect quality, black and ſhining like the *bitumen Judaicum*; very pure, odorous, and cohesive. It comes out almoſt liquid, but hardens in large drops when the ſun ſets. On breaking many of theſe drops on the ſpot, I found that almoſt every one of them had an inner cavity full of very clear water." Plate CCCXCVII.

Piſſeleum, Piſtacia.

"The greateſt breadth of the tears that I ſaw was two inches, and the common breadth is half an inch. The chinks and fiſſures of the marble, from whence this bituminous pitch tranſudes, are not more than the thickneſs of a thread; and for the moſt part are ſo imperceptible, that were it not for the pitch itſelf, whereby they are blackened, they could not by any means be diſtinguiſhed by the naked eye. To the narrowneſs of theſe paſſages is, no doubt, in part owing the ſmall quantity of piſſaſphaltum that tranſpires."

After ſome conjectures about the origin of this mine, our author proceeds to inform us that the piſſaſphaltum of Bua is correſpondent to that foſſil production which by Haſſelquiſt, in his Travels, is called *mumia minerale*, and *mumia nativa Perſiana* by Kempfer, which the Egyptians made uſe of to embalm their kings (A). It is found in a cave of mount Caucaſus, which is kept ſhut, and carefully guarded by order of the king of Perſia. One of the qualities aſſigned by M. Linnæus to the fineſt bitumen is to ſmoke when laid on the fire, as ours does, emitting a ſmell of pitch not diſagreeable. He believes it would be very good for wounds, as the oriental mumia is, and like the pitch of Caſtro, which is frequently uſed by the Roman chirurgeons for fractures, contuſions, and in many external applications. See MINERALOGY.

PISSELÆUM INDICUM, *Barbadoes Tar*; a mineral fluid of the nature of the thicker bitumens, and of all others the moſt approaching, in appearance, colour, and conſiſtence, to the true piſſaſphaltum, but differing from it in other reſpects. It is very frequent in many parts of America, where it is found trickling down the ſides of mountains in large quantities, and ſometimes floating on the ſurface of the waters. It has been greatly recommended internally in coughs and other diſorders of the breaſt and lungs.

PISTACIA, TURPENTINE-TREE, *Piſtachia-nut* and *Maſtich-tree*; a genus of the pentandria order, belonging to the dioecia claſs of plants. There are nine ſpecies; of which the moſt remarkable are, 1. The terebinthus, or piſtachia-tree. This grows naturally in Arabia, Perſia, and Syria, whence the nuts are annually brought to Europe. In thoſe countries it grows to the height of 25 or 30 feet: the bark of the ſtem and old branches is of a dark ruſſet colour, but that of the young branches is of a light brown. Theſe are garniſhed with winged leaves, compoſed ſometimes of two, at other times of three, pair of lobes, terminated by an odd one: theſe lobes approach towards an oval ſhape, and their edges are turned backward; and theſe, when bruiſed, emit a ſmell ſimilar to that of the ſhell of the nut. Some of theſe trees produce male and others female flowers, and ſome have both male and female on the ſame tree. The male flowers come out from the ſides of the branches in looſe bunches or catkins. They have no petals, but five ſmall ſtamina crowned by large four-cornered ſummits filled with farina; and when this is diſcharged, the flowers fall off. The female flowers come out in cluſters from the ſides of the branches: they have no petals, but a large oval germen ſupporting three reflexed ſtyles, and are ſucceeded by oval nuts. 2. The lentiſcus, or common maſtich-tree, grows naturally in Portugal, Spain, and Italy. Being an evergreen, it has been preſerved in this country in order to adorn the green-houſes. In the countries where it is a native, it riſes to the height of 18 or 20 feet, covered with a grey bark on the ſtem; but the branches, which are very numerous, are covered with a reddiſh-brown bark, and are garniſhed with winged leaves, compoſed of three or four pair of ſmall ſpear-ſhaped lobes, without an odd one at the end. 3. The orientalis, or true maſtich-tree of the Levant, from which the maſtich is gathered, has been confounded by moſt botanical writers with the lentiſcus, or common maſtich tree, above deſcribed, though there are conſiderable differences between them. The bark of the tree is brown; the leaves are compoſed of two or three pair of ſpear-ſhaped lobes, terminated by an odd one: the outer lobes are the largeſt; the others gradually diminiſh, the innermoſt being the leaſt. Theſe turn of a browniſh colour towards the autumn, when the plants are expoſed to the open air; but if they are under glaſſes, they keep green. The leaves continue all the year, but are not ſo thick as thoſe of the common ſort, nor are the plants ſo hardy.

Piſtacia.

Culture. The firſt ſpecies is propagated by its nuts; which ſhould be planted in pots filled with light kitchen-garden earth, and plunged into a moderate hot-bed to bring up the plants: when theſe appear, they ſhould have a large ſhare of air admitted to them, and by degrees they ſhould be expoſed to the open air, which at laſt they will bear in all ſeaſons, though not without great danger of being deſtroyed in ſevere winters. The ſecond ſort is commonly propagated by laying down the branches, though it may alſo be raiſed from the ſeed in the manner already directed for the piſtachia-nut tree: and in this manner alſo may the true maſtich-tree be raiſed. But this being more tender than any of the other ſorts, requires to be conſtantly ſheltered in winter, and to have a warm ſituation in ſummer.

(A) "Mumiahi, or native Perſian mummy. It proceeds from a hard rock in very ſmall quantity. It is a bituminous juice, that tranſudes from the ſtony ſuperficies of the hill, reſembling in appearance coarſe ſhoemakers wax, as well in its colour as in its denſity and ductility. While adherent to the rock it is leſs ſolid, but is formed by the warmth of the hands. It is eaſily united with oil, but repels water; it is quite void of ſmell, and very like in ſubſtance to the Egyptian mummy. When laid on burning coals, it has the ſmell of ſulphur tempered a little with that of naphtha, not diſagreeable. There are two kinds of this mummy; the one is valuable for its ſcarcity and great activity. The native place of the beſt mummy is far from the acceſs of men, from habitations, and from ſprings of water, in the province of Daraab. It is found in a narrow cave, not above two fathoms deep, cut like a well out of the maſs, at the foot of the ragged mountain Caucaſus."——*Kempfer. Amæn. Perſ.*

This deſcription agrees perfectly with the piſſaſphaltum or foſſil mummy of Bua, differing only in the privation of ſmell, which it is difficult to imagine is totally wanting in the Perſian mummy.

Piſtil
Piſtachia nuts are moderately large, containing a kernel of a pale greeniſh colour, covered with a reddiſh ſkin. They have a pleaſant, ſweet, unctuous taſte, reſembling that of almonds; and they abound with a ſweet and well-taſted oil, which they yield in great abundance on being preſſed after bruiſing them: they are reckoned amongſt the analeptics, and are wholeſome and nutritive, and are by ſome eſteemed very proper to be preſcribed by way of reſtoratives, eaten in ſmall quantity, to people emaciated by long illneſs.

PISTIL, among botaniſts, the little upright column which is generally found in the centre of every flower. According to the Linnæan ſyſtem, it is the female part of generation, whoſe office is to receive and ſecrete the pollen, and produce the fruit. It conſiſts of three parts, viz. germen, ſtylus, and ſtigma. See BOTANY, p. 434, and p. 454, 2d columns.

PISTOIA is a city of Italy, in the duchy of Tuſcany, ſituated on the river Stella, in a beautiful plain near the foot of the Apennine mountains. By Pliny it is called *Piſtorium*, and is ſaid to have been once a Roman colony. At preſent it is a biſhop's ſee, ſuffragan of Florence. The ſtreets are broad and regular, the houſes tolerably well built, but poorly inhabited for want of trade. Formerly it was an independent republic, but ſince it was ſubdued by the Florentines in 1200, it has been in a declining condition. The cathedral has a very handſome cupola, and a magnificent ſtaircaſe to aſcend to it. In the chapel dedicated to St James, where his relics are preſerved, the walls are almoſt covered with plates of ſilver. Here are four marble ſtatues of very good workmanſhip. The marble pulpit, the baſſo relievos, the veſſel that holds the holy water, and the ſquare ſteeple, are the work of John Piſano. The Jeſuits have a very fine college, and the Franciſcans, Dominicans, and Auguſtinians, good churches. In the church of Madonna dell' Umilta there are two ſtatues, one of Leo X. and the other of Clement VII. The public palace, ſituated in a large ſquare, is a handſome building; ſeveral of the nobility have alſo very good houſes. In the neighbouring mountains, called by the name of Piſtoia, there are many large villages, the chief of which is that of S. Marcello, belonging to the family of Cartoli. Theſe mountains are a part of the Apennines, and border on the territory of Bologna and the county of Vernio; higher up is the ſource of the river Reno. The country about Piſtoia, eſpecially towards Florence, is exceeding fertile and delightful, covered with all ſorts of fruits, corn, wine, &c. and containing a vaſt number of little towns, wealthy villages, and country ſeats, ſo as to be reckoned the richeſt and moſt beautiful in all Tuſcany. It is about 20 miles N. W. of Florence, and 30 N. E. of Piſa. E. Long. 11. 29. N. Lat. 43. 55.

PISTOL, the ſmalleſt piece of fire-arms, borne at the ſaddle-bow, on the girdle, and in the pocket.

PISTOLE, a gold coin, ſtruck in Spain and in ſeveral parts of Italy, Switzerland, &c.—The piſtole has its augmentations and diminutions, which are quadruple piſtoles, double piſtoles, and half piſtoles. See *Money-Table*.

PISTON, in pump-work, is a ſhort cylinder of metal or other ſolid ſubſtance, fitted exactly to the cavity of the barrel or body of the pump. See HYDROSTATICS, ſect. v.

PISTORIUS (John), born at Nidda in 1546, applied himſelf at firſt to the ſtudy of medicine, and was admitted a doctor with applauſe; but his preſcriptions not being attended with all the ſucceſs which he expected, he quitted that profeſſion, and ſtudied the law. His merit procured him the appointment of counſellor to Erneſt Frederick margrave of Bade-Dourlach. He had embraced the Proteſtant religion; but ſome time after he changed his opinion, and returned to the communion of the church of Rome. He became afterwards a doctor of divinity, one of the emperor's counſellors, provoſt of the cathedral of Breſlaw, and domeſtic prelate to the abbot of Fulda. We have of his writings, 1. Several Controverſial Tracts againſt the Lutherans. 2. *Artis Cabaliſticæ Scriptores*, printed at Bale 1587; a ſcarce and curious collection. 3 *Scriptores rerum Polonicarum*. 4. *Scriptores de rebus Germanicis*, in 3 vols. folio, from 1603 to 1613. This is a curious and ſcarce performance, but might have been better digeſted. The author died in 1608, at the age of 52.

Piſtorius
Piſum.

PISUM, PEASE; a genus of the decandria order, belonging to the diadelphia claſs of plants. The ſpecies are, 1. The ſativum, or greater garden pea, whoſe lower ſtipulæ are roundiſh, indented, with taper foot-ſtalks, and many flowers on a foot-ſtalk. 2. The humile, or dwarf pea, with an erect branching ſtalk, and leaves having two pair of round lobes. 3. The umbellatum, roſe, or crown-pea, with four pointed acute ſtipuli, and foot-ſtalks bearing many flowers, which terminate the ſtalks. 4. The maritimum, or ſea-pea, with foot-ſtalks which are plain on their upper ſide, an angular ſtalk, arrow-pointed ſtipulæ, and foot-ſtalks bearing many flowers. 5. The Americanum, commonly called *Cape-Horn pea*, with an angular trailing ſtalk, whoſe lower leaves are ſpear-ſhaped, ſharply indented, and thoſe at the top arrow-pointed. 6. The ochrus, with membranaceous running foot-ſtalks, having two leaves and one flower upon a foot-ſtalk.

There is a great variety of garden-peaſe now cultivated in Britain, which are diſtinguiſhed by the gardeners and ſeedſmen, and have their different titles; but as great part of theſe have been ſeminal variations, ſo if they are not very carefully managed, by taking away all thoſe plants which have a tendency to alter before the ſeeds are formed, they will degenerate into their original ſtate: therefore all thoſe perſons who are curious in the choice of their ſeeds, look carefully over thoſe which they deſign for ſeeds at the time when they begin to flower, and draw out all the plants which they diſlike from the other. This is what they call *roguing their peaſe*; meaning hereby the taking out all the bad plants from the good, that the farina of the former may not impregnate the latter; to prevent which, they always do it before the flowers open. By thus diligently drawing out the bad, reſerving thoſe which come earlieſt to flower, they have greatly improved their peaſe of late years, and are conſtantly endeavouring to get forwarder varieties; ſo that it would be to little purpoſe in this place to attempt giving a particular account of all the varieties now cultivated: therefore we ſhall only mention the names by which they are commonly known, placing them according to their time of coming to the table, or gathering for uſe.

Piſum.

The golden hotſpur.	Nonpareil.
The Charlton.	Sugar dwarf.
The Reading hotſpur.	Sickle pea.
Maſter's hotſpur.	Marrowfat.
Eſſex hotſpur.	Roſe or crown pea.
The dwarf pea.	Rouncival pea.
The ſugar pea.	Gray pea.
Spaniſh Morotto.	Pig pea; with ſome others.

The Engliſh ſea-pea is found wild upon the ſhore in Suſſex and ſeveral other counties in England, and is undoubtedly a different ſpecies from the common pea.

The fifth ſpecies hath a biennial root, which continues two years. This was brought from Cape Horn by Lord Anſon's cook, when he paſſed that Cape, where theſe peaſe were a great relief to the ſailors. It is kept here as a curioſity, but the peaſe are not ſo good for eating as the worſt ſort now cultivated in Britain. It is a low trailing plant; the leaves have two lobes on each foot-ſtalk: thoſe below are ſpear-ſhaped, and ſharply indented on their edges; but the upper leaves are ſmall, and arrow pointed. The flowers are blue, each foot-ſtalk ſuſtaining four or five flowers; the pods are taper, near three inches long; and the ſeeds are round, about the ſize of tares.

The ſixth ſort is annual. This grows naturally among the corn in Sicily and ſome parts of Italy, but is here preſerved in botanic gardens for the ſake of variety. It hath an angular ſtalk, riſing near three feet high; the leaves ſtand upon winged foot-ſtalks, each ſuſtaining two oblong lobes. The flowers are of a pale yellow colour, ſhaped like thoſe of the other ſort of pea, but are ſmall, each foot-ſtalk ſuſtaining one flower; theſe are ſucceeded by pods about two inches long, containing five or ſix roundiſh ſeeds, which are a little compreſſed on their ſides. Theſe are by ſome perſons eaten green; but unleſs they are gathered very young, they are coarſe, and at beſt not ſo good as the common pea. It may be ſown and managed in the ſame way as the garden pea.

We ſhall now proceed to ſet down the method of cultivating the ſeveral ſorts of garden peaſe, ſo as to continue them throughout the ſeaſon.

It is a common practice with the gardeners near London to raiſe peaſe upon hot-beds, to have them very early in the ſpring; in order to which, they ſow their peaſe upon warm borders, under walls or hedges, about the middle of October; and when the plants come up, they draw the earth up gently to their ſtems with a hoe, the better to protect them from froſt. In theſe places they let them remain until the latter end of January, or the beginning of February, obſerving to earth them up from time to time as the plants advance in height (for the reaſons before given); as alſo to cover them in very hard froſt with peaſe-haulm, ſtraw, or ſome other light covering, to preſerve them from being deſtroyed; they then make a hot-bed (in proportion to the quantity of peaſe intended), which muſt be made of good hot dung, well prepared and properly mixed together, that the heat may not be too great. The dung ſhould be laid for two or three feet thick, according as the beds are made earlier or later in the ſeaſon; when the dung is equally levelled, then the earth (which ſhould be light and freſh, but not over rich) muſt be laid thereon about ſix or eight inches thick, laying it equally all over the bed. This being done, the frames (which ſhould be two feet high on the back ſide, and about 14 inches in front) muſt be put on, and covered with glaſſes; after which it ſhould remain three or four days, to let the ſteam of the bed paſs off before you put the plants therein, obſerving every day to raiſe the glaſſes to give vent for the riſing ſteam to paſs off; then, when you find the bed of a moderate temperature for heat, you ſhould, with a trowel, or ſome other inſtrument, take up the plants as carefully as poſſible to preſerve the earth to their roots, and plant them into the hot-bed in rows about two feet aſunder, and the plants about an inch diſtant from each other in the rows, obſerving to water and ſhade them until they have taken root; after which you muſt be careful to give them air at all times when the ſeaſon is favourable, otherwiſe they will draw up very weak, and be ſubject to grow mouldy and decay. You ſhould alſo draw the earth up to the ſhanks of the plants as they advance in height, and keep them always clear from weeds. The water they ſhould have muſt be given them ſparingly; for if they are too much watered, it will cauſe them to grow too rank, and ſometimes rot off the plants at their ſhanks juſt above ground. When the weather is very hot, you ſhould cover the glaſſes with mats in the heat of the day, to ſcreen them from the violence of the heat of the ſun, which is then too great for them: but when the plants begin to fruit, they ſhould be watered oftener, and in greater plenty than before; for by that time the plants will have nearly done growing, and the often refreſhing them will occaſion their producing a greater plenty of fruit.

Pſeudo.

The ſort of pea which is generally uſed for this purpoſe is the dwarf; for all the other ſorts ramble too much to be kept in frames: the reaſon for ſowing them in the common ground, and afterwards tranſplanting them on a hot-bed, is to check their growth, and cauſe them to bear in leſs compaſs; for if the ſeeds were ſown upon a hot-bed, and the plants continued thereon, they would produce ſuch luxuriant plants as could not be contained in the frames, and would bear but little fruit.

The next ſort of pea which is ſown to ſucceed thoſe on the hot-bed is the hotſpur; of which there are reckoned ſeveral varieties, as the golden hotſpur, the Charlton hotſpur, the Maſter's hotſpur, the Reading hotſpur, and ſome others; which are very little differing from each other, except in their early bearing, for which the golden and Charlton hotſpurs are chiefly preferred; though if either of theſe ſorts are cultivated in the ſame place for three or four years, they are apt to degenerate, and be later in fruiting; for which reaſon, moſt curious perſons procure their ſeeds annually from ſome diſtant place; and in the choice of theſe ſeeds, if they could be obtained from a colder ſituation and a poorer ſoil than that in which they are to be ſown, it will be much better than on the contrary, and they will come earlier in the ſpring.

Theſe muſt alſo be ſown on warm borders, towards the latter end of October; and when the plants are come up, you ſhould draw the earth up to their ſhanks, and treat them in every other reſpect as above directed.

In the ſpring you muſt carefully clear them from weeds, and draw ſome freſh earth up to their ſtems; but do not raiſe it too high up to the plants, leſt by

Piſum burying their leaves you ſhould rot their ſtems, as is ſometimes the caſe, eſpecially in wet ſeaſons. You ſhould alſo obſerve to keep them free from vermin, which, if permitted to remain amongſt the plants, will increaſe ſo plentifully as to devour the greateſt part of them. The chief of the vermin which infeſt peaſe are ſlugs, which lie all the day in the ſmall hollows of the earth, near the ſtems of the plants, and in the night-time come out and make terrible deſtruction of the peaſe; and theſe chiefly abound in wet ſoils, or where a garden is neglected and over-run with weeds: therefore you ſhould make the ground clear every way round the peaſe to deſtroy their harbours; and afterwards in a fine mild morning very early, when theſe vermin are got abroad from their holes, you ſhould ſlake a quantity of lime, which ſhould be ſtrewed over the ground pretty thick, which will deſtroy the vermin wherever it happens to fall upon them, but will do very little injury to the peaſe, provided it be not ſcattered too thick upon them.

If this crop of peaſe ſucceeds, it will immediately follow thoſe on the hot-bed; but for fear this ſhould miſcarry, it will be proper to ſow two more crops at about a fortnight or three weeks diſtance from each other, ſo that there may be the more chances to ſucceed. This will be ſufficient till the ſpring of the year, when you may ſow ſeveral more crops of theſe peaſe at a fortnight diſtance from each other. The late ſowings will be ſufficient to continue the early ſort of peaſe through the ſeaſon; but it will be proper to have ſome of the large ſort to ſucceed them for the uſe of the family: in order to which, you ſhould ſow ſome of the Spaniſh Morotto, which is a great bearer and a hardy ſort of pea, about the middle of February, upon a clear open ſpot of ground. Theſe muſt be ſown in rows about four feet aſunder, and the peaſe ſhould be dropped in the drills about an inch diſtance, covering them about two inches deep with earth, being very careful that none of them lie uncovered, which will draw the mice, pigeons, or rooks, to attack the whole ſpot; and it often happens, by this neglect, that a whole plantation is devoured by theſe creatures; whereas, when there are none of the peaſe left in ſight, they do not eaſily find them out.

About a fortnight after this you ſhould ſow another ſpot, either of this ſort or any other large ſort of pea, to ſucceed theſe; and then continue to repeat ſowing once a fortnight, till the middle or latter end of May; only obſerving to allow the marrowfats, and other very large ſorts of peaſe, at leaſt four feet and a half between row and row; and the roſe-pea ſhould be allowed at leaſt eight or ten inches diſtance plant from plant in the rows; for theſe grow very large, and if they have not room allowed them, they will ſpoil each other by drawing them up very tall, and will produce no fruit.

When the plants come up, the earth ſhould be drawn up to their ſhanks (as was before directed), and the ground kept entirely clear from weeds; and when the plants are grown eight or ten inches high, you ſhould ſtick ſome bruſhwood into the ground cloſe to the peaſe for them to ramp upon, which will ſupport them from trailing upon the ground, which is very apt to rot the growing ſorts of peaſe, eſpecially in wet ſeaſons; beſides, by thus ſupporting them, the air can freely paſs between them, which will preſerve the bloſſoms from falling off before their time, and occaſion them to bear much better than if permitted to lie upon the ground, and there will be room to paſs between the rows to gather the peaſe when they are ripe. Piſum.

The dwarf ſorts of peaſe may be ſown much cloſer together than thoſe before-mentioned; for theſe ſeldom riſe above a foot high, and rarely ſpread above half a foot in width, ſo that theſe need not have more room than two feet row from row, and not above an inch aſunder in the rows. Theſe will produce a good quantity of peaſe, provided the ſeaſon be not over dry; but they ſeldom continue long in bearing, ſo that they are not ſo proper to ſow for the main crop when a quantity of peaſe is expected for the table, their chief excellency being for hot-beds, where they will produce a greater quantity of peaſe (provided they are well-managed) than if expoſed to the open air, where the heat of the ſun ſoon dries them up.

The large growing ſorts may be cultivated for the common uſe of the family, becauſe theſe will produce in greater quantities than the other, and will endure the drought better; but the early kind are by far the ſweeter-taſted peaſe.

The beſt of all the large kinds is the marrowfat, which, if gathered young, is a well-taſted pea; and this will continue good through the month of Auguſt, if planted on a ſtrong ſoil.

The gray and other large winter-peaſe are ſeldom cultivated in gardens, becauſe they require a great deal of room, but are uſually ſown in fields. For the proper method of managing them, ſee AGRICULTURE, n° 150.

In the *Muſeum Ruſticum*, Vol. I. p. 109. we find the following method of preparing peaſe for hog-meat, which we ſhall give in the words of the ingenious farmer who communicated it.

"A few years ago (ſays he), I had a plentiful crop of peaſe on a ten acre piece, which lies near my houſe: when they were full podded and nearly ripe, I had them hooked in the uſual manner; but before I could get them in, there came a heavy ſhower of rain which wetted them through and through; and the dull heavy weather, with frequent ſhowers which followed, prevented their drying for a conſiderable time.

"I cauſed the wads to be from time to time turned, to prevent the haulm from rotting; and at length a few days ſunſhine dried them enough to be inned; for as they lay hollow, the wind was greatly aſſiſtant to the operation.

"Before I got them in, on examining ſome of the pods, I found that the peaſe were all ſprouted to a conſiderable length: this was what I had expected, as I gave my crop over for loſt, till after a little recollection, as the weather ſtill continued fine, I determined to threſh them in the field.

"This was accordingly done; and the corn, after it was caſt and riddled to ſeparate it from the rubbiſh, was dried on my malt kiln.

"When this operation was over, I began to reflect in what manner I ſhould diſpoſe of my peaſe, being ſenſible that they could not be proper for ſeed, and ſtanding no chance of diſpoſing of them to any advantage in the market.

"At length, as it was then a time of war, and of courſe there was a great demand for pork for the uſe of the navy, I determined to buy a conſiderable number

Piſum, Pit-coal.

ber of lean hogs, that I might by their means conſume this crop on my own premiſes, and in that manner make the moſt of it.

"My expectations were more than anſwered; for I found, by repeated experience, that three buſhels of the peaſe I have mentioned went nearly as far in fattening the hogs I bought as four buſhels got in dry and hard in the manner uſually practiſed.

"This diſcovery I made ſeveral years ago, and it has turned out to my advantage; for ſince that time I have been quite indifferent as to the weather in which my peaſe are hooked, being rather better pleaſed, as far as relates to them, with wet than dry weather; but if the weather happens to be dry at the time they are ripe, I always cauſe as many as I want for feeding my hogs, which are not a few in a year, to be regularly malted in the ſame manner nearly as my barley: this management has of late ſucceeded very well with me, and I therefore intend to continue it.

"Beſides feeding my hogs with theſe malted peaſe, I have often given them to my horſes, with which they agree very well, and are heartening food.

"Turkeys will fatten apace on them alſo, and be fine meat.

"I have applied my malted peaſe to many other uſes, which I have not at preſent time to enumerate: but were they only uſed for feeding hogs and horſes, it is ſtill worth while to prepare ſome in this manner every year."

PIT-COAL, or STONE-COAL. See COAL and LITHANTHRAX.

Mr Bertrand, in his *Oryctologie Dictionary*, reduces all kinds of coals to ſix general claſſes, *viz.* 1. Lithanthrax ligneus; 2. Petroſſus; 3. Terreſtris; 4. Piceus; 5. Fiſſilis; 6. Mineraliſatus. He ſays, that the Scots coals are heavier, and burn not ſo well as thoſe of Newcaſtle; that thoſe of Liege burn quicker; and thoſe from Braſſac in Auvergne, and from La Foſſe, burn with a more agreeable flame, &c. But Mr Morand, in his *Nomenclature Raiſonnée*, diſtributes all ſorts of pit-coals into four claſſes: In the firſt he places nine varieties, beginning with the *gagas* or *ſuccinum nigrum*, to the variegated lithanthrax; in the ſecond he reckons ſeven varieties, beginning with the *lithanthrax eleganti ſtructura*, to that *facie granulata*: and he forms the fourth claſs with the earthy and poorer kinds of foſſil coals. He ſeems, however, to have been puzzled with the ſlaty coals, as he ranges them in a ſeparate claſs, perhaps to ſhelter himſelf from the critical objections of thoſe numerous ſuperficial naturaliſts, who only look for the apparent configuration, without almoſt any regard to the component parts of foſſils.

The coal-trade is of infinite importance to Great Britain, which never could have arrived at its preſent commercial eminence without it; and this eminence it will be impoſſible to retain if coal ſhould ever become ſcarce. This we truſt is not likely to be the caſe, though Mr Williams expreſſes great fears for it, and informs us that at Newcaſtle and in many parts of Scotland the mines near the ſea are already waſted, the firſt conſequence of which muſt be an enormous riſe in the price. See his obſervations on this ſubject in his *Natural Hiſtory of the Mineral Kingdom*, p. 156, &c. This author ſays, that coal was not diſcovered till between the middle of the 12th and beginning of the 13th centuries: it is therefore, according to him, 400 years ſince it was firſt diſcovered in Britain, but they have not been in common uſe for more than 200 years. The ſame author gives us many pertinent obſervations on the appearances and indications of coal, inſtructions about ſearching for it, remarks on falſe and doubtful ſymptoms of coal; for all which, together with his obſervations on the different kinds of Scots coal, we ſhall refer our readers to the work itſelf; the firſt part of which, occupying the largeſt proportion of the firſt volume, is upon the *ſtrata of coal*, and on the *concomitant ſtrata*. See alſo our article COALERY.

Pitahaya, Pitcairne.

PITAHAYA (*Cactus Pitajaya*, Lin. *Syſt. Vegetabilium. Jacquin Amer.* 151. ed. 2. p. 75. M. *E. Carthagena*), a ſhrub peculiar to California, is a kind of beech, the fruit of which forms the greateſt harveſt of the natives. Its branches are finely fluted, and riſe vertically from the ſtem, ſo as to form a very beautiful top. The fruit is like a horſe-cheſnut. In ſome white, in others yellow, and in others red, but always exquiſitely delicious, being a rich ſweet, tempered with a grateful acid. See CACTUS.

PITCAIRNE (Dr Archibald), a moſt eminent phyſician and ingenious poet, was deſcended from the ancient family of the Pitcairnes of Pitcairne in Fifeſhire, and was born at Edinburgh on the 25th of December 1652. He commenced his ſtudies at the ſchool of Dalkeith; and from thence he was removed to the univerſity of Edinburgh, where he improved himſelf in claſſical learning, and completed a regular courſe of philoſophy. His friends, according to the authors of the *Biographia Britannica*, were deſirous that he ſhould follow the profeſſion of theology. The unpleaſant gloom, however, which at that time hung over religion and its profeſſors in Scotland, could not but very ill ſuit with that native cheerfulneſs of temper and liberality of mind which made him, long after, a mark for the arrows of preciſeneſs and grimace. The law ſeems to have been his own choice, and to this ſcience he turned his attention. With an ardour peculiar to himſelf, and an ambition to excel in whatever he undertook, he purſued it with ſo much intenſeneſs, that his health began to be impaired. On this account, his phyſicians adviſed him to ſet out for the ſouth of France. By the time he reached Paris, he was happily ſo far recovered, that he determined to renew his ſtudies; but being informed that there was no able profeſſor of law in that city, and finding ſeveral gentlemen of his acquaintance engaged in the ſtudy of phyſic, he went with them to the lectures and hoſpitals, and employed himſelf in this manner for ſeveral months till his affairs called him home.

On his return, he applied himſelf chiefly to the mathematics. It is not uſual to ſee the briars of this ſcience and the flowers of poetry growing in the ſame ſoil. Here, however, they were happily united; and to this union perhaps was owing that ſingular command of judgment, over one of the livelieſt of fancies, which appears in every part of his works. His intimacy with Dr David Gregory, the celebrated mathematical profeſſor, began about the ſame time; and probably conduced to cheriſh his natural aptitude for this ſtudy. It was then, in a great meaſure, new to him; it ſoon became his principal delight; his progreſs in it was rapid, and correſpondent to his progreſs in other purſuits. His improvements on the method of infinite ſeries then adopted, which Dr Wallis of Oxford after-

Pitcairne. wards published, were a conspicuous and early proof of his abilities in this science.

Had Dr Pitcairne continued to prosecute the study of the law, and could he have moulded his principles to the times, the first offices and honours of the state might have been looked for without presumption as the probable reward of such talents as he possessed. Struck, however, with the charms of mathematical truth which had been lately introduced into the philosophy of medicine, and hoping to reduce the healing art to geometrical method, he unalterably determined on this less aspiring profession. At the period when he formed this resolution, the ideas of the medical world, already sufficiently confused, were still farther jumbled by the discovery of the circulation of the blood, which had as yet produced nothing but doubt, uncertainty, and astonishment. In Edinburgh at that time there was no school, no hospital, no opportunity of improvement but the chamber and the shop. He therefore soon after returned to Paris. Genius and industry are unhappily not often united in the same character: of such an union, however, Dr Pitcairne is a celebrated instance. During his residence in France, he cultivated the object of his pursuit with his natural enthusiasm, and with a steadiness from which he could not be diverted by the allurements of that joy which, in his hours of social and festive intercourse, he always felt and always gave. Among his various occupations, the study of the ancient physicians seems to have had a principal share. This appears from a treatise which he published some time after his return; and it shows, that he wisely determined to know the progress of medicine from its earliest periods, before he attempted to reform and improve that science.

On the 13th of August 1680, he received, from the faculty of Rheims the degree of Doctor; which, on the 7th of August 1699, was likewise conferred on him by the university of Aberdeen; both being attended with marks of peculiar distinction. Other medical honours are said to have been conferred on him in France and elsewhere; but nothing affords a more unequivocal testimony to his abilities than that which the surgeons of Edinburgh gave, in admitting him, freely and unsolicited, a member of their college. None had such opportunities of judging of his merit as a practitioner, and on no physician did they ever bestow the same public mark of respect. Soon after his graduation at Rheims, he returned to Edinburgh; where, on the 29th of November 1681, the Royal College of Physicians was instituted; and his name, among others, graced the original patent from the crown.

In his *Solutio Problematis de Inventoribus*, the treatise above alluded to, he discovers a wonderful degree of medical literature, and makes use of it in a manner that does great honour both to his head and his heart. His object is to vindicate Dr Harvey's claim to the discovery of the circulation of the blood. The discovery was, at first, controverted by envy, and reprobated by ignorance. When at length its truth was fully established, many invidiously attempted to tear the laurels from the illustrious Englishman, and to plant them on the brows of Hippocrates and others. Had the attempt been directed against himself, the generous soul of Pitcairne could not have exerted more zeal in a defence; and his arguments remain unanswered. Pitcairne.

During his residence in Scotland, his reputation became so considerable, that, in the year 1691, the university of Leyden solicited him to fill the medical chair, at that time vacant. Such an honourable testimony of respect, from a foreign nation, and from such an university, cannot perhaps be produced in the medical biography of Great Britain. The lustre of such characters reflects honour on their profession, and on the country which has the good fortune of giving them birth; and serves to give the individuals of that country not only a useful estimation in their own eyes, but in those also of the rest of the world. Dr Pitcairne's well-known political principles excluded him from public honours and promotion at home: he therefore accepted the invitation from abroad; and, on the 26th of April 1692, delivered, at Leyden, his elegant and masterly inaugural oration: *Oratio qua ostenditur medicinam ab omni philosophorum secta esse liberam.* In this he clears medicine from the rubbish of the old philosophy; separates it from the influence of the different sects; places it on the broad and only sure foundation of experience; shows how little good inquiries into the manner how medicines operate have done to the art; and demonstrates the necessity of a sedulous attention to their effects, and to the various appearances of disease.

Nothing (says an elegant panegyrist* of our author) marks a superiority of intellect so much as the courage requisite to stem a torrent of obstinately prevailing and groundless opinions. For this the genius and talents of Pitcairne were admirably adapted; and, in his oration, he displays them to the utmost. It was received with the highest commendations; and the administrators, to testify their sense of such an acquisition to their university, greatly augmented the ordinary appointment of his chair.

*Dr Charles Webster, in the *Harveian Oration* at Edinburgh for the year 1781; from which performance the present article is chiefly extracted.

He discharged the duties of his office at Leyden so as to answer the most sanguine expectations. He taught with a perspicuity and eloquence which met with universal applause. Independently of the encomiums of Boerhaave and Mead, who were his pupils, the numerous manuscript copies of his lectures, and the mutilated specimen of them† which found its way into the world without his knowledge, show how justly it was bestowed. At the same time, he was not more celebrated as a professor than as a practical physician; and notwithstanding the multiplicity of his business in both these characters, he found leisure to publish several treatises on the circulation, and some other of the most important parts of the animal economy (A).

†*Elementa Medicinæ.*

At the close of the session he set out for Scotland, with an intention of returning in time for the succeeding one. On his marrying (B) the daughter of Sir Archibald

(A) Dr Boerhaave gives the following character of these and some other of Dr Pitcairne's dissertations, which were collected and published at Rotterdam, anno 1701: "Hæc scripta optima sunt et perfecta, sive legas Dissertationem de Motu Sanguinis per Pulmones, sive alia opuscula, sive ultimum tractatum de Opio." *Methodus studii, ab Hallero edita*, p. 569.

(B) He had been married before to a daughter of Colonel James Hay of Pitfour, by whom he had a son and daughter, who both died young.

Pitcairne. Archibald Stevenſon, the object of his journey, her relations would on no account conſent to part with him again. He was therefore reluctantly obliged to remain; and he wrote the univerſity a polite apology, which was received with the utmoſt regret. He even declined the moſt flattering ſolicitations and tempting offers to ſettle in London. Indeed he ſoon came into that extenſive practice to which his abilities intitled him, and was alſo appointed titular profeſſor of medicine in the univerſity of Edinburgh.

The uniformity of a profeſſional life is ſeldom interrupted by incidents worthy of record. Specimens, however, of that brilliant wit with which he delighted his friends in the hours of his leiſure, continue to entertain us (c); and the effects of that eminent ſkill which he exerted in the cure of diſeaſe, ſtill operate to the good of poſterity.

The diſcovery of the circulation, while in ſome meaſure it exploded the chemical and Galenical doctrines, tended to introduce mathematical and mechanical reaſoning in their ſtead. Of this theory (d) Dr Pitcairne was the principal ſupport, and the firſt who introduced it into Britain. A mathematical turn of mind, and a wiſh for mathematical certainty in medicine, biaſſed him in its favour, and he puſhed it to its utmoſt extent. One is at a loſs whether moſt to admire or regret ſuch a waſte of talents in propping a theory which, though ſubverſive of former ones, was to fall before others but a little more ſatisfactory than itſelf. Mechanical phyſicians expected more from geometry than that ſcience could grant. They made it the foundation inſtead of an auxiliary to their inquiries, and applied it to parts of nature not admitting mathematical calculations. By paying more attention afterwards to the ſupreme influence of the living principle, the ſource of all the motions and functions of the body, it was found that theſe could not be explained by any laws of chemiſtry or mechaniſm. They are ſtill, however, involved in obſcurity; and notwithſtanding the numberleſs improvements which have taken place in the ſciences connected with medicine, will perhaps remain inſcrutable while man continues in his preſent ſtage of exiſtence. Pitcairne.

In a ſcience ſo ſlowly progreſſive as that of medicine, Dr Pitcairne did a great deal. By labouring in vain for truth in one road, he ſaved many the ſame drudgery, and thereby ſhowed the neceſſity of another. He not only exploded many falſe notions of the chemiſts and Galeniſts which prevailed in his time, but many of thoſe too of his own ſect. In particular, he ſhowed the abſurdity of referring all diſeaſes and their cures to an alkali or an acid (e). He refuted the idea of ſecretion being performed by pores differently ſhaped (f), Bellini's opinion of effervescences in the

(c) Vide *Pitcarnii Poemata.*—Several of his poems, however, are obſcure, and ſome of them totally unintelligible without a key. In thoſe of them which are of a political kind, he wiſhed not to expreſs himſelf too clearly; and in others, he alludes to private occurrences which were not known beyond the circle of his companions. His poem *(Ad Lindeſium)*, addreſſed to his friend Lindſey, is commented on by the authors of the *Biographia Britannica;* and it is to be regretted that it is the only one on which they have been ſolicitous to throw light. "Some parts (ſay they) of this poem, are hardly intelligible, without knowing a circumſtance in the Doctor's life, which he often told, and never without ſome emotion. It is a well known ſtory of the two Platonic philoſophers, who promiſed one another, that whichever died firſt ſhould make a viſit to his ſurviving companion. This ſtory being read by Mr Lindſey and our author together, they, being both then very young, entered into the ſame engagement. Soon after, Pitcairne, at his father's houſe in Fife, dreamed one morning that Lindſey, who was then at Paris, came to him, and told him he was not dead, as was commonly reported, but ſtill alive, and lived in a very agreeable place, to which he could not yet carry him. By the courſe of the poſt news came of Lindſey's death, which happened very ſuddenly the morning of the dream. When this is known, the poem is eaſily underſtood, and ſhines with no common degree of beauty.

"Lyndeſi! Stygiàs jamdudum vecte per undas,
"Stagnaque Cocyti non adeunda mihi;
"Excute pauliſper Lethæi vincula ſomni,
"Ut ſeriant animum carmina noſtra tuum.
"Te nobis, te redde tuis, promiſſa daturus
"Gaudia; ſed proavo ſis comitante redux:
"Namque novos viros mutataque regna videbis,
"Paſſaque Teutonicas ſceptra Britanna manus*.

* Written in 1689.

"He then proceeds to exclaim againſt the principles and practices which produced this Teutonic violence upon the Britiſh ſceptre; and concludes with a wiſh, that Lindſey might bring Rhadamanthus with him to puniſh them.

"Unus abeſt ſcelerum vindex Rhadamanthus; amice,
"Dii faciant reditus ſit comes ille tui!"

"Every one ſees how much keener an edge is given to the ſatire upon the revolution, by making it an additional reaſon for his friend's keeping his promiſe to return him a viſit after his death."

(f) De circulatione ſanguinis per vaſa minima.

Pitcairne. the animal ſpirits with the blood, and Borelli's of air entering the blood by reſpiration (G). He proved the continuity of the arteries and veins (H); and ſeems to have been the firſt who ſhowed that the blood flows from a ſmaller capacity into a larger; that the aorta, with reſpect to the arterial ſyſtem, is the apex of a cone (I). In this therefore he may be conſidered as the latent ſpring of the diſcoveries reſpecting the powers moving the blood. He introduced a ſimplicity of preſcription unknown in pharmacy before his time (K); and ſuch was the ſtate of medicine in this country, that ſcarcely have the works of any cotemporary or preceding author been thought worthy even of preſervation (L). As to the errors of his philoſophy, let it be remembered, that no theory has as yet ſtood the teſt of many years in an enlightened period. His own hung very looſely about him (M); and the preſent generally received practice differs from his very little in reality. He treated inflammatory and hemorrhagic diſeaſes by bleeding, purging, and bliſtering, as has been done uniformly and ſolely on the different theories ſince. His method of adminiſtering mercury and the bark is obſerved at this day; and with reſpect to febrile, nervous, glandular, and dropſical affections, they ſeem to be as often the opprobriums of the art now as they were then.

Dr Pitcairne was univerſally conſidered as the firſt phyſician of his time. No one appears ever to have had ſo much practice in this country, or ſo many conſultations from abroad; and no one, from all accounts, ever practiſed with greater ſagacity and ſucceſs. The higheſt thought themſelves honoured by his acquaintance, and the loweſt were never denied his aſſiſtance and advice. The emoluments of his profeſſion muſt have been great; but his charities are known to have been correſpondent. The poſſeſſion of money he poſtponed to more liberal objects: he collected one of the fineſt private libraries in the world; which was purchaſed, after his death, by the Czar of Muſcovy. Notwithſtanding the fatigues he underwent in the exerciſe of his profeſſion, his conſtitution was naturally delicate. About the beginning of October 1713, he became affected with his laſt illneſs; and on the 23d he died, regretted by ſcience as its ornament, by his country as its boaſt, and by humanity as its friend. He left a ſon and four daughters: of whom only one of the latter now ſurvives. The preſent noble family of Kelly are his grandchildren.

Some anonymous publications are attributed to Dr Pitcairne, particularly a treatiſe *De Legibus Hiſtoriæ Naturalis*, &c.; but the only ones he thought proper to legitimate are his *Diſſertationes Medicæ*, and a ſhort eſſay *De Salute*.

PITCAITHLY. See PITKEATHLY. Pitcaithly

PITCH, a tenacious oily ſubſtance, drawn chiefly from pines and firs, and uſed in ſhipping, medicine, and various arts: or it is more properly tar inſpiſſated by boiling it over a ſlow fire. See TAR. Pitho.

Foſſil Pitch. See PETROLEUM.

PITCHING, in ſea-affairs, may be defined the vertical vibration which the length of a ſhip makes about her centre of gravity; or the movement by which ſhe plunges her head and after-part alternately into the hollow of the ſea. This motion may proceed from two cauſes: the waves which agitate the veſſel; and the wind upon the ſails, which makes her ſtoop to every blaſt thereof. The firſt abſolutely depends upon the agitation of the ſea, and is not ſuſceptible of inquiry; and the ſecond is occaſioned by the inclination of the maſts, and may be ſubmitted to certain eſtabliſhed maxims.

When the wind acts upon the ſails, the maſt yields to its effort, with an inclination which increaſes in proportion to the length of the maſt, to the augmentation of the wind, and to the comparative weight and diſtribution of the ſhip's lading.

The repulſion of the water, to the effort of gravity, oppoſes itſelf to this inclination, or at leaſt ſuſtains it, by as much as the repulſion exceeds the momentum, or abſolute effort of the maſt, upon which the wind operates. At the end of each blaſt, when the wind ſuſpends its action, this repulſion lifts the veſſel; and theſe ſucceſſive inclinations and repulſions produce the movement of pitching, which is very inconvenient; and, when it is conſiderable, will greatly retard the courſe, as well as endanger the maſt, and ſtrain the veſſel.

PITH, in vegetation, the ſoft ſpongy ſubſtance contained in the central parts of plants and trees *. * See *Plant*.

PITHO, (fab. hiſt.) the goddeſs of perſuaſion among the Romans. She was ſuppoſed to be the daughter of Mercury and Venus, and was repreſented with a diadem on her head, to intimate her influence over the hearts of man. One of her arms appeared raiſed as in the attitude of on orator haranguing in a public aſſembly; and with the other ſhe holds a thunderbolt and fetters, made with flowers, to ſignify the powers of reaſoning and the attractions of eloquence. A caduceus, as a ſymbol of perſuaſion, appears at her feet, with the writings of Demoſthenes and Cicero, the two moſt celebrated among the ancients, who underſtood how to command the attention of their audience, and to rouſe and animate their various paſſions.—A Roman courtezan. She received this name on account of the allurements which her charms poſſeſſed, and of her winning expreſſions.

Morb.*

Pithom, Pithou.

PITHOM, one of the cities that the children of Iſrael built for Pharaoh in Egypt (Exod. i. 11.) during the time of their ſervitude. This is probably the ſame city with Pathumos mentioned by Herodotus, which he places upon the canal made by the kings Necho and Darius to join the Red ſea with the Nile, and by that means with the Mediterranean. We find alſo in the ancient geographers, that there was an arm of the Nile called *Pathmeticus*, *Phatmicus*, *Phatnicus*, or *Phatniticus*. Bochart ſays, that Pithom and Raamſes are about five leagues above the diviſion of the Nile, and beyond this river: but this aſſertion has no proof from antiquity. This author contents himſelf with relating what was ſaid of Egypt in his own time. Marſham will have Pithom to be the ſame as Peluſium or Damietta.

PITHOU or Pithœus (Peter), a Frenchman of great literary eminence, was deſcended from an ancient and noble family in Normandy, and born at Troyes in 1539. His taſte for literature appeared very early, and his father cultivated it to the utmoſt. He firſt ſtudied at Troyes, and was afterwards ſent to Paris, where he became firſt the ſcholar, and then the friend, of Turnebus. Having finiſhed his purſuits in languages and the belles lettres, he was removed to Bourges, and placed under Cujacius in order to ſtudy civil law. His father was well ſkilled in this profeſſion, and has left no inconſiderable ſpecimen of his judgment in the advice he gave his ſon with regard to acquiring a knowledge of it; which was, not to ſpend his time and pains upon voluminous and barren commentators, but to confine his reading chiefly to original writers. He made ſo rapid a progreſs, that at ſeventeen he was able to ſpeak extempore upon the moſt difficult queſtions; and his maſter was not aſhamed to own, that even himſelf had learned ſome things of him. Cujacius afterwards removed to Valence; and Pithœus followed him, and continued to profit by his lectures till the year 1560. He then returned to Paris, and frequented the bar of the parliament there, in order to join practical forms and uſages to his theoretic knowledge.

In 1563, being then 24, he publiſhed *Adverſaria Subſeciva*, a work highly applauded by Turnebus, Lipſius, and other learned men; and which laid the foundation of that great and extenſive fame he afterwards acquired. Soon after this, Henry III. advanced him to ſome conſiderable poſts; in which, as well as at the bar, he acquitted himſelf moſt honourably. Pithœus being a Proteſtant, it was next to a miracle that he was not involved in the terrible maſſacre of St Bartholomew in 1572; for he was at Paris where it was committed, and in the ſame lodgings with ſeveral Huguenots, who were all killed. It ſeems indeed to have frightened him out of his religion; which having, according to the cuſtom of converts, examined and found to be erroneous, he ſoon abjured, and openly embraced the Catholic faith. He afterwards attended the duke of Montmorency into England; and on his return, from his great wiſdom, good nature, and amiable manners, he became a kind of oracle to his countrymen, and even to foreigners, who conſulted him on all important occaſions: an inſtance of which we have in Ferdinand the Grand Duke of Tuſcany, who not only conſulted him, but even ſubmitted to his determination in a point contrary to his intereſts. Henry III. and IV. were greatly obliged to him for combating the League in the moſt intrepid manner, and for many other ſervices, in which he had recourſe to his pen as well as to other means.

Pitiſcus || Pitot.

Pithœus died upon his birth-day in 1596, leaving behind him a wife whom he had married in 1579, and ſome children. Thuanus ſays he was the moſt excellent and accompliſhed man of the age in which he lived; and all the learned have agreed to ſpeak well of him. He collected a very valuable library, containing a variety of rare manuſcripts, as well as printed books; and he took many precautions to hinder its being diſperſed after his death, but in vain. He publiſhed a great number of works upon law, hiſtory, and claſſical literature; and he gave ſeveral new and correct editions of ancient writers. He was the firſt who made the world acquainted with the Fables of Phædrus: which, together with the name of their author, were utterly unknown and unheard of, till publiſhed from a manuſcript of his.

PITISCUS (Samuel), a learned antiquary, born at Zutphen, was rector of the college of that city, and afterwards of St Jerome at Utrecht, where he died on the firſt of February 1717, aged 90. He wrote, 1. *Lexicon Antiquitatum Romanorum*, in two volumes folio; a work which is eſteemed. 2. Editions of many Latin authors, with notes; and other works.

PITKEATHLY, or Pitcaithly, is the name of an eſtate in Strathern in Scotland, famous for a mineral ſpring. An intelligent traveller * gives the following account of it. "The ſituation of the mineral ſpring at Pitcaithly, the efficacy with which its waters are ſaid to operate in the cure of the diſeaſes for which they are uſed, and the accommodations which the neighbourhood affords, are all of a nature to invite equally the ſick and the healthy. Two or three houſes are kept in the ſtyle of hotels for the reception of ſtrangers. There is no long-room at the well; but there are pleaſing walks through the adjoining fields. Good roads afford eaſy acceſs to all the circumjacent country. This delightful tract of Lower Strathern is filled with houſes and gardens, and ſtations from which wide and delightful proſpects may be enjoyed; all of which offer agreeable points to which the company at the well may direct their forenoon excurſions; converſation, muſic, dances, whiſt, and that beſt friend to elegant, lively, and ſocial converſe, the tea-table, are ſufficient to prevent the afternoons from becoming languid: and in the evenings nothing can be ſo delightful as a walk when the ſetting ſun ſheds a ſoft ſlanting light, and the dew has juſt not begun to moiſten the graſs.—Thus is Pitcaithly truly a rural watering place. The company cannot be at any one time more in number than two or three families. The amuſements of the place are ſimply ſuch as a ſingle family might enjoy in an agreeable ſituation in the country; only the ſociety is more diverſified by the continual change and fluctuation of the company." See *Mineral Waters*, p. 55.

* Heron's Journey through the Weſtern parts of Scotland.

PITOT (Henry), of a noble family in Languedoc, was born at Aramont in the dioceſe of Uzez, on the 29th of May 1695, and died there on the 27th of December 1771, aged 76. He learned the mathematics without a maſter, and went to Paris in 1718, where he formed a cloſe friendſhip with the illuſtrious

Pitot, Pits.

Reaumur. In 1724, he was admitted a member of the Royal Academy of Sciences at Paris, and in a few years rose to the degree of a penſioner. Beſides a vaſt number of Memoirs printed in the collection of that ſociety, he publiſhed in 1731 the Theory of the Working of Ships, in one volume 4to; a work of conſiderable merit, which was tranſlated into Engliſh, and made the author be admitted into the Royal Society of London. In 1740, the ſtates-general of Languedoc made choice of him for their chief engineer, and gave him at the ſame time the appointment of inſpector general of the canal which unites the two ſeas. That province is indebted to him for ſeveral monuments of his genius, which will tranſmit his name with luſtre to poſterity. The city of Montpellier being in want of water, Pitot brought from the diſtance of three leagues two ſprings which furniſh a plentiful ſupply of that neceſſary article. They are brought to the magnificent Place du Peyron, and thence are diſtributed through the city. This aſtoniſhing work is the admiration of all ſtrangers. The illuſtrious marſhal de Saxe was the great patron and friend of Pitot, who had taught this hero the mathematics. In 1754 he was honoured with the order of St Michael. In 1735 he had married Maria-Leonina Pharambier de Subballoua, deſcended of a very ancient noble family of Navarre. By this marriage he had only one ſon, who was firſt advocate-general of the Court of Accounts, Aids, and Finances of Montpellier. Pitot was a practical philoſopher, and a man of uncommon probity and candour. He was alſo a member of the Royal Society of Sciences of Montpellier; and his eulogium was pronounced in 1772 by M. de Ratte perpetual ſecretary, in preſence of the ſtates of Languedoc; as it likewiſe was at the Royal Academy of Sciences of Paris by Abbé de Fouchi, who was then ſecretary.

PITS (John), the biographer, was born in 1560, at Aulton in Hampſhire, and educated at Wykeham's ſchool, near Wincheſter, till he was about 18 years of age; when he was ſent to New-college in Oxford, and admitted probationer fellow. Having continued in that univerſity not quite two years, he left the kingdom as a voluntary Romiſh exile, and retired to Douay; thence he went to the Engliſh college at Rheims, where he remained about a year; and then proceeded to Rome, where he continued a member of the Engliſh college near ſeven years, and was made a prieſt. In 1589 he returned to Rheims; and there, during two years, taught rhetoric and the Greek language. He now quitted Rheims on account of the civil war in France; and retired to Pont à Mouſſon in Lorrain, where he took the degrees of maſter of arts and bachelor in divinity. Hence he travelled into Germany, and reſided a year and a half at Triers, where he commenced licentiate in his faculty. From Triers he viſited ſeveral of the principal cities in Germany; and continuing three years at Ingoldſtadt in Bavaria, took the degree of doctor in divinity. Thence having made the tour of Italy, he returned once more to Lorrain; where he was patroniſed by the cardinal of that duchy, who preferred him to a canonry of Verdun; and about two years after he became confeſſor to the ducheſs of Cleves, daughter to the duke of Lorrain. During the leiſure he enjoyed in this employment, he wrote in Latin the lives of the kings, biſhops, apoſtolical men, and writers of England. The laſt of theſe, commonly known and quoted by this title, *De illuſtribus Angliæ ſcriptoribus*, was publiſhed after his death. The three firſt remain ſtill in manuſcript among the archives of the collegiate church of Liverdun. The duke of Cleves dying after Pits had been about twelve years confeſſor to the ducheſs, ſhe returned to Lorrain, attended by our author, who was promoted to the deanery of Liverdun, which, with a canonry and officialſhip, he enjoyed to the end of his life. He died in 1616, and was buried in the collegiate church. Pits was undoubtedly a ſcholar, and not an inelegant writer; but he is juſtly accuſed of ingratitude to Bale, from whom he borrowed his materials, without acknowledgment. He quotes Leland with great familiarity, without ever having ſeen his book: his errors are innumerable, and his partiality to the Romiſh writers moſt obvious; nevertheleſs we are obliged to him for his account of ſeveral popiſh authors, who lived abroad at the beginning of the Reformation.

Pitt.

PITT (Chriſtopher), an eminent Engliſh poet, celebrated for his excellent tranſlation of Virgil's Æneid, was born in the year 1699. Having ſtudied four years at New-college, Oxford, he was preſented to the living of Pimperne in Dorſetſhire, which he held during the remainder of his life. He had ſo poetical a turn, that while he was a ſchool-boy he wrote two large folios of manuſcript poems, one of which contained an entire tranſlation of Lucan. He was much eſteemed while at the univerſity; particularly by the celebrated Dr Young, who uſed familiarly to call him his *ſon*. Next to his fine tranſlation of Virgil, Mr Pitt gained the greateſt reputation by his excellent Engliſh tranſlation of Vida's art of poetry. This amiable poet died in the year 1648, without leaving, it is ſaid, one enemy behind him.

PITT (William) earl of Chatham, a moſt celebrated Britiſh ſtateſman and patriot, was born in November 1708. He was the youngeſt ſon of Robert Pitt, Eſq; of Boconnock in Cornwall; and grandſon of Thomas Pitt, Eſq; governor of Fort St George in the Eaſt Indies, in the reign of queen Anne, who ſold an extraordinary fine diamond to the king of France for 135,000 l. and thus obtained the name of *Diamond Pitt*. His intellectual faculties and powers of elocution very ſoon made a diſtinguiſhed appearance; but at the age of 16 he felt the attacks of an hereditary and incurable gout, by which he was tormented at times during the reſt of his life.

His lordſhip entered early into the army, and ſerved in a regiment of dragoons. Through the intereſt of the ducheſs of Marlborough he obtained a ſeat in parliament before he was 21 years of age. His firſt appearance in the houſe was as repreſentative of the borough of Old Sarum, in the ninth parliament of Great Britain. In the 10th he repreſented Seaford, Aldborough in the 11th, and the city of Bath in the 12th; where he continued till he was called up to the houſe of peers in 1766. The intention of the ducheſs in bringing him thus early into parliament was to oppoſe Sir Robert Walpole, whom he kept in awe by the force of his eloquence. At her death the ducheſs left him 10,000 l. on condition, as was then reported, that he never ſhould receive a place in adminiſtration.

Pitt. However, if any such condition was made, it certainly was not kept on his Lordship's part. In 1746 he was appointed vice-treasurer of Ireland, and soon after paymaster general of the forces, and sworn a privy-counsellor. He discharged the office of paymaster with such honour and inflexible integrity, refusing even many of the perquisites of his office, that his bittercst enemies could lay nothing to his charge, and he soon became the darling of the people. In 1755 he resigned the office of paymaster, on seeing Mr Fox preferred to him. The people were alarmed at this resignation; and being disgusted with the unsuccessful beginning of the war, complained so loudly, that, on the 4th December 1756, Mr Pitt was appointed secretary of state in the room of Mr Fox afterwards Lord Holland; and other promotions were made in order to second his plans. He then took such measures as were necessary for the honour and interest of the nation; but in the month of February 1757, having refused to assent to the carrying on a war in Germany for the sake of his majesty's dominions on the continent, he was deprived of the seals on the 5th of April following. Upon this the complaints of the people again became so violent, that on the 29th of June he was again appointed secretary, and his friends filled other important offices. The success with which the war was now conducted is universally known; yet on the 5th of October 1761, Mr Pitt, to the astonishment of almost the whole kingdom, resigned the seals into his majesty's own hands. The reason of this was, that Mr Pitt, having received certain intelligence that the family-compact was signed between France and Spain, and that the latter was about to join France against us, thought it necessary to prevent her by commencing hostilities first. Having communicated this opinion in the privy council, the other ministers urged that they would think twice before they declared war against that kingdom. "I will not give them leave to think (replied Mr Pitt); this is the time, let us crush the whole house of Bourbon. But if the members of this board are of a different opinion, this is the last time I shall ever mix in its councils. I was called into the ministry by the voice of the people, and to them I hold myself answerable for my conduct. I am to thank the ministers of the late king for their support; I have served my country with success; but I will not be responsible for the conduct of the war any longer than while I have the direction of it." To this bold declaration, the lord who then presided in council made the following reply. "I find the gentleman is determined to leave us; nor can I say that I am sorry for it, since he would otherwise have certainly compelled us to leave him. But if he is resolved to assume the right of advising his majesty, and directing the operations of the war, to what purpose are we called to this council? When he talks of being responsible to the people, he talks the language of the house of commons, and forgets that at this board he is responsible only to the king. However, though he may possibly have convinced himself of his infallibility, 'tis fit it remains that we should be equally convinced before we can resign our understandings to his direction, or join with him in the measure he propose."

This conversation, which was followed by Mr Pitt's resignation, is sufficient to show the haughtiness and imperious temper of our minister. However, these very qualities were sometimes productive of great and good consequences, as appears from the following anecdote. —Preparatory to one of the secret expeditions during the war which ended in 1763 the minister had given orders to the different presiding officers in the military, navy, and ordnance departments, to prepare a large body of forces, a certain number of ships, and a proportionable quantity of stores, &c. and to have them all ready against a certain day. To these orders he received an answer from each of the officers, declaring the total impossibility of a compliance with them. Notwithstanding it was then at a very late hour, he sent immediately for his secretary; and after expressing his resentment at the ignorance or negligence of his majesty's servants, he gave the following commands: —"I desire, Mr Wood, that you will immediately go to Lord Anson; you need not trouble yourself to search the admiralty, he is not to be found there; you must pursue him to the gaming house, and tell him from me, that if he does not obey the orders of government which he has received at my hands, that I will most assuredly impeach him. Proceed from him to Lord Ligonier; and though he should be bolstered with harlots, undraw his curtains, and repeat the same message. Then direct your course to Sir Charles Frederick, and assure him, that if his majesty's orders are not obeyed, they shall be the last which he shall receive from me." In consequence of these commands, Mr Wood proceeded to White's, and told his errand to the first lord of the admiralty; who insisted that the secretary of state was out of his senses, and it was impossible to comply with his wishes: "however, (added he), as madmen must be answered, tell him that I will do my utmost to satisfy him." From thence he went to the commander in chief of the forces, and delivered the same message. He also said that it was an impossible business; "and the secretary knows it, (added the old lord): nevertheless, he is in the right to make us do what we can; and what is possible to do, inform him, shall be done." The surveyor general of the ordnance was next informed of Mr Pitt's resolution; and, after some little consideration, he began to think that the orders might be completed within the time prescribed. The consequence at last was, that every thing, in spite of impossibilities themselves, was ready at the time appointed. Pitt.

After his resignation in 1761, Mr Pitt never had any share in administration. He received a pension of 3000l. a-year, to be continued after his decease, during the survivancy of his lady and son; and this gratuity was dignified with the title of *Baroness of Chatham* to his lady, and that of *Baron* to her heirs male. Mr Pitt at that time declined a title of nobility; but in 1766 accepted of a peerage under the title of *Baron Pynsent and Earl of Chatham*, and at the same time he was appointed lord privy-seal.

This acceptance of a peerage proved very prejudicial to his lordship's character. However, he continued stedfast in his opposition to the measures of administration. His last appearance in the House of Lords was on the 2d of April 1778. He was then very ill and much debilitated: but the question was important, being a motion of the duke of Richmond to address his majesty to remove the ministers, and make peace with America on any terms. His lord-

Pitt. ship made a long speech, which had certainly overcome his spirits: for, attempting to rise a second time, he fell down in a convulsive fit; and though he recovered for that time, his disorder continued to increase till the 11th of May, when he died at his seat at Hayes. His death was lamented as a national loss. As soon as the news reached the House of Commons, which was then sitting, Colonel Barré made a motion, that an address should be presented to his majesty, requesting that the Earl of Chatham should be buried at the public expence. But Mr Rigby having proposed the erecting of a statue to his memory, as more likely to perpetuate the sense of his great merits entertained by the public, this was unanimously carried. A bill was soon after passed, by which 4000l. a-year was settled upon John, now earl of Chatham, and the heirs of the late earl to whom that title may descend.—His lordship was married in 1754 to Lady Hesten, sister to the earl of Temple; by whom he had three sons and two daughters.

Never perhaps was any life so multifarious as that of Lord Chatham; never did any comprise such a number of interesting situations. To bring the scattered features of such a character into one point of view, is an arduous task. The author of the history of his life * has attempted to do it; and with the outlines of what he has said in summing up his character, we shall finish our biographical sketch of this wonderful man.

*History of the Life of William Pitt, Earl of Chatham.

"One of the first things that strikes us, in the recollection of Chatham's life, is the superior figure he makes among his cotemporaries. Men of genius and attraction, a Carteret, a Townshend, and I had almost said a Mansfield, however pleasing in a limited view, appear evidently in this comparison to shrink into narrower dimensions, and walk a humbler circle. All that deserves to arrest the attention, in taking a general survey of the age in which he lived, is comprised in the history of Chatham. No character ever bore the more undisputed stamp of originality. Unresembled and himself, he was not born to accommodate to the genius of his age. While all around him were depressed by the uniformity of fashion, or the contagion of venality, he stood aloof. He consulted no judgment but his own; and he acted from the untainted dictates of a comprehensive soul.

"The native royalty of his mind is eminently conspicuous. He felt himself born to command; and the free sons of Britain implicitly obeyed him. In him was realised the fable of Orpheus; and his genius, his spirit, his eloquence, led millions in his train, subdued the rugged savage, and disarmed the fangs of malignity and envy. Nothing is in its nature so inconsistent as the breath of popular applause: and yet that breath was eminently his during the greater part of his life. Want of success could not divert it; inconsistency of conduct could not change its tenor. The astonishing extent of his views, and the mysterious comprehension of his plans, did not in one respect set him above little things: nothing that was necessary to the execution of his designs was beneath him. In another respect, however, he was infinitely estranged to little things: swallowed up in the business of his country, he did not think of the derangement of his own private affairs; for, though indisposed to all the modes of dissipated expence, his affairs, even when his circumstances were much improved, were always deranged. But the features that seem most eminently to have characterised him, were spirit and intrepidity: they are conspicuous in every action and in every turn of his life; nor did this spirit and intrepidity leave him even at the last. Pitt.

"The manners of lord Chatham were easy and bland, his conversation was spirited and gay, and he readily adapted himself to the complexion of those with whom he associated. That artificial reserve, which is the never-failing refuge of self-diffidence and cowardice, was not made for him. He was unconstrained as artless infancy, and generous as the noon-day sun: yet had he something impenetrable that hung about him. By an irresistible energy of soul, he was haughty and imperious. He was incapable of associating councils, and he was not formed for the sweetest bands of society. He was a pleasing companion, but an unpliant friend.

"The ambition of our hero, however generous in its strain, was the source of repeated errors in his conduct. To the resignation of lord Carteret, and again, from the commencement of the year 1770, his proceedings were bold and uniform. In the intermediate period they were marked with a versatility, incident only in general to the most flexible minds. We may occasionally trace in them the indecision of a candidate, and the suppleness of a courtier. In a word, he aimed at the impossible task of flattering at once the prejudices of a monarch, and pursuing unremittedly the interests of the people.

"A feature, too, sufficiently prominent in his character, was vanity, or perhaps pride and conscious superiority. He dealt surely somewhat too freely with invective. He did not pretend to an ignorance of his talents, or to manage the display of his important services. Himself was too often the hero of his tale; and the successes of the last war the burden of his song‡. ‡ Ending in 1763.

"Patriotism was also the source of some of his imperfections. He loved his country too well; or, if that may sound absurd, the benevolence at least, that embraces the species, had not sufficient scope in his mind. He once styled himself *a lover of honourable war*; and in so doing he let us into one trait of his character. The friend of human kind will be an enemy to all war. He indulged too much a puerile antipathy to the house of Bourbon: and it was surely the want of expansive affections that led him to so unqualified a condemnation of American independency.

"But the eloquence of lord Chatham was one of his most striking characteristics. He far outstripped his competitors, and stood alone the rival of antiquity.

"His eloquence was of every kind. No man excelled him in close argument and methodical deduction: but this was not the style into which he naturally fell. His oratory was unlaboured and spontaneous: he rushed at once upon the subject; and usually illustrated it rather by glowing language and original conception, than by cool reasoning. His person was tall and dignified; his face was the face of an eagle; his piercing eye withered the nerves, and looked through the souls of his opponents; his countenance was stern, and the voice of thunder sat upon his lips: anon, however, he could descend to the easy and the playful. His voice seemed scarcely more adapted to energy and to terror, than

Pittacus. than it did to the melodious, the insinuating, and the sportive. If, however, in the enthusiasm of admiration, we can find room for the frigidity of criticism, his action seemed the most open to objection. It was forcible, uniform, and ungraceful. In a word, the most celebrated orators of antiquity were in a great measure the children of labour and cultivation. Lord Chatham was always natural and himself."

To the misfortune of the republic of letters, and of posterity, his lordship never sought the press. Lord Chesterfield says, "that he had a most happy turn for poetry: but it is more than probable that Chesterfield was deceived; for we are told by his biographer that his verses to Garrick were very meagre, and lord Chatham himself said that he seldom indulged and seldom avowed it. It should seem, then, that he himself set no great value upon it. Perhaps a proper confidence of one's self is essential to all extraordinary merit. Why should we ambitiously ascribe to one mind every species of human excellence? But though he was no poet, it is more than probable, that he would have excelled as much in writing prose as he did in speaking it.

PITTACUS, a native of Mitylene in Lesbos, was one of the seven wise men of Greece: his father's name was Hyrradius. With the assistance of the sons of Alcæus, he delivered his country from the oppression of the tyrant Melanchrus; and in the war which the Athenians waged against Lesbos, he appeared at the head of his countrymen, and challenged to single combat Phrynon the enemy's general. As the event of the war seemed to depend upon this combat, Pittacus had recourse to artifice; and when he engaged, he entangled his adversary in a net which he had concealed under his shield, and easily dispatched him. He was amply rewarded for this victory; and his countrymen, sensible of his merit, unanimously appointed him governor of their city with unlimited authority. In this capacity Pittacus behaved with great moderation and prudence; and after he had governed his fellow-citizens with the strictest justice, and after he had established and enforced the most salutary laws, he voluntarily resigned the sovereign power after having enjoyed it for 10 years, observing that the virtues and innocence of private life were incompatible with the power and influence of a sovereign. His disinterestedness gained him many admirers; and when the Mitylenеans wished to reward his public services by presenting him with an immense tract of territory, he refused to accept more land than what should be contained in the distance to which he could throw a javelin. He died in the 70th year of his age, about 579 years before Christ, after he had spent the last 10 years of his life in literary ease and peaceful retirement.

The following maxims and precepts are ascribed to Pittacus: The first office of prudence is to foresee threatening misfortunes, and prevent them. Power discovers the man. Never talk of your schemes before they are executed; lest, if you fail to accomplish them, you be exposed to the double mortification of disappointment and ridicule. Whatever you do, do it well. Do not that to your neighbour which you would take ill from him. Be watchful for opportunities.

Many of his maxims were inscribed on the walls of Apollo's temple at Delphi, to show to the world how great an opinion the Mityleneans entertained of his abilities as a philosopher, a moralist, and a man. By one of his laws, every fault committed by a man when intoxicated deserved double punishment. Pittenweem.

PITTENWEEM, a small town situated on the Frith of Forth, towards the eastern extremity of the county of Fife in North Britain. It takes its name from a small cave in the middle of it anciently called a *weem*, and is remarkable for nothing but the ruins of a religious house, which is sometimes called an *abbey* and sometimes a *priory*. Which of these is the proper denomination it is hardly worth while to inquire; but it appears from the arms of the monastery, still preserved over the principal gate, that the superior, by whatever title he was called, had the privilege of wearing a mitre. This edifice, which seems never to have been large, was, with other monuments of mistaken piety, alienated from the church at the Reformation; and what parts of it now remain are put to very different uses. Some of the cells of the monks furnish habitations tolerably convenient for the servants of him who, in the ceaseless change of property, has got possession of the lands which formerly belonged to them. That which seems to have been the granary is a decent parish church. The porch of the chapel, the only part of that building which exists, has been alternately employed as a stable and a slaughter-house; and the meat killed there has been commonly exposed to sale in the lower part of the steeple of that edifice which is now dedicated to the offices of parochial devotion. Had the moralizing traveller *, who composed the beautiful and pathetic meditation on the ruins of *Iona*, condescended to visit Pittenweem, he would not have viewed the abbey without emotion. Insignificant as the place at present is, it seems to have been of some consequence in the last century; and we are led to infer, from the following extract from the records, that the inhabitants were opulent, and that the town was fortified. * Johnson.

"Pittenweem, decimo quarto Feb. 1651. The bailies and council being convened, and having received information that his majesty is to be in progress with his court along the coast to morrow, and to stay at Anstruther house that night, have thought it expedient, according to their bounden duty, with all reverence and due respect, and with all the same solemnity they can, to wait upon his majesty, as he comes through this his majesty's burgh, and invite his majesty to eat and drink as he passes; and for that effect hath ordained, that the morn afternoon the town's colours be put upon the bertisene of the steeple, and that at three o'clock the bells begin to ring, and ring on still till his majesty comes hither, and passes to Anstruther: And sicklike, that the minister be spoken to, to be with the bailies and council, who are to be in their best apparel, and with them a guard of 24 of the ablest men, with partizans, and other 24 with muskets, all in their best apparel, William Sutherland commanding as captain of the guard; and to wait upon his majesty, and to receive his highness at the West Port, bringing his majesty and court through the town, until they come to Robert Smith's yeet, where an table is to be covered with my Lord's * best carpet: and that George Hetherwick have in readiness, of fine flour, some great bunns, and other wheat-bread of the best order, baken with * The Earl of Kelly.

Pittosporum || Pityocampasis.

with ſugar, cannell, and other ſpices fitting; and that James Richardſon and Walter Airth have care to have ready eight or ten gallons of good ſtrong ale, with Canary, ſack, Rheniſh wine, tent, white and claret wines, that his majeſty and his court may eat and drink; and that in the mean time, when his majeſty is preſent, the guard do diligently attend about the court; and ſo ſoon as his majeſty is to go away, that a ſign be made to Andrew Tod. who is appointed to attend the colours on the ſteeple head, to the effect he may give ſign to thoſe who attend the cannon of his majeſty's departure, and then the *haill thirty-ſix cannons to be all ſhot at once.* It is alſo thought fitting, that the miniſter, and James Richardſon the oldeſt bailie, when his majeſty comes to the table, ſhow the great joy and ſenſe this burgh has of his majeſty's condeſcendence to viſit the ſame, with ſome other expreſſions of loyalty. All which was acted." N. Lat. 56. 11. W. Long. 2. 49.

PITTOSPORUM, in botany; a genus of the monogynia order, belonging to the pentandria claſs of plants. The calyx is pentaphyllous, inferus and deciduous. The petals are five in number; the ſtyle thread-ſhaped; the capſule ſomewhat angular, trilocular, and contain three or four angulated ſeeds, adhering to the capſule by means of a liquid reſin in the loculaments. Of this there are three ſpecies, *viz.* 1. *Tenuifolium.* 2. *Umbellatum.* 3. *Coriaceum.* The firſt and ſecond are natives of the Cape of Good Hope; the third grows in Madeira, and flowers in May and June.

PITUITARY GLAND. See ANATOMY, p. 758.

PITYOCAMPASIS, in entomology, the caterpillar of the pine-tree, received its compound name from that ſubſtance. It was conſidered as a poiſon, and as a remedy, according to its different employment; but our chief information is derived from M. Reaumur, who has attentively obſerved its manner of life. The animal cannot bear much cold, and is therefore never found in the higher latitudes. It is ſtyled proceſſionary, becauſe it never leaves its hold, where many families reſide, till the evening, when it feeds in trains, led on by two or three, and this train leaves a ribband of ſilk in its way for thoſe behind follow exactly the ſteps of thoſe which preceded, and each leaves its fibre of ſilk. Their neſts are found in autumn; they are born the middle of September, become torpid in December, and recover their ſtrength again in ſpring. They then deſcend from the trees, plunge into the earth, and undergo their laſt change. It is the bombix pityocampa of Fabricius, (*Mantiſſa Inſector.* tom. ii. p. 114. n° 66.), and greatly reſembled the proceſſionary caterpillar of the oak. The ancients uſed it as a veſicatory, and the acrimony ſeems to reſide chiefly in a duſt which is concealed in receptacles on its back. This is its offenſive weapon, for it is thrown out at will, and produces very troubleſome effects, though the hair of the animal and every part of its body ſeem to have a ſimilar, but weaker power. The effect is alſo weaker in winter; but this may depend on the diminiſhed irritability of the human body, as well as on the torpid ſtate of the inſect. Their ſilk is not ſufficiently ſtrong for the loom, and in hot water melts almoſt to a paſte. In the earth it forms neſts of ſtronger ſilk, but it is then found with difficulty: in boxes its ſilk is extremely tender. Adding to all theſe inconveniencies, handling the cones produces all the bad effects of the duſt. Matthiolus recommends them as a ſtyptic, and perhaps they may ſerve for burning on the ſkin inſtead of moxa, the downy ſilk of a ſpecies of artemiſia. The ancients, afraid of its hurtful qualities, uſed them with caution, and enacted laws againſt their being ſold promiſcuouſly: the modern planter is chiefly afraid of them becauſe they deſtroy the beauty of his trees, and he endeavours to collect the eggs by cutting off the branches, which are burnt immediately.

Pivar, Pius.

PIVAT, or PIVOT, a foot or ſhoe of iron or other metal, uſually conical or terminating in a point, whereby a body, intended to turn round, bears on another fixed at reſt, and performs its revolutions. The pivot uſually bears or turns round in a ſole, or piece of iron or braſs hollowed to receive it.

PIUS II. (Æneas-Sylvius Piccolomini), was born on the 18th of October 1405, at Corſigni in Sieneſe, the name of which he afterwards changed into that of *Pienza.* His mother Victoria Forteguerra, when ſhe was with child of him, dreamed that ſhe ſhould be delivered of a mitred infant; and as the way of degrading clergymen at that time was by crowning them with a paper mitre, ſhe believed that Æneas would be a diſgrace to his family. But what to her had the appearance of being a diſgrace, was a preſage of the greateſt honours. Æneas was carefully educated, and made conſiderable proficiency in the belles lettres. After having finiſhed his ſtudies at Sienna, he went in 1431 to the council of Bale with Cardinal Capranica, ſurnamed *De Fermo,* becauſe he was entruſted with the government of that church. Æneas was his ſecretary, and was then only 26 years of age. He afterwards acted in the ſame capacity to ſome other prelates, and to Cardinal Albergati. The council of Bale honoured him with different commiſſions, in order to recompenſe him for the zeal with which he defended that aſſembly againſt Pope Eugene IV. He was afterwards ſecretary to Frederic III. who decreed to him the poetic crown, and ſent him ambaſſador to Rome, Milan, Naples, Bohemia, and other places. Nicolas V. advanced him to the biſhopric of Trieſte, which he quitted ſome time after for that of Sienna. At laſt, after having diſtinguiſhed himſelf in various nunciatures, he was inveſted with the Roman purple by Calixtus III. whom he ſucceeded two years after on the 27th of Auguſt 1458. Pius II. now advanced to the holy ſee, made good the proverb, *Honores mutant mores.* From the commencement of his pontificate, he appeared jealous of the papal prerogatives. In 1460 he iſſued a bull, "declaring appeals from the pope to a council to be null, erroneous, deteſtable, and contrary to the ſacred canons." That bull, however, did not prevent the procurator-general of the parliament of Paris from appealing to a council in defence of the Pragmatic ſanction, which the pope had ſtrenuouſly oppoſed. Pius was then at Mantua, whither he had gone in order to engage the Catholic princes to unite in a war againſt the Turks. The greater part of them agreed to furniſh either troops or money; others refuſed both, particularly the French, who from that moment incurred his holineſs's averſion. That averſion abated under Louis XI. whom he perſuaded in 1461 to aboliſh the Pragmatic ſanction, which the parliament of Paris had ſupported with ſo much vigour.

The following year, 1462, was rendered famous by

Pius. a controverſy which took place between the Cordeliers and Dominicans, whether or not the blood of Jeſus Chriſt was ſeparated from his body while he lay in the grave. It was alſo made a queſtion whether it was ſeparated from his divinity. The Cordeliers affirmed that it was, but the Dominicans were of an oppoſite opinion. They called each other heretics; which obliged the pope to iſſue a bull, forbidding them under pain of cenſure to brand one another with ſuch odious epithets. The bull which his holineſs publiſhed on the 26th of April, retracting what he had written to the council of Bale when he was its ſecretary, did not redound much to his honour. "I am a man (ſays he), and as a man I have erred. I am far from denying that a great many things which I have ſaid and written may deſerve condemnation. Like Paul, I have preached through deception, and I have perſecuted the church of God through ignorance. I imitate the bleſſed Auguſtin, who having ſuffered ſome erroneous ſentiments to creep into his works, retracted them. I do the ſame thing; I frankly acknowledge my ignorances, from a fear leſt what I have written in my younger years ſhould be the occaſion of any error that might afterwards be prejudicial to the intereſts of the holy ſee. For if it be proper for any one to defend and ſupport the eminence and glory of the firſt throne of the church, it is in a peculiar manner my duty, whom God, out of his mercy and goodneſs alone, without any merit on my part, has raiſed to the dignity of *vicar of Jeſus Chriſt*. For all theſe reaſons, we exhort and admoniſh you in the Lord, not to give credit to thoſe writings of ours which tend in any degree to hurt the authority of the apoſtolic ſee, and which eſtabliſh opinions that are not received by the Roman church. If you find, then, any thing contrary to her doctrine either in our dialogues, in our letters, or in any other of our works, deſpiſe theſe opinions, reject them, and adopt our preſent ſentiments. Believe me rather now that I am an old man, than when I addreſſed you in my earlier days. Eſteem a ſovereign pontiff more than a private perſon; except againſt Æneas Sylvius, but receive Pius II." It might be objected to his holineſs, that it was his dignity alone which had made him alter his opinion. He anticipates that objection, by giving a ſhort account of his life and actions, with the whole hiſtory of the council of Bale, to which he went with Cardinal Capranica in 1431; "but (ſays he) I was then a young man, and without any experience, like a bird juſt come from its neſt." In the mean time, the Turks were threatening Chriſtendom. Pius, ever zealous in the defence of religion againſt the infidels, forms the reſolution of fitting out a fleet at the expence of the church, and of paſſing over into Aſia himſelf, in order to animate the Chriſtian princes by his example. He repaired to Ancona with a deſign to embark; but he there fell ſick with the fatigue of the journey, and died on the 16th of Auguſt 1464, aged 59 years. Pius was one of the moſt learned men of his time, and one of the moſt zealous pontiffs; but being of an ambitious and pliant diſpoſition, he ſometimes ſacrificed to that ambition. His principal works are, 1. Memoirs of the council of Bale, from the ſuſpenſion of Eugenius to the election of Felix. 2. The hiſtory of the Bohemians, from their origin to the year 1458. 3. Two books on coſmography. 4. The hiſtory of Frederic III. whoſe vice-chancellor he had been. This performance was publiſhed in 1785 in folio, and is believed to be pretty accurate and very particular. 5. A treatiſe on the education of children. 6. A poem upon the paſſion of Jeſus Chriſt. 7. A collection of 432 letters, printed at Milan, 1473, in folio, in which are found ſome curious anecdotes. 8. The memoirs of his own life, publiſhed by John Gobelin Perſonne his ſecretary, and printed at Rome in 4to in 1584. There is no doubt of this being the genuine production of that pontiff. 9. *Hiſtoria rerum ubicumque geſtarum*, of which only the firſt part was publiſhed at Venice in 1477 in folio. His works were printed at Helmſtadt in 1700, in folio, at the beginning of which we find his life. That verſe of Virgil's Æneid (lib. i. v. 382.) which begins thus,

Sum pius Æneas, ——— ———

and the end of the following verſe,

——— ———*fama ſuper æthera notus,*

have been applied to him. Pius.

Pius IV. (John Angel Cardinal de Medicis), of a different family from that of Florence, was born at Milan in 1499. He was ſon to Bernardin Medechini, and brother of the famous Marquis de Marignan, Charles Vth's general. He raiſed himſelf by his own merit, and filled ſeveral important offices under Popes Clement VII. and Paul III. Julius III. who had entruſted him with ſeveral legations, honoured him with a cardinal's hat in 1549. After the death of Paul IV. he was advanced to St Peter's chair on the 25th of December 1559. His predeceſſor had rendered himſelf deteſtable to the Romans, who treated his memory with every mark of indignity, and Pius IV commenced his pontificate by pardoning them. He did not, however, extend the ſame clemency to the nephews of Pope Paul IV.; for he cauſed Cardinal Caraffe to be ſtrangled in the caſtle of St Angel, and his brother, the Prince de Palliano, to be beheaded. His zeal was afterwards directed againſt the Turks and heretics. In order to ſtop, if poſſible, the progreſs of theſe laſt, he renewed the Council of Trent, which had been ſuſpended. He knew well (ſays Abbé de Choiſy), that that council might make ſome regulations which would have the effect to leſſen his authority; but on the other hand, he perceived that great inconveniences might reſult from its not being aſſembled; and "*in the main* (ſaid he to his confidents) *it is better to feel evil for once than to be always in dread of it.*" In 1561 he diſpatched nuncios to all the Catholic and Proteſtant princes, to preſent them with the bull for calling that important aſſembly. An end was, however, put to it by the induſtry of his nephew, S. Charles Borromeus, in 1563; and, on the 26th of January the year following, he iſſued a bull for confirming its decrees. In 1565 a conſpiracy was formed againſt his life by Benedict Acolti, and ſome other viſionaries. Thoſe madmen had taken it into their head that Pius IV. was not a lawful Pope, and that after his death they would place another in St Peter's chair, with the title of *Pope Angelicus*, under whom errors might be reformed, and peace reſtored to the church. The conſpiracy was diſcovered, and the fanatic Benedict put to death. This pontiff died a little

Pius. the time after, on the 9th of December 1565, aged 66 years, carrying to the grave with him the hatred of the Romans, whom his severities had exasperated. He was a man of great address, and very fruitful in his resources. He adorned Rome with several public edifices; but these ornaments tended greatly to impoverish it. If he was the instrument of raising his relations in the world, it must be allowed, at least, that the greater part of them did him honour.

Pius V. (S. Michael Ghisleri), born at Bosehi or Bosco, in the diocese of Fortona, on the 17th of January 1504, was, according to Abbé de Choisy, son to a senator of Milan. He turned a Dominican friar. Paul IV. informed of his merit and virtue, gave him the bishopric of Sutri, created him cardinal in 1557, and made him inquisitor-general of the faith among the Milanese and in Lombardy; but the severity with which he exercised his office obliged him to quit that country. He was sent to Venice, where the ardour of his zeal met with still greater obstacles. Pius IV. added to the cardinal's hat the bishopric of Mondovi. After the death of that pontiff, he was advanced to St Peter's chair in 1566. The Romans expressed but little joy at his coronation: he was very sensible of it, and said, "*I hope they will be as sorry at my death as they are at my election*;" but he was mistaken. Raised by his merit to the first ecclesiastical preferment in Christendom, he could not divest himself of the severity of his character; and the situation in which he found himself rendered, perhaps, that severity necessary. One of his first objects was to repress the luxury of the clergy, the pride of the cardinals, and the licentious manners of the Romans. He caused the decrees of reformation enacted by the Council of Trent to be put in execution; he prohibited bull-baiting in the Circus; he expelled from Rome the women of the town; and allowed the cardinals to be prosecuted for their debts. The errors which overflowed the Christian world gave him great uneasiness. After having employed gentle and lenient measures in the reclaiming of heretics, he had recourse to severity, and some of them ended their days in the flames of the inquisition. He particularly displayed his zeal for the grandeur of the Holy See in 1568, by ordaining that the bull *In cœna domini*, which was published at Rome every year on *Maunday Thursday*, and which Clement XIV. suppressed, should be published likewise throughout the whole church. That bull, the work of several sovereign pontiffs, principally regards the jurisdiction of the ecclesiastical and civil power. It anathematizes those who appeal from the decrees of popes to a general council; those who favour the appellants; the universities which teach that the pope is subject to a general council; the princes who would restrain the ecclesiastical jurisdiction, or who exact contributions from the clergy. It was rejected by all the sovereign states, excepting a very few. In 1580, some bishops having endeavoured to introduce it into their dioceses, the parliament caused their temporalities to be seized upon, and declared those guilty of high treason who should imitate the fanaticism of those prelates. Pius V. for some time meditated an expedition against the Turks. He had the courage to make war on the Ottoman empire, by forming a league with the Venetians and Philip II. king of Spain. This was the first time that the standard of the two keys was seen displayed against the crescent. The naval armies came to an engagement, on the 7th of October 1571, in Lepanto Bay, in which the confederate Christian princes obtained a signal victory over the Turks, who lost above 30,000 men, and near 200 galleys. This success was principally owing to the Pope, who exhausted both his purse and person in fitting out that armament. He died of the gravel six months after, on the 30th of April 1572, aged 68. He repeated often, in the midst of his sufferings, "*O Lord! increase my pains and my patience.*" His name will for ever adorn the list of Roman pontiffs. It is true that his bull against queen Elisabeth, and his other bull in favour of the inquisition, with his rigorous prosecution of heretics both in France and Ireland, prove that he had more zeal than sweetness in his temper; but in other respects he possessed the virtues of a saint and the qualities of a king. He was the model of the famous Sixtus Quintus, to whom he gave an example of amassing in a few years such savings as were sufficient to make the Holy See be regarded as a formidable power. Sultan Selim, who had no greater enemy than this pope, caused public rejoicings to be made at Constantinople for his death during the space of three days. The pontificate of Pius is also celebrated for the condemnation of Baius, the extinction of the order of Humilies, and the reformation of that of the Cistercians. He was canonized by Clement XI. in 1712. There are extant several of his letters, printed at Anvers in 1640, in 4to. Felibian, in 1672, published his *Life*, translated from the Italian of Agatio di Somma; but we cannot vouch for the fidelity of the translation.

PIX. See *Mint-Marks*.

PIZARRO (Francis), a celebrated Spanish general, the discoverer and conqueror of Peru, in conjunction with Diego Almagro, a Spanish navigator. They are both charged with horrid cruelties to the inhabitants; and they fell victims to their own ambition, jealousy, and avarice. Almagro revolting, was defeated and beheaded by Pizarro, who was assassinated by Almagro's friends in 1541. See Peru.

PLACE, locus, in philosophy, a mode of space, or that part of immoveable space which any body possesses. See Metaphysics, n° 185.

Place, in astronomy. The place of the sun, a star, &c. denotes the sign and degree of the zodiac which the luminary is in; or the degree of the ecliptic, reckoning from the beginning of aries, which the planet or star's circle of longitude cuts: and therefore coincides with the longitude of the sun, planet, or star. As the sine of the sun's greatest declination 23° 30′ : to the sine of any present declination given or observed, for instance, 23° 15′ :: so is the radius 10 : to the sine of his longitude 81° 52′; which, if the declination were north, would give 20° 52′ of gemini; if south, 20° 52′ of capricorn, for the sun's place. See Declination, &c.

The place of the moon being that part of her orbit wherein she is found at any time, is of various kinds, by reason of the great inequalities of the lunar motions, which render a number of equations and reductions necessary before the just point be found. The moon's fictitious place is her place once equated; her place nearly true, is her place twice equated; and her true place thrice equated. See Astronomy, *passim*.

Place, in war, a general name for all kinds of fortresses

Place || Placentia.

treſſes where a party may defend themſelves. Thus, 1. A ſtrong or fortified place is one flanked, and covered with baſtions. 2. A regular place, one whoſe angles, ſides, baſtions, and other parts, are equal; and this is uſually denominated from the number of its angles, as a pentagon, hexagon, &c. 3. Irregular place is one whoſe ſides and angles are unequal.— 4. Place of arms is a ſtrong city or town pitched upon for the chief magazine of an army; or, in a city or garriſon, it is a large open ſpot of ground, uſually near the centre of the place where the grand guard is commonly kept, and the garriſon holds its rendezvous at reviews, and in caſes of alarm to receive orders from the governor. 5. Places of arms of an attack, in a ſiege, is a ſpacious place covered from the enemy by a parapet or epaulement, where the ſoldiers are poſted ready to ſuſtain thoſe at work in the trenches againſt the ſoldiers of the garriſon. 6. Place of arms particular, in a garriſon, a place near every baſtion, where the ſoldiers ſent from the grand place to the quarters aſſigned them relieve thoſe that are either upon the guard or in ſight. 7. Place of arms without, is a place allowed to the covert way for the planting of cannon, to oblige thoſe who advance in their approaches to retire. 8. Place of arms in a camp, a large place at the head of the camp for the army to be ranged in and drawn up in battalia. There is alſo a place for each particular body, troop, or company, to aſſemble in.

Common Place. See *Common-Place.*

PLACENTA, in anatomy and midwifery, a ſoft roundiſh maſs, found in the womb of pregnant women; which, from its reſemblance to the liver, was called by the ancients *hepar uterinum*, uterine liver.

PLACENTIA, called by the natives *Piacenza*, is a town of Italy, and capital of a duchy of the ſame name, with a biſhop's ſee. It is ſeated about 100 paces from the river Po, in a very fertile pleaſant plain, watered by a great number of rivulets, and ſurrounded with hills, abounding in all ſorts of fruits. In its territory there are ſalt ſprings, from which they make a very white ſalt; and there are alſo mines of iron, woods, and warrens. It contains a great number of merchants, and is reckoned three miles in circumference. Its fortifications are inconſiderable, but the citadel is pretty ſtrong. The ſtreets are ſtraight, and the principal ſtreet, called *Stradone*, is 25 common paces broad and 3000 feet long, in a direct line, with 600 ſtone poſts, for ſeparating the foot from the carriage-way, and on both ſides are 11 ſpacious convents. The other buildings of the city are not very remarkable, though it contains 45 churches, 28 convents, and two alms-houſes. The cathedral is pretty much in the Gothic taſte; but the church of the Auguſtines is reckoned the moſt beautiful, and eſteemed worthy of its architect, the celebrated Vignoli. The ducal palace, though large, makes no great appearance on the outſide; but within are ſome good apartments. In the area before the town-houſe ſtands two admirable braſs ſtatues of Alexander and Renatus IV. both of the houſe of Farneſe, and dukes of Parma and Placentia. The biſhop is ſuffragan to the archbiſhop of Milan. At this city begins the Via Æmilia, which extends as far as Rimini on the Adriatic. The number of the inhabitants is about 30,000, among whom there are 2000 eccleſiaſtics. This city has been taken ſeveral times in the wars of Italy. The king of Sardinia took poſſeſſion of it in 1744, it being ceded to him by the queen of Hungary; but it was taken from him in 1746, after a bloody battle. It has a famous univerſity, and the inhabitants are much eſteemed for their politeneſs. There is a great fair here every year on the 15th of April, which is much frequented. It is about 32 miles north-weſt of Parma and 83 eaſt of Turin. E. Long. 10. 24. N. Lat. 45. 5.

Plagiary || Plague.

PLAGIARY, in philology, the purloining another man's works, and putting them off as our own. Among the Romans, *plagiarius* was properly a perſon who bought, ſold, or retained a freeman for a ſlave; and was ſo called, becauſe, by the Flavian law, ſuch perſons were condemned *ad plagas*, "to be whipped."

Thomaſius has an expreſs treatiſe *De plagio literario*; wherein he lays down the laws and meaſures of the right which authors have to one another's writings.— "Dictionary-writers, at leaſt ſuch as meddle with *arts and ſciences* (as is pertinently obſerved by Mr Chambers), ſeem exempted from the common laws of *meum* and *tuum*; they do not pretend to ſet up on their own bottom, nor to treat you at their own coſt. Their works are ſuppoſed, in great meaſure, compoſitions of other peoples; and what they take from others, they do it avowedly, and in the open fun.—In effect, their quality gives them a title to every thing that may be for their purpoſe, wherever they find it; and if they rob, they do not do it any otherwiſe than as the bee does, for the public ſervice. Their occupation is not pillaging, but collecting contributions; and if you aſk them their authority, they will produce you the practice of their predeceſſors of all ages and nations."

PLAGIUM, in law. See Kidnapping.

PLAGUE, Pestilence, or *Peſtilential Fever*, is a very acute, malignant, and contagious diſeaſe; being a putrid fever of the worſt kind, and ſeldom failing to prove mortal. Though it is generally defined a malignant fever, Diemerbrock thinks they ought to be diſtinguiſhed, ſince the fever is not the eſſence of the diſeaſe, but merely a ſymptom or effect of it. See Medicine, n° 221.

The plague, as is generally agreed, is never bred or propagated in Britain, but always imported from abroad, eſpecially from the Levant, Leſſer Aſia, Egypt, &c. where it is very common. Sydenham has remarked that it rarely infeſts this country oftener than once in 40 years, and happily we have been free of it for a much longer period.

Authors are not as yet agreed concerning the nature of this dreadful diſtemper. Some think that inſects are the cauſe of it, in the ſame way that they are the cauſe of blights, being brought in ſwarms from other climates by the wind, when they are taken into the lungs in reſpiration; the conſequence of which is, that they mix with the blood and juices, and attack and corrode the viſcera. Mr Boyle, on the other hand, thinks it originates from the effluvia or exhalations breathed into the atmoſphere from noxious minerals, to which may be added ſtagnant waters and putrid bodies of every kind.

Mr Gibbon thinks that the plague is derived from damp, hot, and ſtagnating air, and the putrefaction

Plague. of animal ſubſtances, eſpecially locuſts. See *Gibbon's Roman Hiſtory*, 4to edit. vol. iv. p. 327—332, where there is alſo a very particular account of the plague which depopulated the earth in the time of the Emperor Juſtinian. Plague.

The Mahometans believe that the plague proceeds from certain ſpirits, or goblins, armed with bows and arrows, ſent by God to puniſh men for their ſins; and that when the wounds are given by ſpectres of a black colour, they certainly prove fatal, but not ſo when the arrows are ſhot by thoſe that appear white. They therefore take no precaution to guard themſelves againſt it. The wiſer profeſſors of this religion, however, at preſent act otherwiſe; for we find a receipt recommended by Sidy Mohammed Zerroke, one of the moſt celebrated Marabout's, prefaced with theſe remarkable words: "The lives of us all are in the hands of God, when it is we muſt die. However, it hath pleaſed him to ſave many perſons from the plague, by taking every morning while the infection rages one pill or two of the following compoſition; *viz.* of myrrh two parts, ſaffron one part, of aloes two parts, of ſyrup of myrtle-berries, *q. ſ.* But this remedy is confined to the more enlightened; for the bigotry of the lower ſort is ſo extreme as to make them deſpiſe all precautions which people of other nations uſe. Of this extreme and fooliſh prejudice Dr Chandler gives an intereſting account when ſpeaking of the plague at Smyrna. This learned author is of opinion that the diſeaſe ariſes from animalcules, which he ſuppoſes to be inviſible. See *Chandler's Travels in Aſia Minor*, p. 279, &c.

It is a remarkable fact, that *plagues* are ſometimes partial, and that they only attack particular animals, or a particular deſcription of perſons, avoiding others altogether, or attacking them but ſlightly. Thus Fernelius informs us of a plague, or murrain, in 1514, which invaded only cats. Dionyſius Halicarnaſſeus mentions a plague which attacked none but maids; and that which raged in the time of Gentilis, killed ſcarce any women, and very few but luſty men. Boterus mentions another plague, which aſſaulted none but the younger ſort; and we have inſtances of the ſame kind of a later ſtanding (A). Cardan ſpeaks of a plague at Baſil, with which the Switzers were infected, and the Italians, Germans, or French, exempted: and John Utenhovius takes notice of a dreadful one at Copenhagen, which, tho' it raged among the Danes, ſpared the Germans, Dutch, and Engliſh, who went with all freedom, and without the leaſt danger, to the houſes of the infected. During the plague which ravaged Syria in 1760, it was obſerved that people of the ſoundeſt conſtitutions were the moſt liable to it, and that the weak and delicate were either ſpared or eaſily cured. It was moſt fatal to the Moors; and when it attacked them it was generally incurable.

When the plague raged in Holland in 1636, a young girl was ſeized with it, had three carbuncles, and was removed to a garden, where her lover, who was betrothed to her, attended her as a nurſe, and ſlept with her as his wife. He remained uninfected, and ſhe recovered, and was married to him. The ſtory is related by Vinc. Fabricius in the *Miſc. Cur. Ann. II. Obſ.* 188.

Many methods have been adopted in different countries to prevent the importation of this dreadful ſcourge of the human race, and to ſtop the progreſs of infection after it has been imported. In England, mayors, bailiffs, head officers of corporations, and juſtices of peace, have power to tax inhabitants, houſes, and lands, &c. within their precincts, for the relief of perſons infected with the plague; and juſtices of the county may tax perſons within five miles round, on a pariſh's inability; the tax to be levied by diſtreſs and ſale of goods, or in default thereof by impriſonment. Infected perſons going abroad, after being commanded to keep houſe for avoiding farther infection, may be reſiſted by watchmen, &c. and puniſhed as vagrants, if they have no ſores upon them; and if they have infectious ſores on them it is felony. Juſtices of peace, &c. are to appoint ſearchers, examiners, and buriers of the dead, in places infected, and adminiſter oaths to them for the performance of their duties, &c. *Stat.* 1 *Jac.* 1. *cap.* 31. See QUARANTINE.

The commiſſion at Moſcow having, in the year 1770, invented a fumigation-powder, which, from ſeveral leſſer experiments, had proved efficacious in preventing the infection of the plague; in order more fully to aſcertain its virtue in that reſpect, it was determined, towards the end of the year, that ten malefactors under ſentence of death ſhould, without undergoing any other precautions than the fumigations, be confined three weeks in a lazaretto, be laid upon the beds, and dreſſed in the clothes, which had been uſed by perſons ſick, dying, and even dead, of the plague in the hoſpital. The experiment was accordingly tried, and none of the ten malefactors were then infected, or have been ſince ill. The fumigation-powder is prepared as follows.

Powder of the firſt ſtrength.] Take leaves of juniper, juniper-berries pounded, ears of wheat, guaiacum-wood pounded, of each ſix pounds; common ſaltpetre pounded, eight pounds; ſulphur pounded, ſix pounds; Smyrna tar, or myrrh, two pounds; mix all the above ingredients together, which will produce a pood of the powder of fumigation of the firſt ſtrength. [*N. B.* A pood is 40 pounds Ruſſian, which are equal to 35 pounds and a half or 36 pounds Engliſh avoirdupoiſe.]

Powder of the ſecond ſtrength.] Take ſouthern-wood cut into ſmall pieces, four pounds; juniper-berries pounded, three pounds; common ſaltpetre pounded, four pounds; ſulphur pounded, two pounds and a half; Smyrna tar, or myrrh, one pound and a half: mix the above together, which will produce half a pood of the powder of fumigation of the ſecond ſtrength.

Odoriferous powder.] Take the root called *kalmus* cut into ſmall pieces, three pounds; leaves of juniper cut into ſmall pieces, four pounds; frankincenſe pounded groſsly, one pound; ſtorax pounded, and roſe-flowers, half a pound; yellow amber pounded, one pound; common ſaltpetre pounded, one pound and a half; ſulphur, a quarter of a pound: mix all the above

(A) See the account of the *yellow fever* under the article PHILADELPHIA, where we find that that diſeaſe was leſs fatal to ſome ſorts of perſons than to others.

Plague. above together, which will produce nine pounds and three quarters of the odoriferous powder.

Remark on the powder of fumigation.] If guaiacum cannot be had, the cones of pines or firs may be uſed in its ſtead; likewiſe the common tar of pines and firs may be uſed inſtead of the Smyrna tar, or myrrh, and mugwort may ſupply the place of ſouthernwood.

Thucydides, who was himſelf infected, lib. ii. gives us an account of a dreadful plague which happened at Athens about the year before Chriſt 430, while the Peloponneſians under the command of Archidamus waſted all her territory abroad; but of theſe two enemies the plague was by far the moſt dreadful and ſevere.

The moſt dreadful plague that ever raged at Rome was in the reign of Titus, A. D. 80. The emperor left no remedy unattempted to abate the malignity of the diſtemper, acting during its continuance like a father to his people. The ſame fatal diſeaſe raged in all the provinces of the Roman empire in the reign of M. Aurelius, A. D. 167, and was followed by a dreadful famine, by earthquakes, inundations, and other calamities. The Romans believed that Æſculapius ſometimes entered into a ſerpent, and cured the plague.

About the year 430 the plague viſited Britain, juſt after the Picts and Scots had made a formidable invaſion of the ſouthern part of the iſland. The plague raged with uncommon fury, and ſwept away moſt of thoſe whom the ſword and famine had ſpared, ſo that the living were ſcarce ſufficient to bury the dead.

About the year 1348 the plague became almoſt general over Europe. A great many authors give an account of this plague, which is ſaid to have appeared firſt in the kingdom of Kathay in the year 1346, and to have proceeded gradually weſtward to Conſtantinople and Egypt. From Conſtantinople it paſſed into Greece, Italy, France, and Africa, and by degrees along the coaſts of the ocean into Britain and Ireland, and afterwards into Germany, Hungary, Poland, Denmark, and the other northern kingdoms. According to Antoninus archbiſhop of Florence the diſtemper carried off 60,000 people in that city, among whom was the hiſtorian John Villani.

In the year 1656 the plague was brought from Sardinia to Naples, being introduced into the city by a tranſport with ſoldiers on board. It raged with exceſſive violence, carrying off in leſs than ſix months 400,000 of the inhabitants. The diſtemper was at firſt called by the phyſicians a malignant fever; but one of them affirming it to be peſtilential, the viceroy, who was apprehenſive leſt ſuch a report would occaſion all communication with Naples to be broke off, was offended with this declaration, and ordered him to be impriſoned. As a favour, however, he allowed him to return and die in his own houſe. By this proceeding of the viceroy, the diſtemper being neglected, made a moſt rapid and furious progreſs, and filled the whole city with conſternation. The ſtreets were crowded with confuſed proceſſions, which ſerved to ſpread the infection through all the quarters. The terror of the people increaſed their ſuperſtition; and it being reported that a certain nun had propheſied that the peſtilence would ceaſe upon building a hermitage for her ſiſter nuns upon the hill of St Martin's, the edifice was immediately begun with the moſt ardent zeal. Perſons of the higheſt quality ſtrove who ſhould perform the meaneſt offices; ſome loading themſelves with Plague. beams, and others carrying baſkets full of lime and nails, while perſons of all ranks ſtripped themſelves of their moſt valuable effects, which they threw into empty hogſheads placed in the ſtreets to receive the charitable contributions. Their violent agitation, however, and the increaſing heats, diffuſed the malady through the whole city, and the ſtreets and the ſtairs of the churches were filled with the dead; the number of whom, for ſome time of the month of July, amounted daily to 15,000.

The viceroy now uſed all poſſible precautions to abate the fury of the diſtemper, and to prevent its ſpreading to the provinces. The infection, however, deſolated the whole kingdom, excepting the provinces of Otranto and the Farther Calabria, and the cities of Gaeta, Sorrento, Paolo, and Belvedere. The general calamity was increaſed in Naples by malecontents, who inſinuated that the diſtemper had been deſignedly introduced by the Spaniards, and that there were people in diſguiſe who went through the city ſowing poiſoned duſt. This idle rumour enraged the populace, who began to inſult the Spaniſh ſoldiers, and threaten a ſedition; ſo that the viceroy, to pacify the mob, cauſed a criminal to be broke upon the wheel, under pretence that he was a diſperſer of the duſt. A violent and plentiful rain falling about the middle of Auguſt, the diſtemper began to abate; and on the eighth of December the phyſicians made a ſolemn declaration that the city was entirely free from infection.

Of the dreadful plague which raged at London in the year 1665, the reader will find an account in the article LONDON, n° 21. In 1720 the city of Marſeilles was viſited with this deſtructive diſeaſe, brought in a ſhip from the Levant; and in ſeven months, during which time it continued, it carried off not leſs than 60,000 people. This deſolation is not yet obliterated from the minds of the inhabitants; ſome ſurvivors remained alive but a few years ago to tranſmit a traditional account of it to after ages. There are two fine pictures painted by Puget repreſenting ſome of the horrid ſcenes of that time. "They are (ſays lady Craven) only too well executed. I ſaw ſeveral dying figures taking leave of their friends, and looking their laſt anxious, kind, and wiſhful prayers on their ſick infants, that made the tears flow down my cheeks. I was told the phyſicians and noblemen who were aſſiſting the ſick and dying, were all portraits: I can eaſily conceive it; for in ſome faces there is a look of reflection and concern which could only be drawn from the life." *Letters*, p. 34, 35. This fatal event has cauſed the laws of quarantine to be very ſtrictly enforced in the Lazaretto here, which is an extenſive inſulated building.

The ravages of this diſeaſe have been dreadful wherever it has made its appearance. On the firſt arrival of the Europeans at the iſland of Gran Canaria, it contained 14,000 fighting men, ſoon after which, two thirds of the whole inhabitants fell a ſacrifice to the plague, which had doubtleſs been introduced by their new viſitors. The deſtruction it has made in Turkey in Europe, and particularly in Conſtantinople, muſt be known to every reader; and its fatal effects have been particularly heightened there by that firm belief which prevails among the people of predeſtination, &c. as has been already mentioned. It is generally

Plain || Plancus.

brought into European Turkey from Egypt; where it is very frequent, eſpecially at *Grand Cairo*. To give even a liſt of all the plagues which have deſolated many flouriſhing countries, would extend this article beyond all bounds, and minutely to deſcribe them all would be impoſſible. For the plague at Smyrna, we refer to Chandler's Travels as above. Reſpecting that which raged in Syria in 1760, we refer to the Abbé Mariti's Travels through Cyprus, Syria, and Paleſtine, vol. 1ſt, p. 278—296. This plague was one of the moſt malignant and fatal that Syria ever experienced; for it ſcarcely made its appearance in any part of the body when it carried off the patient.

PLAIN, or PLANE, in general, an appellation given to whatever is ſmooth and even, or ſimple, obvious, and eaſy to be underſtood; and, conſequently, ſtands oppoſed to rough, enriched, or laboured.

A plain figure, in geometry, is an uniform ſurface; from every point of whoſe perimeter right lines may be drawn to every other point in the ſame.

A plain angle is one contained under two lines, or ſurfaces, in contradiſtinction to a ſolid angle. See ANGLE.

The doctrine of plain triangles, as thoſe included under three right lines, is termed *plain trigonometry*. See the article TRIGONOMETRY.

PLAIN Chart. See the article CHART.

PLAIN-Sailing. See NAVIGATION, p. 685.

PLAISE, the Engliſh name of a ſpecies of pleuronectes. See PLEURONECTES.

PLAN, in general, denotes the repreſentation of ſomething drawn on a plane; ſuch are maps, charts, ichnographies, &c. See MAP, CHART, &c.

The term *plan*, however, is particularly uſed for a draught of a building, ſuch as it appears, or is intended to appear, on the ground, ſhowing the extent, diviſion, and diſtribution of its area or ground-plot into apartments, rooms, paſſages, &c.

A geometrical plan is that wherein the ſolid and vacant parts are repreſented in their natural proportions.

The raiſed plan of a building is the ſame with what is otherwiſe called an *elevation* or *orthography*. See ORTHOGRAPHY.

A perſpective plan is that exhibited by degradations or diminutions, according to the rules of perſpective. See PERSPECTIVE.

To render plans intelligible, it is uſual to diſtinguiſh the maſſives with a black waſh; the projectures on the ground are drawn in full lines, and thoſe ſuppoſed over them in dotted lines. The augmentations or alterations to be made are diſtinguiſhed by a colour different from what is already built; and the tints of each plan made lighter as the ſtories are raiſed.

In large buildings it is uſual to have three ſeveral plans for the three firſt ſtories,

PLANCUS (Francis), doctor of phyſic, born at Amiens in 1696, and who died on the 19th of September 1765, aged 69 years, is author of ſome works which do honour to his memory. 1. A complete Syſtem of Surgery, in 2 vols in 12mo; a treatiſe much recommended by ſurgeons to their pupils. 2. A choice Library of Medicine, taken from periodical publications, both French and others: this curious collection, continued and completed by M. Goulin, makes 9 vols in 4to, or 18 vols in 12mo. 3. A Tranſlation of Vander Wiel's Obſervations on Medicine and Surgery, 1758, 2 vols in 12mo. Plancus was the editor of various editions of works on medicine and ſurgery, and enriched them with notes. He ſhut himſelf up in his ſtudy for a long time before he practiſed his profeſſion.

Plane, Planet.

PLANE, in geometry, denotes a plane ſurface, or one that lies evenly between its bounding lines: and as a right line is the ſhorteſt extenſion from one point to another, ſo a plane ſurface is the ſhorteſt extenſion from one line to another.

In aſtronomy, conics, &c. the term *plane* is frequently uſed for an imaginary ſurface, ſuppoſed to cut and paſs through ſolid bodies; and on this foundation is the whole doctrine of conic ſections built. See ASTRONOMY, Conic *Sections*, &c.

In mechanics planes are either horizontal, that is, parallel to the horizon, or inclined thereto. See MECHANICS.

The determining how far any given plane deviates from an horizontal line, makes the whole buſineſs of levelling. See the article LEVELLING.

In optics, the planes of reflection and refraction are thoſe drawn through the incident and reflected or refracted rays. See OPTICS.

In perſpective we meet with the perſpective plane, which is ſuppoſed to be pellucid, and perpendicular to the horizon; the horizontal plane, ſuppoſed to paſs through the ſpectator's eye, parallel to the horizon; the geometrical plane, likewiſe parallel to the horizon, wherein the object to be repreſented is ſuppoſed to be placed, &c. See PERSPECTIVE.

The plane of projection in the ſtereographic projection of the ſphere, is that on which the projection is made, correſponding to the perſpective plane. See PROJECTION.

PLANE, in joinery, an edged tool or inſtrument for parting and ſhaving of wood ſmooth.—It conſiſts of a piece of wood very ſmooth at bottom, as a ſtock or ſhaft; in the midſt of which is an aperture, through which a ſteel edge, or chiſſel, placed obliquely, paſſes; which, being very ſharp, takes off the inequalities of the wood along which it ſlides.

PLANE-Tree, in botany. See PLATANUS.

PLANET, a celeſtial body, revolving round the ſun as a centre, and continually changing its poſition with reſpect to the fixed ſtars; whence the name *planet*, which is a Greek word, ſignifying "wanderer."

The planets are uſually diſtinguiſhed into primary and ſecondary. The primary ones, called by way of eminence *planets*, are thoſe which revolve round the ſun as a centre; and the ſecondary planets, more uſually called *ſatellites* or *moons*, are thoſe which revolve round a primary planet as a centre, and conſtantly attend it in its revolution round the ſun.

The primary planets are again diſtinguiſhed into ſuperior and inferior. The ſuperior planets are thoſe farther from the ſun than our earth; as Mars, Jupiter, Saturn, and the Georgium Sidus; and the inferior planets are thoſe nearer the ſun than our earth, as Venus and Mercury. See ASTRONOMY.

That the planets are opaque bodies, like our earth, is thought probable for the following reaſons. 1. Since in Venus, Mercury, and Mars, only that part of the diſk

Planet
H
Planetary.

diſk illuminated by the ſun is found to ſhine; and again, Venus and Mercury, when between the earth and the ſun, appear like dark ſpots or maculæ on the ſun's diſk; it is evident, that Mars, Venus, and Mercury, are opaque bodies, illuminated with the borrowed light of the ſun. And the ſame appears of Jupiter, from its being void of light in that part to which the ſhadow of the ſatellites reaches, as well as in that part turned from the ſun; and that his ſatellites are opaque, and reflect the ſun's light, is abundantly ſhown. Again, ſince Saturn, with his ring and ſatellites, only yield a faint light, fainter conſiderably than that of the fixed ſtars, though theſe be vaſtly more remote, and than that of the reſt of the planets; it is paſt doubt that he too with his attendants are opaque bodies. 2. Since the ſun's light is not tranſmitted through Mercury and Venus, when placed againſt him, it is plain they are denſe opaque bodies; which is likewiſe evident of Jupiter, from his hiding the ſatellites in his ſhadow; and therefore, by analogy, the ſame may be concluded of Saturn. 3. From the variable ſpots of Venus, Mars, and Jupiter, it is evident theſe planets have a changeable atmoſphere; which changeable atmoſphere may, by a like argument, be inferred of the ſatellites of Jupiter; and therefore, by ſimilitude, the ſame may be concluded of the other planets. 4. In like manner, from the mountains obſerved in Venus, the ſame may be ſuppoſed in the other planets. 5. Since, then, Saturn, Jupiter, and the ſatellites of both, Mars, Venus, and Mercury, are opaque bodies ſhining with the ſun's borrowed light, are furniſhed with mountains, and encompaſſed with a changeable atmoſphere; they have, of conſequence, waters, ſeas, &c. as well as dry land, and are bodies like the moon, and therefore like the earth. *Q. E. D.* And hence it ſeems alſo highly probable, that the other planets have their animal inhabitants as well as our earth.

PLANETARIUM, an aſtronomical machine, ſo called from its repreſenting the motions, orbits, &c. of the planets, agreeable to the Copernican ſyſtem. See ASTRONOMY, n° 489. and Plate LXXXVIII.

PLANETARY, ſomething that relates to the planets. Hence we ſay, planetary worlds, planetary inhabitants, &c. Huygens and Fontenelle bring ſeveral probable arguments for the reality of planetary animals, plants, men, &c. See PLANET.

Planetary
H
Planiſphere

PLANETARY System, is the ſyſtem or aſſemblage of the planets, primary and ſecondary, moving in their reſpective orbits, round their common centre the ſun. See ASTRONOMY.

PLANETARY Days.—Among the ancients, the week was ſhared among the ſeven planets, each planet having its day. This we learn from Dion Caſſius and Plutarch, *Sympoſ.* l. 4. q. 7. Herodotus adds, that it was the Egyptians who firſt diſcovered what god, that is, what planet, preſides over each day; for that among this people the planets were directors. And hence it is, that in moſt European languages the days of the week are ſtill denominated from the planets; Sunday, Monday, &c. See WEEK.

PLANETARY Years, the periods of time in which the ſeveral planets make their revolutions round the ſun or earth.—As from the proper revolution of the ſun, the ſolar year takes its original; ſo from the proper revolutions of the reſt of the planets about the earth, ſo many ſorts of years do ariſe, viz. the Saturnian year, which is defined by 29 Egyptian years, 174 hours, 58 minutes, equivalent in a round number to 30 ſolar years.—The Jovial year, containing 317 days, 14 hours, 59 minutes.—The Martial year, containing 321 days, 23 hours, 31 minutes.—For Venus and Mercury, as their years, when judged of with regard to the earth, are almoſt equal to the ſolar year; they are more uſually eſtimated from the ſun, the true centre of their motions: in which caſe, the former is equal to 224 days, 16 hours, 40 minutes; the latter to 87 days, 23 hours, 14 minutes.

PLANIMETRY, that part of geometry which conſiders lines and plain figures, without conſidering their height or depth. See GEOMETRY.

PLANISPHERE, ſignifies a projection of the ſphere, and its various circles on a plane; in which ſenſe, maps, whereon are exhibited the meridians and other circles of the ſphere, are planiſpheres. See MAP.

END OF THE FOURTEENTH VOLUME.
