The calcination of metallic bodies, gold, silver, and mercury excepted, is greatly promoted by nitre. This salt exposed to the fire in conjunction with any inflammable substances, extricates their inflammable matter, and bursts with it into flame, accompanied with a hissing noise. This process is usually termed *deflagration* or *detonation*.

All the metallic calces and scoriæ are revived into their metallic state by fusion with any vegetable or animal inflammable matter. They are all more difficult of fusion than the respective metals themselves; and scarcely any of them, those of lead and bismuth excepted, can be made to melt at all, without some addition, in the strongest fire that can be produced in the common furnaces. The additions called *fluxes*, employed for promoting the fusion, consist chiefly of fixed alkaline salts. A mixture of alkaline salt with inflammable matter, as powdered charcoal, is called a *reducing flux*, as contributing at the same time to bring the calx into fusion, and to revive it into metal. Such a mixture is commonly prepared from one part of nitre and two parts of tartar, by grinding them well together, setting the powders on fire with a bit of coal or a red-hot iron, then covering the vessel, and suffering them to deflagrate or burn till they are changed into a black alkaline coaly mass. This is the common reducing flux of the chemists, and is called from its colour the *black flux*. Metallic calces of scoriæ, mingled with twice their weight of this compound, and exposed to a proper fire in a close covered crucible, melt and resume their metallic form; but though they received an increase of weight in the calcination, the revived metal is always found to weigh considerably less than the quantity from which the calx was made.

For a more particular account of all these processes, and an explanation of the principles on which they depend, see Chemistry *passim*, and the articles themselves as they occur in the order of the alphabet.

PART II. PREPARATIONS AND COMPOSITIONS.

Containing those of the LONDON and EDINBURGH PHARMACOPOEIAS.

CHAP. I. *The more Simple Preparations.*

The preparation of some substances not soluble in water. L.

POUND these substances first in a mortar; then, pouring on a little water, levigate them on a hard and polished, but not calcareous, stone, that they may be made as fine as possible. Dry this powder on blotting-paper laid on chalk, and set it in a warm, or at least a dry, place, for some days.

In this manner are to be prepared,
Amber,
Antimony,
Calamine,
Chalk,
Coral,
Oyster-shells, first cleansed from their impurities,
Tutty.

Crabs claws, first broken into small pieces, must be washed with boiling water before they be levigated.

Verdegrise must be prepared in the same manner.

Where large quantities of the foregoing powders are to be prepared, it is customary, instead of the stone and mallet, to employ hand-mills made for this purpose, consisting of two stones; the uppermost of which turns horizontally on the lower, and has an aperture in the middle, for supplying fresh matter, or of returning that which has already passed, till it be reduced to a proper degree of fineness.

For the levigation of hard bodies, particular care should be taken, whatever kind of instruments be used, that they may be of sufficient hardness, otherwise they will be attacked by the powders. The hematites, a hard iron ore, is most conveniently levigated between two iron plates; for if the common levigating stones be used, the preparation, when finished, will contain almost as much foreign matter from the instrument as the hematites.

It has been customary to moisten several powders in levigation, with rose, balm, and other distilled waters: these, nevertheless, have no advantage above common water, since in the subsequent exsiccation they must necessarily exhale, leaving the medicine possessed of no other virtue than what might be equally expected from it when prepared with the cheaper element.

Some few substances, indeed, are more advantageously levigated with spirit of wine than with water. Thus bezoar has the green colour usually expected in this costly preparation considerably improved thereby. A little spirit may be added to the other animal substances, if the weather be very hot and large quantities of them are prepared at once, to prevent their running into putrefaction; an accident which in those circumstances sometimes happens when they are levigated with water only. Crabs-eyes, which abound with animal gelatinous matter, are particularly liable to this inconvenience.

The caution given above for reducing antimony calamine, and tutty, to the greatest subtility possible, demands particular attention. The tenderness of the parts to which the two last are usually applied, requires them to be perfectly free from any admixture of gross irritating particles. The first, when not thoroughly comminuted, might not only, by its sharp needle like spicula, wound the stomach, but likewise answers little valuable purpose as a medicine, proving either an useless load upon the viscera, or at best passing off without any other sensible effect than an increase of the grosser evacuations; while, if reduced to a great degree of fineness, it turns out a medicine of considerable efficacy.

The most successful method of obtaining these powders of the requisite tenuity, is, to wash off the finer parts by means of water, and continue levigating the remainder till the whole become fine enough to remain for some time suspended in the fluid; this process is received in the Edinburgh pharmacopœia, and there directed in the preparation of the following article.

Prepared antimony. E.

Let the antimony be first pounded in an iron mortar, and then levigated on a porphyry with a little water. After this, put it into a large vessel, and pour a quantity of water on it. Let the vessel be repeatedly shaken, that the finer part of the powder may be diffused through the water; the liquor is then to be poured off, and set by till the powder settles. The gross part, which the water would not take up, is to be further levigated, and treated in the same manner. 91

By this method, which is that commonly practised in the preparation of colours for the painter, powders may be obtained of any required degree of tenuity; and without the least mixture of the gross parts, which are always found to remain in them after long continued levigation: all the coarser matter settles at first, and the finer powder continues suspended in the water longer and longer, in proportion to the degree of its fineness. The same process may likewise be advantageously applied to other hard pulverisable bodies of the mineral kingdom, or artificial preparations of them; provided they be not soluble in, or specifically lighter than, water. The animal and absorbent powders, crabs-claws, crabs eyes, oyster-shells, egg-shells, chalk, pearl, coral, and bezoar, are not well adapted to this treatment; nor indeed do they require it. These substances are readily soluble in acid juices without much comminution: if no acid be continued in the first passages, they are apt to concrete, with the mucous matter usually lodged there, into hard indissoluble masses; the greater degree of fineness they are reduced to, the more they are disposed to form such concretions, and become liable to obstruct the orifices of the small vessels.

Preparations and Compositions.

Prepared calomine. E.

92 Calamine previouſly calcined for the uſe of thoſe who make braſs, is to be treated in the ſame manner as antimony.

Prepared chalk.

93 Chalk firſt triturated, and then frequently waſhed with water, till it imparts to it neither taſte nor colour, is to be treated in the ſame manner as antimony.

As calamine is intended for external application, and often to parts very eaſily irritated, too much pains cannot be beſtowed in reducing it to a fine powder; and the frequent waſhing of the chalk may have the effect of freeing it from ſome foreign matters: But with regard to this ſubſtance, the after part of the proceſs, if not improper, is, in our opinion at leaſt, unneceſſary: and this obſervation may alſo be made with reſpect to the oculi, or more properly lapilli cancrorum, which the Edinburgh college direct to be treated in the ſame manner.

The preparation of hog's lard and mutton ſuet. L.

94 Cut them into pieces, and melt them over a ſlow fire; then ſeparate them from the membranes by ſtraining.

Theſe articles had formerly a place alſo among the preparations of the Edinburgh college: But now they introduce them only into their liſt of the materia medica; as the apothecary will in general find it more for his intereſt to purchaſe them thus prepared, than to prepare them for himſelf: for the proceſs requires to be very cautiouſly conducted, to prevent the fat from burning or turning black.

The purification of gum ammoniacum. L.

95 If gum ammoniac do not ſeem to be pure, boil it in water till it become ſoft; then ſqueeze it through a canvaa bag, by means of a preſs. Let it remain at reſt till the reſinous part ſubſide; then evaporate the water; and toward the end of the evaporation reſtore the reſinous part, mixing it with the gummy.

In the ſame manner are purified aſſafœtida and ſuch like gum reſins.

You may alſo purify any gum which melts eaſily, ſuch as Galbanum, by putting it in an ox-bladder, and holding it in boiling water till it be ſo ſoft that it can be ſeparated from its impurities by preſſing through a coarſe linen cloth.

In ſtraining all the gums, care ſhould be taken that the heat be neither great nor long continued; otherwiſe a conſiderable portion of the more active volatile matter will be loſt; an inconvenience which cannot by any care be wholly avoided. Hence the purer tears, unſtrained, are in general to be preferred, for internal uſe, to the ſtrained gums.

As an additional reaſon for this preference, we may add, that ſome of the gum-reſins, purified in the common way, by ſolution in water, expreſſion and evaporation, are not ſo eaſily ſoluble in aqueous menſtrua after as before ſuch depuration. On theſe accounts this proceſs is entirely omitted by the Edinburgh college; and in every caſe where a gummy reſinous ſubſtance, before it be taken, is to be diſſolved in water, it may be as effectually freed from impurities at the time of ſolution as by this proceſs. And when it is to be employed in a ſolid ſtate, care ſhould be taken that the purer parts alone be ſelected.

The burning of hartſhorn. L.

Burn pieces of hartſhorn till they become perfectly white; then reduce them to a very fine powder. 9

The pieces of horn generally employed in this operation are thoſe left after diſtillation.

In the burning of hartſhorn, a ſtrong fire and the free admiſſion of air are neceſſary. The potter's furnace was formerly directed for the ſake of convenience; but any common furnace or ſtove will do. If ſome lighted charcoal be ſpread on the bottom of the grate, and above this the pieces of the horns are laid, they will be burnt to whiteneſs, ſtill retaining their original form.

Burnt hartſhorn is not now conſidered as a pure earth, having been found to be a compound of calcareous earth and phoſphoric acid. It is the weakeſt of the animal abſorbents, and is difficultly ſoluble in acids; but whether it be of equal or ſuperior uſe in diarrhœas to more powerful abſorbents, muſt be left to obſervation.

The drying of herbs and flowers.

Let theſe, ſpread out lightly, be dried by a gentle heat. *L.* 97

Herbs and flowers muſt be dried by a gentle heat, from a ſtove or common fire. They muſt be taken in ſuch quantities at a time, that the proceſs will be ſpeedily finiſhed; for by this means their medical powers are beſt preſerved. The moſt certain teſt of this is the perfect preſervation of the natural colour: but the leaves of cicuta, and of other plants containing a volatile matter, muſt be immediately pounded, after being dried, and afterwards kept in a phial with a ground ſtopper. *E.*

The directions given by the London college are here leſs explicit, and perhaps leſs proper, than thoſe of the Edinburgh college: for there can be no doubt of the propriety of drying theſe ſubſtances haſtily, by the aid of artificial heat, rather than by the heat of the ſun. In the application of artificial heat, the only caution requiſite is to avoid burning; and of this a ſufficient teſt is afforded by the preſervation of colour. And the direction given with regard to cicuta may perhaps with advantage be followed with moſt of the other flowers and herbs, afterwards to be exhibited in powder.

The purifying of honey. L.

Melt the honey by the heat of a water bath, and remove the ſcum. 98

The intention of this proceſs is to purify the honey from wax, or other droſſy matters that have been united with it by the violence of the preſs in its ſeparation from the comb, and from meal and ſuch like ſubſtances, which are ſometimes fraudulently mixed with it. When the honey is rendered liquid and thin by the heat, theſe lighter matters riſe freely to the ſurface.

This preparation is not ſo neceſſary for honey that is to be uſed as an article of diet, as for that which is employed

Preparations and Compositions.

employed in the preparation of oxymels: hence the Edinburgh college, who have rejected all the oxymels, have omitted this process.

The preparation of millipeds. L. E.

99 The millipeds are to be inclosed in a thin canvas cloth, and suspended over hot proof-spirit in a close vessel, till they be killed by the steam, and rendered friable.

This is a convenient way of rendering millipeds pulverisable, without endangering any loss of such virtues as they may possess.

The directions given by both colleges are precisely the same, and delivered in almost the same words.

The extraction of pulps. L. E.

100 Unripe pulpy fruits, and ripe ones if they be dry, are to be boiled in a small quantity of water until they become soft: then press out the pulp through a strong hair-sieve, and afterwards boil it down to the consistence of honey in an earthen vessel, over a gentle fire; taking care to keep the matter continually stirring, to prevent its burning.

The pulp of cassia fistularis is in like manner to be boiled out from the bruised pod, and reduced afterwards to a proper consistence, by evaporating the water.

The pulps of fruits that are both ripe and fresh, are to be pressed out through the sieve, without any previous boiling.

In the extraction of pulps, the direction of both colleges so nearly agree, that it is unnecessary to give a separate translation of each. We may only observe, that the London college, instead of softening the fruits by boiling them in a small quantity of water, direct them to be put in a moist place. This direction, though proper in some cases, is not generally the most suitable.

The drying of squills. L. E.

101 Let the squill, cleared from its outer skin, be cut transversely into thin slices, and dried with a very gentle heat. When properly managed, the squill is friable, and retains its bitterness and acrimony.

By this method the squill dries much sooner than when its several coats are only separated, as has been usually directed; the internal part is here laid bare, but, in each of the entire coats, it is covered with a thin skin, which impedes the exhalation of the moisture. The root loses in this process four-fifths of its original weight; the parts which exhale appear to be merely watery: six grains of the dry root being equivalent to half a dram of the fresh; a circumstance to be particularly regarded in the exhibition of this medicine. In the preceding editions of our pharmacopœias, a particular caution was given, not to use an iron knife for cutting squills, but one of wood, ivory, or bone: the reason of this caution is said to be, not so much that the squill would receive any ill qualities from the iron; as, that its acrid juice, adhering to the knife, might render a wound received by it extremely painful, or even dangerous: but as no danger is to be apprehended from such an accident, the direction appears unnecessary. Dried squills furnish us with a medicine, sometimes advantageously employed as an emetic, often as an expectorant, but still more frequently as a powerful diuretic.

Preparations and Compositions.

The burning of sponge.

102 Beat the sponge, after cutting it in pieces; and, when separated from its gritty matter, burn it in a close iron vessel, until it becomes black and friable; afterwards rub it to a very fine powder. *L.*

Put the sponge, cut into small pieces, and well freed from adhering earthy matters, into a close earthen vessel. Place it on the fire, and let it be stirred frequently till it become black and friable; then reduce it to a powder in a glass or marble mortar. *E.*

This medicine has been in use for a considerable time, and employed against scrofulous disorders and cutaneous foulnesses, in doses of a scruple and upwards. Its virtues seem to depend on a volatile salt just formed, and combined with its own oil. If the sponge be distilled with a strong heat, it yields a large proportion of that salt in its proper form. The salt is in this preparation so far extricated, that if the burnt sponge be ground in a brass mortar, it corrodes the metal so as to contract a disagreeable taint, and sometimes an emetic quality.

Bees, earthworms, and other animal substances, have by some been prepared in the same manner, and recommended in different diseases: but as these substances fall much short of sponge in the quantity of volatile salt producible from them by fire, they are probably inferior also in medicinal efficacy. Of all the animal matters that have been tried, raw silk is the only one which exceeds or equals sponge, in the produce of salt.

A good deal of address is requisite for managing this process in perfection. The sponge should be cut small, and beaten for some time in a mortar, that all the stony matters may be got out, which compared with the weight of the sponge when prepared, will sometimes amount to a considerable quantity. The burning should be discontinued as soon as the matter is become thoroughly black. If the quantity put into the vessel at once be large, the outside will be sufficiently burnt before the inside be affected; and the volatile salt of the former will in part escape, before that in the latter is begun to be formed. The best method of avoiding this inconvenience seems to be, to keep the sponge continually stirring, in such a machine as is used for the roasting of coffee.

And from this circumstance the iron vessel directed by the London college is preferable to the earthen one directed by that of Edinburgh. But the pounding in a glass or marble mortar, directed by the latter, is a necessary caution which the former college have omitted.

The purification of storax. L.

103 Dissolve the storax in rectified spirit of wine, and strain the solution: afterwards reduce it to a proper thickness with a gentle heat.

Storax was formerly directed to be purified by means of water; hence it was styled *styracis collatio*: but the method now adopted is much preferable, for the active parts

Preparations and Compositions.

parts of the ſtorax totally diſſolve in ſpirit of wine, the impurities alone being left. And as theſe active parts do not riſe in diſtillation, the ſpirit may be again recovered by diſtillation.

Purified filings of iron. E.

104 Apply a magnet to a ſieve placed on filings of iron, ſo that the filings may be attracted upwards through the ſieve.

Ruſt of iron, commonly called *ſhavings of iron, prepared.* E.

105 Set purified filings of iron in a moiſt place, that they may turn to ruſt, which is to be ground into an impalpable powder.

The cleanſing of iron filings by means of a magnet is very tedious, and does not anſwer ſo well as might be expected; for if they are ruſty, they will not be attracted by it, or not ſufficiently: nor will they by this means be entirely freed from braſs, copper, or other metallic ſubſtances which may adhere to them. It appears from the experiments of Henckel, that if iron be mixed by fuſion with even its own weight of any of the other metals, regulus of antimony alone excepted, the compound will be vigorouſly attracted by the loadſtone. The ruſt of iron is to be procured at a moderate rate from the dealers in iron, free from any impurities except ſuch as may be waſhed off by water.

The ruſt of iron is by ſome preferred as a medicine to the calces or croci made by a ſtrong fire. Hoffman relates, that he has frequently given it with remarkable ſucceſs in obſtinate chlorotic caſes accompanied with exceſſive headachs and other violent ſymptoms; and that he uſually joined with it pimpinella, arum root, and ſalt of tartar, with a little cinnamon and ſugar. The doſe is from four or five grains to twenty or thirty; ſome have gone as far as a dram: but all the preparations of this metal anſwer beſt in ſmall doſes, which ſhould rather be often repeated than enlarged.

Scales of iron purified. E.

106 Let the ſcales of iron, which may be had at the anvils of the workmen, be purified by the magnet; for the magnet only attracts the ſmaller and purer parts, leaving the more thick and impure behind.

This is perhaps of all the forms the moſt eligible for obtaining the pure matter in ſuch a divided ſtate as to render it eaſily acted on by different menſtrua; and the mode of purification here propoſed is not only very effectual, but alſo very eaſily put into practice.

The extraction of mucilage. Gen.

107 Boil the gums or mucilaginous ſeeds in a ſufficient quantity of water till it becomes viſcid, nearly reſembling the white of an egg; and then ſtrain it by preſſure through a linen cloth.

By this means vegetable mucilage may be eaſily obtained from many different ſubſtances in its pure ſtate. And although this proceſs is not directed in our pharmacopœias, yet we think that it might with advantage be adopted.

Chap. II. *Of Conſerves.*

Preparations and Compoſitions. 108

Conſerves are compoſitions of recent vegetable matters and ſugar, beaten together into an uniform maſs.

This management is introduced for preſerving certain ſimples, unbruiſed, in an agreeable form, with as little alteration as poſſible in their native virtues; and to ſome ſubjects it is very advantageouſly applied. Vegetables, whoſe virtues are loſt or deſtroyed by drying, may in this form be kept uninjured for a length of time: for, by carefully ſecuring the mouth of the containing veſſel, the alteration, as well as diſſipation, of their active principles, is generally prevented; and the ſugar preſerves them from the corruption which juicy vegetables would otherwiſe undergo. There are, however, ſundry vegetables whoſe virtues are impaired by this treatment. Mucilaginous ſubſtances by long lying with ſugar, become leſs glutinous; and aſtringents become ſenſibly ſofter on the palate. Many of the fragrant flowers are of ſo tender and delicate a texture, as almoſt entirely to loſe their peculiar qualities on being beaten or bruiſed.

In general, it is obvious, that in this form, on account of the large admixture of ſugar, ſubſtances of conſiderable activity can alone be taken to advantage as medicines. And, indeed, conſerves are at preſent conſidered chiefly as auxiliaries to medicines of greater efficacy, or as intermedia for joining them together. They are very convenient for reducing into boluſes or pills the more ponderous powders, as mercurius dulcis, the calces of iron, and other mineral preparations; which, with liquid or leſs conſiſtent matters, as ſyrups, will not cohere.

The ſhops were formerly encumbered with many conſerves altogether inſignificant; the few now retained have in general either an agreeable flavour to recommend them, or are capable of anſwering ſome uſeful purpoſes as medicines. Their common doſe is the bulk of a nutmeg, or as much as can be taken up at once or twice upon the point of a knife. There is in general no great danger of exceeding in this particular.

Conſerves of wood ſorrel;
ſea wormwood;
the red roſe;
the outer rind of the Seville orange. L.

Pluck the leaves from the ſtalks, the unblown petals from the cups, taking off the heels. Take off the outer rind of the oranges by a grater; then beat each of them with a wooden peſtle in a marble mortar, firſt by themſelves, afterwards with three times their weight of double refined ſugar, until they be mixed.

Conſerves of the freſh leaves of mint;
red roſes not blown;
the outer rind of Seville oranges raſped off by a grater. E.

Theſe are directed to be prepared with triple their weight of ſugar in the ſame manner as the conſerves of the London college. The ſugar ſhould be pounded by itſelf, and paſſed through a ſieve before it be mixed with the vegetable maſs; for without this it cannot

Preparation and Compositions.

cannot be properly incorporated. Roſe buds, and ſome other vegetables, are prepared for mixing with ſugar by a ſmall wooden mill contrived for that purpoſe.

In the ſame manner conſerves may be prepared from many other vegetables. But beſides the conſerves for which general directions are given, there are others, for which, either on account of the particular mode of preparation, or of the proportion, our pharmacopœias have thought it neceſſary to give particular directions. But before taking notice of theſe, it is neceſſary to mention the medical properties of the conſerves above enumerated.

Conſerve of the leaves of wood ſorrel. L.

109 This is a very elegant and grateful conſerve; in taſte it is lightly acidulous, with a peculiar flavour, which ſome compare to that of green-tea. It is taken occaſionally for quenching thirſt, and cooling the mouth and fauces, in diſtempers where the heat of the body is much increaſed.

Conſerve of the tops of ſea wormwood. L.

110 The conſerve of wormwood has been celebrated in dropſies: Matthiolus relates, that ſeveral perſons were cured by it of that diſtemper without the aſſiſtance of any other medicine. Where the diſorder indeed proceeds from a ſimple laxity or flaccidity of the ſolids, the continued uſe of this medicine may be of ſome ſervice; as it appears to be an elegant mild corroborant. It is directed to be given in the doſe of half an ounce about three hours before meals.

Conſerve of the buds of red roſes. L. E.

111 This is a very agreeable and uſeful conſerve. A dram or two diſſolved in warm milk are frequently given as a light aſtringent, in weakneſs of the ſtomach, and likewiſe in coughs and phthiſical complaints. In the German ephemerides, examples are related of very dangerous phthiſes cured by the continued uſe of this medicine: In one of theſe caſes, twenty pounds of the conſerve were taken in the ſpace of a month; and in another, upwards of thirty. Riverius mentions ſeveral other inſtances of this kind. There is, however, much room for fallacy in ſuch obſervations; as phthiſis has not at all times been accurately diſtinguiſhed from obſtinate catarrhs, and ſome other affections; the antiſeptic property of the ſugar may perhaps have ſome ſhare in the effect.

Conſerve of the yellow rind of Seville orange-peel. L. E.

112 This conſerve is a very elegant one, containing all the virtues of the peel in a form ſufficiently agreeable, both with regard to the doſe and the conveniency of taking. It is a pleaſant warm ſtomachic; and with this intention is frequently uſed.

Conſerve of the leaves of ſpearmint. E.

113 The conſerve of mint retains the taſte and virtues of the herb. It is given in weakneſs of the ſtomach and retchings to vomit: and frequently does ſervice in ſome caſes of this kind, where the warmer and more active preparations of mint would be leſs proper.

Conſerve of arum.

114 Take of the freſh root of arum bruiſed, half a pound; double refined ſugar, a pound and a half. Beat them together in a mortar. Preparation and Compoſitions.

The root of arum, in its recent ſtate, is a ſubſtance of great activity; but this activity is almoſt entirely loſt on drying. Hence the compound powder which had formerly a place in our pharmacopœias is now rejected. And as neither water nor ſpirit extract its activity, this conſerve is perhaps the beſt form in which it can be preſerved in our ſhops. It may be given to adults in doſes of a dram.

Conſerve of hips. L.

Take of pulp of ripe hips one pound; double refined ſugar, powdered, twenty ounces. Mix them into a conſerve. 115

The conſerve of hips is of ſome eſteem as a ſoft cooling reſtringent; three or four drams or more are given at a time, in bilious fluxes, ſharpneſs of urine, and hot indiſpoſitions of the ſtomach: A good deal of care is requiſite on the part of the apothecary in making this conſerve: the pulp is apt to carry with it ſome of the prickly fibres, with which the inſide of the fruit is lined; if theſe be retained in the conſerve, they will irritate the ſtomach, ſo as to occaſion vomiting.

Conſerve of ſloes. L. E.

Put the ſloes in water upon the fire that they may ſoften, taking care that they be not broken; then, the ſloes being taken out of the water, preſs out the pulp, and mix it with three times its weight of double refined ſugar into a conſerve. 116

This preparation is a gentle aſtringent, and may be given as ſuch in the doſe of two or three drams. The degree of its aſtringency will vary according to the maturity of the ſloes, and the length of time for which the conſerve has been kept.

Conſerve of ſquills.

Take of freſh ſquills, one ounce; double-refined ſugar, five ounces. Beat them together in a mortar into a conſerve. 117

This conſerve is directed to be prepared in a ſmall quantity, to guard againſt its varying in ſtrength. It may be given to adults from half a dram to two ſcruples, eſpecially when freſh.

But the conſerve of ſquills is a more uncertain and leſs agreeable mode of exhibiting this article, than the powder of the dried root, particularly when made into pills, or given in the form of bolus with any other conſerve.

Conſerve of chervil. Suec.

Take of freſh leaves of chervil, double-refined ſugar, each equal parts. Beat them together into a conſerve. 118

Chervil has by ſome been extolled as an uſeful diuretic; and this is perhaps one of the moſt pleaſant forms under which it can be exhibited.

Conſerve of millipeds. Brun.

Take of live millipeds, one pound; double-refined ſugar, two pounds and an half. Beat them together into a conſerve. 119

If the millipeds poſſeſs thoſe virtues which ſome have alleged, this is perhaps one of the beſt forms under

Preparations and Compositions.

der which they can be exhibited. And by children, to whom they are frequently preſcribed, it may be eaſily taken, when other forms cannot be introduced.

Vitriolated conſerve of roſes. Brun.

120 To each pound of the conſerve of roſes add two drams of the diluted vitriolic acid.

This may be in ſome caſes an uſeful means of increaſing ſomewhat the aſtringency of the conſerve of roſes: But for the purpoſes for which the vitriolic acid is in general employed, the quantity that can thus be introduced is too inconſiderable to be of much ſervice.

Chap. III. *Of Juices.*

121 Juices are obtained from the ſucculent parts of plants, by including them, after being properly cut, bruiſed, &c. in a hair bag, and preſſing them, between wooden cheeks, in the common ſcrew-preſs, as long as any liquor exudes.

The harder fruits require to be previouſly well beaten or ground; but herbs are to be only moderately bruiſed, for if theſe are over-bruiſed, a large quantity of the herbaceous matter will be forced out along with the juice. Hempen or woollen bags are apt to communicate a diſagreeable flavour; the threads of theſe likewiſe ſwell in proportion as they imbibe moiſture, ſo as in great meaſure to prevent the free percolation of the juice.

The fluids thus extracted from ſucculent fruits, both of the acid and ſweet kind, from moſt of the acrid herbs, as ſcurvy-graſs and water-creſſes, from the acid herbs, as ſorrel and wood ſorrel, from the aperient lactéſcent plants, as dandelion and hawkweed, and from ſundry other vegetables, contain great part of the peculiar taſte and virtues of the reſpective ſubjects. The juices, on the other hand, extracted from moſt of the aromatic herbs as thoſe of mint and the fragrant Turkey balm, commonly called *balm of Gilead*, have ſcarcely any thing of the flavour of the plants, and ſeem to differ little from decoctions of them made in water boiled till the volatile odorous parts have been diſſipated. Many of the odoriferous flowers, as the lily, violet, hyacinth, not only impart nothing of their fragrance to their juice, but have it totally deſtroyed by the previous bruiſing. From want of ſufficient attention to theſe particulars, practitioners have been frequently deceived in the effects of preparations of this claſs: juice of mint has been often preſcribed as a ſtomachic, tho' it wants thoſe qualities by which mint itſelf and its other preparations operate.

The juices, thus forcibly preſſed out from plants, differ from thoſe which flow ſpontaneouſly, or from inciſions; theſe laſt conſiſting chiefly of ſuch fluids as are not diffuſed through the whole ſubſtance of the vegetable ſubject, but elaborated in diſtinct veſſels, or ſecreted into particular receptacles. From poppy heads, ſlightly wounded, there iſſues a thick milky liquor, which dries by a moderate warmth into opium; whilſt the juice obtained from them by preſſure is of a dark-green colour, and far weaker virtue.

Juices newly expreſſed are generally thick, viſcid, and very impure: By colature, a quantity of groſs matter is ſeparated, the juice becomes thinner, limpid, and better fitted for medicinal purpoſes, though as yet not entirely pure: on ſtanding, it becomes again turbid, and apt to run into a fermentative or putrefactive ſtate. Clarification with whites of eggs renders the juices more perfectly fine; but there are few that will bear this treatment without a manifeſt injury to their flavour, taſte, and virtue.

The moſt effectual method of purifying and preſerving theſe liquors, is to let the ſtrained juices ſtand in a cool place till they have depoſited their groſſer feces, and then gently paſs them ſeveral times through a fine ſtrainer till perfectly clear; when about a fortieth part of their weight of good ſpirit of wine may be added, and the whole ſuffered to ſtand as before: a freſh ſediment will now be depoſited, from which the liquor is to be poured off, ſtrained again, and put into ſmall bottles which have been waſhed with ſpirit and dried. A little oil is to be poured on the ſurface, ſo as very nearly to fill the bottles, and the mouths cloſed with leather, paper, or ſtopped with ſtraw, as the flaſks in which Florence wine is brought to us: this ſerves to keep out duſt, and ſuffers the air, which in proceſs of time ariſes from all vegetable liquors, to eſcape; which air would otherwiſe endanger the burſting of the bottles; or, being imbibed afreſh, render their contents vapid and foul. The bottles are to be kept on the bottom of a good cellar or vault, placed up to the necks in ſand. By this method ſome juices may be preſerved for a year or two; and others for a much longer time.

It has already been obſerved, that there are great differences in juices, in regard to their being accompanied in the expreſſion with the virtues of the ſubjects. There are equal differences in regard to their preſerving thoſe virtues, and this independently of the volatility of the active matter, or its diſpoſition to exhale. Even the volatile virtue of ſcurvy-graſs may by the above method be preſerved almoſt entire in its juice for a conſiderable time: while the active parts of the juice of the wild cucumber quickly ſeparate and ſettle to the bottom, leaving the fluid part inert. Juices of arum root, iris root, bryony root, and ſundry other vegetables, throw off in like manner their medicinal parts to the bottom.

Compound juice of ſcurvy-graſs.

122 Take of the juice of garden ſcurvy-graſs two pints; brook lime and water-creſſes, of each one pint; Seville oranges, twenty ounces by meaſure. Mix them, and, after the feces have ſubſided, pour off the liquor, or ſtrain it. *L.*

Take of juice of garden ſcurvy-graſs, water-creſſes, both expreſſed from the freſh herbs, Seville oranges, of each two pounds; ſpirituous nutmeg-water, half a pound. Mix them and let them ſtand till the feces have ſubſided, then pour off the clear liquor. *E.*

By this formula the Edinburgh college have rejected the brook lime and the ſugar of their former editions. The ſugar was certainly a very improper addition; for though it may preſerve dry vegetable matters, yet when added to juices largely impregnated with watery and mucilaginous matter, it would no doubt furniſh that very principle moſt favourable to the production of the vinous fermentation. For the compound horſe-radiſh water they have ſubſtituted the ſpirituous water of nutmegs: Beſides that, this water has the ſame property

of preſerving the juices from fermentation; it is alſo much more agreeable to the palate, and will make the juices ſit eaſier on the ſtomach.

The London college have retained nearly their former formula, giving it only a more proper name.

Both theſe compoſitions are of conſiderable uſe for the purpoſes expreſſed in the title: the orange juice is an excellent aſſiſtant to the ſcurvy-graſs and other acrid antiſcorbutics; which, when thus mixed, have been found from experience to produce much better effects than when employed by themſelves. Theſe juices may be taken from an ounce or two to a quarter of a pint, two or three times a-day: they generally increaſe the urinary ſecretion, and ſometimes induce a laxative habit. Preſerved with the cautions abovementioned, they will keep good for a conſiderable time; though, whatever care be taken, they are found to anſwer better when freſh; and from the difficulty of preſerving them ſo, they have of late been very much laid aſide, eſpecially ſince we have been provided with more convenient and uſeful remedies.

Inspissated Juices.

123 When vegetable juices, or watery or ſpirituous decoctions or infuſions, are expoſed to a continued heat, the fluid gradually evaporating, carries off with it ſuch volatile matters as it was impregnated with, and leaves the more fixed united together into one maſs. The maſs which remains from the evaporation of the expreſſed juice of a plant is called *inſpiſſated juice;* from watery decoctions or infuſions, an *extract;* from ſpirituous tinctures, a *reſin*, or *eſſential extract*. The term *extract* is frequently uſed alſo as a general appellation of all the three kinds. Inſpiſſated juices and watery decoctions, particularly the former, when evaporated no further than to the conſiſtence of oil or honey, are called *robs;* and ſpirituous tinctures, reduced to a like conſiſtence, are called *balſams*.

What relates to the expreſſion of juices has already been delivered, with the moſt effectual means of preſerving them in their liquid ſtate, and a general account of what ſubſtances do or do not give out their virtues with their juices. In the inſpiſſation of juices, there is further to be conſidered the volatility or fixity of their medicinal parts: if a plant loſes its virtue, or part of its virtue, in being dried, it is obvious that the juice muſt loſe as much in being inſpiſſated to dryneſs, how gentle ſoever the heat be with which the inſpiſſation is performed. It is likewiſe to be obſerved, that the medicinal parts of ſome juices are kept in a ſtate of perfect ſolution by the watery fluid, ſo as to be completely retained by it after the liquor has been made fine by ſettling, ſtraining, or other means; while the medicinal parts of others, not diſſoluble by watery menſtrua, are only diffuſed through the liquor in the ſame manner as the feculencies are, and ſeparate along with theſe on ſtanding.

Inſpiſſated juice of the elder-berry. L.

124 Take of expreſſed and depurated juice of elder-berries two pints; inſpiſſate it in a water bath, ſaturated with ſea-ſalt.

Inſpiſſated juice, commonly called *rob of elder-berries.* E.

Take of juice of ripe elder-berries, five pounds; pureſt ſugar, one pound. Evaporate with a gentle heat to the conſiſtence of pretty thick honey. Preparations and Compoſitions.

This preparation, made with or without ſugar, keeps well, and proves a medicine of conſiderable importance as an aperient, generally promoting the natural excretions by ſtool, urine, or ſweat. The doſe is from a dram or two to an ounce or more. A ſpoonful, diluted with water, is uſually taken in common colds at bed-time.

Inſpiſſated juice of wolfsbane. E.

Bruiſe the freſh leaves of aconitum; and including them in a hempen bag, ſtrongly compreſs them in a preſs, ſo that they may give out their juice: let the juice be evaporated in open veſſels in a water-bath, to the conſiſtence of pretty thick honey: An empyreuma is to be avoided by conſtantly ſtirring the mixture towards the end of the proceſs. 125

After the matter has become cold, let it be put up in glazed earthen veſſels, and moiſtened with rectified ſpirit-of-wine.

In the ſame manner are prepared inſpiſſated juices of belladonna or deadly nightſhade, and hyoſcyamus or henbane.

In theſe inſpiſſated juices, the active parts of the plant are obtained in a concentrated ſtate, and in a condition which admits of preparation for a conſiderable length of time. They furniſh, therefore, a convenient form for exhibiting theſe articles which, in the practice of medicine, are perhaps more frequently uſed in the ſtate of inſpiſſated juice than any other. This is particularly the caſe with the hyoſcyamus, which may often be advantageouſly employed when opium is indicated, but diſagrees with the patient. But aconite and belladonna may in general, with greater advantage, be exhibited under the form of powder made from the dried leaves.

It is very remarkable that the London college have given no place to theſe articles. We cannot however help thinking, that their pharmacopœia would be enriched by introducing not only the articles themſelves, but likewiſe theſe preparations, eſpecially as they are not unfrequently preſcribed by Britiſh practitioners.

Inſpiſſated juice of hemlock. E.

Having expreſſed the juice of the leaves and ſtalks of hemlock when flowering, in the ſame manner as directed for that of the aconitum, evaporate it to the conſiſtence of pretty thin honey; when it is cooled, add of the powder of the dried leaves of the plant as much as to make it into a maſs fit for forming pills. Care, however, is to be taken, that the evaporation proceed only to ſuch length, that as much of the powder can be mixed with the inſpiſſated juice as ſhall make up about a fifth part of the whole maſs. 126

A preparation ſimilar to this was publiſhed at Vienna by Dr Stoerk, who recommends it as an efficacious reſolvent in many obſtinate diſorders, where the common remedies avail nothing. He obſerves, that ſmall doſes ſhould always be begun with, as two grains, made into a pill twice a-day; and that by gradually

Preparations and Compositions.

increasing the dose, it may be given to two, three, or even four drams a-day, and continued in such quantities for several weeks: that it may be used in safety in infancy, old age, and pregnancy: that it neither accelerates nor disturbs the circulation; neither heats, nor cools, nor affects the animal functions: that it increases the secretions, and renders the mouth moist; seldom purges; very rarely vomits; sometimes augments perspiration; often produces a copious discharge of viscid urine; but in many patients does not increase any of the sensible evacuations: that it removes obstructions and their consequences; relieves rheumatic pains, though of long continuance; discusses scirrhous tumors, both internal and external; and cures dropsies and consumptions proceeding from schirrhosities: that it often dissolves cataracts, or stops their progress, and has sometimes removed the gutta serena: that inveterate cutaneous eruptions, scald heads, malignant ulcers, cancers, the malignant fluor albus and gonorrhœa of long standing, obstinate remains of the venereal disease, and caries of the bones, generally yield to it: that for the most part it is necessary to continue this medicine for a considerable time before the cure be effected, or much benefit perceived from it: that in some cases it failed of giving any relief; that he met with some persons who could not bear its effects; and that consequently there must be some latent difference in the habit, the diagnostic signs of which are at present unknown: that though it is by no means infallible any more than other medicines, yet the great number of deplorable cases that have been happily cured by it, is sufficient to recommend it to further trials. The efficacy of this medicine is confirmed by many eminent practitioners abroad; though the trials hitherto made of it in this country have not been attended with much success. Somewhat, perhaps, may depend on the time of the plant's being gathered, and the manner of the preparation of the extract. Dr Stoerk himself takes notice of some mistakes committed in this respect: some have left the herb in a heap for several days, whence part of it withered, part rotted, and the juice became thick and mucilaginous; others have taken a very large quantity of the juice, and boiled it down in copper vessels with a great heat; by which means a strong fetor was diffused to a considerable distance, and the most efficacious parts dissipated: others, with officious care, have clarified the juice, and thus obtained a black tenacious extract, retaining but a small degree of the specific smell of the plant. The extract, duly prepared, according to the above prescription, is of a greenish brown colour, and a very disagreeable smell, like that of mice. But though there be reason to believe that much of the extract used here had been ill prepared, we can by no means admit that its general inefficacy was owing to this cause; for though there are not many instances of its discovering any valuable medicinal powers, there are several of its having activity enough, even in small doses, to produce alarming symptoms.

Modern practice, however, seems to hold a middle place; being neither influenced by the extravagant encomiums of Dr Stoerk, nor frightened by the wary suspicions of Dr Lewis. The inspissated juice of the hemlock is accordingly given with freedom in a great variety of complaints, without our experiencing the wonderful effects ascribed to it by the former, or the baneful consequences dreaded by the latter. Like other preparations of this valuable herb, it is no doubt a very useful addition to our pharmacopœia; nor does its use seem to be more hazardous than that of opium and some other narcotics.

Preparations and Compositions.

The London college direct the inspissated juice of cicuta to be prepared in the same manner as that of the elder-berry, and without the addition of any of the powder. This is the most pure extract; and the powder may easily be occasionally added. They direct the cicuta to be collected as soon as the flowers appear: And at that time the leaves are most fully impregnated with their active powers.

Inspissated juice of black currants. L.

Inspissated juice of lemons. L.

These two the London college also direct to be prepared in the same manner with the elder-berry juice. And under this form the agreeable and useful acid of these vegetables, in a concentrated state, may be preserved for a considerable length of time. 127

Chap. IV. *Extracts and Resins.*

Observations on Extracts with Water.

These extracts are prepared by boiling the subject in water, and evaporating the strained decoction to a thick consistence. 128

This process affords us some of the more active parts of the plants, free from the useless indissoluble earthy matter, which makes the largest share of their bulk. There is a great difference in vegetable substances, with regard to their fitness for this operation; some yielding to it all its virtues, and others scarce any. Those parts in which the sweet, glutinous, emollient, cooling, bitter, austere, astringent virtues reside, are for the most part totally extracted by the boiling water, and remain almost entire on evaporating it: whilst those which contain the peculiar odour, flavour, and aromatic quality, are either not extracted at all, or exhale along with the menstruum. Thus gentian root, which is almost simply bitter, yields an extract possessing in a small volume the whole taste and virtues of the root.—Wormwood, which has a degree of warmth and strong flavour joined to the bitter, loses the two first in the evaporation, and gives an extract not greatly different from the foregoing: the aromatic quality of cinnamon is dissipated by this treatment, its astringency remaining; while an extract made from the flowers of lavender and rosemary discovers nothing either of the taste, smell, or virtues of the flowers.

General Rules for making Extracts with Water.

1. It is indifferent, with regard to the medicine, whether the subject be used fresh or dry; since nothing that can be preferred in this process will be lost by drying. With regard to the facility of extraction, there is a very considerable difference; vegetables in general giving out their virtues more readily when moderately dried than when fresh. 129

2. Very

Preparations and Compositions.

2. Very compact dry ſubſtances ſhould be reduced into exceeding ſmall parts, previous to the affuſion of the menſtruum.

3. The quantity of water ought to be no greater than is neceſſary for extracting the virtues of the ſubject. A difference herein will ſometimes occaſion a variation in the quality of the product; the larger the quantity of liquor, the longer time will be requiſite for evaporating it, and conſequently the more volatile parts of the ſubject will be diſſipated. A long-continued heat likewiſe makes a conſiderable alteration in the matter which is not volatile. Sweet ſubſtances, by long boiling with water, become naufeous; and the draſtic purgatives loſe their virulence, though without any remarkable ſeparation of their parts.

4. The decoctions are to be depurated by colature; and afterwards ſuffered to ſtand for a day or two, when a conſiderable quantity of ſediment is uſually found at the bottom. If the liquor poured off clear be boiled down a little, and afterwards ſuffered to cool again, it will depoſite a freſh ſediment, from which it may be decanted before you proceed to finiſh the evaporation. The decoctions of very reſinous ſubſtances do not require this treatment, and are rather injured by it; the reſin ſubſiding along with the inactive dregs.

5. The evaporation is moſt conveniently performed in broad ſhallow veſſels; the larger the ſurface of the liquor, the ſooner will the aqueous parts exhale: This effect may likewiſe be promoted by agitation.

6. When the matter begins to grow thick, great care is neceſſary to prevent its burning. This accident, almoſt unavoidable if the quantity be large, and the fire applied as uſual under the evaporating pan, may be effectually provided againſt, by carrying on the inſpiſſation after the common manner, no farther than to the conſiſtence of a ſyrup, when the matter is to be poured into ſhallow tin or earthen pans, and placed in an oven, with its door open, moderately heated; which acting uniformly on every part of the liquid, will ſoon reduce it to any degree of conſiſtence required. This may likewiſe be more ſecurely done, by ſetting the evaporating veſſel in boiling water, but the evaporation is in this way very tedious.

Obſervations on Extracts with Rectified Spirit.

130 Rectified ſpirit of wine diſſolves the eſſential oils and reſins of vegetables, and does not readily carry off the oil in its exhalation; the heat ſufficient to exhale pure ſpirit being much leſs than that in which water evaporates to any conſiderable degree, or moſt eſſential oils diſtil. Hence a reſinous or ſpirituous extract of wormwood, contrary to that made with water, contains the warmth and flavour, as well as bitterneſs, of the herb; one made from cinnamon poſſeſſes its aromatic virtue, as well as its aſtringency; and one from lavender and roſemary flowers, retains great part of their flavour and virtues; the volatile parts, which are carried off by water in its evaporation, being left behind by the ſpirit.

The ſpirit employed for this purpoſe ſhould be perfectly free from any ill flavour, which would be communicated in part to the preparation; and from any admixture of phlegm or water, which would not only vary its diſſolving power, but likewiſe, evaporating towards the end of the inſpiſſation, would promote the diſſipation of the volatile parts of the ſubject. Hence, alſo, the ſubject itſelf ought always to be dry: thoſe ſubſtances which loſe their virtue by drying, loſe it equally on being ſubmitted to this treatment with the pureſt ſpirit.

Preparations and Compoſitions.

The inſpiſſation ſhould be performed from the beginning, in the gentle heat of a water bath. It is not needful to ſuffer the ſpirit to evaporate in the air: greateſt part of it may be recovered by collecting the vapour in common diſtilling veſſels. If the diſtilled ſpirit be found to have brought over any flavour from the ſubject, it may be advantageouſly reſerved for the ſame purpoſes again.

It is obſervable, that though rectified ſpirit be the proper menſtruum of the pure volatile oils, and of the groſſer reſinous matter of vegetables, and water of the mucilaginous and ſaline; yet theſe principles are, in almoſt all plants, ſo intimately combined together, that whichever of theſe liquors is applied at firſt, it will take up a portion of what is directly ſoluble only in the other. Hence ſundry vegetables, extremely reſinous, and whoſe virtues conſiſt chiefly in their reſin, afford nevertheleſs very uſeful extracts with water, though not equal to thoſe which may be obtained by a prudent application of ſpirit. Hence alſo the extracts made from moſt vegetables by pure ſpirit, are not mere reſins; a part of the gummy matter, if the ſubject contained any ſuch, is taken up along with the reſin; an admixture of great advantage to it in a medicinal view. The ſpirituous extracts of ſeveral vegetable ſubſtances, as mint leaves, rhubarb, ſaffron, diſſolve in water as well as in ſpirit.

Pure reſins are prepared by mixing, with ſpirituous tincture of very reſinous vegetables, a quantity of water. The reſin, incapable of remaining diſſolved in the watery liquor, ſeparates and falls to the bottom; leaving in the menſtruum ſuch other principles of the plant as the ſpirit might have extracted at firſt along with it.

Obſervations on Extracts with Spirit and Water.

There are ſundry vegetables, particularly thoſe of a reſinous nature, which are treated to better advantage with a mixture of water and ſpirit, than with either of them ſingly. The virtues of reſinous woods, barks, and roots, may indeed be in great part extracted by long boiling in freſh portions of water; but at the ſame time they ſuffer a conſiderable injury from the continued heat neceſſary for the extraction, and for the ſubſequent evaporation of ſo large a quantity of the fluid. Rectified ſpirit of wine is not liable to this inconvenience; but the extracts obtained by it from the ſubſtances here intended, being almoſt purely reſinous, are leſs adapted to general uſe than thoſe in which the reſin is divided by an admixture of the gummy matter, of which water is the direct menſtruum. 131

There are two ways of obtaining theſe compound or gummy-reſinous extracts: one, by uſing proof-ſpirit, that is, a mixture of about equal parts of ſpirit and water, for the menſtruum; the other, by digeſting the ſubject firſt in pure ſpirit and then in water, and afterwards uniting into one maſs the parts which

Preparations and Compositions.

the two menſtrua have ſeparately extracted. In ſome caſes, where a ſufficiency of gummy matter is wanting in the ſubject, it may be artificially ſupplied, by inſpiſſating the ſpirituous tincture to the conſiſtence of a balſam, then thoroughly mixing with it a thick ſolution of any ſimple gum, as mucilage of gum-arabic, and drying the compound with a gentle heat. By this method are obtained elegant gummy-reſins, extemporaneouſly miſcible with water into milky liquors.

Obſervations on extracts by long digeſtion.

132 It has been obſerved, that the virtues of vegetable decoctions are altered by long boiling. Decoctions or infuſions of drallic vegetables, by long continued boiling or digeſtion, loſe more and more of their virulence; and at the ſame time depoſite more and more of a groſs ſediment, reſulting probably from the decompoſition of their active parts. On this foundation it has been attempted to obtain ſafe and mild preparations from ſundry virulent drugs; and ſome of the chemiſts have ſtrongly recommended the proceſs, though without ſpecifying, or giving any intimation of, the continuance of boiling requiſite for producing the due mildneſs in different ſubjects. M. Beaumé, in his *Elemens de Pharmacie*, lately publiſhed, has given a particular account of an extract of opium prepared on this principle; of which extract, as it is alleged to be very uſeful in practice, it may not be improper to give a ſhort deſcription: And this we ſhall accordingly ſubjoin to our account of the opium purificatum of the London college.

Obſervations on particular extracts.

133 *Extract of chamomile,*
broom tops,
gentian,
liquorice,
blackhellebore,
rue,
ſavin. L.

Boil the article in diſtilled water, preſs out the decoction, ſtrain it, and ſet it apart that the feces may ſubſide; then boil it again in a water-bath ſaturated with ſea-ſalt to a conſiſtence proper for making pills.

The ſame kind of bath is to be uſed in the preparation of all the extracts, that the evaporation may be properly performed.

Extract of gentian. E.

134 Take of gentian root as much as you pleaſe. Having cut and bruiſed it, pour upon it four times its quantity of water. Boil to the conſumption of one half of the liquor; and ſtrongly expreſſing it, ſtrain. Evaporate the decoction to the conſiſtence of thick honey in veſſels expoſed to the vapour of hot water.

In preparing this and every other extract, it is neceſſary to keep up a conſtant ſtirring towards the end of the proceſs, in order to prevent an empyreuma, and that the extract may be of an uniform conſiſtence, and free of clots.

In the ſame manner are prepared,

Extract of the roots of black hellebore;
leaves of the pulſatilla nigricans;
leaves of rue;
leaves of white poppies;
imperfectly ripe ſeeds of hemlock.

All the above extracts contain the virtues of the vegetable in a ſtate of tolerable perfection.

The extract of chamomile loſes in its formation the ſpecific flavour of the plant; but it is ſaid to furniſh a bitter remarkably antiſeptic, and to be given with advantage in different ſtomach ailments to the extent of a ſcruple or two, either by itſelf, or in conjunction with other remedies. The extract of broom tops is chiefly employed in hydropic caſes; and when taken to the quantity of about a dram, is ſaid to operate as a powerful diuretic.

The mode of preparing theſe extracts directed by the London and Edinburgh colleges is not eſſentially different: but ſome advantage will ariſe from employing the diſtilled water directed by the former; and the directions given by the latter with regard to the quantity of water to be uſed, and the degree of boiling to be employed before expreſſion, are not without ſome uſe.

The extract is the only preparation of the pulſatilla nigricans, and it ſeems ſufficiently well ſuited to be brought into this form. The extract of the white poppy-heads is not perhaps ſuperior in any reſpect to opium; but to thoſe who may think otherwiſe, it is convenient to preſerve them in this form for preparing the ſyrup occaſionally. The ſeeds of hemlock have by ſome been thought ſtronger, or at leaſt that they produce giddineſs ſooner, than the leaves; but this extract has not hitherto come into general uſe.

Compound extract of coloquintida. L.

Take of pith of coloquintida, cut ſmall, ſix drams; ſocotorine aloes, powdered, an ounce and a half; ſcammony, powdered, half an ounce; ſmaller cardamon ſeeds, huſked and powdered, one dram; proof ſpirit, one pint. Digeſt the coloquintida in the ſpirit, with a gentle heat, during four days. To the expreſſed tincture add the aloes and ſcammony: when theſe are diſſolved, diſtil off the ſpirit, ſo that what remains may be of a conſiſtence proper for making pills, adding the ſeeds towards the end of the proceſs. 135

This compoſition anſwers very effectually as a cathartic, ſo as to be relied on in caſes where the patient's life depends on that effect taking place: the doſe is from fifteen grains to half a dram. The proof ſpirit is a very proper menſtruum for the purgative materials; diſſolving nearly the whole ſubſtance of the aloes and ſcammony, except the impurities; and extracting from the colocynth, not only the irritating reſin, but great part of the gummy matter. In the former pharmacopœias three ſpices were employed in this compoſition, cinnamon, mace, and cloves: the cardamom ſeeds, now introduced, are preferable, on account of their aromatic matter being of a leſs volatile nature; though a conſiderable part of the flavour, even of theſe, is diſſipated during the evaporation of the phlegmatic part of the proof-ſpirit.

Elaterium. L.

Slit ripe wild cucumbers, and paſs the juice, very lightly 136

lightly preſſed, through a fine hair ſieve, into a glaſs veſſel; then ſet it by for ſome hours until the thicker part has ſubſided. Pour off the thinner part ſwimming at the top, and ſeparate the reſt by filtering: cover the thicker part, which remains after filtration, with a linen cloth, and dry it with a gentle heat.

What happens in part in preparing the extract of hemlock, happens in this preparation completely, viz. the ſpontaneous ſeparation of the medicinal matter of the juice on ſtanding for a little time: and the caſe is the ſame with the juices of ſeveral other vegetables, as thoſe of arum root, iris root, and bryony root. Preparations of this kind have been commonly called *fæculæ*. The filtration above directed, for draining off ſuch part of the watery fluid as cannot be ſeparated by decantation, is not the common filtration through paper, for this does not ſucceed here: the groſſer parts of the juice, falling to the bottom, form a viſcid cake upon the paper, which the liquid cannot paſs through. The ſeparation is to be attempted in another manner, ſo as to drain the fluid from the top: this is effected by placing one end of ſome moiſtened ſtrips of woollen cloth, ſkains of cotton, or the like, in the juice, and laying the other end over the edge of the veſſel, ſo as to hang down lower than the ſurface of the liquor: by this management the ſeparation ſucceeds in perfection.

Elaterium is a very violent hydragogue cathartic. In general, previous to its operation, it excites conſiderable ſickneſs at the ſtomach, and not unfrequently it produces ſevere vomiting. Hence it is ſeldom employed till other remedies have been tried in vain. But in ſome inſtances of aſcites it will produce a complete evacuation of water where other cathartics have had no effect. Two or three grains are in general a ſufficient doſe. And perhaps the beſt mode of exhibiting it is by giving it only to the extent of half a grain at a time, and repeating that doſe every hour till it begins to operate.

Extract of logwood. L.

Take of ſhavings of logwood, one pound. Boil it four times, or oftener, in a gallon of diſtilled water, to one half; then, all the liquors being mixed and ſtrained, boil them down to a proper conſiſtence.

The extract of logwood has been uſed for a conſiderable time in ſome of our hoſpitals. It has an agreeable ſweet taſte, with ſome degree of aſtringency; and hence becomes ſerviceable in diarrhœas, for moderately conſtringing the inteſtines and oriſices of the ſmaller veſſels: it may be given from a ſcruple to half a dram, and repeated five or ſix times a-day with advantage. During the uſe of this medicine, the ſtools are frequently tinged red by it, which has occaſioned ſome to be alarmed as if the colour proceeded from blood: the practitioner therefore ought to caution the patient againſt any ſurpriſe of this kind.

The active parts of the logwood are difficultly extracted by means of water alone: hence the Edinburgh college call in the aid of ſpirit of wine, directing this extract to be prepared in the ſame manner as that of jalap, afterwards to be mentioned. And of the two modes, we are inclined to conſider the latter as intitled to the preference.

Extract of Peruvian bark. L.

Preparations and Compoſitions.

Take of Peruvian bark, coarſely powdered, one pound; diſtilled water, 12 pints. Boil it for one or two hours, and pour off the liquor, which, while hot, will be red and pellucid; but, as it grows cold, will become yellow and turbid. The ſame quantity of water being again poured on, boil the bark as before, and repeat this boiling until the liquor, being cold, remains clear. Then reduce all theſe liquors, mixed together and ſtrained, to a proper thickneſs by evaporation. 138

This extract muſt be prepared under two forms; one *ſoft*, and fit for making pills; the other *hard*, that it may be reducible to a powder.

Extract of Peruvian bark with the reſin. L.

Take of Peruvian bark, reduced to coarſe powder, one pound; rectified ſpirit of wine, four pints. Digeſt it for four days, and pour off the tincture; boil the reſiduum in 10 pints of diſtilled water to two; then ſtrain the tincture and decoction ſeparately, evaporating the water from the decoction, and diſtilling off the ſpirit from the tincture, until each begins to be thickened. Laſtly, mix the reſinous with the aqueous extract, and make the maſs fit for forming into pills. 139

Extract of Peruvian bark. E.

The Edinburgh college, who have not given a place to any pure watery extract of the bark, direct their extract of this medicine to be prepared in the ſame manner as their extract of jalap, that is, almoſt preciſely in the ſame manner as the extract with reſin of the London college. It is, however, we think with propriety, that the London college have given a place to both extracts; for neither is without its uſe. 140

Peruvian bark is a reſinous drug; the reſin melts out by the heat, but is not perfectly diſſolved by the water: hence, in cooling, it ſeparates, renders the liquor turbid, and in part falls to the bottom, as appears manifeſtly upon examining the ſediment by ſpirit of wine. This extract might be made to better advantage by the aſſiſtance of ſpirit of wine, after the ſame manner as that of jalap; and this method the Edinburgh college have directed. But all the ſpirits which can be expected to be employed for this proceſs among us, are accompanied with ſome degree of bad flavour: this adheres moſt ſtrongly to the phlegmatic part of the ſpirit, which evaporating laſt, muſt communicate this ill flavour to the extract; a circumſtance of very great conſequence, as this medicine is deſigned for thoſe whoſe ſtomachs are too weak to bear a due quantity of bark in ſubſtance. Ten or twelve grains of the hard extract are reckoned equivalent to about half a dram of the bark itſelf.

In the Peruvian bark, however, we may readily diſtinguiſh two different kinds of taſtes, an aſtringent and a bitter one; the former ſeems to reſide principally in the reſinous matter, and the latter chiefly in the gummy. The watery extract is moderately ſtrong in point of bitterneſs, but of the aſtringency it has only a ſmall degree. The pure reſin, on the other hand, is ſtrong in aſtringency, and weak in bitterneſs. Both qualities

are

Preparations and Compositions.

are united in the extract with the refin; which appears to be the beſt preparation of this kind that can be obtained from this valuable drug.

Extract of caſcarilla. L.

141 This extract, which is now for the firſt time introduced into the pharmacopœia of the London college, and which has not yet obtained a place in that of Edinburgh, is directed to be prepared by ſpirit and water in the ſame manner as the extract of bark with the refin. It poſſeſſes, in a concentrated ſtate, the active conſtituent parts of the caſcarilla, and has accordingly been already received into ſeveral of the beſt foreign pharmacopœias. In ſome of theſe, as the Pharmacopœia Suecica, it is a mere watery extract: but in others, as the Pharmacopœia Roſſica, the aid both of ſpirits and water are conjoined; and this we conſider as the beſt preparation.

Extract of jalap. E.

142 Take of jalap root one pound; rectified ſpirit of wine, four pounds. Digeſt four days, and pour out the tincture. Boil the remaining magma in ten pounds of water to two pounds; then ſtrain the decoction, and evaporate it to the conſiſtence of pretty thin honey. Draw off the ſpirit from the tincture by diſtillation till what remains becomes thick. Then mix the liquors thus inſpiſſated; and keeping them conſtantly ſtirring, evaporate to a proper conſiſtence.

The extract of jalap is directed to be prepared by the London college in the ſame manner as their extract of Peruvian bark with the reſin, which differs in nothing from the mode of preparation above directed.

This extract is an uſeful purgative; by ſome thought preferable to the crude root, as being of more uniform ſtrength, and as the doſe, by the rejection of the woody parts, is rendered ſmaller: the mean doſe is 12 grains. If the ſpirituous tincture were inſpiſſated by itſelf, it would afford a reſinous maſs, which, unleſs thoroughly divided by proper admixtures, occaſions violent griping, and yet does not prove ſufficiently cathartic; the watery decoctions yield an extract which operates very weakly: both joined together, as in this preparation, compoſe an effectual and ſafe purge. This method of making extracts might be advantageouſly applied to ſeveral other reſinous ſubſtances, as the dry woods, roots, barks, &c. A ſmall quantity of ſpirit takes up the reſin; and much leſs water than would otherwiſe be neceſſary, extracts all the other ſoluble parts.

In a former edition of the Edinburgh Pharmacopœia, a little fixed alkaline ſalt was ordered to be added to the water in which the jalap is boiled after the action of ſpirit; on a ſuppoſition that this would enable the water to extract more from the root than it could by itſelf. But, ſo far as the quantity of the alkaline ſalt could go, it had the oppoſite effect, impeding the action of the water. The reſinous parts of the jalap are diſſolved by the ſpirit; and little other than the gummy matter remains for water to extract. Now, if pure gum arabic be put into water along with any alkaline ſalt, the ſalt will render the water incapable of diſſolving the gum: if the gum be diſſolved firſt, the addition of any alkaline ſalt will precipitate it.

Extract of ſenna. L.

Take of ſenna, one pound; diſtilled water, one gallon. 143
Boil the ſenna in the diſtilled water, adding after its decoction a little rectified ſpirit of wine. Evaporate the ſtrained liquor to a proper thickneſs.

This extract had no place in our former pharmacopœias, but may be conſidered as an uſeful addition.

The reſinous parts of ſenna are in ſo ſmall a proportion to the gummy, that they are readily boiled out together. The ſpirit may be added when the decoction is reduced to one half or to three pints.

This extract is given as a gentle purgative from 10 grains to a ſcruple; or, in leſs quantity, as an aſſiſtant to the milder laxatives.

Purified opium. L.

Take of opium, cut into ſmall pieces, one pound; 144
proof-ſpirit of wine, 12 pints. Digeſt the opium with a gentle heat, ſtirring now and then till it be diſſolved, and filter through paper. Diſtil the tincture, ſo prepared, to a proper thickneſs.

Purified opium muſt be kept in two forms; one *ſoft*, proper for forming into pills; the other *hard*, which may be reduced into powder.

Opium was formerly purified by means of water; and in this ſtate it had the name in our pharmacopœia of *extractum thebaicum*. But proof-ſpirit has been found, by experiments, to be the beſt menſtruum for opium, having diſſolved three-fourths of dried opium, which was much more than was taken up either by rectified ſpirit or water. Hence we thus obtained moſt entirely the conſtituents of opium free from any adhering impurities: but it has been imagined that ſome particular advantages ariſe from the parts which are extracted by water, eſpecially after long digeſtion; and accordingly the following extract of opium has been recommended by Mr Beaumé.

Extract of opium prepared by long digeſtion.

Let five pounds of good opium, cut in pieces, be boil- 145
ed about half an hour, in 12 or 15 quarts of water: ſtrain the decoction, and boil the remainder once or twice in freſh water, that ſo much of the opium as is diſſoluble in water may be got out. Evaporate the ſtrained decoctions to about ſix quarts; which being put into a tin cucurbit, placed in a ſand-bath, keep up ſuch a fire as may make the liquor nearly boil, for three months together if the fire is continued day and night, and for ſix months if it is intermitted in the night; filling up the veſſel with water in proportion to the evaporation, and ſcraping the bottom with a wooden ſpatula from time to time, to get off the ſediment which begins to precipitate after ſome days digeſtion. The ſediment needs not to be taken out till the boiling is finiſhed; at which time the liquor is to be ſtrained when cold, and evaporated to an extract of a due conſiſtence for being formed into pills.

The author obſerves, that by keeping the liquor ſtrongly boiling, the tedious proceſs may be conſiderably expedited, and the ſix months digeſtion reduced to

to four months: that in the beginning of the digeſtion, a thick, viſcous, oily matter riſes to the top, and forms a tenacious ſkin as the liquor cools; this is ſuppoſed to be an logous to eſſential oils, though wanting their volatility: that the oil begins to diſappear about the end of the firſt month, but ſtill continues ſenſible till the end of the third, forming oily clouds as often as the liquid cools: that the reſin at the ſame time ſettles to the bottom in cooling, preſerving for a long while its reſinous form, but by degrees becoming powdery, and incapable of being any longer ſoftened, or made to cohere by the heat: that when the proceſs is finiſhed, part of it ſtill continues a perfect reſin, diſſoluble in ſpirit of wine, and part an indiſſoluble powder: that when the digeſted liquor is evaporated to about a quart, and ſet in the cold till next day, it yields a browniſh earthy ſaline matter, called the *eſſential ſalt of opium*, in figure nearly like the ſedative ſalt obtained from borax, intermingled with ſmall needled cryſtals. He gives an account of his having made this preparation ſix or ſeven times. The veſſel he made uſe of was about two inches and a half diameter in the mouth: the quantity of water evaporated was about 24 ounces a day, and from 130 to 140 quarts during the whole digeſtion. Out of 64 ounces of opium, 17 ounces remained undiſſolved in the water; the quantity of reſinous matter precipitated during the digeſtion, was 12 ounces: from the liquor, evaporated to a quart, he obtained a dram of eſſential ſalt, and might, he ſays, have ſeparated more; the liquor being then further evaporated to a pilular conſiſtence, the weight of the extract was 31 ounces.

It is ſuppoſed that the narcotic virtue of opium reſides in the oily and reſinous parts; and that the gummy extract, prepared by the above proceſs, is endowed with the calming, ſedative, or anodyne powers of the opium, diveſted of the narcotic quality as it is of the ſmell, and no longer productive of the diſorders which opium itſelf, and the other preparations of it, frequently occaſion. A caſe is mentioned, from which the innocence and mildneſs of the medicine are apparent; 50 grains having been taken in a day, and found to agree well, where the common opiate preparations could not be borne. But what ſhare it poſſeſſes of the proper virtues of opium is not ſo clear; for the cure of convulſive motions of the ſtomach and vomitings, which at length happened after the extract had been continued daily in the above doſes for ſeveral years *(pluſieurs années)*, cannot perhaps be aſcribed fairly to the medicine.

If the theory of the proceſs, and of the alteration produced by it in the opium, be juſt, a preparation equivalent to the above may be obtained in a much ſhorter time. If the intention is to ſeparate the reſinous and oily parts of opium, they may be ſeparated by means of pure ſpirit of wine, in as many hours as the digeſtion requires months. The ſeparation will alſo be as complete, in regard to the remaining gum, tho' ſome part of the gum will in this method be loſt, a little of it being taken up by the ſpirit along with the other principles.

In what particular part of opium its peculiar virtues reſide, has not perhaps been inconteſtably aſcertained; but this much ſeems clear from experiment, that the pure gum, freed from all that ſpirit can diſſolve, does not differ eſſentially in its ſoporific power from the reſinous part.

Preparations and Compoſitions

There are grounds alſo to preſume, that by whatever means we deſtroy or diminiſh what is called the *narcotic, ſoporific, virulent quality of opium*, we ſhall deſtroy or diminiſh likewiſe its ſalutary operation. For the ill effects which it produces in certain caſes, ſeem to be no other than the neceſſary conſequences of the ſame power, by which it proves ſo beneficial in others.

Extract of wormwood. Suec.

146 Take any quantity of the tops of wormwood, and pour upon it double its weight of water. Boil it for a ſhort time over a gentle fire, then preſs out the liquor. Boil the reſiduum again in a freſh quantity of water, and after expreſſion, ſtrain it. Let the ſtrained liquor be evaporated in a water-bath to a proper conſiſtence.

In this extract we have one of the ſtrongeſt vegetable bitters in its moſt concentrated ſtate: and though it is not perhaps to be conſidered as ſuperior to the extract of gentian, yet it furniſhes a good variety, and is a more agreeable form for exhibiting the wormwood than that of ſtrong tincture.

Extract of dandelion. Suec.

147 This is directed to be prepared from the roots of the dandelion, collected early in the ſpring, or late in the autumn, in the ſame manner as the extractum abſinthii. And as far as the dandelion really poſſeſſes a reſolvent, aperient, or diuretic power, it furniſhes a convenient form for obtaining theſe effects from it. But as the dandelion is well known to abound with a milky juice, it is probable that the activity of the medicine would be increaſed from employing ſpirit alſo in the extraction of its medical virtues.

Watery extract of aloes. Suec.

148 Take of hepatic aloes one pound; cold ſpring-water, four pounds; juice of citrons, one pound. Macerate them in a glaſs veſſel for one or two days, ſhaking the veſſel from time to time. When the reſinous and feculent parts have ſubſided, pour off the liquor; and to the reſiduum add freſh water, till by this treatment it obtains a little impregnation. Let the ſtrained liquors be then evaporated in a warm bath to the conſiſtence of honey.

Although aloes are perhaps upon the whole a better medicine, in their crude ſtate, where the gummy and reſinous matters are united, than in thoſe preparations where either is retained ſeparately, yet the gummy extract which is thus obtained is at leaſt leſs diſagreeable, having little ſmell or taſte, while at the ſame time it is a very powerful purgative: hence it may be uſefully employed at leaſt on ſome occaſions.

Gummy extract of myrrh. Brun.

149 Take of myrrh, half a pound; ſpring-water, four pounds. Let the myrrh be diſſolved by gentle digeſtion and repeated agitation of the veſſel for four or five days: let the water ſwimming above the myrrh be then poured off, ſtrained, and evaporated to the conſiſtence of an extract.

Preparations and Compositions.

This watery extract of myrrh may be useful in some cases, as being much deprived of the heating qualities which it has in its crude state: and if it furnishes us in phthisis pulmonalis with that useful remedy which some imagine, it may probably be most advantageously exhibited under this form.

Refined liquorice. Dan.

150 Take any quantity of Spanish liquorice, cut it into small fragments, dissolve it in tepid water, and strain the solution. Let the liquor be poured off from the feculent part after it has subsided, and inspissated by a gentle heat.

The extract of liquorice already mentioned, when it is prepared with due skill and attention, is unquestionably an article superior to this; but it is very rarely met with in the shops of our druggists or apothecaries as prepared by themselves. In its place they very commonly employ either the extract brought from Spain, or that prepared by the makers of liquorice at home; both of which very commonly abound with impurities. It has even been said, that a portion of sand is not unfrequently mixed with it to increase the weight: but whether the impurities arose from this cause, or from the slovenly mode of preparing it, considerable advantage must arise from freeing it from all these before it be employed for any purpose in medicine. And in modern practice it is frequently used, not only in troches and pills, but also for suspending powders in waters; such as the powder of Peruvian bark: and the powder of bark, when thus suspended, is in general taken more readily by children than in any other form. Hence considerable advantage must arise from a proper and easy mode of purifying it, which the above process affords. We are of opinion, therefore, that although a place be with propriety given to the extract of liquorice prepared by the apothecaries themselves, refined liquorice ought also to be introduced into our pharmacopœias; and it would be very convenient to keep it in the shops in a soft consistence fit for making pills, as it would not only answer that purpose, but admit of a ready solution in water when requisite. To this consistence, indeed, an objection occurs, from its being apt to grow mouldy; but this may be effectually prevented by the addition of a small proportion of spirit.

Besides the extracts which we have here selected from the foreign pharmacopœias, many others also still retain a place in several of these; such, for example, as the *extractum arnicæ*, *artemisiæ*, *bryoniæ*, *cardui*, *centaurei*, *cochleariæ*, *croci*, &c. Several of these had formerly a place in our pharmacopœias, but are now with propriety rejected; because, where these substances are to be employed, they may with much more advantage be exhibited under other forms. And, indeed, although under the form of extract we have a condensation of some active principles, yet by the action of fire others are very apt to be lost. Hence, where any article can be conveniently exhibited in substance, that form is in general preferable; and recourse should be had to extracts only with a view to some particular intention. Our colleges therefore have with propriety diminished the number of them; and even those which they have adopted are but seldom to be had recourse to in preference to other forms. In the formation of many of those extracts, retained by the foreign colleges, the most valuable principles are either entirely dissipated or destroyed by the fire. We think, however, that advantage may sometimes be obtained from adopting these which are here selected.

The chapter on extracts and resins in the London pharmacopœia is concluded with the two following general directions:

1. All the extracts, during the time of inspissation, must be gently agitated.

2. On all the softer watery extracts, a small quantity of spirit of wine must be sprinkled.

Chap. V. *Expressed Oils.*

Expressed oils are obtained chiefly from certain seeds and kernels of fruits, by thoroughly pounding them in a stone mortar, or, where the quantities are large, grinding them in mills, and then including them in a canvas bag, which is wrapt in a hair-cloth, and strongly pressed between iron plates. The canvas, if employed alone, would be squeezed so close to the plates of the press as to prevent the oil from running down: by the interposition of the hair-cloth a free passage is allowed it. 151

Sundry machines have been contrived, both for grinding the subject and pressing out the oil, in the way of business. To facilitate the expression, it is usual to warm either the plates of the press, or the subject itself after the grinding, by keeping it stirring in a proper vessel over the fire; the oil, liquefied by the heat, separates more freely and more plentifully. When the oil is designed for medicinal purposes, this practice is not to be allowed; for heat, especially if its degree be sufficient to be of any considerable advantage for promoting the separation, renders the oil less soft and palatable, impresses a disagreeable flavour, and increases its disposition to grow rancid: hence the colleges both of London and Edinburgh expressly require the operation to be performed without heat.

Nor are the oils to be kept in a warm place after their expression. Exposed for a few days to a heat no greater than that of the human body, they lose their emollient quality, and become highly rancid and acrimonious. Too much care cannot be taken for preventing any tendency to this acrid irritating state in medicines, so often used for abating immoderate irritation.

So much are these oils disposed to this injurious alteration, that they frequently contract an acrimony and rancidity while contained in the original subjects. Hence great care is requisite in the choice of the unctuous seeds and kernels, which are often met with very rancid; almonds are particularly liable to inconveniences of this kind.

Expressed oils are prepared for mechanic uses from sundry different subjects, as nuts, poppy-seed, hemp-seed, rape-seed, and others. Those directed for medicinal purposes in the London and Edinburgh pharmacopœias are the following:

Oil of almonds. L. E.

Pound fresh almonds, either sweet or bitter, in a mortar, then press out the oil in a cold press. 152

In

In the same manner is to be expressed oil of linseed and oil of mustard-seed.

The oil of almonds is prepared from the sweet and bitter almonds indifferently, the oils obtained from both sorts being exactly the same. Nor are the differences of the other oils very considerable, the discriminating qualities of the subjects not residing in the oils that are thus obtained by expression. The oil of linseed requires indeed some peculiarities from containing a proportion of vegetable mucilage; but the oil of mustard-seed is as soft, insipid, and void of pungency, as that of sweet almonds, the pungency of the mustard remaining entire in the cake left after the expression. The several oils differ in some of their properties from each other; but in medicinal qualities they appear to be all nearly alike, and agree in one common emollient virtue. They soften and relax the solids, and obtund acrimonious humours; and thus become serviceable internally in pains, inflammations, heat of urine, hoarseness, tickling coughs, &c. in glysters, for lubricating the intestines, and promoting the ejection of indurated feces; and in external applications, for tension and rigidity of particular parts. Their common dose is half an ounce; in some cases they are given to the quantity of three or four ounces. The most commodious forms for their exhibition we shall see hereafter in the chapter of Emulsions.

Castor oil. L.

153 This oil is directed by the London college to be prepared in the same manner as that of almonds, the seeds or nuts being taken from the husks before putting them into the mortar. Palma Christi, or castor oil, (See *Oleum Palmæ Christi*, and Ricinus), is a gentle and useful purgative: it generally produces its effects without griping, and may be given with safety where acrid purgatives are improper. With adults, from half an ounce to an ounce is generally requisite for a dose. This article, however, is very seldom prepared by our apothecaries, being in general imported under the form of oil from the West Indies: hence the Edinburgh college have not mentioned it among their preparations, but merely given it a place in their list of the materia medica. But when our apothecaries prepare it for themselves, they are more certain of obtaining a pure oil, and one too obtained without the aid of heat, which is often employed, and gives a much inferior oil. It is therefore with propriety that the London college have given directions for the preparation of it by the apothecary himself. But even the London college have not thought it necessary to give directions for the preparation of the following expressed oils, which, as well as the *oleum ricini*, are also introduced into the list of the materia medica by the Edinburgh college.

Expressed oil of bay berries,
mace,
olives,
palm.

154 These also are principally considered as possessing only an emollient virtue; but as far as they have been supposed to exert any peculiar qualities, these we have had occasion to mention in other parts of the work, when treating of the articles from which they are obtained. See Olea, Mace, &c.

Preparations and Compositions

Oil of chocolate nuts. Suec.

Express the oil from the nuts slightly toasted, and freed from their coverings. 155

In this oil we have the nutritious part of chocolate, free from those aromatics with which it is united in the state in which it is kept in our shops. And although under the form of chocolate it sits perhaps more easily on the stomach than in most other forms; yet where, from any particular circumstance, aromatics are contraindicated, the oil in its pure state gives us an opportunity of employing in different ways this mild nutritious article.

Oil of hyoscyamus. Suec.

This oil is directed to be obtained by expression from the seeds of the hyoscyamus, in the same manner as that of almonds. 156

Of the narcotic powers of the hyoscyamus some observations have already been offered. This oil, although an expressed one, is said to retain these virtues; and accordingly it has entered the composition of some anodyne ointments and plasters. We are, however, inclined to think, that when the sedative power of hyoscyamus is wanted under the form of oil, it may be best obtained from impregnating olive oil by the leaves of the plant.

Egg oil. Suec.

Take any quantity of fresh eggs, boil them till they be quite hard; then take out the yolks, break them in pieces, and roast them gently in a frying-pan till they feel greasy when pressed between the fingers; put them while warm into a hair-bag, and express the oil. 157

The yolk of the egg is well known to be a mild nutritious substance: but notwithstanding the many virtues at one time attributed to it, of being paregoric and styptic, as externally applied; and of being useful in stomach complaints, dysentery, and different affections of the alimentary canal, when taken internally;—it is much to be doubted whether it be in any other way useful in medicine than as an article of diet; and we are very uncertain whether any particular purpose in medicine will be answered by this expressed oil: but as it holds a place in most of the foreign pharmacopœias of modern date, it may justly be considered as deserving some attention.

Notwithstanding the justice of the observation respecting the great similarity of expressed oils in general, yet there can be no doubt that in some instances they obtain a peculiar impregnation. This manifestly appears in the *oleum ricini*, *oleum nucis moschatæ*, and some of the others mentioned above. Indeed oils expressed from aromatic substances in general retain some admixture of the essential oil of the subject from which they are expressed. Nor is this surprising, when we consider that in some cases the essential oil exists in a separate state even in the growing plant.

The rinds of the several varieties of oranges, lemons, and citrons, yield by a kind of expression their essential

Preparations and Compositions.

oils almoſt pure, and nearly ſimilar to thoſe which are obtained from them by diſtillation. The eſſential oils, in which the fragrance and aromatic warmth of theſe fruits reſide, are contained in numerous little veſicles, which may be diſtinguiſhed by the naked eye, ſpread all over the ſurface of the peel. If the rind be cut in ſlices, and the ſlices ſeparately doubled or bent in different parts, and ſqueezed between the fingers, the veſicles burſt at the bending, and diſcharge the oil in a number of fine ſlender jets. A glaſs plate being ſet upright in a glaſs or porcelain veſſel, and the ſlices ſqueezed againſt the plates, the little jets unite into drops upon the plate, and trickle down into the veſſel beneath. But though this proceſs affords the true native oil in the ſame ſtate wherein it exiſted in the ſubject, unaltered by fire or other agents, it is not practicable to advantage unleſs where the fruit is very plentiful, as only a ſmall part of the oil it contains can thus be extracted or collected.

The oil is more perfectly ſeparated by rubbing the rind upon a lump of ſugar. The ſugar, by the inequality of its ſurface, produces the effect of a raſp in tearing open the oily veſicles, and in proportion as the veſicles are opened the ſugar imbibes the oil. When the outward part of the lump is ſufficiently moiſtened, it is ſcraped off, and the operation continued on the freſh ſurface. The oil thus combined with the ſugar is fit for moſt of the uſes to which it is applied in a fluid ſtate. Indeed the pure eſſential oils obtained by diſtillation are often purpoſely mixed with ſugar to render their uſe the more commodious.

Chap. VI. *Eſſential Oils.*

258 Essential oils are obtained only from odoriferous ſubſtances; but not equally from all of this claſs, nor in quantity proportional to their degree of odour. Some which, if we were to reaſon from analogy, ſhould ſeem very well fitted for this proceſs, yield extremely little oil, and others none at all. Roſes and camomile flowers, whoſe ſtrong and laſting ſmell promiſes abundance, are found upon experiment to contain but a ſmall quantity; the violet and jeſſamine flower, which perfume the air with their odour, loſe their ſmell upon the gentleſt coction, and do not afford the leaſt perceptible mark of oil on being diſtilled unleſs immenſe quantities are ſubmitted to the operation at once; while ſavin, whoſe diſagreeable ſcent extends to no great diſtance, gives out the largeſt proportion of oil of almoſt any vegetable known.

Nor are the ſame plants equally fit for this operation when produced in different ſoils or ſeaſons, or at different times of their growth. Some yield more oil if gathered when the flowers begin to fall off than at any other time. Of this we have examples in lavender and rue; others, as ſage, afford the largeſt quantity when young, before they have ſent forth any flowers; and others, as thyme, when the flowers have juſt appeared. All fragrant herbs yield a larger proportion of oil when produced in dry ſoils and warm ſummers than in oppoſite circumſtances. On the other hand, ſome of the diſagreeable ſtrong-ſcented ones, as wormwood, are ſaid to contain moſt in rainy ſeaſons and when growing in moiſt rich grounds.

Several of the chemiſts have been of opinion, that herbs and flowers, moderately dried, yield a greater quantity of eſſential oil than if they were diſtilled when freſh. It is ſuppoſed, that the oil being already blended, in freſh plants, with a watery fluid, great part of it remains diffuſed through the water after the diſtillation, divided into particles too minute to unite and be collected; whereas in drying, the oily parts, on the exhalation of the moiſture which kept them divided and diſperſed, run together into globules, which have little diſpoſition to mingle with watery fluids, and eaſily ſeparate from the water employed in the diſtillation.

Preparations and Compoſitions.

This theory, however, does not appear to be quite ſatisfactory; for though the oil be collected in the ſubject into diſtinct globules, it does not riſe in that form, but is reſolved into vapour, and blended and coagitated by the heat with the vapour of the water; and if the oil in a dry plant was leſs diſpoſed to unite with aqueous fluids than in a freſh one, the dry ought to yield a weaker infuſion than the freſh; the contrary of which is generally found to obtain. As the oil of the dry plant is moſt perfectly extracted and kept diſſolved by the water before the diſtillation, it is difficult to conceive any reaſon why it ſhould have a greater tendency to ſeparate from the water afterwards.

The opinion of dry plants yielding moſt oil ſeems to have ariſen from an obſervation of Hoffman, which has probably been miſunderſtood: "A pound (he ſays) of dry ſpike flowers yields an ounce of oil, but if they were diſtilled freſh they would ſcarcely yield above half an ounce; and the caſe is the ſame in balm, ſage, &c. The reaſon is, that in drying the watery humidity exhales; and as from two pounds of a freſh plant we do not obtain above one pound of dry, and little of the ſubtile oil evaporates in the drying, it follows, that more oil ought to be afforded by the dry than by the freſh." The meaning of which ſeems to be no more than this, that if two pounds of a freſh plant are by drying reduced to one without any loſs of the oil, then the one pound dry ought to be equivalent to the two freſh. A late writer quotes an experiment of Neumann, which appears to be miſunderſtood in the ſame manner; for Neumann, in the place referred to, ſays only that dry wormwood is found to yield much more oil than an *equal weight* of the freſh plant. Trials are yet wanting in which freſh and dry plants have been brought to a fair compariſon, by dividing a quantity of the ſubject into two equal weights, and diſtilling one while freſh, and the other after it has been carefully and moderately dried.

But whatever may be the effect of moderate exſiccation, it is certain, that if the drying be long continued, the produce of oil will be diminiſhed, its colour altered, and its ſmell impaired.

With regard to the proportion of water to be employed, if whole plants moderately dried are uſed, or the ſhavings of wooda, as much of either may be put into the veſſel as, lightly preſſed, will occupy half its cavity; and as much water may be added as will fill two-thirds of it. The water and ingredients altogether ſhould never take up more than three-fourths of the ſtill: there ſhould be liquor enough to prevent any danger of an empyreuma, but not ſo much as to be too apt to boil over into the receiver.

The

The maceration ſhould be continued ſo long that the water may fully penetrate the parts of the ſubject. To promote this effect, woods ſhould be thinly ſhaved acroſs the grain or ſawn, roots cut tranſverſely into thin ſlices, barks reduced into coarſe powder, and ſeeds ſlightly bruiſed. Very compact and tenacious ſubſtances require the maceration to be continued a week or two, or longer; for thoſe of a ſofter and looſer texture, two or three days are ſufficient; while ſome tender herbs and flowers not only ſtand in no need of maceration, but are even injured by it.

Whether the addition of ſea-ſalt, which ſome have recommended, be of any real ſervice, is much to be doubted. The uſes generally aſſigned to it are, to penetrate and unlock the texture of the ſubject more effectually than ſimple water could do, and to prevent the fermentation or putrefaction which the matter is apt to run into during the length of time for which the maceration is often continued. But ſea-ſalt ſeems rather to harden and condenſe, than to ſoften and reſolve, both vegetable and animal ſubjects; and if it prevents putrefaction, it muſt, on that very account, be injurious rather than of ſervice. The reſolution here aimed at approaches near to a beginning putrefaction; and ſaline ſubſtances, by retarding this, prolong the maceration far beyond the time that would otherwiſe be neceſſary. It is in the power of the operator, when he perceives the proceſs coming near this pitch, to put a ſtop to it at pleaſure, by proceeding immediately to diſtillation. By this means the whole affair will be finiſhed in a very little time, with at leaſt equal advantage in every other reſpect; provided the manual operations of pounding, raſping, and the like, which are equally neceſſary in either caſe, be minutely complied with.

Bodies of a very viſcous and compact texture were directed, in the Edinburgh pharmacopœia, to be fermented for ſome days with a little yeſt. Half their quantity of water is ſufficient for performing the fermentation; as much more as is neceſſary is to be added afterwards before the diſtillation. This proceſs undoubtedly promotes the reſolution of the ſubject, and the extrication of the oil. It rarely happens, however, that aſſiſtances of this kind are needful. Particular care muſt be had not to continue the fermentation too long; or to give a bad flavour to the oil by an ill-choſen ferment, or uſing too large a quantity of any.

Some chemiſts pretend, that by the addition of ſalts and acid ſpirits they have been enabled to gain more oil from certain vegetable matters than could poſſibly be got from them without ſuch aſſiſtance. Experiments made on purpoſe to ſettle this point ſeem to prove the contrary: this at leaſt is conſtantly found to be true, that where there is any reaſon to think the produce greater than uſual, the quality of the oil is proportionally injured. The quantity of true eſſential oil in vegetables can by no means be increaſed; and what is really contained in them may be eaſily ſeparated without any addition of this kind. All that ſaline matters can do in this reſpect is to make the water ſuſceptible of a greater degree of heat than it can ſuſtain by itſelf, and thus enable it to carry up a groſs unctuous matter not volatile enough to riſe with pure water: this groſs matter, mingling with the pure oil, increaſes the quantity, but at the ſame time muſt neceſſarily debaſe its quality. And indeed, when water alone is uſed, the oil which comes over about the end of the operation is remarkably leſs fragrant, and of a thicker conſiſtence, than that which riſes at the beginning: diſtilled a ſecond time, with a gentle heat, it leaves a large quantity of groſs almoſt inſipid reſinous matter behind.

The choice of proper inſtruments is of great conſequence for the performance of this proceſs to advantage. There are ſome oils which paſs freely over the ſwan-neck of the head of the common ſtill; others, leſs volatile, cannot eaſily be made to riſe ſo high. For obtaining theſe laſt, we would recommend a large low head, having a rim or hollow canal round it. In this canal the oil is detained on its firſt aſcent, and thence conveyed at once into the receiver, the advantages of which are ſufficiently obvious.

With regard to the fire, the operator ought to be expeditious in raiſing it at firſt, and to keep it up, during the whole proceſs, of ſuch a degree that the oil may freely diſtil; otherwiſe the oil will be expoſed to an unneceſſary heat; a circumſtance which ought as much as poſſible to be avoided. Fire communicates to all theſe oils a diſagreeable impregnation, as is evident from their being much leſs grateful when newly diſtilled, than after they have ſtood for ſome time in a cool place; the longer the heat is continued, the more alteration it muſt produce in them.

The greater number of oils require for their diſtillation the heat of water ſtrongly boiling: but there are many alſo which riſe with a heat conſiderably leſs; ſuch as thoſe of lemon and citron-peel, of the flowers of lavender and roſemary, and of almoſt all the more odoriferous kinds of flowers. We have already obſerved, that theſe flowers have their fragrance much injured, or even deſtroyed, by beating or bruiſing them; it is impaired alſo by the immerſion in water in the preſent proceſs, and the more ſo in proportion to the continuance of the immerſion and the heat: hence oils, diſtilled in the common manner, prove much leſs agreeable in ſmell than the ſubjects themſelves. For the diſtillation of ſubſtances of this claſs another method has been contrived; inſtead of being immerſed in water, they are expoſed only to its vapour. A proper quantity of water being put into the bottom of the ſtill, the odoriferous herbs or flowers are laid lightly in a baſket, of ſuch a ſize that it may enter into the ſtill, and reſt againſt its ſides, juſt above the water. The head being then fitted on, and the water made to boil, the ſteam, percolating through the ſubject, imbibes the oil, without impairing its fragrance, and carries it over to the receiver. Oils thus obtained poſſeſs the odour of the ſubject in an exquiſite degree, and have nothing of the diſagreeable ſcent perceivable in thoſe diſtilled by boiling them in water in the common manner.

It may be proper to obſerve, that thoſe oils which riſe with a leſs heat than that of boiling water, are generally called, by the chemical and pharmaceutical writers, *light* oils; and thoſe which require the heat of water ſtrongly boiling, are called *ponderous*. We have avoided theſe expreſſions, as they might be thought to relate to the comparative *gravities* of the oils; with which the volatility or fixedneſs have no connection. Olive oil is lighter than moſt of the eſ-

Preparations and Compositions.

ſential oils; but the heat requiſite to make it diſtil, exceeds that in which the heavieſt eſſential oil diſtils, conſiderably more than the heat of boiling water exceeds that of ice.

The water employed in the diſtillation of eſſential oils always imbibes ſome portion of the oil; as is evident from the ſmell, taſte, and colour, which it acquires. It cannot, however, retain above a certain quantity; and therefore, ſuch as has been already uſed and conſequently ſaturated with oil, may be advantageouſly employed, inſtead of common water, in a ſecond, third, or any future diſtillation of the ſame ſubject.

Some late chemical writers recommend, not the water which comes over, but that which remains in the ſtill, to be uſed a ſecond time. This can be of no ſervice: as containing only ſuch parts of the vegetable as are incapable of ariſing in diſtillation, and which ſerve only to impede the action of the water as a menſtruum, and to endanger an empyreuma.

After the diſtillation of one oil, particular care ſhould be taken to cleanſe the worm before it be employed in the diſtillation of a different plant. Some oils, thoſe of wormwood and aniſeeds for inſtance, adhere to it ſo tenaciouſly, as not to be melted out by heat, or waſhed off by water: the beſt way of cleanſing the worm from theſe, is to run a little ſpirit of wine through it.

Eſſential oils, after they are diſtilled, ſhould be ſuffered to ſtand for ſome days, in veſſels looſely covered with paper, till they have loſt their diſagreeable fiery odour, and become limpid: then put them up in ſmall bottles, which are to be kept quite full, cloſely ſtopped, in a cool place: with theſe cautions, they will retain their virtues in perfection for many years.

When carelefsly kept, they in time gradually loſe their flavour, and become groſs and thick. Some endeavour to recover them after they have undergone this change, by grinding them with about thrice their weight of common ſalt, then adding a large proportion of water, and diſtilling them afreſh: the purer part riſes thin and limpid, poſſeſſing a great degree of the priſtine ſmell and taſte of the oil, though inferior in both reſpects to the original oil. This rectification, as it is called, ſucceeds equally without the ſalt: the oils, when thus altered, are nearly in the ſame ſtate with the turpentines, and other thickened oily juices, which readily yield their purer oil in diſtillation with water alone.

When eſſential oils have entirely loſt their ſmell, ſome recommend adding them in the diſtillation of a freſh quantity of the oil of the ſame plant; by which means they are ſaid to ſatiate themſelves anew with the odorous matter, and become entirely renovated. This practice, however, ought doubtleſs to be diſapproved, as being no other than a ſpecious ſophiſtication; for it can do no more than divide, between the old and the new, the active matter which belongs to the new alone.

Eſſential oils, medicinally conſidered, agree in the general qualities of pungency and heat; in particular virtues, they differ as much as the ſubject from which they are obtained, the oil being the direct principle in which the virtues, or at leaſt a conſiderable part of the virtues, of the ſeveral ſubjects reſide. Thus the carminative virtue of the warm ſeeds, the diuretic of juniper-berries, the emmenagogue of ſavin, the nervine of roſemary, the ſtomachic of mint, the antiſcorbutic of ſcurvy-graſs, the cordial of aromatics, &c. are ſuppoſed to be concentrated in their oil. Preparations and Compoſitions.

There is another remarkable difference in eſſential oils, the foundation of which is leſs obvious, viz. the degree of their pungency and heat. Theſe are by no means in proportion, as might be expected, to thoſe of the ſubject they were drawn from. The oil of cinnamon, for inſtance, is very pungent and fiery; in its undiluted ſtate it is almoſt cauſtic; whereas cloves, a ſpice which in ſubſtance is far more pungent than the other, yields an oil which is far leſs ſo. This difference ſeems to depend partly on the quantity of oil afforded, cinnamon yielding much leſs than cloves, and conſequently having its active matter concentrated into a ſmaller volume; partly on a difference in the nature of the active parts themſelves; for though eſſential oils contain always the ſpecific odour and flavour of their ſubjects, whether grateful or ungrateful, they do not always contain the whole pungency; this reſides frequently in a more fixed reſinous matter, and does not riſe with the oil. After the diſtillation of cloves, pepper, and ſome other ſpices, a part of their pungency is found to remain behind: a ſimple tincture of them in rectified ſpirit of wine is even more pungent than their pure eſſential oils.

The more grateful oils are frequently uſed for reconciling to the ſtomach medicines of themſelves diſguſtful. It has been cuſtomary to employ them as correctors for the reſinous purgatives; an uſe which they do not ſeem to be well adapted to. All the ſervice they can here be of, is, to make the reſin ſit more eaſily at firſt on the ſtomach: far from abating the irritating quality on which the virulence of its operation depends, theſe pungent oils ſuperadd a freſh ſtimulus.

Eſſential oils are never given alone, on account of their extreme heat and pungency; which in ſome is ſo great, that a ſingle drop let fall upon the tongue produces a gangrenous eſchar. They are readily imbibed by pure dry ſugar, and in this form may be conveniently exhibited. Ground with eight or ten times their weight of ſugar, they become ſoluble in aqueous liquors, and thus may be diluted to any aſſigned degree. Mucilages alſo render them miſcible with water into an uniform milky liquor. They diſſolve likewiſe in ſpirit of wine; the more fragrant in an equal weight, and almoſt all of them in leſs than four times their own quantity; theſe ſolutions may be either taken on ſugar, or mixed with ſyrups, or the like: on mixing them with water, the liquor grows milky, and the oil ſeparates.

The more pungent oils are employed externally againſt paralytic complaints, numbneſs, pains, and aches, cold tumors, and in other caſes where particular parts require to be heated or ſtimulated. The tooth-ach is ſometimes relieved by a drop of theſe almoſt cauſtic oils, received on cotton, and cautiouſly introduced into the hollow tooth.

Eſſential

Preparations and Compositions.

Essential oil of anise, L.
caraway,
lavender,
peppermint,
spearmint,
origanum,
pennyroyal,
rosemary,
juniper-berry,
sassafras root.

159 Let these oils be drawn off by distillation, from an alembic with a large refrigeratory; but, to prevent an empyreuma, water must be added to the ingredient; in which they must be macerated before distillation.

The water which comes over with the oil in distillation is to be kept for use.

Essential oils. E.

Of the herbs of garden mint,
Of peppermint,
Of savin,
Of the tops of rosemary,
Of the flowering spikes of lavender,
Of aniseeds,
Of juniper-berries,
Of sassafras root,
Of Jamaica pepper.

160 These are prepared almost in the same manner as the simple distilled waters, excepting that for procuring the oil a somewhat less quantity of water is to be used. Seeds and woody matters are first to be bruised or rasped. The oil rises with the water; and as it is lighter or heavier, swims on the surface, or sinks to the bottom, from which it is afterwards to be separated.

It is, however, to be remarked, that, in preparing these distilled waters and oils, so many varieties must necessarily take place from the goodness of the subject itself, its texture, the time of the year, and such like circumstances, that a certain and general rule, which should strictly apply to each example, can scarcely be laid down; wherefore we have only explained the general method, leaving many things to be varied by the judgment of the operator.

To the directions for preparing these essential oils given by the London and Edinburgh colleges, we shall here next subjoin a few remarks on their medical properties.

Essential oil of aniseeds. L. E.

161 This oil possesses the taste and smell of the aniseeds in perfection. It is one of the mildest of the distilled oils; 15 or 20 drops may be taken at a time without danger, though common practice rarely goes so far as half this number. Its smell is extremely durable and diffusive; milk drawn from the breast after taking it, is found impregnated with its odour; and possibly this may be, in part, the foundation of the pectoral virtues usually ascribed to it; in flatulencies and colics, it is said by some to be less effectual than the seeds themselves.

It is remarkable of this oil, that it congeals, even when the air is not sensibly cold, into a butyraceous consistence: and hence, in the distillation of it, the operator ought not to be over-solicitous in keeping the water in the refrigeratory too cool: it behoves him rather to let it grow somewhat hot, particularly towards the end of the process; otherwise the oil congealing may so stop up the worm, as to endanger blowing off the head of the still, or at least a considerable quantity of oil will remain in it.

Essential oil of caraway seeds. L.

The flavour of this exactly resembles that of the caraway itself. It is a very hot and pungent oil; a single drop is a moderate dose, and five or six is a very large one. It is not unfrequently used as a carminative; and supposed by some to be peculiarly serviceable for promoting urine, to which it communicates some degree of its smell. 162

Essential oil of lavender flowers. L. E.

This oil, when in perfection, is very limpid, of a pleasant yellowish colour, extremely fragrant, possessing in an eminent degree the peculiar smell generally admired in the flowers. It is a medicine of great use, both externally and internally, in paralytic and lethargic complaints, rheumatic pains, and debilities of the nervous system. The dose is from one drop to five or six. 163

Lavender flowers yield the most fragrant oil, and considerably the largest quantity of it, when they are ready to fall off spontaneously, and the leaves begin to show themselves: the seeds give out extremely little. The flowers may be separated from the rest of the plant, by drying it a little, and then gently beating it: they should be immediately committed to distillation, and the process conducted with a well regulated gentle heat; too great heat would not only change the colour of the oil, but likewise make a disagreeable alteration in its smell.

Essential oil of the leaves of peppermint. L. E.

This possesses the smell, taste, and virtues of the peppermint in perfection; the colour is a pale greenish yellow. It is a medicine of great pungency and subtilty; and diffuses, almost as soon as taken, a glowing warmth through the whole system. In colics, accompanied with great coldness, and in some hysteric complaints, it is of excellent service. A drop or two are in general a sufficient dose. 164

Essential oil of the leaves of common mint. L. E.

This oil smells and tastes strongly of the mint, but is in both respects somewhat less agreeable than the herb itself. It is an useful stomachic medicine; and not unfrequently exhibited in want of appetite, weakness of stomach, retching to vomit, and other like disorders, when not accompanied with heat or inflammation: two or three drops, or more, are given for a dose. It is likewise employed externally for the same purposes; and is an useful ingredient in the stomachic plaster of the shops. 165

Essential oil of the leaves of origanum. L.

This oil has a very pungent acrimonious taste, and a penetrating smell. It has been chiefly employed externally as an errhine and for easing pains of the teeth. 166

Essential

Preparations and Compositions.

Essential oil of the leaves of tennyroyal. L.

167 This oil, in smell and taste, resembles the original plant; the virtues of which it likewise possesses. It is given in hysteric cases, from one to four or five drops.

Essential oil of rosemary. L. E.

168 The oil of rosemary is drawn from the plant in flower. When in perfection, it is very light and thin, pale, and almost colourless; of great fragrancy, though not quite so agreeable as the rosemary itself. It is recommended, in the dose of a few drops, in nervous and hysteric complaints. Boerhaave holds it in great esteem against epilepsies and suppressions of the uterine purgations occasioned by weakness and inactivity.

Essential oil of juniper-berries. L. E.

169 This oil is a very warm and pungent one; of a strong flavour, not unlike that of the berries. In the dose of a drop or two, it proves a serviceable carminative and stomachic; in one of six, eight, or more, a stimulating, detergent, diuretic, and emmenagogue; it seems to have somewhat of the nature of the turpentines, or their distilled oil; like which it communicates a violent smell to the urine.

The oil of these berries resides partly in vesicles spread through the substance of the fruit, and partly in little cells contained in the seeds: when the berry is dry, and the oil hardened into a resinous substance, it becomes visible, on breaking the seeds, in form of little transparent drops. In order therefore to obtain this oil to advantage, we ought, previous to the distillation, to bruise the berry thoroughly, so as to break the seeds, and entirely lay open the oily receptacles.

Essential oil of sassafras. L. E.

170 This is the most ponderous of all the known essential oils, but rises in distillation with sufficient ease: it appears limpid as water, has a moderately pungent taste, a very fragrant smell, exactly resembling that of the sassafras. It stands greatly commended as a sudorific, and for purifying the blood and juices: it is likewise supposed to be of service in humoral asthmas and coughs. The dose is from one drop to eight or ten; though Geoffroy goes as far as twenty.

The decoction remaining after the distillation of the oil, affords by inspissation an useful extract, of a mild, bitterish, subastringent taste. Hoffman says, he has given it with great benefit, in doses of a scruple, as a corroborant in cachectic cases, in the decline of intermitting fevers, and for abating hypochondriacal spasms.

Essential oil of savin leaves. L. E.

171 Savin is one of the plants which, in former editions of the Edinburgh pharmacopœia, were directed to be lightly fermented before the distillation: this, however, is not very necessary; for savin yields, without fermentation, and even without any such maceration, a very large quantity of oil. The oil of savin is a celebrated uterine and emmenagogue: in cold phlegmatic habits, it is undoubtedly a medicine of great service, though not capable of performing what it has been often represented to do. The dose is, two or three drops, or more.

Essential oil of Jamaica pepper. E.

172 This is a very elegant oil, and may be used as a succedaneum to those of some of the dearer spices. It is of a fine pale colour; in flavour more agreeable than the oil of cloves, and not far short of that of nutmegs. It sinks in water, like the oils of some of the eastern spices.

Oil of fossil tar. L.

173 Distil fossil tar, the *bitumen petroleum*, in a sand heat.

The oil obtained from this tar will be more or less thin according to the continuance of the distillation; and by its continuance the tar will at last be reduced to a black coal; and then the oil will be pretty deep in colour, though perfectly fluid. This oil has a property similar to that of the tincture of nephritic wood in water, appearing blue when looked upon, but of an orange colour when held between the eye and the light. By long keeping it loses this property. It is less disagreeable than some of the other empyreumatic oils which had formerly a place in our pharmacopœia, such as the oleum lateritium, though very acrid and stimulating.

Oil of turpentine. L.

174 Take of common turpentine five pounds; water four pints. Distil the turpentine with the water from an alembic of copper. After the distillation of the oil, what remains is yellow resin.

Rectified oil of turpentine. L.

175 Take of oil of turpentine one pound; water four pints. Distil.

The process here proposed for rectifying this oil, is not only tedious but accompanied with danger. For unless the luting be very close, some of the vapour will be apt to get through; and if this catch fire, it will infallibly burst the vessels. This rectified oil, which in many pharmacopœias is styled æthereal, does not considerably differ in specific gravity, smell, taste, or medical qualities, from the former.

The spirit of turpentine, as this essential oil has been styled, is not unfrequently taken internally as a diuretic and sudorific. And in these ways it has sometimes a considerable effect when taken even to the extent of a few drops only. It has, however, been given in much larger doses, especially when mixed with honey. Recourse has principally been had to such doses in cases of chronic rheumatism, particularly in those modifications of it which are styled *sciatica* and *lumbago*. But they have not been often successful, and sometimes they have had the effect of inducing bloody urine.

Animal oil. L.

176 Take of oil of hartshorn one pound. Distil three times.

Rectified oil of horns, or animal oil. E.

177 Take of empyreumatic oil, newly distilled from the horns of animals, as much as you will. Distil with a gentle heat, in a matrass furnished with a head, as long as a thin colourless oil comes over, which is to be freed of alkaline salt and spirit by means of water.

water. That this oil may remain limpid and good, it ought to be put up in ſmall phials, completely filled and inverted, having previouſly put into each phial a few drops of water, that on inverting it the water may interpoſe itſelf between the oil and the mouth of the phial.

The quantity of oil employed in this proceſs ſhould be conſiderable: for it leaves ſo much black matter behind in the ſeveral diſtillations, that it is reduced at laſt to a ſmall portion of its original quantity. It is ſaid, that the product is rendered more limpid, by mixing the oil with quicklime into a ſoft paſte; the lime keeping down more of the groſs matter than would remain without ſuch an addition. The quicklime may here alſo perhaps act by abſtracting fixed air; to the abſorption of which we are diſpoſed to refer in ſome meaſure the ſpoiling of the oil on expoſure to the atmoſphere.

The oil was firſt introduced by Dippelius, whoſe name it has ſince generally borne.

Animal oils thus rectified, are thin and limpid, of a ſubtle, penetrating, not diſagreeable ſmell and taſte. They are ſtrongly recommended as anodynes and antiſpaſmodics, in doſes from 15 to 30 drops. Hoffman reports, that they procure a calm and ſweet ſleep, which continues often for 20 hours, without being followed by any languor or debility, but rather leaving the patient more alert and cheerful than before; that they procure likewiſe a gentle ſweat, without increaſing the heat of the blood: that given to 20 drops or more, on an empty ſtomach, ſix hours before the acceſſion of an intermittent fever, they frequently remove the diſorder; and that they are likewiſe a very generous remedy in inveterate and chronical epilepſies and in convulſive motions, eſpecially if given before the uſual time of the attack, and preceded by proper evacuations

The empyreumatic oils of vegetables, rectified in the ſame manner by repeated diſtillations, ſuffer a like change with the animal; loſing their dark colour and offenſive ſmell, and becoming limpid, penetrating, and agreeable: in this ſtate they are ſuppoſed, like the animal oil, to be anodyne, antiſpaſmodic, and diaphoretic or ſudorific. It is obſervable, that all the empyreumatic oils diſſolve in ſpirit of wine, and that the oftener they are rectified or rediſtilled, they diſſolve the more readily; a circumſtance in which they differ remarkably from eſſential oils, which, by repeated diſtillations, become more and more difficult of ſolution.

How far theſe preparations really poſſeſs the virtues that have been aſcribed to them, has not yet been ſufficiently determined by experience; the tedioufneſs and trouble of the rectification having prevented their coming into general uſe, or being often made. They are liable alſo to a more material inconvenience, in regard to their medicinal uſe, precarioufneſs in their quality; for how perfectly ſoever they be rectified, they gradually loſe in keeping the qualities they had received from that proceſs, and return more and more towards their original fetid ſtate.

Oil and ſalt of amber. E.

8 Take equal parts of amber reduced to a powder and of pure ſand. Mix them, and put them into a glaſs retort, of which the mixture may fill one half: then adapt a large receiver, and diſtil in a ſand-furnace, with a fire gradually increaſed. At firſt a ſpirit will come over, with ſome yellow oil; then more yellow oil, along with a little ſalt; and on raiſing the heat, more of the ſalt, with a reddiſh and black coloured oil. When the diſtillation is finiſhed, empty the liquor out of the receiver; and having collected together the ſalt which adheres to the ſides, dry it by gentle preſſure between the folds of blotting paper; then purify it by ſolution in warm water and by cryſtallization.

Rectified oil of amber.

Diſtil the oil in a glaſs retort with ſix times its quantity of water till two-thirds of the water have paſſed into the receiver; then ſeparate the rectified oil from the water, and keep it for uſe in cloſe ſhut veſſels. *E.* 179

Take of oil of amber one pound. Diſtil three times *L.*

The London college introduce their directions for the preparation of the ſal and oleum ſuccini at an after part of their work, under the head of *Aides*. Here we may only obſerve, that they direct it to be prepared from the amber alone, without the intervention of ſand. But this makes no eſſential difference in the article when prepared.

The Edinburgh college have rejected what was formerly called the ſpirit, as being nothing elſe than the watery parts, fraught with the inert impurities of the bitumen and a very ſmall portion of the ſalt. In the diſtillation of amber, the fire muſt for ſome time be continued gentle, ſcarce exceeding the degree at which water boils, till the aqueous phlegm and thin oil have ariſen; after which it is to be ſlowly increaſed. If the fire were urged haſtily, the amber would ſwell up, and riſe in its whole ſubſtance into the receiver, without undergoing the required decompoſition or ſeparation of its parts. When ſand or ſimilar intermedia are mixed with it, it is leſs ſubject to this rarefaction, and the fire may be raiſed ſomewhat more expeditiouſly: though this little advantage is perhaps more than counterbalanced by the room which the ſand takes up in the retort.

Our chemiſts generally leave the receiver unluted, that it may be occaſionally removed as the ſalt riſes and concretes in the neck of the retort; from whence it is every now and then ſcraped out to prevent the oil from carrying it down into the receiver. When a groſs thick oil begins to ariſe, and no more ſalt appears, the diſtillation is ſtopt, though it might perhaps be continued longer to advantage.

Mr Pott informs us (in a curious diſſertation on the ſalt of amber, publiſhed in the ninth volume of the Memoirs of the Academy of Sciences of Berlin), that the Pruſſian workmen, who prepare large quantities of this ſalt for exportation, from cuttings and ſmall pieces of amber, perform the diſtillation without any intermedium, and in an open fire: that ſweeping out the ſalt from the neck of the retort being found too troubleſome, they ſuffer the oil to carry it down into the receiver, and afterwards ſeparate it by means of bibulous paper, which imbibes the oil, and leaves the ſalt dry; which paper is afterwards ſqueezed and diſtilled: that they continue the diſtillation till all that can be forced

Preparations and Compositions.

forced over has ariſen, taking care only to catch the laſt thick oil in a ſeparate receiver; and that from this they extract a conſiderable quantity of ſalt, by ſhaking it in a ſtrong veſſel with three or four freſh portions of hot water, and evaporating and cryſtallizing the filtered waters.

The ſpirit of amber, ſo called, is no more than a ſolution of a ſmall proportion of the ſalt in phlegm or water; and therefore is very properly employed for diſſolving the ſalt in order to its cryſtallization.

The ſalt, freed from as much of the oil as ſpongy paper will imbibe, retains ſo much as to appear of a dark brown colour. Mr Pott ſays, the method he has found to ſucceed beſt, and with leaſt loſs, is, to diſſolve the ſalt in hot water, and put into the paper, through which the ſolution is to be filtered, a little cotton ſlightly moiſtened with oil of amber: this, he ſays, detains a good deal of the oil of the ſalt, and the ſolution paſſes through the more pure. The liquor being evaporated with a very gentle fire, as that of a water-bath, and ſet to ſhoot, the firſt cryſtals prove tranſparent, with a ſlight yellowiſh tinge; but thoſe which follow are brown, oily, and bitter, and are therefore to be further depurated in the ſame manner. The whole quantity of cryſtals amounts to about one-thirtieth of the weight of the crude amber employed. By ſublimation from ſea-ſalt, as directed in former editions of the Edinburgh pharmacopœia, the ſalt is thought to be more perfectly and more expeditiouſly purified: Mr Pott objects to ſublimation, that a part of the ſalt is decompoſed by it, a coaly matter being left behind, even though the ſalt was previouſly purified by cryſtallization: it may be preſumed, however, that this coal proceeds rather from the burning of ſome remains of the oily matter, than from the decompoſition of any part of the true ſalt.

Pure ſalt of amber has a penetrating, ſubaſtringent, acid, taſte. It diſſolves both in water and in rectified ſpirit; though not readily in either, and ſcarcely at all in the latter without the aſſiſtance of heat: of cold water in ſummer, it requires for its ſolution about twenty times its own weight; of boiling water only about twice its weight. Expoſed in a glaſs veſſel, to a heat little greater than that of boiling water, it firſt melts, then riſes in a white fume, and concretes again in the upper part of the glaſs into fine white flakes, leaving, unleſs it was perfectly pure, a little coaly matter behind. It effervesces with alkalis both fixed and volatile, and forms with them neutral compounds much reſembling thoſe compoſed of the ſame alkalis and vegetable acids. Mixed with acid liquors, it makes no ſenſible commotion. Ground with fixed alkaline ſalts, it does not exhale any urinous odour. By theſe characters, it is conceived this ſalt may be readily diſtinguiſhed from all the other matters that have been mixed with or vended for it. With regard to its virtue, it is accounted aperient, diuretic, and, on account of its retaining ſome portion of the oil, antihyſteric: Boerhaave gives it the character of *diureticorum et antihyſtericorum princeps*. Its great price, however, has prevented its coming much into uſe; and perhaps its real virtues are not equal to the opinion generally entertained of them.

The rectified oil has a ſtrong bituminous ſmell, and a pungent acrid taſte. Given in a doſe of ten or twelve drops, it heats, ſtimulates, and promotes the fluid ſecretions: It is chiefly celebrated in hyſterical diſorders, and in deficiencies of the uterine purgations. Sometimes it is uſed externally, in liniments for weak or paralytic limbs and rheumatic pains. This oil differs from all thoſe of the vegetable kingdom, and agrees with the mineral petrolea, in not being ſoluble either in its rectified or unrectified ſtate, by ſpirit of wine, fixed alkaline lixivia, or volatile alkaline ſpirits; the oil, after long digeſtion or agitation, ſeparating as freely as common oil does from water.

Preparations and Compositions.

Oil of wine. L.

180 Take alcohol, vitriolic acid, of each one pint. Mix them by degrees, and diſtil; taking care that no black foam paſſes into the receiver. Separate the oily part of the diſtilled liquor from the volatile vitriolic acid. To the oily part add as much water of pure kali as is ſufficient to take away the ſulphureous ſmell: then diſtil the ether with a gentle heat. The oil of wine remains in the retort, ſwimming on the watery liquor, from which it is to be ſeparated.

Some caution is requiſite in mixing the two liquors, that the conſequent heat and ebullition, which would not only diſſipate a part of the mixture, but hazard the breaking of the veſſel and the hurt of the operator, may be avoided. The ſecureſt way is to add the vitriolic acid to the ſpirit of wine by a little at a time, waiting till the firſt addition be incorporated before another quantity be put in. By this, the enſuing heat is inconſiderable, and the mixture is effected without inconvenience.

Eſſential oil of wormwood. Roſſ.

181 Let the freſh leaves of wormwood ſlightly dried be macerated with a ſufficient quantity of water, and then ſubject to diſtillation; and let the oil which comes over be ſeparated from the water which accompanies it.

This is one of the more ungrateful oils: it ſmells ſtrongly of the wormwood, and contains its particular naſeous taſte, but has little or nothing of its bitterneſs, this remaining entire in the decoction left after the diſtillation: its colour, when drawn from the freſh herb, is a dark green; from the dry, a browniſh yellow. This oil is recommended by Hoffman as a mild anodyne in ſpaſmodic contractions; for this purpoſe, he directs a dram of it to be diſſolved in an ounce of rectified ſpirit of wine, and ſeven or eight drops of the mixture taken for a doſe in any convenient vehicle. Boerhaave greatly commends, in tertian fevers, a medicated liquor compoſed of about ſeven grains of this oil ground firſt with a dram of ſugar, then with two drams of the ſalt of wormwood, and afterwards diſſolved in ſix ounces of the diſtilled water of the ſame plant: two hours before the fit is expected, the patient is to bathe his feet and legs in warm water, and then to drink two ounces of the liquor every quarter of an hour till the two hours are expired: by this means, he ſays, all caſes of this kind are generally cured with eaſe and ſafety, provided there be no ſchirroſity or ſuppuration. The oil of wormwood is employed chiefly as a vermifuge; and for this purpoſe is ſometimes applied both externally to the belly, and

Preparations and Compositions.

taken internally; it is moſt conveniently exhibited in the form of pills, into which it may be reduced by mixing it with crumb of bread.

In the ſame manner with the oil of wormwood, the following oils, mentioned on the authority of the pharmacopœia Roſſica, are alſo directed to be prepared.

Eſſential oil of orange-ſkins. Roſſ.

Eſſence of lemons.

182 Of theſe eſſential oils, as exiſting in a ſeparate ſtate in the growing vegetable, we have already offered ſome obſervations. They are obtained in a very pure ſtate by diſtillation. They are now rejected from our pharmacopœias, being employed rather as perfumes than as medicines. This is particularly the caſe with the eſſence of lemons, which is a pleaſant oil, of a fine ſmell, very nearly as agreeable as that of the freſh peel; it is one of the lighteſt and moſt volatile eſſential oils we have, perfectly limpid, and almoſt colourleſs. It is taken in doſes of two or three drops, as a cordial, in weakneſs of the ſtomach, &c. though more frequently uſed as a perfume. It gives a fine flavour to the officinal volatile aromatic ſpirit of the Edinburgh college, or the compound ſpirit of ammonia, as it is now ſtyled by that of the London: and it may be remarked, that it enters the formula of both colleges, altho' neither of them has given it a place among their preparations, probably as it is one of thoſe articles which the apothecary rarely prepares for himſelf. When ſoap is given in the form of pills, by the addition of a few drops of this oil they are thought to ſit more eaſily on the ſtomach.

Eſſential oil of cloves. Roſſ.

183 This oil is ſo ponderous as to ſink in water, and is not eaſily elevated in diſtillation: if the water which comes over be returned on the remaining cloves, and the diſtillation repeated, ſome more oil will generally be obtained, though much inferior in quality to the firſt. The oil of cloves is uſually deſcribed as being "in taſte exceſſively hot and fiery, and of a gold yellow colour," *(Boerh. proceſſ.)*. Such indeed is the compoſition which we receive under this name from Holland; but the genuine oil of cloves is one of the milder oils: it may be taken with great ſafety (duly diluted) to the quantity of 10 or 12 drops or more. Nor is its colour at all yellow, unleſs it has been long and careleſsly kept, or diſtilled by too violent a fire: when in perfection, it is limpid and colourleſs, of a pleaſant, moderately warm, and pungent taſte, and a very agreeable ſmell, much reſembling that of the ſpice itſelf. The Dutch oil of cloves contains a large quantity of expreſſed oil, as evidently appears upon examining it by diſtillation. This, however, cannot be the addition to which it owes its acrimony. A mean proportion of a reſinous extract of cloves communicates to a large one of oil a deep colour, and a great degree of acrimony.

Eſſential oil of camomile. Roſſ.

184 An oil of camomile had formerly a place in our pharmacopœias made by infuſion of the recent plant, and its flowers in olive oil; and again ſeparating it by preſſure after impregnating it with the active parts of the plant by heat. This, however, was intended only for external application; but the eſſential oil is meant to be uſed internally.

It is a very pungent oil, of a ſtrong not ungrateful ſmell, reſembling that of the flowers: its colour is yellow, with a caſt of greeniſh or brown. It is ſometimes given in the doſe of a few drops, as a carminative, in hyſteric diſorders, and likewiſe as a vermifuge: it may be conveniently made into pills with crumb of bread.

Oil of cinnamon. Roſſ.

185 This valuable oil is extremely hot and pungent, of a moſt agreeable flavour, like that of the cinnamon itſelf. In cold languid caſes, and debilities of the nervous ſyſtem, it is one of the moſt immediate cordials and reſtoratives. The doſe is one, two, or three drops: which muſt always be carefully diluted by the mediation of ſugar, &c.: for ſo great is the pungency of this oil, that a ſingle drop let fall upon the tongue, undiluted, produces, as Boerhaave obſerves, a gangrenous eſchar. In the diſtillation of this oil, a ſmart fire is required; and the low head, with a channel round it, recommended for the diſtillation of the leſs volatile oils, is particularly neceſſary for this, which is one of the leaſt volatile, and which is afforded by the ſpice in exceeding ſmall quantity. The diſtilled water retains no ſmall portion of the oil; but this oil being very ponderous, great part of it ſubſides from the water, on ſtanding for two or three weeks in a cool place.

Eſſential oil of fennel-ſeeds. Roſſ.

186 The oil obtained from ſweet fennel-ſeeds is much more elegant and agreeable than that of the common fennel. It is one of the mildeſt of theſe preparations: it is nearly of the ſame degree of warmth with that of aniſeeds; to which it is likewiſe ſimilar in flavour, though far more grateful. It is given from two or three drops to ten or twelve, as a carminative, in cold indiſpoſitions of the ſtomach; and in ſome kinds of coughs for promoting expectoration.

Eſſential oil of rhodium. Roſſ.

187 This oil is extremely odoriferous, and principally employed as a perfume in ſcenting pomatums, and the like. Cuſtom has not as yet received any preparation of this elegant aromatic wood into internal uſe among us.

Eſſential oil of mace. Roſſ.

188 The eſſential oil of mace is moderately pungent, very volatile, and of a ſtrong aromatic ſmell, like that of the ſpice itſelf. It is thin and limpid, of a pale yelloviſh colour, with a portion of thicker and darker coloured oil at the bottom. This oil, taken internally to the extent of a few drops, is celebrated in vomiting, ſingultus, and colic pains; and in the ſame complaints it has alſo been adviſed to be applied externally to the umbilical region. It is, however, but rarely to be met with in the ſhops.

Eſſential oil of marjoram. Roſſ.

189 This oil is very hot and penetrating, in flavour not near ſo agreeable as the marjoram itſelf; when in perfection, it is of a pale yellow colour; by long keeping,

Preparations and Compositions.

it turns reddiſh: if diſtilled with too great a heat, it riſes of this colour at firſt. It is ſuppoſed by ſome to be peculiarly ſerviceable in relaxations, obſtructions, and mucous diſcharges of the uterus: the doſe is one or two drops.

Eſſential oil of nutmegs. Roſſ.

190 The eſſential oil of nutmegs poſſeſſes the flavour and aromatic virtues of the ſpice in an eminent degree. It is ſimilar in quality to the oil of mace, but ſomewhat leſs grateful.

Eſſential oil of rue. Roſſ.

191 The oil of rue has a very acrid taſte, and a penetrating ſmell, reſembling that of the herb, but rather more unpleaſant. It is ſometimes made uſe of in hyſteric diſorders and as an anthelmintic; and alſo in epilepſies proceeding from a relaxed ſtate of the nerves.

Rue yields its oil very ſparingly. The largeſt quantity is obtained from it when the flowers are ready to fall off, and the ſeeds begin to ſhow themſelves: ſuitable maceration, previous to the diſtillation, is here extremely neceſſary.

Eſſential oil of ſavory. Roſſ.

192 Savory yields on diſtillation a ſmall quantity of eſſential oil, of great ſubtility and volatility; and it is unqueſtionably an active article, but among us it is not employed in medicine.

Eſſential oil of tanſy. Roſſ.

193 Tanſy yields on diſtillation an oil of a greeniſh colour inclining to yellow. It ſmells ſtrongly of the herb, and poſſeſſes at leaſt its aromatic property in a concentrated ſtate.

Oil of wax. Dan.

194 Melt yellow bees-wax with twice its quantity of ſand, and diſtil in a retort placed in a ſand-furnace. At firſt an acid liquor riſes, and afterwards a thick oil, which ſticks in the neck of the retort, unleſs it be heated by applying live coal. This may be rectified into a thin oil, by diſtilling it ſeveral times, without addition, in a ſand-heat.

Boerhaave directs the wax, cut in pieces, to be put into the retort firſt, ſo as to fill one half of it; when as much ſand may be poured thereon as will fill the remaining half. This is a neater, and much leſs troubleſome way, than melting the wax, and mixing it with the ſand before they are put into the retort. The author above-mentioned highly commends this oil againſt roughneſs and chaps of the ſkin, and other like purpoſes: the college of Straſburgh ſpeak alſo of it being given internally, and ſay it is a powerful diuretic *(ingens diureticum)* in doſes from two to four or more drops; but its diſagreeable ſmell has prevented its coming into uſe among us.

The number of eſſential oils which have now a place in the London and Edinburgh pharmacopœias, and likewiſe in the foreign ones of modern date, is much leſs conſiderable than formerly; and perhaps thoſe ſtill retained afford a ſufficient variety of the more active and uſeful oils. Moſt of the oils mentioned above, particularly thoſe which have a place in the London and Edinburgh pharmacopœias, are prepared by our chemiſts in Britain, and are eaſily procurable in a tolerable degree of perfection: but the oils from the more expenſive ſpices, though ſtill introduced among the preparations in the foreign pharmacopœias, are, when employed among us, uſually imported from abroad. Preparations and Compoſitions.

Theſe are frequently ſo much adulterated, that it is not an eaſy matter to meet with ſuch as are fit for uſe. Nor are theſe adulterations eaſily diſcoverable. The groſſer abuſes, indeed, may be readily detected: thus, if the oil be mixed with ſpirit of wine, it will turn milky on the addition of water; if with expreſſed oils, rectified ſpirit will diſſolve the eſſential, and leave the other behind; if with oil of turpentine, on dipping a piece of paper in the mixture, and drying it with a gentle heat, the turpentine will be betrayed by its ſmell. But the more ſubtle artiſts have contrived other methods of ſophiſtication, which elude all trials of this kind.

Some have looked upon the ſpecific gravity of oils as a certain criterion of their genuineneſs; and accordingly we have given a table of the gravity of ſeveral. This, however, is not to be abſolutely depended on: for the genuine oils, obtained from the ſame ſubjects, often differ in gravity as much as thoſe drawn from different ones. Cinnamon and cloves, whoſe oils uſually ſink in water, yield, if ſlowly and warily diſtilled, an oil of great fragrancy, which is nevertheleſs ſpecifically lighter than the aqueous fluid employed in the diſtillation of it; while, on the other hand, the laſt runnings of ſome of the lighter oils prove ſometimes ſo ponderous as to ſink in water.

As all eſſential oils agree in the general properties of ſolubility in ſpirit of wine, indiſſolubility in water, miſcibility with water by the intervention of certain intermedia, volatility in the heat of boiling water, &c. it is plain that they may be variouſly mixed with each other, or the dearer ſophiſticated with the cheaper, without any poſſibility of diſcovering the abuſe by any trials of this kind. And indeed it would not be of much advantage to the purchaſer, if he had infallible criteria of the genuineneſs of every individual oil. It is of as much importance that they be *good*, as that they be *genuine*; for genuine oils, from inattentive diſtillation and long and careleſs keeping, are often weaker both in ſmell and taſte than the common ſophiſticated ones.

The ſmell and taſte ſeem to be the only certain teſts of which the nature of the thing will admit. If a bark ſhould have in every reſpect the appearance of good cinnamon, and ſhould be proved indiſputably to be the genuine bark of the cinnamon-tree; yet if it want the cinnamon flavour, or has it but in a low degree, we reject it; and the caſe is the ſame with the oil. It is only from uſe and habit, or compariſons with ſpecimens of known quality, that we can judge of the goodneſs either of the drugs themſelves or of their oils.

Moſt of the eſſential oils, indeed, are too hot and pungent to be taſted with ſafety; and the ſmell of the ſubject is ſo much concentrated in them, that a ſmall variation in this reſpect is not eaſily diſtinguiſhed; but we can readily dilute them to any aſſignable degree. A drop of the oil may be diſſolved in ſpirit of wine, or received on a bit of ſugar, and diſſolved by that intermedium in water. The quantity of liquor which it thus impregnates with its flavour, or the degree of

flavour

flavour which it communicates to a certain determinate quantity, will be the meaſure of the degree of goodneſs of the oil.

We ſhall here ſubjoin the reſult of ſome experiments, ſhowing *the quantity of eſſential oil obtained from different vegetables*, reduced into the form of a table. The firſt column contains the names of the reſpective vegetable ſubſtances; the ſecond, the quantity of each which was ſubmitted to the diſtillation; and the third, the quantity of oil obtained. In every other part of this article, where *pound* weights are mentioned, the Troy pound of 12 ounces is meant: but theſe experiments having been all made by a pound of 16 ounces, it was thought expedient to ſet down the matter of fact in the original weights: eſpecially as the ſeveral materials, in the large quantity commonly required for the diſtillation of oils, are purchaſed by weights of the ſame kind. But to remove any ambiguity which might ariſe from hence, and to enable the reader to judge more readily of the product, a reduction of the weights is given in the next column; which ſhows the number of parts of each of the ſubjects from which one part of oil was obtained. To each article is affixed the author's name from whom the experiment was taken. The different diſtillations of one ſubject, ſeveral of which are inſerted in the table, ſhow how variable the product of oil is, and that the exotic ſpices, as well as our indigenous plants, do not always contain the ſame proportion of this active principle; though it muſt be obſerved, alſo, that part of the differences may probably ariſe from the operation itſelf having been more or leſs carefully performed.

Preparations and Compoſitions.

195 TABLE *of the Quantity of* ESSENTIAL OIL *obtained from different* VEGETABLES.

		yielded of eſſential oil		ſo that one part of oil was obtained from

Chap. VII. *Salts.*

Diluted or weak vitriolic acid. L.

196 Take of vitriolic acid, one ounce by weight; distilled water, 8 ounces by weight. Mix them by degrees.

Weak vitriolic acid, commonly called *weak spirit of vitriol.* E.

Take of vitriolic acid, one part; water, seven parts. Mix them.

In the former editions of our pharmacopœias, directions were given for the preparation of the vitriolic acid by the apothecary himself, under the heads of *spirit and oil of vitriol, spirit or oil of sulphur by the bell*, &c.: but as it is now found that all these modes are expensive, and that this acid may be furnished at a cheaper rate from the trading chemists preparing it on a large scale, it is with propriety that both colleges have now rejected it from the preparations, and introduced it only into the list of the materia medica.

When, however, it is of the degree of concentration there required, it can be employed for very few purposes in medicine. The most simple form in which it can be advantageously employed internally, is that in which it is merely diluted with water: and it is highly proper that there should be some fixed standard in which the acid in this state should be kept. It is, however, much to be regretted, that the London and Edinburgh colleges have not adopted the same standard with respect to strength: for in the one, the strong acid constitutes an eighth; and in the other, only a ninth of the mixture. The former proportion, which is that of the Edinburgh college, we are inclined to prefer, as it gives exactly a dram of acid to the ounce: but the dilution by means of distilled water, which is directed by the London, is preferable to spring-water; which, even in its purest state, is rarely free from impregnations in part affecting the acid.

The acid of vitriol is the most ponderous of all the liquids we are acquainted with, and the most powerful of the acids. If any other acid be united with a fixed alkaline salt or earth, on the addition of the vitriolic, such acid will be dislodged, and arise on applying a moderate heat, leaving the vitriolic in possession of the alkali; though without this addition it would not yield to the most vehement fire. Mixed with water, it instantly creates great heat, insomuch that glass vessels are apt to crack from the mixture, unless it be very slowly performed: exposed to the air, it imbibes moisture, and soon acquires a remarkable increase of weight. In medicine, it is employed chiefly as subservient to other preparations: it is also frequently mixed with juleps and the like, in such quantity as will be sufficient to give the liquor an agreeable tartness, and it then is a cooling antiseptic, a restringent, and a stomachic.

It is particularly useful for allaying inordinate actions of the stomach, when under the form of singultus or vomiting. For its medical properties, see Acids and Vitriol.

Nitrous acid. L.

Take of purified nitre, by weight, 60 ounces; vitriolic acid, by weight, 29 ounces. Mix and distil. 197

The specific gravity of this is to the weight of distilled water as 1550 to 1000.

Nitrous acid, commonly called *Glauber's spirit of nitre.* E.

Take of purest nitre, bruised, two pounds; vitriolic acid, one pound. Having put the nitre into a glass retort, pour on it the spirit; then distil in a sand-heat, gradually increasing the fire, till the sand-pot becomes of a dull red colour.

Here the vitriolic acid expels the nitrous, in red corrosive vapours, which begin to issue immediately on mixture; and which the operator ought cautiously to avoid. A pound of acid of vitriol is sufficient to expel all the acid from about two pounds of nitre, not from more: some direct equal parts of the two. The spirit, in either case, is in quality the same; the difference, in this respect, affecting only the residuum. If two parts of nitre be taken to one of vitriolic acid, the remaining alkaline basis of the nitre is completely saturated with the vitriolic acid; and the result is a neutral salt, the same with vitriolated tartar, as we shall

Preparations and Compositions.

shall see hereafter. If more nitre be used, a part of the nitre in substance will remain blended with this neutral salt: if less nitre, it cannot afford alkali enough to saturate the vitriolic acid, and the residuum will not be a neutral salt, but a very acid one. In this last case there is one conveniency; the acid salt being readily soluble in water, so as to be got out without breaking the retort, which the others are not.

Diluted or weak nitrous acid. L.

198 Take of nitrous acid, distilled water, each one pound. Mix them.

Weak nitrous acid. E.

Take of nitrous acid, water, equal weights. Mix them, taking care to avoid the noxious vapours.

In the old editions both of the London and Edinburgh pharmacopœias, directions were given for the preparation of aquafortis simplex and duplex; but these were no more than different forms of preparing an impure nitrous acid, unfit for medical purposes. They are therefore, with propriety, superseded by the more simple formulæ of nitrous acid and diluted or weak nitrous acid, mentioned above. In making the diluted acid, distilled water is preferable to common water.

The vapour separated during the mixing of nitrous acid and water, is the permanently elastic fluid called *nitrous acid air*, which is deleterious to animal life.

The acid of nitre is next in strength to the vitriolic, and dislodges all others from alkaline salts or eartha. It differs from all the other acids in deflagrating with inflammable matters: if a solution of any inflammable substance, as hartshorn, &c. in this acid, be set to evaporate, as soon as the matter approaches to dryness, a violent detonation ensues. The chief use of this acid is as a menstruum for certain minerals, and as the basis of some particular preparations to be mentioned hereafter. It has been given likewise, diluted with any convenient vehicle, as a diuretic, from 10 to 50 drops.

Muriatic acid. L.

199 Take of dry sea-salt, 10 pounds; vitriolic acid, six pounds; water, five pounds. Add the vitriolic acid first mixed with the water by degrees, to the salt; then distil.

The specific gravity of this acid is to distilled water as 1170 to 1000.

Muriatic acid, commonly called *spirit of sea-salt.* E.

Take of sea-salt, two pounds; vitriolic acid, water, each one pound. Let the salt be first put into a pot, and brought to a red heat, that the oily impurities may be consumed; then put it into the retort. Next mix the acid with the water, and when the mixture has cooled, pour it upon the salt. Lastly, distil in a sand heat with a middling heat, as long as any acid comes over.

The marine, or muriatic acid, arises, not in red fumes like the nitrous, but in white ones. The addition of water is more necessary here than in the foregoing process; the marine vapours being so volatile, as scarcely to condense without some adventitious humidity. The acid of vitriol is most conveniently mixed with the water in an earthen or stone-ware vessel: for unless the mixture be made exceedingly slow, it grows so hot as to endanger breaking a glass one.

Preparations and Compositions.

The spirit of sea-salt is the weakest of the mineral acids, but stronger than any of the vegetable: it requires a greater fire to distil it than that of nitre, yet it is more readily dissipated by the action of the air. It is used chiefly as a menstruum for the making of other preparations; sometimes, likewise, it is given, properly diluted, as an antiphlogistic, aperient, and diuretic, from 10 to 60 or 70 drops.

Distilled vinegar.

Take of vinegar five pints. Distil with a gentle fire, in glass vessels, so long as the drops fall free from empyreuma. *L.* 200

Let eight pounds of vinegar be distilled in glass vessels with a gentle heat. Let the two first pounds that come over be thrown away as containing too much water; let four pounds next following be reserved as the distilled vinegar. What remains is a still stronger acid, but too much acted on by the heat. *E.*

This process may be performed either in a common still with its head, or in a retort. The better kinds of wine-vinegar should be used: those prepared from malt liquors, however fine and clear they may seem to be, contain a large quantity of a viscous substance, as appears from the slimyness and ropyness to which they are very much subject: this not only hinders the acid parts from rising freely, but likewise is apt to make the vinegar boil over into the recipient, and at the same time disposes it to receive a disagreeable impression from the fire. And indeed, with the best kind of vinegar, if the distillation be carried on to any great length, it is extremely difficult to avoid an empyreuma. The best method of preventing this inconvenience is, if a retort be used, to place the sand but a little way up its sides, and when somewhat more than half the liquor is come over, to pour on the remainder a quantity of fresh vinegar equal to the liquor drawn off. This may be repeated three or four times; the vinegar supplied at each time being previously heated. The addition of cold liquor would not only prolong the operation, but also endanger the breaking of the retort. If the common still be employed, it should likewise be occasionally supplied with fresh vinegar in proportion as the spirit runs off; and this continued until the process can be conveniently carried no farther: the distilled spirit must be rectified by a second distillation in a retort or glass alembic; for although the head and receiver be of glass or stone ware, the acid will contract a metallic taint from the pewter worm.

The residuum of this process is commonly thrown away as useless, although, if skilfully managed, it might be made to turn to good account; the most acid parts of the vinegar still remaining in it. Mixed with about three times its weight of fine dry sand, and committed to distillation in a retort, with a well-regulated fire, it yields an exceeding strong acid spirit, together with an empyreumatic oil, which taints the spirit with a disagreeable odour. This acid is nevertheless, without any rectification, better for some purposes (as a little

of it will go a great way) than the pure ſpirit; particularly for making the diuretic or acetated kali of the London college; for there the oily matter, on which its ill flavour depends, is burnt out by the calcination.

The ſpirit of vinegar is a purer and ſtronger acid than vinegar itſelf, with which it agrees in other reſpects. (See VINEGAR). Their principal difference from the mineral acid conſiſts in their being milder, leſs ſtimulating, leſs diſpoſed to affect the kidneys and promote the urinary ſecretions, or to coagulate the animal juices. The matter left after the diſtillation in glaſs veſſels, though not uſed in medicine, would doubtleſs prove a ſerviceable detergent ſaponaceous acid; and in this light ſtands recommended by Boerhaave.

Concentrated vinegar. Suec.

Let white wine vinegar be frozen in a wooden veſſel in cold winter weather; and let the fluid ſeparated from the ice be preſerved for uſe. It may be conſidered as ſufficiently ſtrong, if one dram of it be capable of ſaturating a ſcruple of the fixed vegetable alkali.

This is a very eaſy mode for obtaining the acid of vinegar in a concentrated ſtate, and freed from a conſiderable portion of its water. But at the ſame time we do not thus obtain the acid either ſo much concentrated, or in ſo pure a ſtate as by the following proceſs.

Acetous acid. L.

Take of verdegriſe, in coarſe powder, two pounds. Dry it perfectly by means of a water-bath ſaturated with ſea-ſalt; then diſtil it in a ſand-bath, and after that diſtil the liquor. Its ſpecific gravity is to that of diſtilled water as 1050 to 1000.

By this proceſs, it may be readily concluded that we obtain the acetous acid in its moſt concentrated ſtate, and with the leaſt admixture of water. And after the re-diſtillation, it may alſo be ſuppoſed that it will be free from all mixture of the copper. But the internal uſe of it has been objected to by ſome, on the ſuppoſition that it may ſtill retain a portion of the metal; and hitherto it has, we believe, been but little employed.

Cryſtallized acid of tartar. Suec.

Take of prepared chalk, frequently waſhed with warm water, two pounds; ſpring water, 32 pounds. After ſlight boiling, by degrees add of cream of tartar 7 pounds, or as much as is ſufficient for ſaturation. Removing the veſſel from the fire, let it ſtand for half an hour, then cautiouſly pour off the clear liquor into a glaſs veſſel. Waſh the reſiduum or tartareous ſelenites by pouring water on it three or four times. To this reſiduum afterwards add of weak vitriolic acid 16 pounds, let it be digeſted for a day, frequently ſtirring it with a wooden ſpatula. After this pour the acid liquor into a glaſs veſſel: but with the reſiduum mix 16 pounds of ſpring water; ſtrain it through paper, and again pour water on the reſiduum till it become inſipid. Let the acid liquors mixed together in a glaſs veſſel be boiled to the conſiſtence of a thin ſyrup; which being ſtrained, muſt be ſet apart for the formation of cryſtals. Let the cryſtals collected after repeated diſtillations be dried on paper, and afterwards kept in a dry place. Preparations and Compoſitions.

If before cryſtallization a little of the inſpiſſated acid liquor be diluted with four times its quantity of pure water, and a few drops of vinegar of litharge be put into it, a white ſediment will immediately be depoſited. If a few drops of the diluted nitrous acid be then added, the mixture will become limpid, if the tartareous liquor be pure and entirely free from the vitriolic acid; but if it be not, it will become white. This fault, however, may be corrected, if the acid of tartar be diluted with ſix pounds of water and a few ounces of the tartareous ſelenites be added to it. After this it may be digeſted, ſtrained, and cryſtallized.

By this proceſs, the acid of tartar may be obtained in a pure ſolid form. It would, however, be perhaps an improvement of the proceſs, if quicklime were employed in place of chalk. For Dr Black has found that quicklime abſorbs the whole of the tartareous acid, and then the ſupernatant liquor contains only the alkaline part of the tartar; whereas, when chalk is employed, it contains a ſolution of ſoluble tartar, the chalk taking up only the ſuperabundant acid. By this method then a greater quantity of tartareous acid might be obtained from the ſediment. The tartareous acid has not hitherto been much employed in its pure ſtate. But beſides being uſeful for ſome purpoſes in medicine, for which the cream of tartar is at preſent in uſe, and where that ſuperſaturated neutral may be leſs proper, there is alſo reaſon to ſuppoſe, that from the employment of the pure acid, we ſhould arrive at more certainty in the preparation of the antimonium tartarizatum, or tartar emetic, than by employing the cream of tartar, the proportion of acid in which varies very much from different circumſtances. The pure acid of tartar might alſo probably be employed with advantage for bringing other metallic ſubſtances to a ſaline ſtate.

Diſtilled acid of tartar. Suec.

Let pounded crude tartar be put into a tubulated earthen or iron retort till it fills about two-thirds of it, and let diſtillation be performed by gradually increaſing the heat. Into the recipient, which ſhould be very large, an acid liquor will paſs over together with the oil; which being ſeparated from the oil, muſt again be diſtilled from a glaſs retort. If the reſiduum contained in the earthen or iron retort be diluted with water, ſtrained through paper, and boiled to dryneſs, it gives what is called the *alkali* of tartar. If this do not appear white, it may be made ſo by burning, ſolution, ſtraining, and evaporation. 204

This is another mode of obtaining both the acid and alkali of tartar in a pretty pure ſtate; and, as well as the former, it is not unworthy of being adopted into our pharmacopœias.

Aerated water. Roſſ.

Let ſpring water be ſaturated with the fixed air, or aerial acid, ariſing from a ſolution of chalk in vitriolic acid, or in any ſimilar acid. Water may alſo be impregnated by the fixed air riſing from fermenting liquors. 205

The aerial acid, on which we have already had occaſion

to

Preparations and Compositions.

to make some observations, besides the great influence which it has as affecting different saline bodies into whose composition it enters, is also frequently employed in medicine, with a view to its action on the human body. The late ingenious Dr Dobson, in his Commentary on Fixed Air, has pointed out many purposes for which it may be usefully employed, and several different forms under which it may be used. But there is no form under which it is at present more frequently had recourse to than that of aerated or mephitic water, as it has often been called. And although not yet received either into the London or Edinburgh pharmacopœias, it is daily employed in practice, and is we think justly intitled to a place among the saline preparations.

The most convenient mode of impregnating water with the aerial acid, and thus having it in our power to exhibit that acid as it were in a diluted state, is by means of a well known and sufficiently simple apparatus, contrived by that ingenious philosopher Dr Nooth. Such a machine ought, we think, to be kept in every shop for the more ready preparation of this fluid. Water properly impregnated with the aerial acid has an agreeable acidulous taste. It is often employed with great advantage in the way of common drink, by those who are subjected to stomach complaints, and by calculous patients. But, besides this, it furnishes an excellent vehicle for the exhibition of many other medicines.

Besides the simple aerated water, the Pharmacopœia Rossica contains also an aqua aëris fixi martialis, or ferruginous aerated water. This is prepared by suspending iron wires in that water till the water be fully saturated with the metal. And in consequence of this acid, simple water becomes a menstruum both for different metallic and earthy substances. But water in this state may be considered rather as fitted for those purposes for which chalybeates are in use, than as a preparation of the aerial acid.

Salt and oil of amber. L.

206 Take of amber two pounds. Distil in a sand heat, gradually augmented: an acid liquor, oil, and salt impregnated with oil, will ascend.

On this article we have already offered some observations under the head of Essential Oils. The directions here given by the London college differ chiefly from those of the Edinburgh college formerly mentioned, in no sand being employed: But when care is taken that the sand be pure, it can give no improper impregnation to the medicine, and may prevent some inconveniences in the distillation, particularly that of the amber rising in substance into the receiver.

Purified salt of amber. L.

207 Take of salt of amber half a pound; distilled water, one pint. Boil the salt in the distilled water, and set aside the solution to crystallize.

Salt of amber, when perfectly pure, is white, of an acid taste, and not ungrateful. It requires, for its solution, of cold water, in summer, about twenty times its weight; and of boiling water about twice its weight; it is scarcely soluble in rectified spirit without the assistance of heat.

It is given as a cooling diuretic in doses of a few grains, and also in hysterical complaints.

Preparations and Compositions.

Flowers of benzoin.

208 Take of benzoin, in powder, one pound. Put it into an earthen pot, placed in sand; and, with a slow fire, sublime the flowers into a paper cone fitted to the pot.

If the flowers be of a yellow colour, mix them with white clay, and sublime them a second time. *L.*

Put any quantity of powdered benzoin into an earthen pot, to which, after fitting it with a large conical paper cap, apply a gentle heat that the flowers may sublime. If the flowers be impregnated with oil, let them be purified by solution in warm water and crystallization. *E.*

Benzoin, exposed in a retort to a gentle fire, melts, and sends up into the neck white, shining crystalline flowers, which are followed by an oily substance. These flowers, which are at present considered as a peculiar acid, are by some termed *acidum benzoicum*. On raising the heat a little (a recipient being applied to the neck of the retort), a thin yellowish oil comes over, intermingled with an acid liquor, and afterwards a thick butyraceous substance: this last, liquefied in boiling water, gives out to it a considerable quantity of saline matter (separable by filtration and proper exhalation), which appears in all respects similar to the flowers.

It appears, therefore, that the whole quantity of flowers which benzoin is capable of yielding, cannot be obtained by the above processes, since a considerable portion arises after the time of their being discontinued. The greatest part of the flowers arise with a less degree of heat than what is necessary to elevate the oil; but if the operation be hastily conducted, or if the fire be not exceedingly gentle, the oil will arise along with the flowers, and render them foul. Hence in the way of trade, it is extremely difficult to prepare them of the requisite whiteness and purity; the heat which becomes necessary, when large quantities of the benzoin are employed, being so great as to force over some of the oil along with them.

In order, therefore, to obtain these flowers in perfection, only a small quantity of benzoin should be put into the vessel at a time; and that this may not be any impediment to the requisite dispatch, a number of shallow, flat-bottomed, earthen dishes may be employed, each fitted with another vessel inverted over it, or a paper cone. With these you may fill a sand furnace; having fresh dishes charged in readiness to replace those in the furnace, as soon as the process shall appear finished in them: the residuum of the benzoin should be scraped out of each of the vessels before a fresh parcel be put in.

These flowers, when made in perfection, have an agreeable taste and fragrant smell. They totally dissolve in spirit of wine; and likewise, by the assistance of heat, in water; but separate again from the latter upon the liquor's growing cold, shooting into saline spicula, which unite together into irregular masses. By the mediation of sugar they remain suspended in cold water, and thus form an elegant balsamic syrup. Some have held them in great esteem as pectoral and

sudorific, in the dose of half a scruple or more: but at present they are rarely used, on account of the offensive oil which, as usually prepared, they are tainted with, and from which a fresh sublimation from tobacco-pipe clay, as formerly practised, did not free them so effectually as might be wished. The observations above related, point out the method of depurating them more perfectly, *viz.* by solution, filtration, and crystallization.

They enter the composition of the paregoric elixir, or tinctura opii camphorata, as it is now called.

Salt of tartar. E.

9 Take of tartar, what quantity you please. Roll it up in a piece of moist bibulous paper, or put it into a crucible, and surrounding it with live coals, burn it to a coal; next, having beat this coal, calcine it in an open crucible with a moderate heat, taking care that it do not melt, and continue the calcination till the coal becomes of a white, or at least of an ash colour. Then dissolve it in warm water; strain the liquor through a cloth, and evaporate it in a clean iron vessel; diligently stirring it towards the end of the process with an iron spatula, to prevent it from sticking to the bottom of the vessel. A very white salt will remain, which is to be left a little longer on the fire, till the bottom of the vessel becomes almost red. Lastly, when the salt is grown cold, let it be put up in glass vessels well shut.

Native tartar is a saline substance, compounded of an acid, of a fixed alkali, and of oily, viscous, and colouring matter. The purpose of the above process is, to free it from every other matter but the fixed alkali. From the mistaken notion that tartar was essentially an acid mixed only with impurities, it has been generally supposed that the effect of this operation was the conversion of an acid into an alkali by means of heat. But since Mr Scheele has discovered that the proper matter of tartar, freed from the oily and colouring parts, is really a salt compounded of an acid, which is predominant, and a fixed alkali, we have no farther need of such an obscure theory. The acid of the tartar by this process is dissipated by means of the heat: and the oily, viscous, and colouring matters, are partly dissipated, and partly brought to the state of insoluble earthy matter, easily separable by the future lixiviation from the alkali, wherewith they were loosely combined. But by the last of these processes, something farther is carried on than the separation of the more palpable foreign matters. By allowing the salt, freed from the water of the lixivium, to remain on the fire till the bottom of the vessel become almost red, any oily matter that may still be present seems to be decomposed by the united action of the heat and fixed alkali, forming with a part of the latter, by their reciprocal action, a volatile alkaline salt, which is forthwith discharged in elastic vapours. Besides the complete discharge of the above principles, the remaining fixed alkali also suffers a considerable loss of its fixed air, or aerial acid; with which, when fully saturated, it forms the imperfect neutral salt, denominated by Dr Black *mild fixed alkali*: on this account it is somewhat caustic, considerably deliquescent, and in proportion to its possessing these properties more or less, it more or less nearly approaches to the state of pure alkali. It is not, however, so effectually deprived of fixed air as to be sufficiently caustic for a number of purposes. Where causticity is not required, the salt thus purified is abundantly fit for most pharmaceutical purposes; but as native tartar generally contains small portions of neutral salts besides the foreign matters already noticed, it is necessary, if we wish to have a very pure alkali for nice operations, to employ crystallization and other means, beside the process here directed. Preparations and Compositions.

The white and red sorts of tartar are equally fit for the purpose of making fixed salt; the only difference is, that the white affords a somewhat larger quantity than the other: from 16 ounces of this sort, upwards of four ounces of fixed alkaline salt may be obtained. The use of the paper is to prevent the smaller pieces of the tartar from dropping down into the ash-hole, through the interstices of the coals, upon first injecting it into the furnace.

The calcination of the salt (if the tartar was sufficiently burnt at first) does not increase its strength so much as is supposed: nor is the greenish or blue colour any certain mark either of its strength, or of its having been, as was formerly supposed, long exposed to a vehement fire: for if the crucible be perfectly clean, close covered, and has stood the fire without cracking, the salt will turn out white, though kept melted and reverberated ever so long; while, on the other hand, a slight crack happening in the crucible, or a spark of coal falling in, will in a few minutes give the salt the colour admired. The colour, in reality, is a mark rather of its containing some inflammable matter than of its strength.

The vegetable alkali prepared from tartar has now no place in the London pharmacopœia, or at least it is included under the following article.

Prepared kali. L.

Take of pot-ash, two pounds; boiling distilled water, three pints. Dissolve and filtre through paper; evaporate the liquor till a pellicle appears on the surface; then set it aside for a night, that the neutral salts may crystallize; after which pour out the liquor, and boil away the whole of the water, constantly stirring, lest any salt should adhere to the pot. In like manner is purified impure kali from the ashes of any kind of vegetable. The same salt may be prepared from tartar burnt till it becomes of an ash-colour. 210

Fixed vegetable alkaline salt purified E.

Let the fixed alkaline salt, called in English *pearl-ashes*, be put into a crucible, and brought to a somewhat red heat, that the oily impurities, if there be any, may be consumed; then having beat and agitated it with an equal weight of water, let them be well mixed. After the feces have subsided, pour the ley into a very clean iron pot, and boil to dryness, diligently stirring the salt towards the end of the process, to prevent its sticking to the vessel. This salt, if it hath been rightly purified, though it be very dry, if rubbed with an equal weight of water, may be dissolved into a liquor void of colour or smell. 211

The potash used in commerce is an alkali mixed with a considerable quantity of remaining charcoal,

Preparations and Compositions.

sulphur, vitriolated tartar, and oily matter. In the large manufactures, the alkaline part is indeed considerably freed from impurities by mixing the weed-ashes with water, evaporating the clear ley, and burning the residuum in an oven; but besides that this process is insufficient for the complete separation of the impurities, it also superadds a quantity of stony matter, giving to the alkali the *pearl* appearance (whence its name), and rendering it altogether unfit for pharmaceutical purposes. By the processes here directed, the alkali is effectually freed from all these heterogeneous matters, excepting perhaps a small proportion of vitriolated tartar, or other neutral salts, which may very generally be neglected. As in the process no after calcination is directed, it is probable that the fixed alkali thus prepared will not prove so caustic, that is to say, is not so considerably deprived of fixed air, as in the process directed for preparing the salt of tartar. It is, however, sufficiently pure for most purposes: and we consider the above process as the most convenient and cheap method of obtaining the vegetable fixed alkali in its mild state.

The purified vegetable alkali has been known in our pharmacopœias under the different names of *salt of wormwood*, *salt of tartar*, &c. But all these being now known to be really the same, the terms, as leading to error, have been with justice expunged; and it has been a desideratum to discover some short name equally applicable to the whole. The term employed by the Edinburgh college is too long, being rather a description than a name; but to that employed by the London college, *Kali*, objections have also been made. And it must be allowed, that besides the inconvenience which arises from its being an indeclinable word, the fossil alkali is equally intitled to the same appellation. Besides this, as a considerable portion of the fossil alkali is prepared from burning a vegetable growing on the sea-coasts, which has the name of *kali*, the Kali spinosum of Linné, some apparent contradiction and ambiguity may thence arise. And the London college would perhaps have done better, if they had adopted the term *Potassa*; a name which has been appropriated to this salt by some of the most eminent modern chemists.

The purified potassa is frequently employed in medicine, in conjunction with other articles, particularly for the formation of saline neutral draughts and mixtures: But it is used also by itself in doses from three or four grains to 15 or 20; and it frequently operates as a powerful diuretic, particularly when aided by proper dilution. See PEARL-*Ash* and POT-ASH.

Water of kali. L.

212 Take of kali, one pound, set it by in a moist place till it be dissolved, and then strain it.

This article had a place in former editions of our pharmacopœias under the titles of *ley of tartar*, or *oil of tartar per deliquium*, &c. It is, however, to be considered as a mere watery solution of the mild vegetable alkali, formed by its attracting moisture from the air; and therefore it is with propriety styled the *water of kali*.

The solutions of fixed alkaline salts, made by exposing them to a moist air, are generally considered as being purer than those made by applying water directly: for though the salt be repeatedly dissolved in water, filtered, and exsiccated; yet, on being liquefied by the humidity of the air, it will still deposite a portion of earthy matter: but it must be observed, that the exsiccated salt leaves always an earthy matter on being dissolved in water, as well as on being deliquated in the air. Whether it leaves more in the one way than in the other, is not determined with precision. The deliquated lixivium is said to contain nearly one part of alkaline salt to three of an aqueous fluid. It is indifferent, in regard to the lixivium itself, whether the white ashes of tartar, or the salt extracted from them, be used; but as the ashes leave a much greater quantity of earth, the separation of the ley proves more troublesome.

The water of kali of the present edition of the London pharmacopœia, then, may be considered as an improvement of the lixivium tartari of their former edition. But the Edinburgh college, considering this solution as being in no respect different from that made by pure water, have entirely rejected this preparation from their pharmacopœia, and probably with justice.

Water of pure kali. L.

Take of kali, four pounds; quicklime, six pounds; distilled water, four gallons. Put four pints of water to the lime, and let them stand together for an hour; after which, add the kali and the rest of the water; then boil for a quarter of an hour: suffer the liquor to cool, and strain. A pint of this liquor ought to weigh 16 ounces. If the liquor effervesces with any acid, add more lime. 213

A preparation similar to this had a place in the former edition of the London pharmacopœia, under the title of *soap-ley*. Quicklime, by depriving the mild alkali of its aerial acid, renders it caustic: hence this ley is much more acrimonious, and acts more powerfully as a menstruum of oils, fats, &c. than a solution of the potassa alone. The lime should be used fresh from the kiln; by long keeping, even in close vessels, it loses its strength: such should be made choice of as is thoroughly burnt or calcined, which may be known by its comparative lightness.

All the instruments employed in this process should be either of wood, earthen ware, or glass: the common metallic ones would be corroded by the ley, so as either to discolour or communicate disagreeable qualities to it. If it should be needful to filter or strain the liquor, care must be taken that the filter or strainer be of vegetable matter: woollen, silk, and that sort of filtering paper which is made of animal substances, are quickly corroded and dissolved by it.

The liquor is most conveniently weighed in a narrow-necked glass bottle, of such a size, that the measure of a wine pint may arise some height into its neck; the place to which it reaches being marked with a diamond. A pint of the common leys of our soap-makers weighs more than 16 ounces: it has been found that their soap-ley will be reduced to the standard here proposed, by mixing it with something less than an equal measure of water.

Although this liquor is indeed pure alkali dissolved in water, yet we are inclined to give the preference

to

to the name employed by the Edinburgh college, as well as to the modes of preparing it, directed in the following formula.

Cauſtic ley. E.

Take of freſh burnt quicklime, eight ounces; purified fixed vegetable alkaline ſalt, ſix ounces. Throw the quicklime, with 28 ounces of warm water, into an iron or earthen veſſel. The ebullition and extinction of the lime being perfectly finiſhed, inſtantly add the alkaline ſalt; and having thoroughly mixed them, ſhut the veſſel till it cools. Stir the cooled matter, and pour out the whole into a glaſs funnel, whoſe throat muſt be ſtopped up with a piece of clean rag. Let the upper mouth of the funnel be covered, while the tube of it is inſerted into a glaſs veſſel, ſo that the ley may gradually drop through the rag into that veſſel. When it firſt gives over dropping, pour into the funnel ſome ounces of water; but cautiouſly, and in ſuch a manner, that the water ſhall ſwim above the matter. The ley will again begin to drop, and the affuſion of water is to be repeated in the ſame manner, until three pounds have dropped, which takes up the ſpace of two or three days; then agitating the ſuperior and inferior parts of the ley together, mix them, and put up the liquor in a well-ſhut veſſel.

If the ley be rightly prepared, it will be void of colour or ſmell; nor will it raiſe an effervescence with acids, except perhaps a very ſlight one. Colour and odour denote the ſalt not ſufficiently calcined; and effervescence, that the quicklime has not been good.

The reaſons and propriety of the different ſteps in the above proceſs will be beſt underſtood by ſtudying the theory on which it is founded. The principle of mildneſs in all alkaline ſalts, whether fixed or volatile, vegetable or foſſil, is very evidently fixed air, or the aerial acid: But as quicklime has a greater attraction for fixed air than any of theſe ſalts, ſo if this ſubſtance be preſented to any of them, they are thereby deprived of their fixed air, and forthwith become cauſtic This is what preciſely happens in the above proceſſes. The propriety of cloſely ſhutting the veſſels through almoſt every ſtep of the operation, is ſufficiently obvious; viz. to prevent the abſorption of fixed air from the atmoſphere, which might defeat our intentions. When only a piece of cloth is put into the throat of the funnel, the operation is much more tedious, becauſe the pores of the cloth are ſoon blocked up with the wet powdery matter. To prevent this, it may be convenient to place above the cloth a piece of fine Fly's wirework; but as metallic matters are apt to be corroded, the method uſed by Dr Black is the moſt eligible. The Doctor firſt drops a rugged ſtone into the tube of the funnel, in a certain place of which it forms itſelf a firm bed, while the inequalities on its ſurface afford interſtices of ſufficient ſize for the paſſage of the filtering liquor. On the upper ſurface of this ſtone he puts a thin layer of lint or clean tow; immediately above this, but not in contact with it, he drops a ſtone ſimilar to the former, and of a ſize proportioned to the ſwell in the upper part of the tube of the funnel. The interſtices between this ſecond ſtone and the funnel are filled up with ſtones of a leſs dimenſion, and the gradation uniformly continued till pretty ſmall ſand is employed. Finally, this is covered with a layer of coarſer ſand and ſmall ſtones to ſuſtain the weight of the matter, and to prevent its being inviſcated in the minute interſtices of the fine ſand. The throat of the funnel being thus built up, the ſtony fabric is to be freed of clay and other adhering impurities, by making clean water paſs through it till the water comes clear and tranſparent from the extremity of the funnel. It is obvious, that in this contrivance, the author has, as uſual, copied nature in the means ſhe employs to depurate watery matters in the bowels of the earth; and it might be uſefully applied for the filtration of various other fluids. Preparations and Compoſitions.

It is a very neceſſary caution to pour the water gently into the funnel; for if it be thrown in a forcible ſtream, a quantity of the powdery matter will be waſhed down, and render all our previous labour uſeleſs. That part of the ley holding the greateſt quantity of ſalt in ſolution will no doubt be heavieſt, and will conſequently ſink loweſt in the veſſel: the agitation of the ley is therefore neceſſary, in order to procure a ſolution of uniform ſtrength through all its parts. If the ſalt has been previouſly freed of oily and other inflammable matters, this ley will be colourleſs and void of ſmell. If the quicklime has been ſo effectually deprived of its own fixed air, as to be able to abſorb the whole of that in the alkali, the ley will make no effervescence with acids, being now deprived of fixed air, to the diſcharge of which by acids this appearance is to be aſcribed in the mild or aerated alkalis.

The cauſtic ley is therefore to be conſidered as a ſolution of pure alkali in water. See the article FIXED AIR.

It may be proper to obſerve, for the ſake of underſtanding the whole of the theory of the above proceſs, that while the alkali has become cauſtic, from being deprived of fixed air by the quicklime, the lime has in its turn become mild and inſoluble in water from having received the fixed air of the alkali.

The cauſtic ley, under various pompous names, has been much uſed as a lithontriptic; but its fame is now beginning to decline. In acidities in the ſtomach, attended with much flatulence and laxity, the cauſtic ley is better adapted than mild alkalis; as in its union with the acid matter it does not ſeparate air. When covered with mucilaginous matters, it may be ſafely taken into the ſtomach: and by ſtimulating, it coincides with the other intentions of cure; by ſome dyſpeptic patients it has been employed with advantage.

Pure kali. L.

Take of water of pure kali, one gallon. Evaporate it to dryneſs; after which let the ſalt melt on the fire, and pour it out. 215

The ſtrongeſt common cauſtic. E.

Take of cauſtic ley, what quantity you pleaſe. Evaporate it in a very clean iron veſſel on a gentle fire till, 216

Preparations and Compositions.

till, on the ebullition ceasing, the saline matter gently flows like oil, which happens before the vessel becomes red. Pour out the caustic thus liquefied on a smooth iron plate; let it be divided into small pieces before it hardens, which are to be kept in well shut phials.

These preparations may be considered as differing in no essential particular. But the directions given by the Edinburgh college are the most precise and distinct.

The effect of the above processes is simply to discharge the water of the solution, whereby the causticity of the alkali is more concentrated in any given quantity. These preparations are strong and sudden caustics. The caustic prepared in this way has an inconvenience of being apt to liquefy too much on the part to which it is applied, so that it is not easily confined within the limits in which it is intended to operate; and indeed the suddenness of its action depends on this disposition to liquefy.

Lime with pure kali. L.

217 Take of quicklime, five pounds and four ounces; water of pure kali, 16 pounds by weight. Boil away the water of pure kali to a fourth part; then sprinkle in the lime, reduced to powder by the affusion of water. Keep it in a vessel close stopped.

The milder common caustic. E.

218 Take of caustic ley, what quantity you please. Evaporate in an iron vessel till one-third remains; then mix with it as much new slaked quicklime as will bring it to the consistence of pretty solid pap, which is to be kept in a vessel closely stopped.

These preparations do not essentially differ from each other, while the chief difference between the present formula and that which stood in the last edition of the London pharmacopœia is in the name. It was then styled the *strongest common caustic*.

Here the addition of lime in substance renders the preparation less apt to liquefy than the foregoing, and consequently it is more easily confinable within the intended limits, but proportionally slower in its operation. The design of keeping or of slaking the lime is, that its acrimony may be somewhat abated.

Exposed long to the air, these preparations gradually resume their power of effervescence, and lose proportionally the additional activity which the quicklime had produced in them.

Prepared natron. L.

219 Take of barilla, powdered, two pounds; distilled water, one gallon. Boil the barilla in four pints of water for half an hour, and strain. Boil that part which remains after straining with the rest of the water, and strain. Evaporate the mixed liquors to two pints, and set them by for eight days; strain this liquor again; and, after due boiling, set it aside to crystallize. Dissolve the crystals in distilled water; strain the solution, boil, and set it aside to crystallize.

The name of *natron*, here used by the London college for the fixed fossil alkali, has, as well as their name for the vegetable alkali, been objected to. And though they are here supported by the authority of the ancients, yet perhaps they would have done better in following the best modern chemists by employing the term *salt of soda*. This article differs in name only from the following.

Preparations and Compositions.

220

Fixed fossil alkaline salt purified. E.

Take of ashes of Spanish kali, commonly called *soda* or *barilla*, as much as you please. Bruise them; then boil in water till all the salt be dissolved. Strain this through paper, and evaporate in an iron vessel, so that after the liquor has cooled the salt may concrete into crystals.

By the above processes, the fossil alkali is obtained sufficiently pure, being much more disposed to crystallize than the vegetable alkali; the admixture of this last, objected to by Dr Lewis, is hereby in a great measure prevented.

It is with great propriety, that in this, as well as many other processes, the London college direct the use of distilled water, as being free from every impregnation.

The natron, or fossil alkali, is found lying on the ground in the island of Teneriff, and some other countries. The native productions of this salt seem to have been better known to the ancients than to late naturalists; and it is, with good reason, supposed to be the nitre of the Bible. How far the native natron may supersede artificial means to procure it from mixed bodies, we have not been able to learn with certainty.

The fossil alkali is not only a constituent of different neutrals, but is also sometimes employed as a medicine by itself. And in its purified state it has been by some reckoned useful in affections of the scrofulous kind. See NATRUM.

Prepared ammonia. L.

221 Take of sal ammoniac, powdered, one pound; prepared chalk, two pounds. Mix and sublime.

Water of ammonia. L.

222 Take of sal ammoniac, one pound; pot-ash, one pound and a half; water, four pints. Draw off two pints, by distillation, with a slow fire.

Volatile alkali from sal ammoniac, commonly called *volatile sal ammoniac.*

223 Take of sal ammoniac, one pound; chalk, very pure and dry, two pounds; mix them well, and sublime from a retort into a refrigerated receiver.

Spirit of sal ammoniac. E.

224 Take sal ammoniac, purified vegetable fixed alkali, of each sixteen ounces; water, two pounds. Having mixed the salts, and put them into a glass retort, pour in the water; then distil to dryness with a sand-bath, gradually raising the heat.

These articles, which in the last edition of the London pharmacopœia were styled *the volatile salt and spirit of sal ammoniac*, were then directed to be prepared in the same manner.

Sal ammoniac is a neutral salt, composed of volatile alkali and marine acid. In these processes the acid is absorbed by the fixed alkali or chalk; and the volatile alkali is of course set at liberty.

The volatile alkali is, however, in its mild state, being

being combined with the fixed air, or diſcharged from the fixed alkali or chalk on their uniting with the muriatic acid.

The fixed alkali begins to act on the ſal ammoniac, and extricates a pungent urinous odour as ſoon as they are mixed. Hence it is moſt convenient not to mix them till put into the diſtilling veſſel. The two ſalts may be diſſolved ſeparately in water, the ſolutions poured into a retort, and a receiver immediately fitted on. An equal weight of the fixed ſalt is fully, perhaps more than ſufficient to extricate all the volatile.

Chalk does not begin to act on the ſal ammoniac till a conſiderable heat be applied. Hence they may be without inconvenience, and indeed ought to be thoroughly mixed together before they are put into the retort. The ſurface of the mixture may be covered with a little more powdered chalk, to prevent ſuch particles of the ſal ammoniac as may happen to lie uppermoſt from ſubliming unchanged. Though the fire muſt here be much greater than when fixed alkaline ſalt is uſed, it muſt not be ſtrong, nor ſuddenly raiſed; for if it be, a part of the chalk (though of itſelf not capable of being elevated by any degree of heat) will be carried up along with the volatile ſalt. M. du Hamel experienced the juſtneſs of this obſervation. He relates, in the Memoirs of the French Academy of Sciences for the year 1735, that he frequently found his volatile ſalt, when a very ſtrong fire was uſed in the ſublimation, amount to more, ſometimes by a half, than the weight of the crude ſal ammoniac employed; and although not three-fourths of this concrete are pure volatile ſalt, yet the fixed earthy matter, when once volatilized by the alkali, aroſe along with it again on the gentleſt reſublimation, diſſolved with it in water, and exhaled with it in the air.

When all the ſalt has ſublimed, and the receiver grown cool, it may be taken off, and luted to another retort charged with freſh materials. This proceſs may be repeated till the recipient appears lined with volatile ſalt to a conſiderable thickneſs: the veſſel muſt then be broken in order to get out the ſalt.

The volatile ſalt and ſpirit of ſal ammoniac are the pureſt of all the medicines of this kind. They are ſomewhat more acrimonious than thoſe produced directly from animal ſubſtances, which always contain a portion of the oil of the ſubject, and receive from thence ſome degree of a ſaponaceous quality. Theſe laſt may be reduced to the ſame degree of purity by combining them with acids into ammoniacal ſalts, and afterwards recovering the volatile alkali from theſe compounds by the proceſſes above directed.

The matter which remains in the retort after the diſtillation of the ſpirit, and ſublimation of the volatile ſal ammoniac, is found to conſiſt of marine acid united with the fixed alkali or chalk employed. When fixed alkaline ſalt has been uſed as the intermedium, the reſiduum, or *caput mortuum* as it is called, yields, on ſolution and cryſtallization, a ſalt exactly ſimilar to the ſpirit of ſea ſalt coagulated afterwards deſcribed; and hence we may judge of the extraordinary virtues formerly attributed to this ſalt under the names of *ſal antihyſtericum*, *antihypochondriacum*, *febrifugum*, *digeſtivum Sylvii*, &c.

The caput mortuum of the volatile ſalt, where chalk is employed as an intermedium, expoſed to a moiſt air, runs into a pungent liquor, which proves nearly the ſame with a ſolution of chalk made directly in the marine acid. It is called by ſome *oleum cretæ*, oil of chalk. If calcined ſhells, or other animal limes, be mingled with ſal ammoniac, a maſs will be obtained, which likewiſe deliqueſces in the air, and forms a liquor of the ſame kind. Preparations and Compoſitions.

Water of pure ammonia. L.

Take of ſal ammoniac, one pound; quicklime, two pounds; water, one gallon. Add to the lime two pints of the water. Let them ſtand together an hour: then add the ſal ammoniac and the other ſix pints of water boiling, and immediately cover the veſſel. Pour out the liquor when cold, and diſtil off with a ſlow fire one pint. 225

Cauſtic volatile alkali, commonly called *ſpirit of ſal ammoniac with quicklime.* E.

Take of quicklime, freſh burnt, two pounds; water, one pound. Having put the water into an iron or ſtone ware veſſel, add the quicklime previouſly beat; cover the veſſel for 24 hours; when the lime has fallen into a fine powder, put it into the retort; then add 16 ounces of ſal ammoniac, diluted with four times its weight of water; and, ſhutting the mouth of the retort, mix them together by agitation. Laſtly, diſtil into a refrigerated receiver, with a very gentle heat, ſo that the operator can eaſily bear the heat of the retort applied to his hands. Twenty ounces of liquor are to be drawn off. In this diſtillation the veſſels are to be ſo luted as thoroughly to exclude the vapours, which are very penetrating. After the diſtillation, however, they are to be opened, and the alkali poured out before the retort hath altogether cooled. 226

The theory of this proceſs is preciſely the ſame with that directed for the preparation of cauſtic ley. The effect of the quicklime on the ſal ammoniac is very different from that of the chalk and fixed alkali in the foregoing proceſs. Immediately on mixture a very penetrating vapour exhales; and in diſtillation the whole of the volatile ſalt ariſes in a liquid form, no part of it appearing in a concrete ſtate, how gently ſoever the liquor be re-diſtilled. This ſpirit is far more pungent than the other both in ſmell and taſte; and, like fixed alkalis rendered cauſtic by the ſame intermedium, it raiſes no effervescence on mixture with acids. The whole of the phenomena are to be aſcribed to the abſorption of fixed air from the alkali by means of the quicklime; and from being thus deprived of the aerial acid the volatile alkali is brought to a cauſtic ſtate.

This ſpirit is held to be too acrimonious for internal uſe, and has therefore been chiefly employed for ſmelling to in faintings, &c. though, when properly diluted, it may be given inwardly with ſafety. It is a powerful menſtruum for ſome vegetable ſubſtances, as Peruvian bark, from which the other ſpirits extract little. It is alſo moſt convenient for the purpoſe of rendering oils miſcible with water, as in the preparation of what is called in extemporaneous practice *the oily mixture.*

Some have mixed a quantity of this with the officinal ſpirits both of ſal ammoniac and of hartſhorn; which thus become more pungent, ſo as to bear an addition

Preparations and Compositions.

addition of a conſiderable quantity of water, without any danger of the diſcovery from the taſte or ſmell. This abuſe would be prevented, if what has been formerly laid down as a mark of the ſtrength of theſe ſpirits (ſome of the volatile ſalt remaining undiſſolved in them) were attended to. It may be detected by adding to a little of the ſuſpected ſpirit about one-fourth its quantity or more of rectified ſpirit of wine; which, if the volatile ſpirit be genuine, will precipitate a part of its volatile ſalt, but occaſions no viſible ſeparation or change in the cauſtic ſpirit, or in thoſe which are ſophiſticated with it.

Others have ſubſtituted for the ſpirit of ſal ammoniac a ſolution of crude ſal ammoniac and fixed alkaline ſalt mixed together. This mixture depoſites a ſaline matter on the addition of ſpirit of wine, like the genuine ſpirit; from which, however, it may be diſtinguiſhed, by the ſalt which is thus ſeparated not being a volatile alkaline, but a fixed neutral ſalt. The abuſe may be more readily detected by a drop or two of ſolution of ſilver in aquafortis, which will produce no change in the appearance of the true ſpirit, but will render the counterfeit turbid and milky.

The volatile liquor, ſalt, and oil, of hartſhorn. L.

227 Take of hartſhorn, ten pounds. Diſtil with a fire gradually increaſed. A volatile liquor, ſalt, and oil, will aſcend. The oil and ſalt being ſeparated, diſtil the liquor three times. To the ſalt add an equal weight of prepared chalk, and ſublime thrice, or till it become white.

The ſame volatile liquors, ſalt, and oil, may be obtained from any parts (except the fat) of all kinds of animals.

The volatile alkali obtained from hartſhorn, whether in a ſolid or fluid ſtate, is preciſely the ſame with that obtained from ſal ammoniac. And as that proceſs is the eaſieſt, the Edinburgh college have entirely rejected the preſent. While, however, the names of ſpirit and ſalt of hartſhorn are ſtill in daily uſe, ammonia, or the volatile alkali, is ſtill prepared from bones and other animal ſubſtances by ſeveral very extenſive traders.

The wholeſale dealers have very large pots for the diſtillation of hartſhorn, with earthen heads almoſt like thoſe of the common ſtill; for receivers, they uſe a couple of oil jars, the mouths of which are luted together; the pipe that comes from the head enters the lowermoſt jar through a hole made on purpoſe in its bottom. When a large quantity of the ſubject is to be diſtilled, it is cuſtomary to continue the operation for ſeveral days ſucceſſively; only unluting the head occaſionally to put in freſh materials.

When only a ſmall quantity of ſpirit or ſalt is wanted, a common iron pot, ſuch as is uſually fixed in ſand furnaces, may be employed, an iron head being fitted to it. The receiver ought to be large, and a glaſs, or rather tin adopter, inſerted between it and the pipe of the head.

The diſtilling veſſel being charged with pieces of the horn, a moderate fire is applied, which is ſlowly increaſed, and raiſed at length almoſt to the utmoſt degree. At firſt a watery liquor ariſes, the quantity of which will be ſmaller or greater according as the horns were more or leſs dry: this is ſucceeded by the ſalt and oil: the ſalt at firſt diſſolves as it comes over in the phlegm, and thus forms what is called *ſpirit*. When the phlegm is ſaturated, the remainder of the ſalt concretes in a ſolid form to the ſides of the recipient. If it be required to have the whole of the ſalt ſolid and undiſſolved, the phlegm ſhould be removed as ſoon as the ſalt begins to ariſe, which may be known by the appearance of white fumes; and that this may be done the more commodiouſly, the receiver ſhould be left unluted till this firſt part of the proceſs be finiſhed. The white vapours which now ariſe ſometimes come with ſuch vehemence as to throw off or burſt the receiver. To prevent this accident, it is convenient to have a ſmall hole in the luting, which may be occaſionally ſtopped with a wooden peg, or opened, as the operator ſhall find proper. After the ſalt has all ariſen, a thick dark-coloured oil comes over. The proceſs is now to be diſcontinued; and the veſſels, when grown cold, unluted.

All the liquid matters being poured out of the receiver, the ſalt which remains adhering to its ſides is to be waſhed out with a little water and added to the reſt. It is convenient to let the whole ſtand for a few hours, that the oil may the better diſengage itſelf from the liquor, ſo as to be firſt ſeparated by a funnel, and afterwards more perfectly by filtration through wet paper. The ſalt and ſpirits are then to be farther purified as above directed.

The ſpirit of hartſhorn met with in the ſhops is extremely precarious in point of ſtrength; the quantity of ſalt contained in it (on which its efficacy depends) varying according as the diſtillation in rectifying it is continued for a longer or ſhorter time. If after the volatile ſalt has ariſen, ſo much of the phlegm or watery part be driven over as is juſt ſufficient to diſſolve it, the ſpirit will be fully ſaturated, and as ſtrong as it can be made. If the proceſs be not at this inſtant ſtopped, the phlegm, continuing to ariſe, muſt render the ſpirit continually weaker and weaker. The diſtillation therefore ought to be diſcontinued at this period, or rather while ſome of the ſalt ſtill remains undiſſolved; the ſpirit will thus prove always equal, and the buyer be furniſhed with a certain criterion of its ſtrength. Very few have taken any notice of the above-mentioned inconvenience of theſe kinds of ſpirits; and the remedy is firſt hinted at in the *Pharmacopœia Reformata*. The purity of the ſpirit is eaſily determined from its clearneſs and grateful odour.

Volatile alkaline ſalts, and their ſolutions called *ſpirits*, agree in many reſpects with fixed alkalis, and their ſolutions or leys: as in changing the colour of blue flowers to a green; effervеſcing, when in their mild ſtate, with and neutralizing acids; liquefying the animal juices; and corroding the fleſhy parts, ſo as, when applied to the ſkin, and prevented from exhaling by a proper covering, to act as cauſtics; diſſolving oils and ſulphur, though leſs readily than the fixed alkalis, on account probably of their not being able to bear any conſiderable heat, by which their activity might be promoted. Their principal difference from the other alkalis ſeems to conſiſt in their volatility. They exhale or emit pungent vapours in the coldeſt ſtate of the atmoſphere; and by their ſtimulating ſmell they prove ſerviceable in languors and faintings. Taken internally, they diſcover a greater colliquating as well as ſtimulating power; the blood drawn from a vein,

vein, after their uſe has been continued for ſome time, is ſaid to be remarkably more fluid than before; they are likewiſe more diſpoſed to operate by perſpiration, and to act on the nervous ſyſtem. They are particularly uſeful in lethargic caſes; in hyſterical and hypochondriacal diſorders; and in the languors, headachs, inflations of the ſtomach, flatulent colics, and other ſymptoms which attend them. They are generally found more ſerviceable to aged perſons, and in phlegmatic habits, than in the oppoſite circumſtances. In ſome fevers, particularly thoſe of the low kind, accompanied with a cough, hoarſeneſs, and a redundance of phlegm, they are of great utility; raiſing the *vis vitæ*, and exciting a ſalutary diaphoreſis; but in putrid fevers, ſcurvies, and wherever the maſs of blood is thin and acrimonious, their uſe is ambiguous. As they are more powerful than the fixed in liquefying tenacious humours, ſo they prove more hurtful where the fluids are already in a colliquated ſtate. In vernal intermittents, particularly thoſe of the ſlow kind, they are often the moſt efficacious remedy. Dr Biſſet obſerves, in his Eſſay on the Medical Conſtitution of Great Britain, that though many caſes occur which will yield to no other medicine than the bark, yet he has met with many which were only ſuppreſſed from time to time by the bark, but were completely cured by alkaline ſpirits. He tells us, that theſe ſpirits will often carry off vernal intermittents without any previous evacuation: but that they are generally more effectual if a purge be premiſed; and in plethoric or inflammatory caſes, or where the fever perſonates a remittent, veneſection is neceſſary.

Theſe ſalts are moſt commodiouſly taken in a liquid form, largely diluted; or in that of a bolus, which ſhould be made up only as it is wanted. The doſe is from a grain or two to ten or twelve. Ten drops of a well made ſpirit, or ſaturated ſolution, are reckoned to contain about a grain of the ſalt. In intermittents, 15 or 20 drops of the ſpirit are given in a tea-cupful of cold ſpring water, and repeated five or ſix times in each intermiſſion.

The volatile ſalts and ſpirits prepared from different animal ſubſtances, have been ſuppoſed capable of producing different effects on the human body, and to receive ſpecific virtues from the ſubject. The ſalt of vipers has been eſteemed particularly ſerviceable in diſorders occaſioned by the bite of that animal; and a ſalt drawn from the human ſkull, in diſeaſes of the head. But modern practice acknowledges no ſuch different effects from theſe preparations; and chemical experiments have ſhown their identity. There is indeed, when not ſufficiently purified, a very perceptible difference in the ſmell, taſte, degree of pungency, and volatility of theſe ſalts; and in this ſtate their medicinal virtues vary conſiderably enough to deſerve notice: but this difference they have in common, according as they are more or leſs loaded with oil, not as they are produced from this or that animal ſubſtance. As firſt diſtilled, they may be looked on as a kind of volatile ſoap, in which the oil is the prevailing principle; in this ſtate they have much leſs of the proper alkaline acrimony and pungency than when they have undergone repeated diſtillations, and ſuch other operations as diſengage the oil from the ſalt; for by theſe means they loſe their ſaponaceous quality, and acquiring greater degrees of acrimony, become medicines of a different claſs. Theſe preparations therefore do not differ near ſo much from each other, as they do from themſelves in different ſtates of purity. To which may be added, that when we conſider them as loaded with oil, the virtues of a diſtilled animal oil itſelf are likewiſe to be brought into the account. Preparations and Compoſitions.

Theſe oils, as firſt diſtilled, are highly fetid and offenſive, of an extremely heating quality, and of ſuch activity, that, according to Hoffman's account, half a drop diſſolved in a dram of ſpirit of wine is ſufficient to raiſe a copious ſweat. By repeated rectifications, they loſe their offenſiveneſs, and at the ſame time become mild in their medicinal operation. The rectified oils may be given to the quantity of twenty or thirty drops, and are ſaid to be anodyne and antiſpaſmodic, to procure a calm ſleep and gentle ſweat, without heating or agitating the body, as has been obſerved in treating of the animal oil. It is obvious, therefore, that the ſalts and ſpirits muſt differ, not only according to the quantity of oil they contain, but according to the quality of the oil itſelf in its different ſtates.

The volatile ſalt and ſpirits, as firſt diſtilled, are of a brown colour, and a very offenſive ſmell: by repeated rectification, as directed in the proceſſes above ſet down, they loſe great part of the oil on which theſe qualities depend, the ſalt becomes white, the ſpirit limpid as water, and of a grateful odour; and this is the mark of ſufficient rectification.

It has been objected to the repeated rectification of theſe preparations, that, by ſeparating the oil, it renders them ſimilar to the pure ſalt and ſpirit of ſal ammoniac, which are procurable at an eaſier rate. But the intention is not to purify them wholly from the oil, but to ſeparate the groſſer part, and to ſubtilize the reſt, ſo as to bring it towards the ſame ſtate as when the oil is rectified by itſelf. The rectification of ſpirit of hartſhorn has been repeated twenty times ſucceſſively, and found ſtill to participate of oil, but of an oil very different from what it was in the firſt diſtillation.

The rectified oils, in long-keeping, become again fetid. The ſalts and ſpirits alſo, however carefully rectified, ſuffer in length of time the ſame change; reſuming their original brown colour and ill ſmell; a proof that the rectification is far from having diveſted them of oil. Any intentions, however, which they are thus capable of anſwering, may be as effectually accompliſhed by a mixture of the volatile alkali with the animal oil, in its rectified ſtate, to any extent that may be thought neceſſary.

Vitriolated kali. L.

Take of the ſalt which remains after the diſtillation of the nitrous acid, two pounds. Diſtilled water, two gallons. Burn off the ſuperfluous acid with a ſtrong fire in an open veſſel; then boil it a little while in the water; ſtrain and ſet the liquor aſide to cryſtallize. 228

The ſalt thus formed is the ſame with the vitriolated tartar of the laſt edition of the London pharmacopœia; but it is now prepared in a cheaper and eaſier manner, at leaſt for thoſe who diſtil the nitrous acid. In both ways a neutral is formed, conſiſting of the fixed vege-

Preparations and Compositions.

table alkali, united to the vitriolic acid. But a similar compound may also be obtained by the following process of the Edinburgh pharmacopœia.

Vitriolated fixed vegetable alkali, commonly called *vitriolated tartar*. E.

229 Take of vitriolic acid, diluted with six times its weight of water, as much as you please. Put it into a capacious glass vessel, and gradually drop into it, of purified fixed vegetable alkali, diluted with six times its weight of water, as much as is sufficient thoroughly to neutralize the acid. The effervescence being finished, strain the liquor through paper; and after proper evaporation, set it aside to crystallize

The operator ought to take care that the vapour separated during the effervescence shall not be applied to his nostrils; as fixed air, when applied to the olfactory nerves, is highly deleterious to life.

This is an elegant and one of the least troublesome ways of preparing this salt. The Edinburgh college, in their former editions, ordered the acid liquor to be dropped into the alkaline: by the converse procedure now received, it is obviously more easy to secure against a redundance of acidity; and for the greater certainty in this point, it may be expedient, as in the foregoing process, to drop in a little more of the alkaline ley than the cessation of the effervescence seems to require.

In a former edition of the same pharmacopœia, the acid was directed to be diluted only with its equal weight of water, and the alkali with that quantity of water which it is capable of imbibing from the atmosphere By that imperfection there was not water enough to keep the vitriolated tartar dissolved; on which account, as fast as the alkali was neutralized by the acid, a great part fell to the bottom in a powdery form. In order to obtain perfect and well formed crystals, the liquor should not be set in the cold, but continued in moderate heat, such as the hand can scarcely bear, that the water may slowly evaporate.

It is remarkable, that although the vitriolic acid and fixed alkaline salt do each readily unite with water, and strongly attract moisture, even from the air, yet the neutral resulting from the combination of these two, vitriolated tartar, is one of the salts most difficult of solution, very little of it being taken up by cold water.

Vitriolated tartar, in small doses, as a scruple or half a dram, is an useful aperient; in large ones, as four or five drams, a mild cathartic, which does not pass off so hastily as the bitter cathartic salt or salt of Glauber, and seems to extend its action further. The wholesale dealers in medicines have commonly substituted for it an article otherwise almost useless in their shops, the residuum of Glauber's spirit of nitre This may be looked on as a venial fraud, if the spirit has been prepared as formerly directed, and the residuum dissolved and crystallized: but it is a very dangerous one if the vitriolic acid has been used in an over proportion, and the caput mortuum employed without crystallization; the salt in this case, instead of a mild neutral one, of a moderately bitter taste, proving highly acid. The purchaser ought therefore to insist on the salt being in a crystalline form. The crystals when perfect are oblong, with six flat sides, and terminated at each end by a six sided pyramid: some appear composed of two pyramids joined together by the bases; and many, in the most perfect crystallizations we have seen, are very irregular. They decrepitate in the fire, somewhat like those of sea-salt, for which they have sometimes been mistaken.

Salt of many virtues. E.

230 Take nitre in powder, flowers of sulphur, of each equal parts. Mix them well together, and inject the mixture by little and little at a time into a red-hot crucible: the deflagration being over, let the salt cool, after which it is to be put up in a glass vessel well shut. The salt may be purified by dissolving it in warm water, filtering the solution, and exhaling it to dryness, or by crystallization.

This is another method of uniting the vitriolic acid with the common vegetable fixed alkali. Both the nitre and the sulphur are decompounded in the operation: the acid of the nitre, and the inflammable principle of the sulphur, detonate together, and are dissipated; while the acid of the sulphur (which, as we have already seen, is no other than the vitriolic acid) remains combined with the alkaline basis of the nitre. The shops accordingly have substituted the foregoing preparation for the sal polychrest.

Vitriolated natron. L.

231 Take of the salt which remains after the distillation of the muriatic acid, two pounds; distilled water, two pints and an half. Burn out the superfluous acid with a strong fire in an open vessel; then boil it for a little in the water: strain the solution, and set it by to crystallize.

Vitriolated soda, commonly called *cathartic salt of Glauber*. E.

232 Dissolve in warm water the mass which remains after the distillation of spirit of sea-salt: filter the solution, and crystallize the salt.

The directions given for the preparation of this salt, long known by the name of *sal mirabile Glauberi*, are nearly the same in the pharmacopœias of both colleges; but those of the London college are to be preferred, as being most accurate and explicit.

In a former edition of the Edinburgh pharmacopœia, it was ordered, that if the crystals (obtained as above) proved too sharp, they should be again dissolved in water, and the filtered liquor evaporated to such a pitch only as may dispose the salt to crystallize. But there is no great danger of the crystals proving too sharp, even when the spirit of salt is made with the largest proportion of oil of vitriol directed under that process. The liquor which remains after the crystallization is indeed very acid; and with regard to this preparation, it is convenient it should be so; for otherwise the crystals will be very small, and likewise in a small quantity. Where a sufficient proportion of oil of vitriol has not been employed in the distillation of the spirit, it is necessary to add some to the liquor, in order to promote the crystallization of the salt.

The title of *cathartic salt*, which this salt has often had, expresses its medical virtues. Taken from half

an ounce to an ounce, or more, it proves a mild and useful purgative; and in smaller doses, largely diluted, a serviceable aperient and diuretic. The shops frequently substitute for it the bitter cathartic salt, which is nearly of the same quality, but somewhat more unpleasant, and, as is said, less mild in operation. They are very easily distinguishable from each other, by the effect of alkaline salts upon solutions of them. The solutions of Glauber's salt suffer no visible change from this addition, its own basis being a true fixed alkali: but the solution of the bitter cathartic salt grows instantly white and turbid; its basis, which is an earth, being extricated copiously by the alkaline salt.

Purified nitre. L.

Take of nitre two pounds; distilled water, four pints. Boil the nitre in the water till it be dissolved; strain the solution, and set it aside to crystallize.

Common nitre contains usually a considerable portion of sea-salt, which in this process is separated, the sea-salt remaining dissolved after the greatest part of the nitre has crystallized. The crystals which shoot after the first evaporation are large, regular, and pure: but when the remaining liquor is further evaporated, and this repeated a second or third time, the crystals prove at length small, imperfect, and tipt with little cubical crystals of sea-salt.

When rough nitre, in the state wherein it is first extracted from the earths impregnated with it, is treated in this manner, there remains at last a liquor, called *mother-ley*, which will no longer afford any crystals. This appears to participate of the nitrous and marine acids, and to contain an earthy matter dissolved by those acids. On adding alkaline lixivia, the earth is precipitated; and when thoroughly washed with water, proves insipid. If the liquor be evaporated to dryness, a bitterish saline matter is left; which being strongly calcined in a crucible, parts with the acids, and becomes, as in the other case, insipid.

This earth has been celebrated as an excellent purgative, in the dose of a dram or two; and, in smaller doses, as an alterant in hypochondriacal and other disorders. This medicine was for some time kept a great secret, under the name of *magnesia alba*, *nitrous panacea*, *Count Palma's powder*, *il polvere albo Romano*, *poudre de Sentinelli*, &c. till Lancisi made it public in his notes on the *Metallotheca Vaticana*. It has been supposed, that this earth is no other than a portion of the lime commonly added in the elixation of nitre at the European nitre-works: but though the specimens of magnesia examined by Neumann, and some of that which has lately been brought hither from abroad, gave plain marks of a calcareous nature; yet the true magnesia must be an earth of a different kind, calcareous earths being rather astringent than purgative. The earthy basis of the bitter cathartic salt is found to have the properties ascribed to the true magnesia of nitre, and appears to be the very same species of earth: from that salt therefore this medicine is now prepared, as will be seen hereafter. The magnesia alba differs from calcareous earths, in having a less powerful attraction for fixed air, and in not becoming caustic by calcination.

Acetated kali. L.

Preparations and Compositions.

234 Take of kali one pound; boil it with a slow fire in four or five times its quantity of distilled vinegar; the effervescence ceasing, let there be added at different times more distilled vinegar, until the last vinegar being nearly evaporated, the addition of fresh will excite no effervescence, which will happen when about twenty pounds of distilled vinegar are consumed; afterwards let it be dried slowly. An impure salt will be left, which melt for a little while with a slow fire; then let it be dissolved in water, and filtered through paper. If the fusion has been rightly performed, the strained liquor will be colourless; if otherwise, of a brown colour. Lastly, evaporate this liquor with a slow fire, in a very shallow glass vessel; frequently stirring the mass, that the salt may be more completely dried, which should be kept in a vessel close stopped. The salt ought to be very white, and dissolve wholly, both in water and spirit of wine, without leaving any feces. If the salt, although white, should deposite any feces in spirit of wine, that solution in the spirit should be filtered through paper, and the salt again dried.

Acetated fixed vegetable alkali, commonly called *regenerated tartar*. E.

235 Take of salt of tartar one pound; boil it with a very gentle heat in four or five times its quantity of distilled vinegar; add more distilled vinegar at different times, till on the watery part of the former quantity being nearly dissipated by evaporation, the new addition of vinegar ceases to raise any effervescence. This happens when about twenty pounds by weight of distilled vinegar has been consumed. The impure salt remaining after the exsiccation, is to be liquefied with a gentle heat for a short time, and it is proper that it should only be for a short time; then dissolve it in water, and strain through paper. If the liquefaction has been properly performed, the strained liquor will be limpid; but if otherwise, of a brown colour. Evaporate this liquor with a very gentle heat in a shallow glass vessel, occasionally stirring the salt as it becomes dry, that its moisture may sooner be dissipated. Then put it up into a vessel very closely stopped, to prevent it from liquefying in the air.

This salt had formerly the name of *diuretic salt* in the London pharmacopœia; but that which they now employ, or perhaps in preference to it, the name of *potassa acetata*, gives a clearer idea of its nature.

The purification of this salt is not a little troublesome. The operator must be particularly careful, in melting it, not to use a great heat, or to keep it long liquefied: a little should be occasionally taken out, and put into water; and as soon as it begins to part freely with its black colour, the whole is to be removed from the fire. In the last drying, the heat must not be so great as to melt it; otherwise it will not prove totally soluble. If the filtration in spirit of wine be exsiccated, and the remaining salt liquefied with a very gentle fire, it gains the leafy appearance which has procured it the name *terra foliata*.

Preparations and Compositions.

In the fourth volume of the Memoirs of the correspondents of the French Academy, lately published, Mr Cadet has given a method of making the salt white at the first evaporation, without the trouble of any farther purification. He observes, that the brown colour depends on the oily matter of the vinegar being burnt by the heat commonly employed in the evaporation; and his improvement consists in diminishing the heat at the time that this burning is liable to happen. The process he recommends is as follows:

Dissolve a pound of salt of tartar in a sufficient quantity of cold water; filter the solution, and add by degrees as much distilled vinegar as will saturate it, or a little more. Set the liquor to evaporate in a stone-ware vessel in a gentle heat, not so strong as to make it boil. When a pellicle appears on the surface, the rest of the process must be finished in a water-bath. The liquor acquires by degrees an oily consistence, and a pretty deep brown colour; but the pellicle or scum on the top looks whitish, and when taken off and cooled, appears a congeries of little brilliant silver-like plates. The matter is to be kept continually stirring, till it be wholly changed into this white flaky matter; the complete drying of which is most conveniently effected in a warm oven.

We shall not take upon us to determine whether the pure or impure salt is preferable as a medicine; observing only, that the latter is more of a saponaceous nature, the former more acrid, though somewhat more agreeable to the stomach. Mr Cadet reckons the salt prepared in his method superior both to the brown and white sorts made in the common way, as possessing both the oily quality of the one and the agreeableness of the other, and as being always uniform or of the same power: whereas the others are liable to vary considerably, according to the degree of heat employed in the evaporation. They are all medicines of great efficacy, and may be so dosed and managed as to prove either mildly cathartic, or powerfully diuretic: few of the saline deobstruents come up to them in virtue. The dose is from half a scruple to a dram or two. A bare mixture, however, of alkaline salt and vinegar, without exsiccation, is not perhaps much inferior as a medicine to the more elaborate salt. Two drams of the alkali, saturated with vinegar, have been known to occasion ten or twelve stools in hydropic cases, and a plentiful discharge of urine, without any inconvenience.

Water of acetated ammonia. L.

236 Take of ammonia, by weight, two ounces; distilled vinegar, four pints; or as much as is sufficient to saturate the ammonia. Mix.

Spirit of Mindererus. E.

237 Take any quantity of the volatile alkaline salt of sal ammoniac, and gradually pour upon it distilled vinegar till the effervescence ceases; occasionally stirring the mixture to promote the action of the vinegar on the salt.

Though this article has long been known by the name of Spiritus Mindereri, so called from the inventor; yet that employed by the London college is undoubtedly preferable, as giving a proper idea of its constituent parts.

This is an excellent aperient saline liquor. Taken warm in bed, it proves commonly a powerful diaphoretic or sudorific; and as it operates without heat, it has place in febrile and inflammatory disorders, where medicines of the warm kind, if they fail of procuring sweat, aggravate the distemper. Its action may likewise be determined to the kidneys, by walking about in a cool air. The common dose is half an ounce, either by itself, or along with other medicines adapted to the intention. Its strength is not a little precarious, depending much on that of the vinegar; an inconvenience which cannot easily be obviated, for the saline matter is not reducible to the form of a concrete salt.

Preparations and Compositions.

Tartarized kali. L.

238 Take of kali one pound; crystals of tartar, three pounds; distilled water, boiling, one gallon. To the salt, dissolved in water, throw in gradually the crystals of tartar, powdered: filter the liquor, when cold, through paper: and, after due evaporation, set it apart to crystallize.

Tartarized vegetable fixed alkali, commonly called *soluble tartar.* E.

239 Take of purified fixed vegetable alkaline salt one pound; water, 15 pounds. To the salt dissolved in the boiling water gradually add crystals of tartar in fine powder, as long as the addition thereof raises any effervescence, which almost ceases before three times the weight of the alkaline salt hath been injected; then strain the cooled liquor through paper, and after due evaporation set it aside to crystallize.

Common white tartar is perhaps preferable for this operation to the crystals usually met with. Its impurities can here be no objection; since it will be sufficiently depurated by the subsequent filtration.

The preparation of this medicine by either of the above methods is very easy; though some chemists have rendered it sufficiently troublesome, by a nicety which is not at all wanted. They insist upon hitting the very exact point of saturation between the alkaline salt and the acid of the tartar; and caution the operator to be extremely careful, when he comes near this mark, lest by imprudently adding too large a portion of either, he render the salt too acid or too alkaline. If the liquor be suffered to cool a little before it be committed to the filter, and then properly exhaled and crystallized, no error of this kind can happen, though the saturation should not be very exactly hit: for since crystals of tartar are very difficultly soluble even in boiling water, and when dissolved therein concrete again upon the liquor's growing cold, if any more of them has been employed than is taken up by the alkali, this superfluous quantity will be left upon the filter; and, on the other hand, when too much of the alkali has been used, it will remain uncrystallized. The crystallization of this salt indeed cannot be effected without a good deal of trouble: it is therefore most convenient to let the acid salt prevail at first; to separate the superfluous quantity, by suffering the liquor to cool a little before filtration; and then proceed to the total evaporation of the aqueous fluid, which will leave behind it the neutral salt required. The most proper vessel for this purpose is a stone-ware one; iron discolours the salt.

Soluble

Soluble tartar, in doſes of a ſcruple, half a dram, or a dram, is a mild cooling aperient: two or three drams commonly looſen the belly; and an ounce proves pretty ſtrongly purgative. It has been particularly recommended as a purgative for maniacal and melancholic patients. Malouin ſays, it is equal in purgative virtue to the cathartic ſalt of Glauber. It is an uſeful addition to the purgatives of the reſinous kind, as it promotes their operation, and at the ſame time tends to correct their griping quality. But it muſt never be given in conjunction with any acid; for all acids decompound it, abſorbing its alkaline ſalt, and precipitating the tartar. On this account it is improper to join it to tamarinds, or ſuch like acid fruits; which is too often done in the extemporaneous practice of thoſe phyſicians who are fond of mixing different cathartics together.

Tartarized natron. L.

40 Take of natron, 20 ounces; cryſtals of tartar, powdered, 2 pounds; diſtilled water, boiling, 10 pints. Diſſolve the natron in the water, and gradually add the cryſtals of tartar: filter the liquor through paper; evaporate, and ſet it aſide to cryſtallize.

Tartarized ſoda, commonly called *Rochel ſalt.* E.

41 The Rochel ſalt may be prepared from purified foſſil alkaline ſalt and cryſtals of tartar, in the ſame manner as directed for the ſoluble tartar.

This is a ſpecies of ſoluble tartar, made with the ſalt of kali or ſoda, which is the ſame with the mineral alkali, or baſis of ſea-ſalt. It cryſtallizes far more eaſily than the preceding preparation, and does not, like it, grow moiſt in the air. It is alſo conſiderably leſs purgative, but is equally decompounded by acids. It appears to be a very elegant ſalt, and begins now to come into eſteem in this country, as it has long been in France.

Purification of alum. L.

42 Take of alum, one pound; chalk, one dram by weight; diſtilled water, one pint. Boil them a little, ſtrain, and ſet the liquor aſide to cryſtallize.

We have already offered ſome obſervations on alum (ſee ALUM); and in general we may ſay that it comes from the alum works in England in a ſtate of ſuch purity as to be fit for every purpoſe in medicine: accordingly we do not obſerve that the purification of alum has a place in any other pharmacopœias; but by the preſent proceſs it will be freed, not only from different impurities, but alſo from ſuperabundant acid.

Burnt alum. L. E.

43 Take of alum, half a pound. Burn it in an earthen veſſel ſo long as it bubbles.

This, with ſtrict propriety, ought rather perhaps to be called dried alum than burnt alum; for the only effect of the burning here directed is to expel the water. In this ſtate it is ſo acrid as to be frequently employed as an eſcharotic; and it is with this intention chiefly that it has a place in our pharmacopœias: but it has ſometimes alſo been taken internally, particularly in caſes of cholic.

Salt or ſugar of milk. Suec.

44 Take of the whey of milk, prepared by runnet, any quantity: let it be boiled over a moderate fire to the conſiſtence of a ſyrup; then put it in a cold place, that cryſtals may be formed. Let the fluid which remains be again managed in the ſame manner, and let the cryſtals formed be waſhed with cold water. Preparations and Compoſitions.

It has been by ſome imagined, that the ſuperiority of one milk over another depends on its containing a larger proportion of this ſaline or ſaccharine part; and particularly, that upon this the reputed virtues of aſs milk depend. Hence this preparation has been greatly celebrated in diſorders of the breaſt, but it is far from anſwering what has been expected from it. It has little ſweetneſs, and is difficult of ſolution in water. A ſaline ſubſtance, much better deſerving the name of ſugar, may be obtained by evaporating new milk, particularly that of the aſs, to dryneſs, digeſting the dry matter in water till the water has extracted its ſoluble parts, and then inſpiſſating the filtered liquor. This preparation is of great ſweetneſs, though neither white nor cryſtalline; nor is it perhaps in the pure cryſtallizable parts of milk that its medicinal virtues reſide; and ſo little reliance is put on it as a medicine, that it has no place in the London or Edinburgh pharmacopœias; although it long has ſtood, and ſtill ſtands, in the foreign ones.

Salt of ſorrel. Suec.

Take any quantity of the expreſſed juice of the leaves of wood ſorrel; let it boil gently, that the feculent matter may be ſeparated; then ſtrain it till it be clear, and after this boil it on a moderate fire to the conſiſtence of a ſyrup. Put it into long-necked glaſs veſſels, and place it in a cold ſituation that it may cryſtallize. Let theſe cryſtals be diſſolved in water, and again formed into purer ones. 245

To make the ſorrel yield its juice readily, it ſhould be cut to pieces, and well bruiſed in a ſmall mortar, before it be committed to the preſs. The magma which remains in the bag ſtill retaining no inconſiderable quantity of ſaline matter, may be advantageouſly boiled in water, and the decoction added to the expreſſed juice. The whole may be afterwards depurated together, either by the method above directed, or by running the liquor ſeveral times through a linen cloth. In ſome caſes the addition of a conſiderable portion of water is neceſſary, that the juice, thus diluted, may part the more freely with its feculencies; on the ſeparation of which the ſucceſs of the proceſs much depends.

The evaporation ſhould be performed either in ſhallow glaſs baſons, or in ſuch earthen ones as are of a compact cloſe texture; ſuch are thoſe uſually called *ſtone-ware.* The common earthen veſſels are ſubject to have their glazing corroded, and are ſo extremely porous, as readily to imbibe and retain a good quantity of the liquor; metallic veſſels are particularly apt to be corroded by theſe acid kinds of juices.

Theſe juices are ſo viſcid, and abound ſo much with heterogeneous matter, of a quite different nature from any thing ſaline, that a pellicle, or pure ſaline incruſtation upon the ſurface, is in vain expected. Boerhaave, therefore, and the more expert writers in pharmaceutical chemiſtry, with great judgment direct the evaporation of the ſuperfluous moiſture to be continued

Preparations and Compositions.

until the matter has acquired the conſiſtence of cream. If it be now ſuffered to ſtand for an hour or two in a warm place, it will, notwithſtanding the former depurations, depoſite a freſh ſediment, from which it ſhould be warily decanted before it be put into the veſſel in which it is deſigned to be cryſtallized.

Some recommend an unglazed earthen veſſel as preferable for this purpoſe to a glaſs one; the ſmoothneſs of the latter being ſuppoſed to hinder the ſalt from ſticking thereto; while the juice eaſily inſinuating itſelf into the pores of the former, has a great advantage of ſhooting its ſaline ſpicula to the ſides. Others ſlightly incruſtate the ſides and bottom of whatever veſſel they employ with a certain mineral ſalt, which greatly diſpoſes the juice to cryſtallize, to which of itſelf it is very averſe; but this addition is, with regard to its medical virtue, quite different from the ſalt here intended.

The liquor which remains after the cryſtallization may be depurated by a gentle colature, and after due inſpiſſation ſet to ſhoot again; when a farther produce of cryſtals will be obtained.

The proceſs for obtaining this ſalt is very tedious; and the quantity of ſalt which the juices afford is extremely ſmall: hence they are hardly ever made or expected in the ſhops. They may be ſomewhat ſooner ſeparated from the mucilage and other feculencies, by clarification with whites of eggs, and by adding very pure white clay.

In the manner above deſcribed, ſalts may alſo be obtained from other acid, auſtere, and bitteriſh plants, which contain but a ſmall quantity of oil.

The virtues of the eſſential ſalts have not been ſufficiently determined from experience. This much, however, is certain, that they do not, as has been ſuppoſed, poſſeſs the virtues of the ſubjects entire, excepting only the acids and ſweets. The others ſeem to be almoſt all of them nearly ſimilar, whatever plant they were obtained from. In watery extracts of wormwood, carduus, camomile, and many other vegetables, kept for ſome time in a ſoft ſtate, there may be obſerved fine ſaline efflorеſcences on the ſurface, which have all nearly the ſame taſte, ſomewhat of the nitrous kind. They are ſuppoſed by ſome to be in reality no more than an impure ſpecies of volatile nitre (that is, a ſalt compoſed of the nitrous acid and volatile alkali): thoſe which were examined by the chemiſts of the French academy deflagrated in the fire, and being triturated with fixed alkali, exhaled an urinous odour; plain marks of their containing thoſe two ingredients.

Acid ſalt of borax. Succ.

246 Take of borax, an ounce and a half; warm ſpring-water, one pound. Mix them in a glaſs veſſel, that the borax may be diſſolved; then pour into it three drams of the concentrated acid of vitriol: evaporate the liquor till a pellicle appears upon it; after this let it remain at reſt till the cryſtals be formed. Let them be waſhed with cold water, and kept for uſe.

This ſalt, which has long been known by the title of the *ſedative ſalt of Homberg*, is not unfrequently formed by ſublimation: but the proceſs by cryſtallization here directed is leſs troubleſome, though the ſalt proves generally leſs white, and is apt likewiſe to retain a part of Glauber's ſalt, eſpecially if the evaporation be long protracted.

Preparations and Compoſitions.

The ſalt of borax to the taſte appears to be a neutral; but when it is examined by alkalis, it ſhows the properties of an acid, effervеſcing, uniting, and cryſtallizing with them, and it deſtroys their alkaline quality. It diſſolves both in water and ſpirit of wine, although not very readily in either.

The virtues attributed to it may in ſome degree be inferred from the name of *ſedative*, by which it was long diſtinguiſhed. It has been ſuppoſed to be a mild anodyne, to diminiſh febrile heat, to prevent or remove delirium, and to allay, at leaſt for ſome time, ſpaſmodical affections, particularly thoſe which are the attendants of hypochondriaſis and hyſteria. It may be given in doſes from two to twenty grains.

Purified ſal ammoniac. Succ.

Diſſolve ſal ammoniac in ſpring-water; ſtrain the liquor through paper; evaporate it to dryneſs in a glaſs veſſel by means of a moderate fire. 247

The ſal ammoniac imported from the Mediterranean often contains ſuch impurities as to render the above proceſs neceſſary; but that which is prepared in Britain from ſoot and ſea-ſalt, is in general brought to market in a ſtate of very great purity. Hence this proceſs is now altogether omitted both in the London and Edinburgh pharmacopœias. It furniſhes, however, when neceſſary, an eaſy and effectual mode of obtaining a pure ammonia muriata.

Chap. VIII. *Magneſia.*

White magneſia.

Take of bitter purging ſalt, kali, each two pounds; diſtilled water, boiling, 20 pints. Diſſolve the bitter ſalt and the kali ſeparately in 10 pints of water, and filter through paper; then mix them. Boil the liquor a little while, and ſtrain it while hot through linen, upon which will remain the white magneſia; then waſh away, by repeated affuſions of diſtilled water, the vitriolated kali. *L.* 248

Take of bitter purging ſalt, purified fixed vegetable alkali, equal weights. Diſſolve them ſeparately in double their quantity of warm water, and let the liquor be ſtrained or otherwiſe freed from the feces; then mix them, and inſtantly add eight times their quantity of warm water. Let the liquor boil a little, ſtirring it very well at the ſame time; then let it reſt till the heat be ſomewhat diminiſhed; after which ſtrain it through a cloth: the magneſia will remain upon the cloth, and it is to be waſhed with pure water till it be altogether void of ſaline taſte. *E.*

The proceſſes here directed by the London and Edinburgh colleges are nearly the ſame; but the former ſeem to have improved ſomewhat on the latter, both in ſimplifying the proceſs, and in the employment of diſtilled water.

The *bitter cathartic ſalt*, or *Epſom ſalt*, is a combination of the vitriolic acid and magneſia. In this proceſs, then, a double elective attraction takes place: the vitriolic

ara- and posi-

vitriolic acid forſakes the magneſia, and joins the mild alkali, for which it has a greater attraction; while the magneſia in its turn unites with the fixed air diſcharged from the mild alkali, and ready to be abſorbed by any ſubſtance with which it can combine.

We have therefore two new products, viz. a vitriolated tartar, and magneſia united with fixed air. The former is diſſolved in the water, and may be preſerved for uſe; the latter, as being much leſs ſoluble, ſinks to the bottom of the veſſel. The intention of employing ſuch a large quantity of water and of the boiling is, that the vitriolated tartar may be all thoroughly diſſolved; this ſalt being ſo ſcarcely ſoluble in water, that without this expedient a part of it might be precipitated along with the magneſia. It might perhaps be more convenient to employ the mineral alkali; which forming a Glauber's ſalt with the vitriolic acid, would require leſs water for its ſuſpenſion. By the after ablutions, however, the magneſia is ſufficiently freed from any portion of vitriolated tartar which may have adhered to it.

The ablutions ſhould be made with very pure water; for nicer purpoſes diſtilled water may be uſed with advantage; and ſoft water is in every caſe neceſſary. Hard water for this proceſs is peculiarly inadmiſſible, as the principle in waters giving the property called *hardneſs* is generally owing to an imperfect nitrous ſelenite, whoſe baſe is capable of being diſengaged by magneſia united with fixed air. For though the attraction of magneſia itſelf to the nitrous acid is not greater than that of calcareous earths; yet when combined with fixed air, a peculiar circumſtance intervenes; whence it is deducible, that the ſum of the forces tending to join the calcareous earth with the air of the magneſia, and the magneſia with the acid, is greater than the ſum of the forces tending to join the calcareous earth with the acid, and the magneſia with the fixed air.

This phenomenon muſt therefore depend on the preſence of fixed air, and its greater attraction for lime than for magneſia. On this account, if hard water be uſed, a quantity of calcareous earth muſt infallibly be depoſited on the magneſia; while the nitrous acid with which it was combined in the water, will in its turn attach itſelf to a portion of the magneſia, forming what may be called a *nitrous magneſia*.

All the alkalis, and alſo calcareous earths, have a greater attraction for fixed air than magneſia has: Hence, if this laſt be precipitated from its ſolution in acids by cauſtic alkali, it is then procured free from fixed air: but for this purpoſe calcination is more generally employed in the manner deſcribed in the proceſs which next follows. Magneſia is ſcarcely at all ſoluble in water: the infinitely ſmall portion which this fluid is capable of taking up, is owing to the fixed air of the magneſia; and it has been lately diſcovered, that water impregnated with this acid is capable of diſſolving a conſiderable portion: for this purpoſe it is neceſſary to employ magneſia already ſaturated with fixed air, as magneſia deprived of this air would quickly abſtract it from the water, whereby the force of the latter would be very conſiderably diminiſhed. Such a ſolution of magneſia might be uſeful for ſeveral purpoſes in medicine.

Magneſia is the ſame ſpecies of earth with that obtained from the mother-ley of nitre, which was for ſeveral years a celebrated ſecret in the hands of ſome particular perſons abroad. Hoffman, who deſcribes the preparations of the nitrous magneſia, gives it the character of an uſeful antacid, a ſafe and inoffenſive laxative in doſes of a dram or two, and a diaphoretic and diuretic when given in ſmaller doſes of 15 or 20 grains. Since his time, it has had a conſiderable place in the practice of foreign phyſicians; and is now in great eſteem among us, particularly in heart-burns, and for preventing or removing the many diſorders which children are ſo frequently thrown into from a redundance of acid humours in the firſt paſſages: it is preferred, on account of its laxative quality, to the common abſorbents, which, unleſs gentle purgatives be occaſionally given to carry them off, are apt to lodge in the body, and occaſion a coſtiveneſs very detrimental to infants. Preparations and Compoſitions.

Magneſia alba, when prepared in perfection, is a white and very ſubtile earth, perfectly void of ſmell or taſte, of the claſs of thoſe which diſſolve in acids. It diſſolves freely even in the vitriolic acid; which, in the common way of making ſolutions, takes up only an inconſiderable portion of other earths. Combined with this acid, it forms the bitter purging or Epſom ſalt, very eaſily ſoluble in water; while the common abſorbents form with the ſame acid almoſt inſipid concretes, very difficult of ſolution. Solutions of magneſia in all acids are bitter and purgative, while thoſe of the other earths are more or leſs auſtere and aſtringent. A large doſe of magneſia, if the ſtomach contain no acid to diſſolve it, does not purge or produce any ſenſible effect; a moderate one, if an acid be lodged there, or if acid liquors be taken after it, procures ſeveral ſtools; whereas the common abſorbents, in the ſame circumſtances, inſtead of looſening, bind the belly. It is obvious, therefore, that magneſia is ſpecifically different from the other earths, and that it is applicable to ſeveral uſeful purpoſes in medicine.

Magneſia was formerly made with the mother-water of nitre evaporated to dryneſs, or precipitated by a fixed alkali. It has gone under different names, as the *white powder of the Count of Palma*, *powder of ſentinelle*, *polychreſt*, *laxative powder*, &c. It ſeems to have got the character *white*, to diſtinguiſh it from the dark-coloured mineral called alſo *magneſia* or *manganeſe*; a ſubſtance poſſeſſing very different properties. We have not heard that pure native magneſia has been found in its uncombined ſtate. A combination of it with ſulphur has been diſcovered to cover a ſtratum of coal at Littry in Lower Normandy. It has alſo been found in certain ſerpentine earths in Saxony, and in marly and alum earths.

Calcined magneſia.

Take of white magneſia, four ounces. Expoſe it to a ſtrong heat for two hours; and, when cold, ſet it by. Keep it in a veſſel cloſely ſtopped. *L.* 242

Let magneſia, put into a crucible, be continued in a red heat for two hours; then put it up in cloſe glaſs veſſels. *E.*

By this proceſs the magneſia is freed of fixed air; which, according to Dr Black's experiments, conſti-

tutes

Preparations and Compositions.

tutes about $\frac{1}{7}$ths of its weight. A kind of opaque foggy vapour is observed to escape during the calcination, which is nothing else than a quantity of fine particles of magnesia buoyed off along with a stream of the disengaged air. About the end of the operation, the magnesia exhibits a kind of luminous or phosphorescent property; and this may be considered as a pretty exact criterion of its being deprived of air.

Calcined magnesia is equally mild as when saturated with fixed air; and this circumstance is sufficient to establish a difference between it and calcareous earths, all of which are converted by calcination into a caustic quicklime.

The calcined magnesia is used for the same general purposes as the magnesia combined with fixed air. In certain affections of the stomach, accompanied with much flatulence, the calcined magnesia is found preferable, not only as containing more of the real earth of magnesia in a given quantity, but as being also deprived of its air. It neutralizes the acid of the stomach without that extrication of air which is often a troublesome consequence in employing the aerated magnesia in these complaints. It is proper to observe, that magnesia, whether combined with or deprived of fixed air, is similar to the mild calcareous earths in promoting and increasing putrefaction. The same has even been observed with respect to the Epsom and some other salts which have this earth for their base.

Chap. IX. *Preparations of Sulphur.*

Washed flowers of sulphur. L.

250 Take of flowers of sulphur, one pound; distilled water, four pints. Boil the flowers of sulphur a little while in the distilled water; then pour off this water, and wash off the acid with cold water; lastly, dry the flowers.

In the former editions of our pharmacopœias directions were given for the preparation of the flowers of sulphur themselves; but as a large apparatus is necessary for doing it with any advantage, it is now scarcely ever attempted by the apothecaries. When the flowers are properly prepared, no change is made on the qualities of the sulphur. Its impurities only are separated; and at the same time it is reduced to a finer powder than it can easily be brought to by any other means. But as the flowers of sulphur are generally sublimed in very capacious rooms, which contain a large quantity of air, or in vessels not perfectly close, some of those that arise at first are apt to take fire, and thus are changed into a volatile acid vapour, which mingling with the flowers that sublime afterwards, communicates to them a considerable degree of acidity. In this case the ablution here directed is for the general use of the medicine absolutely necessary; for the flowers thus tainted with acid sometimes occasion gripes, and may in other respects be productive of effects different from those of pure sulphur. There are, however, some particular combinations to which they are supposed to be better adapted when unwashed, such as their union with mercury into æthiops mineral; and accordingly for that preparation the unwashed flowers are directed by the London college.

Sulphurated kali. L.

Preparations and Compositions.

Take of flowers of sulphur, one ounce; kali, five ounces. Mix the salt with the melted sulphur, by frequently stirring, until they unite into an uniform mass. 251

This preparation, in the former editions of our pharmacopœias, had the name of *hepar sulphuris*, or *liver of sulphur*.

It is much more convenient to melt the sulphur first by itself, and add the salt of tartar by degrees, as here directed, than to grind them together, and afterwards endeavour to melt them, as ordered in former editions: for in this last case the mixture will not flow sufficiently thin to be properly united by stirring; and the sulphur either takes fire or sublimes in flowers, which probably has been the reason why so large a proportion of it has been commonly directed. Even in the present method a considerable part of the sulphur will be dissipated; and if it were not, the hepar would not be of its due quality: for one part of sulphur requires two of the alkaline salt to render it perfectly soluble in water, which this preparation ought to be.

The hepar sulphuris has a fetid smell and a nauseous taste. Solutions of it in water, made with sugar into a syrup, have been recommended in coughs and other disorders of the breast. Our pharmacopœias, nevertheless, have deservedly rejected this syrup, as common practice has almost done the balsams. Solutions of the hepar in water have been also recommended in herpetic and other cutaneous affections. Some physicians have even employed this solution, in a large quantity, as a bath for the cure of psora; and in cases of tinea capitis it has often been used by way of lotion.

The hepar, digested in rectified spirit of wine, imparts a rich gold colour, a warm, somewhat aromatic taste, and a peculiar, not ungrateful smell. A tincture of this kind is kept in the shops under the name of another mineral. The hepar sulphuris has been by some strongly recommended to prevent the effects of mineral poison.

Sulphurated oil and sulphurated petroleum. L.

Take of flowers of sulphur, four ounces; olive oil, sixteen ounces. Boil the flowers of brimstone with the oil, in a pot slightly covered, until they be united. 252

In the same manner is made *sulphurated petroleum*.

These articles are analogous to what had formerly a place in our pharmacopœias under the titles of *balsamum sulphuris simplex, crassum, et Barbadense*. And, besides these, a place was also given to the *balsamum sulphuris anisatum, terebinthinatum*, &c. While these articles, however, are now banished from our pharmacopœias, even those retained are less in use than formerly.

These preparatinns are more conveniently and safely made in a tall glass body, with the mouth at least an inch in diameter, than in the circulatory or close vessels in which they have commonly been directed to be prepared: for when the sulphur and oil begin to act vehemently upon each other, they not only rarify into a large volume, but likewise throw out impetuously great quantities of an elastic vapour; which, if the vessels be closed, or the orifices not sufficient to allow it

it a free exit, will infallibly burſt them. Hoffman relates a very remarkable hiſtory of the effects of an accident of this kind. In the veſſel above recommended the proceſs may be completed, without danger, in four or five hours, by duly managing the fire, which ſhould be very gentle for ſome time, and afterwards increaſed ſo as to make the oil juſt bubble or boil; in which ſtate it ſhould be kept till all the ſulphur appears to be taken up.

Eſſential oils, employed as menſtrua for ſulphur, undergo a great alteration from the degree of heat neceſſary for enabling them to diſſolve the ſulphur: and hence the balſams have not near ſo much of their flavour as might be expected. It ſhould therefore ſeem more eligible to add a proper quantity of the eſſential oils to the ſimple balſam: theſe readily incorporate by a gentle warmth, if the veſſel be now and then ſhaken. We may thus compoſe a balſam more elegant than thoſe made in the manner formerly recommended, and which retains ſo much of the flavour of the oil as is in ſome meaſure ſufficient to cover the taſte of the ſulphur, and render it ſupportable.

The balſams of ſulphur have been ſtrongly recommended in coughs, conſumptions, and other diſorders of the breaſt and lungs; but the reputation which they have had in theſe caſes does not appear to have been built on any fair trial or experience of their virtues. They are manifeſtly hot, acrimonious, and irritating; and therefore ſhould be uſed with the utmoſt caution. They have frequently been found to injure the appetite, offend the ſtomach and viſcera, parch the body, and occaſion thirſt and febrile heats. The doſe of the ſimple balſam is from ten to forty drops: thoſe with eſſential oils are not given in above half theſe quantities. Externally, they are employed for cleanſing and healing foul running ulcers. Boerhaave conjectures that their uſe in theſe caſes gave occaſion to the virtues aſcribed to them when taken internally.

Precipitated ſulphur. L.

253 Take of ſulphurated kali, ſix ounces; diſtilled water, one pound and a half; vitriolic acid, diluted, as much as is ſufficient. Boil the ſulphurated kali in the diſtilled water until it be diſſolved. Filter the liquor through paper, to which add the vitriolic acid. Waſh the precipitated powder by often pouring on water till it becomes inſipid.

This preparation is not ſo white as that of the laſt pharmacopœia, which was made with quicklime; and which in ſome pharmacopœias had the name of *milk of ſulphur*.

Pure milk of ſulphur is not different in quality from pure ſulphur itſelf; to which it is preferred in unguents, &c. only on account of its colour. The whiteneſs does not proceed from the ſulphur having loſt any of its parts in the operation, or from any new matter ſuperadded: for if common ſulphur be ground with alkaline ſalts, and ſet to ſublime, it riſes of a white like colour, the whole quantity of the alkali remaining unchanged; and if the milk be melted with a gentle fire, it returns into yellow ſulphur again.

It may be obſerved, that the name *lac ſulphuris*, or *milk of ſulphur*, applied among us to the precipitate, is by the French writers confined to the white liquor before the precipitate has fallen from it.

Chap. X. *Preparations of Antimony.*

Antimony is compoſed of a metal, united with ſulphur or common brimſtone.

If powdered antimony be expoſed to a gentle fire, the ſulphur exhales; the metallic part remaining in form of a white calx, reducible, by proper fluxes, into a whitiſh brittle metal, called *regulus*. This is readily diſtinguiſhed from the other bodies of that claſs, by its not being ſoluble in aquafortis; its proper menſtruum is aqua-regia. 254

If aqua-regia be poured on crude antimony, the metallic part will be diſſolved; and the ſulphur thrown out, partly to the ſides of the veſſel, and partly to the ſurface of the liquor, in the form of a greyiſh yellow ſubſtance. This, ſeparated and purified by ſublimation, appears on all trials the ſame with pure common brimſtone.

The metal freed from the ſulphur naturally blended with it, and afterwards fuſed with common brimſtone, reſumes the appearance and qualities of crude antimony.

The antimonial metal is a medicine of the greateſt power of any known ſubſtance; a quantity too minute to be ſenſible in the tendereſt balance, is capable of producing violent effects, if taken diſſolved, or in a ſoluble ſtate. If given in ſuch a form as to be immediately miſcible with the animal fluids, it proves violently emetic; if ſo managed as to be more ſlowly acted on, cathartic; and in either caſe, if the doſe be extremely ſmall, diaphoretic. Thus, though vegetable acids extract ſo little from this metal, that the remainder ſeems to have loſt nothing of its weight, the tinctures prove in large doſes ſtrongly emetic, and in ſmaller ones powerfully diaphoretic. The regulus has been caſt into the form of pills, which acted as violent cathartics, though without ſuffering any ſenſible diminution of weight in their paſſage through the body; and this repeatedly for a great number of times.

This metal, diveſted of the inflammable principle which it has in common with other metallic bodies that are reducible to a calx, becomes indiſſoluble and inactive. The calx, nevertheleſs, urged with a ſtrong fire, melts into a glaſs, which is as eaſy of ſolution, and as violent in operation, as the regulus itſelf: the glaſs, thoroughly mixed with ſuch ſubſtances as prevent its ſolubility, as wax, reſin, and the like, is again rendered mild.

Vegetable acids, as has already been obſerved, diſſolve but an extremely minute portion of this metal: the ſolution nevertheleſs is powerfully emetic and cathartic. The nitrous and vitriolic acids only corrode it into a powder, to which they adhere ſo ſlightly as to be ſeparable in a conſiderable degree by water, and totally by fire, leaving the regulus in form of a calx ſimilar to that prepared by fire alone. The marine acid has a very different effect: this reduces the regulus into a violent corroſive; and though it difficultly unites, yet it adheres ſo very cloſely as not to be ſeparable by any ablution, nor by fire, the regulus ariſing along with it. The nitrous or vitriolic acids expel the marine, and thus reduce the corroſive into a calx ſimilar to the foregoing.

Sulphur remarkably abates the power of this metal: and hence crude antimony, in which the regu-

Preparations and Compositions

lus appears to be combined with ſulphur, from one-fourth to one-half its weight, proves altogether mild. If a part of the ſulphur be taken away by ſuch operations as do not deſtroy or calcine the metal, the remaining maſs becomes proportionally more active.

The ſulphur of antimony may be expelled by deflagration with nitre: the larger the quantity of nitre, to a certain point, the more of the ſulphur will be diſſipated, and the preparation will be the more active. If the quantity of nitre be more than ſufficient to conſume the ſulphur, the reſt of it, deflagrating with the inflammable principle of the regulus itſelf, renders it again mild.

The ſulphur of antimony is likewiſe abſorbed in fuſion by certain metals and by alkaline ſalts. Theſe laſt, when united with ſulphur, prove a menſtruum for all the metals (zinc excepted); and hence, if the fuſion be long continued, the regulus is taken up, and rendered ſoluble in water.

From theſe particulars with reſpect to antimony, it may naturally be concluded, that it not only furniſhes us with an uſeful and active medicine, but that it may alſo be exhibited for medical purpoſes under a great variety of different forms, and that the effects of theſe will be conſiderably diverſified. And this has in reality been the caſe. For further information reſpecting antimony, and its uſes in medicine, we refer our readers to the articles ANTIMONY; MATERIA MEDICA, p. 653, &c.; and CHEMISTRY-*Index*. But although there is perhaps no preparation there mentioned, which is not fitted to ſerve ſome uſeful purpoſe; yet the colleges both of London and Edinburgh have now reſtricted the number of preparations in their pharmacopœias to a few only. And it is highly probable, that from the proper employment of them, every uſeful purpoſe to be anſwered by antimony may be accompliſhed.

Calcined antimony. L.

255 Take of antimony, powdered, eight ounces; nitre, powdered, two pounds. Mix them, and caſt the mixture by degrees into a red hot crucible. Burn the white matter about half an hour; and, when cold, powder it; after which waſh it with diſtilled water.

In the laſt edition of the London pharmacopœia this preparation had the name of *calx of antimony*; and it may be conſidered as at leaſt very nearly approaching to ſome other antimonials of the old pharmacopœias, particularly to the nitrated diaphoretic antimony, waſhed ditto, and ſtibiated nitre; none of which are now received as ſeparate formulas of our pharmacopœia, and indeed even the calx of antimony itſelf, at leaſt as thus prepared, has now no place in the Edinburgh pharmacopœia.

The calx of antimony, when freed by waſhing from the ſaline matter, is extremely mild, if not altogether inactive. Hoffman, Lemery, and others, aſſure us, that they have never experienced from it any ſuch effects as its uſual title imports: Boerhaave declares, that it is a mere metallic earth, entirely deſtitute of all medicinal virtue: and the committee of the London college admit that it has no ſenſible operation. The common doſe is from five grains to a ſcruple, or half a dram; though Wilſon relates, that he has known it given by half ounces, and repeated two or three times a-day, for ſeveral days together.

Preparations and Compoſitions.

Some report that this calx, by keeping for a length of time, contracts an emetic quality: From whence it has been concluded, that the powers of the regulus part are not entirely deſtroyed; that the preparation has the virtues of other antimonials which are given as alteratives; that is, in ſuch ſmall doſes as not to ſtimulate the primæ viæ; and that therefore diaphoretic antimony, or calcined antimony, as it is now more properly ſtyled, is certainly among the mildeſt preparations of that mineral, and may be uſed for children, and ſimilar delicate conſtitutions where the ſtomach and inteſtines are eaſily affected. The obſervations, however, from which theſe concluſions are drawn, does not appear to be well founded: Ludovici relates, that after keeping the powder for four years, it proved as mild as at firſt: and the Straſburgh pharmacopœia, with good reaſon, ſuſpects, that where the calx has proved emetic, it had either been given in ſuch caſes as would of themſelves have been attended with this ſymptom (for the great alexipharmac virtues attributed to it have occaſioned it to be exhibited even in the more dangerous malignant fevers, and other diſorders which are frequently accompanied with vomiting); or that it had not been ſufficiently calcined, or perfectly freed from ſuch part of the regulus as might remain uncalcined. The uncalcined part being groſſer than the true calx, the ſeparation is effected by often waſhing with water, in the ſame manner as directed for ſeparating earthy powders from their groſſer parts.

It has been obſerved, that when diaphoretic antimony is prepared with nitre abounding with ſea-ſalt, of which all the common nitre contains ſome portion, the medicine has proved violently emetic. This effect is not owing to any particular quality of the ſea-ſalt, but to its quantity, by which the proportion of the nitre to the antimony is rendered leſs.

The *nitrum ſtibiatum*, as it was called, is produced by the deflagration of the ſulphur of the antimony with the nitre, in the ſame manner as the *ſal polychreſt*, from which it differs no otherwiſe than in retaining ſome portion of the antimonial calx.

Notwithſtanding the doubts entertained by ſome reſpecting the activity of the antimonium calcinatum, yet the London college have in our opinion done right in retaining it. For while it is on all hands allowed that it is the mildeſt of our antimonials, there are ſome accurate obſervers who conſider it as by no means inefficacious. Thus Dr Healde tells us, that he has been in the habit of employing it for upwards of 40 years, and is much deceived, if, when genuine, it be not productive of good effects.

Nitrated calx of antimony. E.

256 Take of antimony calcined for making the glaſs of antimony, and nitre, equal weights. Having mixed, and put them into a crucible, let them be heated, ſo that the matter ſhall be of a red colour for an hour; then let it be taken out of the crucible, and, after beating it, waſh it repeatedly with warm water till it be inſipid.

Although this preparation agrees nearly in name with the

the preceding, and has been considered as being nearly a complete calx of antimony, yet there can be no doubt that it is a medicine of a much more active nature than the former; and in place of being one of the mildest of the antimonials, it often operates with great violence when given in doses of a few grains only.

But as the effects of every preparation of antimony, not already conjoined with an acid, must depend on the quantity and condition of the acid in the stomach, so the ablution of the base of the nitre in this process gives full power to the acid of the stomach to act as far as possible on the calx; whereas, when the unwashed calx is employed, a great quantity of the acid in the stomach is neutralized by the alkaline base of the nitre adhering to the calx. The nitrated calx of antimony is supposed to be nearly the same with the article which has been so much celebrated, and has had such an extensive sale under the title of *Dr James's fever powder*. And it was as an article which might be employed in the place of James's powder, that the Edinburgh college introduced this into their pharmacopœia. There is, however, reason to believe, that the preparation of James's powder is somewhat different from that here directed; but their effects, as far as our observation goes, appear to be very nearly the same.

The nitrated calx of antimony has been thought by some preferable to emetic tartar, where the permanent effects of a long-continued nausea are required, and where we wish our antimonials to pass the pylorus and produce purging. But, like every other preparation where the reguline part is only rendered active by the acid in the stomach, the nitrated calx of antimony is in all cases of uncertain operation: sometimes proving perfectly inert, and at other times very violent in its effects. The dose is generally 10 or 12 grains, and this is often given all at once; an inconvenience not attending the emetic tartar; the quantity and effects of which we can generally measure with surprising minuteness.

There is, however, reason to believe, that by means of James's powder, and the nitrated calx, an artificial termination of fever is sometimes accomplished, and that too more frequently than by emetic tartar. This perhaps may sometimes be the consequence of the violence with which they operate. At the same time it must be admitted, that even the most violent operation by no means ensures an immediate recovery, but that on the contrary it is sometimes manifestly attended with bad effects.

Crocus of antimony.

Take of antimony, powdered; nitre, powdered, of each one pound; sea salt, one ounce. Mix, and put them by degrees into a red-hot crucible, and melt them with an augmented heat. Pour out the melted matter; and, when cold, separate it from the scoriæ. *L.*

Equal parts of antimony and nitre are to be injected by degrees into a red-hot crucible; when the detonation is over, separate the reddish metallic matter from the whitish crust; beat it into a powder, and edulcorate it by repeated washings with hot water, till the water comes off insipid. *E.*

Here the antimonial sulphur is almost totally consumed, and the metallic part left divested of its corrector. These preparations, given from two to six grains, generally act as violent emetics, greatly disordering the constitution. But the operation, like that of every preparation of antimony whose reguline part is not joined with an acid, must be liable to variations, according to the quantity and condition of the acid in the stomach. Their principal use is in maniacal cases, as the basis of some other preparations; and among the farriers, who frequently give to horses an ounce or two a day, divided into different doses as an alterative: in these, and other quadrupeds, this medicine acts chiefly as a diaphoretic. Preparations and Compositions.

The chemists have been accustomed to make the crocus with a less proportion of nitre than what is directed above; and without any farther melting than what ensues from the heat which the matter acquires by deflagration, which, when the quantity is large, is very considerable: a little common salt is added to promote the fusion. The mixture is put by degrees into an iron pot or mortar, somewhat heated, and placed under a chimney: when the first ladleful is in, a piece of lighted charcoal is thrown to it, which sets the matter on fire; the rest of the mixture is then added by little and little; the deflagration is soon over, and the whole appears in perfect fusion: when cold, a considerable quantity of scoriæ is found on the surface; which scoriæ are easily knocked off with a hammer. The crocus prepared after this manner is of a redder colour than that of the former editions of the London pharmacopœia. And indeed the method now directed by the London college may be considered as founded on this: It differs principally from that of the Edinburgh college in the employment of the sea-salt, by which the process is much facilitated.

Muriated antimony. L.

Take of the crocus of antimony, powdered; vitriolic acid, each one pound; dry sea-salt, two pounds. Pour the vitriolic acid into a retort, adding by degrees the sea-salt and crocus of antimony, previously mixed; then distil in a sand-bath. Let the distilled matter be exposed to the air several days, and then let the fluid part be poured off from the dregs. 258

Butter of antimony. E.

Take of crude antimony, one part; corrosive sublimate of mercury, two parts. Grind them first separately; then thoroughly mix them together, taking the utmost care to avoid the vapours. Put the mixture into a coated glass retort (having a short wide neck), so as to fill one half of it: the retort being placed in a sand-furnace, and a receiver adapted to it, give first a gentle heat, that only a dewy vapour may arise: the fire being then increased, an oily liquor will ascend and congeal in the neck of the retort, appearing like ice, which is to be melted down by a live coal cautiously applied. This oily matter is to be rectified in a glass retort into a pellucid liquor. 259

The process here directed by the Edinburgh college, and which is nearly the same with what stood in

Preparations and Compositions.

the former edition of the London pharmacopœia, is extremely dangerous, insomuch that even the life of the operator, though tolerably versed in common pharmacy, may be much endangered for want of due care. Boerhaave relates, that one, who from the title he gives him is not to be supposed inexpert in chemical operations, or unacquainted with the danger attending this, was suffocated for want of proper care to prevent the bursting of the retort. The fumes which arise, even upon mixing the antimony with the sublimate, are highly noxious, and sometimes issue so copiously and suddenly, as very difficultly to be avoided. The utmost circumspection therefore is necessary.

The caustic, or butter as it is called, appears to be a solution of the metallic part of the antimony in the marine acid of the sublimate: the sulphur of the antimony, and the mercury of the sublimate, remain at the bottom of the retort united into an æthiops. This solution does not succeed with spirit of salt in its liquid state, and cannot be effected, unless (as in the case of making sublimate) either the acid be highly concentrated, and both the ingredients strongly heated; or when the antimony is exposed to the vapours of the acid distilled from the black calx of manganese. By this last process a perfect solution of the regulus of antimony in the muriatic acid is effected. Of this more simple, more safe, and less expensive method of preparing muriated antimony, an account is given by Mr Russel in the Transactions of the Royal Society of Edinburgh.

If regulus of antimony were added in the distillation of spirit of sea-salt without water, a solution would also be made.

The method, however, now directed by the London college, in which vitriolic acid and sea-salt are employed to give a double elective attraction, is perhaps to be considered as preferable to any of the others. In this they have followed very nearly the directions given in the Pharmacopœia Suecica, which are taken from the process of Mr Scheele.

When the congealed matter that arises into the neck of the retort is liquified by the moisture of the air, it proves less corrosive than when melted down and rectified by heat; though it seems, in either case, to be sufficiently strong for the purposes of consuming fungous flesh and the callous lips of ulcers. It is remarkable, that though this saline concrete readily and almost entirely dissolves by the humidity of the air, only a small quantity of white powder separating, it nevertheless will not dissolve on putting water to it directly: even when previously liquefied by the air, the addition of water will precipitate the solution. And accordingly, by the addition of water is formed that once celebrated article known by the title of *mercurius vitæ*, or *Algeroth's powder*. This preparation, though never used by itself, is employed both by the Edinburgh and by some of the foreign colleges, in the formation of emetic tartar, the most useful of all the antimonials. And although chemists are not altogether agreed with regard to the best mode of making the tartarized antimony, yet we shall afterwards have occasion to observe, when treating of that article, that the preparation of it from the muriated antimony, or rather from its precipitate (Algeroth's powder), is perhaps the best mode which has yet been practised. And were it even with no other intention than this, a safe, easy, and cheap method of forming a muriated antimony, may be considered as an important improvement in our pharmacopœias.

Preparations and Compositions.

Antimonial powder. L.

Take of antimony, coarsely powdered, hartshorn-shavings, each two pounds; mix, and put them into a wide red-hot iron pot, stirring constantly till the mass acquires a grey-colour. Powder the matter when cold, and put it into a coated crucible. Lute to it another crucible inverted, which has a small hole in its bottom: augment the fire by degrees to a red heat, and keep it so for two hours. Lastly, reduce the matter, when cold, to a very fine powder. 2(

In this preparation, the metallic part of the antimony in a state of calx will be united with that part of the hartshorn which is indestructible by the action of fire, viz. its absorbent earth. If this powder be properly prepared, it is of a white colour. It is a mild antimonial preparation, and is given as an alterative from three to six grains for a dose. In this quantity, however, it sometimes creates nausea, and even vomits. In larger doses it proves emetic, and operates by stool.

Precipitated sulphur of antimony. L.

Take of antimony, powdered, two pounds; water of pure kali, four pints; distilled water, three pints; Mix, and boil them with a slow fire for three hours, constantly stirring, and adding the distilled water as it shall be wanted; strain the hot ley through a double linen cloth, and into the liquor, whilst yet hot, drop by degrees as much diluted vitriolic acid as is sufficient to precipitate the sulphur. Wash off, with warm water, the vitriolated kali. 2(

Golden sulphur of antimony. E.

Boil, in an iron pot, four pounds of caustic ley diluted with three pints of water, and throw in by degrees two pounds of powdered antimony; keeping them continually stirring with an iron spatula for three hours, over a gentle fire, and occasionally supplying more water. The liquor loaded with the sulphur of antimony being then strained through a woollen cloth, drop into it gradually, while it continues hot, so much spirit of nitre, diluted with an equal quantity of water, as shall be sufficient to precipitate the sulphur, which is afterwards to be carefully washed with hot water. 2(

The foregoing preparations are not strictly sulphurs; they contain a considerable quantity of the metallic part of the antimony, which is reducible from them by proper fluxes. These medicines must needs be liable to great variation in point of strength; and in this respect they are, perhaps, the most precarious, though some have affirmed that they are the most certain of the antimonial medicines.

They prove emetic when taken on an empty stomach, in a dose of four, five, or six grains; but at present they are scarcely prescribed with this intention; being chiefly used as alterative deobstruents, particularly in cutaneous disorders. Their emetic quality is easily blunted, by making them up into pills with resins

fins or extracts, and giving them on a full ſtomach: with theſe cautions they have been taken in the quantity of 16 grains a-day, and continued for a conſiderable time, without occaſioning any diſturbance upwards or downwards. As their ſtrength is precarious, they ſhould be taken at firſt in very ſmall doſes, and increaſed by degrees according to their effect.

A compoſition of the golden ſulphur, with ſweet mercury, has been found a powerful, yet ſafe alterative, in cutaneous diſorders; and has completed a cure after ſalivation had failed. In venereal caſes, likewiſe, this medicine has produced excellent effects. A mixture of equal parts of the ſulphur and calomel (well triturated together, and made into pills with extracts, &c.) may be taken from four to eight or ten grains, morning and night; the patient keeping moderately warm, and drinking after each doſe a draught of a decoction of the woods, or other ſimilar liquor. This medicine generally promotes perſpiration, ſcarcely occaſioning any tendency to vomit or purge, or affecting the mouth.

Tartarized antimony. L.

Take of crocus of antimony, powdered, one pound and an half; cryſtals of tartar, two pounds; diſtilled water, two gallons: boil in a glaſs veſſel about a quarter of an hour; filter through paper, and ſet aſide the ſtrained liquor to cryſtallize.

Emetic tartar. E.

Take of the butter of antimony what quantity you chooſe; pour it into warm water, in which ſo much of the purified vegetable fixed alkali has been previouſly diſſolved, that the antimonial powder may be precipitated, which, after being well waſhed, is to be dried. Then to five pounds of water add of this powder nine drams, of cryſtals of tartar, beat into a very fine powder, two ounces and a half; boil for a little till the powders be diſſolved. Let the ſtrained ſolution be ſlowly evaporated in a glaſs veſſel to a pellicle, ſo that cryſtals may be formed.

We have here two modes of making the moſt common, and perhaps we may add the moſt uſeful, of all the antimonial preparations, long known in the ſhops under the name of *emetic tartar*. Theſe modes differ conſiderably from each other; but in both, the reguline part of the antimony is united with the acid of the tartar. It is perhaps difficult to ſay to which mode of preparation the preference is to be given; for on this ſubject the beſt chemiſts are ſtill divided in their opinion. The mode directed by the London college is nearly the ſame with that in former editions of their pharmacopœia, while that now adopted by the Edinburgh college in which they have nearly followed the Pharmacopœia Roſſica, is of later date. That in both ways a good emetic tartar may be formed, is very certain: but in our opinion, when it is formed of the precipitate from the muriatic acid, or the *poudre d'Algerotti*, as it has been called, there is the leaſt chance of its being uncertain in its operation: and this method comes recommended to us on the authority of Bergman, Scheele, and ſome other of the firſt names in chemiſtry. Bergman adviſes, that the calx be precipitated by ſimple water, as being leaſt liable to variation; and this is the direction followed in the Pharmacopœia Roſſica. But when the calx is precipitated by an alkaline ley, as is directed by the Edinburgh college, it is more certainly freed from the muriatic acid, and will of courſe be milder. Preparations and Compoſitions.

In the after part of the proceſs, whether precipitate or crocus have been uſed, the quantity of the antimonial ought always to be ſome drams more than is abſolutely neceſſary for ſaturating the acid of tartar, ſo that no cryſtals may ſhoot which are not impregnated with the active metallic part of the antimony. And in order to ſecure an uniform ſtrength, ſome attention is neceſſary in collecting the cryſtals, as ſome may contain more metal than others. After they are all ſeparated from the liquor, they ought to be beat together in a glaſs mortar into a fine powder, that the medicine may be of uniform ſtrength.

Emetic tartar is, of all the preparations of antimony, the moſt certain in its operation.

It will be ſufficient, in conſidering the medicinal effects of antimonials, that we ſhould obſerve, once for all, that their emetic property depends on two different conditions of the reguline part: the firſt is where the reguline part is only active, by being rendered ſo from meeting with an acid in the ſtomach: the ſecond is where the reguline part is already joined with an acid, rendering it active. It is obvious, that thoſe preparations, reducible to the firſt head, muſt always be of uncertain operation. Such then is the equal uncertainty in the chemical condition and medicinal effects of the croci, the hepata, and the calces; all of which proceſſes are different ſteps or degrees of freeing the reguline part from ſulphur and phlogiſton. It is equally plain, that the preparations coming under the ſecond head muſt be always conſtant and certain in their operation. Such a one is emetic tartar, the doſe and effects of which we can meaſure with great exactneſs.

The title of this medicine expreſſes its principal operation. It is one of the beſt of the antimonial emetics, acting more powerfully than the quantity of crocus contained in it would do by itſelf, though it does not ſo much ruffle the conſtitution. And indeed antimonials in general, when thus rendered ſoluble by vegetable acids, are more ſafe and certain in their effects than the violent preparations of that mineral exhibited by themſelves; the former never varying in their action from a difference in the food taken during their uſe, or other ſimilar circumſtances; which occaſioning more or leſs of the others to be diſſolved, make them operate with different degrees of force. Thus, crude antimony, where acid food has been liberally taken, has ſometimes proved violently emetic; whilſt in other circumſtances it has no ſuch effect.

The doſe of emetic tartar, when deſigned to produce the full effect of an emetic, is from two to four grains. It may likewiſe be advantageouſly given in much ſmaller doſes as a naufeating and ſudorific medicine.

Vitrified antimony. L.

Take of powdered antimony, four ounces. Calcine it in a broad earthen veſſel, with a fire gradually raiſed, ſtirring with an iron rod until it no longer emits a ſulphureous ſmoke. Put this powder into a crucible, ſo as to fill two-thirds of it. A cover being fitted 265

Preparations and Compositions.

on, make a fire under it, at firſt moderate, afterwards ſtronger, until the matter be melted. Pour out the melted glaſs.

Glaſs of antimony. E.

266 Strew antimony, beat into a coarſe powder like ſand, upon a ſhallow unglazed earthen veſſel, and apply a gentle heat underneath, that the antimony may be heated ſlowly; keeping it at the ſame time continually ſtirring to prevent it from running into lumps. White vapours of a ſulphureous ſmell will ariſe from it. If they ceaſe to exhale with the degree of heat firſt applied, increaſe the fire a little, ſo that vapours may again ariſe: go on in this manner, till the powder, when brought to a red heat, exhales no more vapours. Melt the calx in a crucible with an intenſe heat, till it aſſumes the appearance of melted glaſs: then pour it out on a heated braſs plate or diſh.

The calcination of antimony, in order to procure tranſparent glaſs, ſucceeds very ſlowly, unleſs the operator be wary and circumſpect in the management of it. The moſt convenient veſſel is a broad ſhallow diſh, or a ſmooth flat tile, placed under a chimney. The antimony ſhould be the purer ſort, ſuch as is uſually found at the apex of the cones; this, groſsly powdered, is to be evenly ſpread over the bottom of the pan, ſo as not to lie above a quarter of an inch thick on any part. The fire ſhould be at firſt no greater than is juſt ſufficient to raiſe a fume from the antimony, which is to be now and then ſtirred: when the fumes begin to decay, increaſe the heat, taking care not to raiſe it ſo high as to melt the antimony, or run the powder into lumps; after ſome time the veſſel may be made red-hot, and kept in this ſtate until the matter will not, upon being ſtirred, any longer fume. If this part of the proceſs be duly conducted, the antimony will appear in an uniform powder, without any lumps, and of a grey colour.

With this powder fill two-thirds of a crucible, which is to be covered with a tile, and placed in a wind-furnace. Gradually increaſe the fire till the calx be in perfect fuſion, when it is to be now and then examined by dipping a clean iron wire into it. If the matter which adheres to the end of the wire appears ſmooth and equally tranſparent, the vitrification is completed, and the glaſs may be poured out upon a hot ſmooth ſtone or copperplate, and ſuffered to cool ſlowly to prevent its cracking and flying in pieces. It is of a tranſparent yellowiſh red colour.

The glaſs of antimony uſually met with in the ſhops, is ſaid to be prepared with certain additions; which may, perhaps, render it not ſo fit for the purpoſe here deſigned. By the method above directed, it may be eaſily made of the requiſite perfection without any addition.

As antimony may be rendered nearly or altogether inactive by calcination, it might be expected that the calx and glaſs of the preſent proceſs would be likewiſe inert. But here the calcination is far leſs perfect than in the other caſe, where the inflammable principle of the regulus is totally burnt out by deflagration with nitre; there the calx is of perfect whiteneſs, and a glaſs made from that calx (with the addition of any ſaline flux, for of itſelf it will not vitrify) has little colour; but here ſo much of the inflammable principle is left, that the calx is grey, and the glaſs of a high colour. The calcined antimony is ſaid by Boerhaave to be violently emetic. Experience has ſhown that the glaſs is ſo, inſomuch as to be unſafe for internal uſe. At preſent it is chiefly employed in forming ſome other antimonial preparations, particularly the cerated glaſs of antimony, the next article to be mentioned; and the wine of antimony, afterwards to be treated of under the head of wines. It is alſo not unfrequently employed in the formation of emetic tartar; and it was directed for that purpoſe in the laſt edition of the Edinburgh pharmacopœia, being perhaps even ſuperior to the crocus of antimony.

Preparations and Compositions.

Cerated glaſs of antimony. E.

267 Take of yellow wax, a dram; glaſs of antimony, reduced into powder, an ounce. Melt the wax in an iron veſſel, and throw into it the powdered glaſs: keep the mixture over a gentle fire for half an hour, continually ſtirring it; then pour it out on paper, and when cold grind it into powder.

The glaſs melts in the wax with a very gentle heat: after it has been about twenty minutes on the fire, it begins to change its colour, and in ten more comes near to that of Scotch ſnuff; which is a mark of its being ſufficiently prepared; the quantity ſet down above loſes about one dram of its weight in the proceſs.

This medicine was for ſome time much eſteemed in dyſenteries: ſeveral inſtances of its good effects in theſe caſes may be ſeen in the fifth volume of the Edinburgh Eſſays, from which the above remarks on the preparations are taken. The doſe is from two or three grains to twenty, according to the age and ſtrength of the patient. In its operation, it makes ſome perſons ſick and vomit; it purges almoſt every one: though it has ſometimes effected a cure without occaſioning any evacuation or ſickneſs. It is now, however, much leſs uſed than formerly.

Mr Geoffroy gives two pretty ſingular preparations of glaſs of antimony, which ſeem to have ſome affinity with this. One is made by digeſting the glaſs, very finely levigated, with a ſolution of maſtich made in ſpirit of wine, for three or four days, now and then ſhaking the mixture; and at laſt evaporating the ſpirit ſo as to leave the maſtich and glaſs perfectly mixed. Glaſs of antimony thus prepared, is ſaid not to prove emetic, but to act merely as a cathartic, and that not of the violent kind. A preparation like this was firſt publiſhed by Hartman, under the name of *Chyliſta*.

The other preparation is made by burning ſpirit of wine on the glaſs three or four times, the powder being every time exquiſitely rubbed upon a marble. The doſe of this medicine is from ten grains to 20 or 30: it is ſaid to operate mildly both upwards and downwards, and ſometimes to prove ſudorific.

Ceruſe of antimony. Brun.

268 Take of regulus of antimony, one part; nitre, three parts. Deflagrate them together in the manner directed for the calcined antimony.

The reſult of this proceſs and that formerly directed for the calcined antimony are nearly the ſame.

It is not neceſſary to uſe ſo much nitre here as when

Preparations and Compositions.

antimony itself is employed: for the sulphur which the crude mineral contains, and which requires for its dissipation nearly an equal weight of nitre to the antimony, is here already separated. Two parts of nitre to one of the regulus are sufficient. It is better, however, to have an over, than an under, proportion of nitre, lest some parts of the regulus should escape being sufficiently calcined.

It may be proper to observe, that though crude antimony and the regulus yield the same calces, yet the salts separated in washing the calces are very different. As crude antimony contains common sulphur, the acid of the sulphur unites with the alkaline basis of the nitre, and the result is a neutral salt. As the regulus contains the phlogistic, or inflammable principle, but no sulphur, the nitre is alkalised, as it would be by charcoal or such like inflammable bodies, and is at the same time rendered more acrimonious than the common alkaline salts; probably owing to the calx absorbing the air of the alkali. If only equal parts of the regulus and nitre be employed, and the fire kept up strong for an hour or more, the salt will prove more caustic than even the potential caustic of the shops. But the causticity of the salt will still be far greater, if, instead of the simple regulus of antimony, the martial regulus be used.

Kermes mineral. Suec.

269 Take of crude antimony, powdered, half a pound; fixed vegetable alkali, two pounds; boiling water, eight pounds. Boil them together in an iron pot for a quarter of an hour, continually stirring the mixture with an iron spatula, and filter as speedily as possible while it is hot. The filtered liquor, set in cool places, will soon deposite a powder, which must be repeatedly washed, first with cold and afterwards with warm water, until it be perfectly insipid.

This medicine has of late been greatly esteemed in France, especially under the names of *Kermes mineral*, *pulvis Carthusianus*, *poudre des Chartreaux*, &c. It was originally a preparation of Glauber, and for some time kept a great secret, till at length the French king purchased the preparation from M. de la Ligerie, for a considerable sum, and communicated it to the public in the year 1720. In virtue, it is not different from the sulphurs above-mentioned; all of them owe their efficacy to a part of the regulus of the antimony, which the alkaline salt, by the mediation of the sulphur, renders soluble in water.

Chemists are, however, divided in their opinions with respect to the precise chemical condition of the reguline part in the preparations called *kepata of antimony*. Some have alleged that they contain not a particle of alkaline salt: it is at any rate certain, that the quantity and condition of the reguline part must vary according to the different proportions of the ingredients, the time of the precipitation, the greater or less degree of causticity of the alkali employed, and several other circumstances. At best, the whole of them are liable to the same uncertainty in their operation as the calces of antimony.

Panacea of antimony.

270 Take of antimony, six ounces; nitre, two ounces; common salt, an ounce and a half; charcoal, an ounce. Reduce them into a fine powder, and put the mixture into a red-hot crucible, by half a spoonful at a time, continuing the fire a quarter of an hour after the last injection: then either pour the matter into a cone, or let it cool in the crucible; which when cold must be broken to get it out. In the bottom will be found a quantity of regulus; above this a compact liver-coloured substance; and on the top a more spongy mass: this last is to be reduced into powder, edulcorated with water, and dried, when it appears of a fine golden colour.

This preparation is supposed to have been the basis of Lockyer's pills, which were formerly a celebrated purge. Ten grains of the powder, mixed with an ounce of white sugar candy, and made up into a mass with mucilage of gum tragacanth, may be divided into an hundred small pills; of which one, two, or three, taken at a time, are said to work gently by stool and vomit. The compact liver coloured substance, which lies immediately above the regulus, operates more severely. This last appears to be nearly of the same nature with the crocus of antimony, and the former with the golden sulphur.

Chap. XI. *Preparations of silver.*

Nitrated silver. L.

271 Take of silver, one ounce; diluted nitrous acid, four ounces. Dissolve the silver in the nitrous acid, in a glass vessel, over a sand-heat; then evaporate with an heat gently raised: afterwards melt the residuum in a crucible, that it may be poured into proper forms, carefully avoiding too great a heat.

Salt of silver, commonly called *lunar caustic.* E.

272 Take of purest silver, beat into plates, and cut in pieces, four ounces; weak nitrous acid, eight ounces; purest water, four ounces. Dissolve the silver in a phial with a gentle heat, and evaporate the solution to dryness. Then put the mass into a large crucible, and apply the heat, at first gently, but augment it by degrees till the mass flows like oil; then pour it into iron moulds, previously heated, and greased with tallow.

These processes do not differ in any material particular. But the name of *nitrated silver* is preferable to the more indefinite one of *salt of silver*.

Strong spirit of nitre will dissolve somewhat more than half its weight of pure silver; and the weaker of the aquæfortes, formerly described, proportionally less, according to their quantity of pure nitrous acid. Sometimes this spirit contains a portion of the vitriolic or marine acids; which, however minute, renders it unfit for dissolving this metal, and should therefore be carefully separated before the solution be attempted. The method which the refiners employ for examining the purity of their aquafortis, and purifying it if necessary, is to let fall into it a few drops of a perfect solution of silver already made: if the liquor remain clear, and grow not in the least turbid or whitish, it is fit for use; otherwise, they add a small quantity more of the solution, which immediately turns the whole of a milky white colour; the mixture being then suffered to rest for some time, deposites a white sediment; from which it is warily decanted, examined afresh, and,

Preparations and Compositions

if need be, farther purified by a fresh addition of the solution.

The silver beat into thin plates, as directed in the second of the above processes, needs not be cut in pieces: the solution will go on the more speedily if they are only turned round into spiral circumvolutions, so as to be conveniently got into the glass, with care that the several surfaces do not touch each other. By this management, a greater extent of the surface is exposed to the action of the menstruum, than when the plates are cut in pieces and laid above each other. Good aquafortis will dissolve about half its weight of silver; and it is not advisable to use a greater quantity of the menstruum than is sufficient for effecting the solution, for all the surplus must be evaporated in the subsequent fusion.

It is necessary to employ very pure water; for if hard water were used in this process, the nitrous acid would forsake a part of the silver to join with the calcareous earth of the imperfect nitrous selenite; whereby a part of the silver would be precipitated.

The crucible ought to be large enough to hold five or six times the quantity of the dry matter; for it bubbles and swells up greatly, and is consequently apt to run over. During this time, also, little drops are now and then spurted up, whose causticity is increased by their heat, against which the operator ought therefore to be on his guard. The fire must be kept moderate till this ebullition ceases, and till the matter becomes consistent in the heat that made it boil before: then quickly increase the fire till the matter flows thin at the bottom like oil, when it is to be immediately poured into the mould, without waiting till the fumes cease to appear; for when this happens, the preparation proves not only too thick to run freely into the mould, but likewise less corrosive than it is expected to be.

For want of a proper iron mould, one may be formed of tempered tobacco-pipe clay, not too moist, by making in a lump of it, with a smooth stick first greased, as many holes as there is occasion for: pour the liquid matter into these cavities, and when congealed take it out by breaking the mould. Each piece is to be wiped clean from the grease, and wrapt up in soft dry paper, not only to keep the air from acting on them, but likewise to prevent their corroding or discolouring the fingers in handling.

This preparation is a strong caustic; and is frequently employed as such for consuming warts and other fleshy excrescences, keeping down fungous flesh in wounds or ulcers, and other similar uses. It is rarely applied where a deep eschar is required, as in the laying open of imposthumations and tumors; for the quantity necessary for these purposes, liquefying by the moisture of the skin, spreads beyond the limits within which it is intended to operate.

The lunar pills.

273 Dissolve pure silver in aquafortis, as in the foregoing process; and after due evaporation, set the liquor aside to crystallize. Let the crystals be again dissolved in common water, and mixed with a solution of equal their weight of nitre. Evaporate this mixture to dryness, and continue the exsiccation with a gentle heat, keeping the matter constantly stirring till no more fumes arise.

Preparations and Compositions.

Here it is necessary to continue the fire till the fumes entirely cease, as more of the acid is required to be dissipated than in the preceding process. The preparation is, nevertheless, in taste very sharp, intensely bitter and nauseous: applied to ulcers, it acts as a caustic, but it is much milder than the foregoing. Boerhaave, Boyle, and others, commend it highly in hydropic cases. The former assures us, that two grains of it made into a pill with crumb of bread and a little sugar, and taken on an empty stomach (some warm water, sweetened with honey, being drank immediately after), purge gently without griping, and bring away a large quantity of water, almost without the patient's perceiving it: that it kills worms, and cures many inveterate ulcerous disorders. He nevertheless cautions against using it too freely, or in too large a dose; and observes, that it always proves corrosive and weakening, especially to the stomach.

CHAP. XII. *Preparations of iron.*

Ammoniacal iron. L.

274 Take of iron filings, one pound; sal ammoniac, two pounds. Mix, and sublime. What remains at the bottom of the vessel mix by rubbing together with the sublimed matter, and again sublime.

Martial flowers, commonly called *Ens Veneris.* E.

275 Take of colcothar of martial vitriol, washed and well dried; sal ammoniac, equal weights. Having mixed them well, sublime.

Though the mode of preparation directed by the two colleges is here different, yet the preparation is fundamentally the same; and it is perhaps difficult to say which mode of preparation is to be preferred as the easiest and best.

The name of *ens veneris* has by some been very improperly applied to this preparation, as it contains not a particle of copper. The proper *ens veneris* is prepared from the blue vitriol; but, as we shall soon see, is often not materially different from the *martial flowers.*

The success of this process depends principally on the fire being hastily raised, that the sal ammoniac may not sublime before the heat be sufficient to enable it to carry up a sufficient quantity of the iron. Hence glass vessels are not so proper as earthen or iron ones: for when the former are used, the fire cannot be raised quickly enough, without endangering the breaking of them. The most convenient vessel is an iron pot: to which may be luted an inverted earthen jar, having a small hole in its bottom to suffer the elastic vapours, which arise during the operation, to escape. It is of advantage to thoroughly mix the ingredients together, moisten them with a little water, and then gently dry them; and to repeat the pulverization, humectation, and exsiccation, two or three times, or oftener. If this method be followed, the sal ammoniac may be increased to three times the quantity of the iron, or farther; and a single sublimation will often be sufficient to raise flowers of a very deep orange colour.

This preparation is supposed to be highly aperient and

and attenuating; though no otherwiſe ſo than the reſt of the chalybeates, or at moſt only by virtue of the ſaline matter joined to the iron. It has been found of ſervice in hyſterical and hypochondriacal caſes, and in diſtempers proceeding from a laxity and weakneſs of the ſolids, as the rickets. It may be conveniently taken in the form of a bolus, from two or three grains to ten: it is naufeous in a liquid form (unleſs in ſpirituous tincture); and occaſions pills to ſwell and crumble, except ſuch as are made of the gums.

Ruſt of iron. L.

276 Take of iron-filings, one pound; expoſe them to the air, often moiſtening them with water, until they be corroded into ruſt; then powder them in an iron mortar, and waſh off with diſtilled water the very fine powder. But the remainder, which cannot by moderate rubbing be reduced into a powder capable of being eaſily waſhed off, muſt be moiſtened, expoſed to the air for a longer time, and again powdered and waſhed as before. Let the waſhed powder be dried.

Ruſt of iron, commonly called *prepared iron-filings.* E.

Set purified filings of iron in a moiſt place, that they may turn to ruſt, which is to be ground into an impalpable powder.

The cleanſing of iron filings by means of a magnet is very tedious, and does not anſwer ſo well as might be expected; for if they be ruſty, they will not be attracted by it, or not ſufficiently: nor will they by this means be entirely freed from braſs, copper, or other metallic ſubſtances which may adhere to them. It appears from the experiments of Henckel, that if iron be mixed by fuſion with even its own weight of any of the other metals, regulus of antimony alone excepted, the compound will be vigorouſly attracted by the loadſtone. The ruſt of iron is to be procured at a moderate rate from the dealers in iron, free from any impurities, except ſuch as may be waſhed off by water

The ruſt of iron is preferable as a medicine to the calces or croci, made by a ſtrong fire. Hoffman relates, that he has frequently given it with remarkable ſucceſs in obſtinate chlorotic caſes accompanied with exceſſive headachs and other violent ſymptoms; and that he uſually joined with it pimpinella, arum root, and ſalt of tartar, with a little cinnamon and ſugar. The doſe is from four or five grains to twenty or thirty. Some have gone as far as a dram: but all the preparations of this metal anſwer beſt in ſmall doſes, which ſhould rather be often repeated than enlarged.

Tartarized iron. L.

277 Take of filings of iron, one pound; powdered cryſtals of tartar, two pounds. Mix them with diſtilled water into a thick paſte. Expoſe it to the air in an open earthen veſſel for eight days; then grind the matter, dried in a bath of ſand, to a very fine powder.

This is an uſeful preparation of iron, in which that metal is chiefly brought to a ſaline ſtate by means of the cream of tartar. It has now for the firſt time a place in the London pharmacopœia; but it had before been introduced into ſome of the foreign ones, particularly the pharmacopœia Genevenſis, under the title of *mars tartariſatus*; and indeed it is almoſt preciſely the ſame with the *mars ſolubilis* of the old editions of the Edinburgh pharmacopœia. Preparations and Compoſitions.

Vitriolated iron. L.

278 Take of filings of iron, vitriolic acid, each eight ounces; diſtilled water, three pints. Mix them in a glaſs veſſel; and when the effervescence has ceaſed, place the mixture for ſome time upon hot ſand; then pour off the liquor, ſtraining it through paper; and after due exhalation ſet it aſide to cryſtallize.

Vitriol of iron, or *ſalt of ſteel.* E.

279 Take of purified filings of iron, ſix ounces; vitriolic acid, eight ounces; water, two pounds and a half. Mix them; and when the effervescence ceaſes, let the mixture ſtand for ſome time upon warm ſand; then ſtrain the liquor through paper, and after due evaporation ſet it aſide to cryſtallize.

During the diſſolution of the iron an elaſtic vapour riſes, which on the approach of flame catches fire and explodes, ſo as ſometimes to burſt the veſſel. To this particular therefore the operator ought to have due regard.

This vapour is alſo noxious to animal life. It is the inflammable air of Dr Prieſtley.

The chemiſts are ſeldom at the trouble of preparing this ſalt according to the directions above given; but in its ſtead ſubſtitute common green vitriol, purified by ſolution in water, filtration, and cryſtallization. The only difference between the two is, that the common vitriol contains ſomewhat more metal in proportion to the acid: and hence in keeping, its green colour is much ſooner debaſed by a ruſty browniſh caſt. The ſuperfluous quantity of metal may be eaſily ſeparated, by ſuffering the ſolution of the vitriol to ſtand for ſome time in a cold place, when a browniſh yellow ochery ſediment will fall to the bottom; or it may be perfectly diſſolved, and kept ſuſpended by a ſuitable addition of oil of vitriol. If the vitriol be ſuſpected to contain any cupreous matter, which the common Engliſh vitriol ſeldom does, though almoſt all the foreign vitriols do, the addition of ſome bright iron wire to the ſolution will both diſcover, and effectually ſeparate, that metal: for the acid quits the copper to diſſolve a proportionable quantity of the iron; and the copper, in its ſeparation from the acid, adheres to the undiſſolved iron, and forms a ſkin of a true copper colour on its ſurface. Even a vitriol of pure copper may, on this principle, be converted into a pure vitriol of iron.

But though the vitriolic acid appears in this operation to have ſo much ſtronger a diſpoſition to unite with iron than with copper, that it totally rejects the latter when the former is preſented to it; the operator may nevertheleſs give a dangerous impregnation of copper to the pureſt and moſt ſaturated ſolution of iron in the vitriolic acid, by the uſe of copper veſſels. If the martial ſolution be boiled in a copper veſſel, it never fails to diſſolve a part of the copper, diſtinguiſhable by its giving a cupreous ſtain to a piece of bright iron immerſed in it. By the addition of the iron, the copper

Preparations and Compositions.

copper is separated; by boiling it again without iron, more of the copper is diſſolved; and this may in like manner be ſeparated by adding more iron.

The ſalt of ſteel is one of the moſt efficacious preparations of this metal; and not unfrequently made uſe of in cachectic and chlorotic caſes, for exciting the uterine purgations, ſtrengthening the tone of the viſcera, and deſtroying worms. It may be conveniently taken in a liquid form, largely diluted with water: Boerhaave directs it to be diſſolved in an hundred times its weight of water, and the ſolution to be taken in the doſe of twelve ounces on an empty ſtomach, walking gently after it. Thus managed, he ſays, it opens the body, proves diuretic, kills and expels worms, tinges the excrements black, or forms them into a matter like clay, ſtrengthens the fibres, and thus cures many different diſtempers. The quantity of vitriol in the above doſe of the ſolution is fifty-ſeven grains and a half; but in common practice, ſuch large doſes of this ſtrong chalybeate are never ventured on. Four or five grains, and in many caſes half a grain, are ſufficient for the intention in which chalybeate medicines are given. Very dilute ſolutions, as that of a grain of the ſalt in a pint of water, may be uſed as ſuccedanea to the natural chalybeate waters, and will in many caſes produce ſimilar effects.

Colcothar of vitriol. E.

280 Let calcined vitriol be urged with a violent fire till it becomes of a very red colour.

In this preparation, the iron which had been brought to a ſaline ſtate by means of the acid of vitriol, is again deprived of that acid by the action of fire. It may be conſidered therefore as differing in nothing from the reſiduum which remains in the retort, when vitriolic acid is diſtilled from martial vitriol. The colcothar is very rarely employed by itſelf for medical purpoſes; but it is uſed in the preparation of ſome other chalybeates, particularly the martial flowers, when prepared according to the method directed by the Edinburgh college.

Martial æthiops. Gen.

281 Take of the ruſt of iron, as much as you pleaſe; olive oil, a ſufficient quantity to make it into a paſte. Let this be diſtilled in a retort by a ſtrong fire to dryneſs. Keep the reſiduum reduced to a fine powder in a cloſe veſſel.

An article under this name had formerly a place in ſome of the old pharmacopœias, and is deſcribed by Lemery in the Memoirs of the French Academy; but it was formed by a tedious proceſs, continued for ſeveral months by the aid of water. Here the proceſs is much ſhorter, and is ſuppoſed to give nearly the ſame product. Some have recommended it, on the ſuppoſition that the iron is here obtained in a very ſubtile ſtate; but it is not in general ſuppoſed to have any advantage over the other more common chalybeates.

Opening and aſtringent crocus of iron.

282 Theſe are prepared by mixing iron filings with twice their weight of powdered ſulphur, deflagrating in a red-hot crucible; and in the one caſe keeping the preparation over the fire till it aſſumes a red colour; in the other, by reverberating it for a long time in the moſt extreme degree of heat. Preparations and Compositions.

Preparations under theſe names ſtill retain a place in ſome of the foreign pharmacopœias, but they are variouſly prepared. They may, however, be conſidered as poſſeſſing the ſame medical powers: and although the preparations mentioned above probably differ from each other in their virtues, yet that difference is not of ſuch a nature as is imported by the titles by which they are uſually diſtinguiſhed. For all the preparations of iron probably act by an aſtringent quality; and that which is above denominated the *aſtringent crocus* has probably leaſt effect in that way. At one period, theſe preparations were not unfrequently in uſe; and they were given in the form of bolus, electuary, or pill, from a few grains to a ſcruple; but among us they are at preſent ſo little in uſe as to have no place in our pharmacopœias.

Chap. XIII. *Preparations of Mercury.*

We have already treated of mercury in various parts of our work as we found occaſion, and what we have already diſcuſſed it is unneceſſary to repeat. See Mercury, Chemistry-*Index*, Materia Medica, p. 653. Metallurgy, and Quicksilver. On the whole, it appears evident that there is no article which has been employed for medical purpoſes in a greater variety of forms. The colleges of London and Edinburgh have admitted into their pharmacopœias only a few of theſe; but from the ſelection they have made, there is reaſon to believe that every uſeful purpoſe for which mercury has been employed may be anſwered; and theſe purpoſes are both numerous and conſiderable. For it is at leaſt very generally allowed among intelligent practitioners, that there are few articles kept in the ſhops of our apothecaries which can be conſidered as ſo extenſively uſeful. 283

Mercury or quickſilver, in its crude ſtate, is a ponderous metallic fluid, totally volatile in a ſtrong fire, and calcinable by a weaker one (though very difficultly) into a red powdery ſubſtance. It diſſolves in the nitrous acid, is corroded by the vitriolic, but not acted on by the marine in its liquid ſtate: it nevertheleſs may be combined with this laſt ſkilfully applied in the form of fume. Quickſilver unites by trituration with earthy, unctuous, reſinous, and other ſimilar ſubſtances, ſo as to loſe its fluidity: triturated with ſulphur, it forms a black maſs, which by ſublimation changes into a beautiful red one.

For the general virtues of the mercurial preparations, ſee ſome of the articles above referred to, and Medicine. Here we ſhall only obſerve, that while in certain circumſtances they act as ſtimulants, and even as corroſives, to the parts to which they are applied; under a different management, when introduced into the habit, they ſeem to forward circulation through even the ſmalleſt and moſt remote veſſels of the body; and may be ſo managed as to promote all the excretions. But while they thus operate as a powerful ſtimulus to the ſanguiferous, and probably alſo to the lymphatic ſyſtem, they ſeem to exert but little influence on the nervous ſyſtem. By this means they prove eminently ſerviceable in ſome inveterate chronical diſorders, proceeding from obſtinate obſtructions of the glands. Crude mercury

hae

has no effect this way. Resolved into fume, or divided into minute particles, and prevented from reuniting by the interposition of other substances, it operates very powerfully, unless the dividing body be sulphur, which restrains its action. Combined with a small quantity of the mineral acids, it acts effectually, though in general mildly; with a larger, it proves violently corrosive.

Purified quicksilver. L.

Take of quicksilver, filings of iron, each four pounds. Rub them together, and distil from an iron vessel.

As in the distillation of quicksilver glass retorts are very liable to be broken, an iron one is here with propriety directed: and by the addition of the filings of iron, matters which might otherwise arise with the quicksilver will be more apt to be detained in the retort. But still this happens so readily, even merely with that degree of heat which is necessary to elevate the mercury, that it is very doubtful whether much advantage be obtained from this process; and accordingly it has now no place in the pharmacopœia of the Edinburgh college.

Acetated quicksilver. L.

Take of purified quicksilver, one pound; diluted nitrous acid, two pounds; water of kali, as much as is sufficient. Mix the quicksilver with the acid in a glass vessel, and dissolve it in a sand-bath; then drop in by degrees the water of kali, that the calx of quicksilver may be precipitated; wash this calx with plenty of distilled water, and dry it with a gentle heat. These things being done, take of the calx of quicksilver, above described, one pound; acetous acid, as much as is necessary to dissolve the calx. Mix them in a glass vessel; and the solution being completed, strain it through paper; then evaporate it till a pellicle appears, and set it aside to crystallize. Keep these crystals in a vessel close stopped.

Of all the saline preparations of mercury, it has long been the opinion of the best chemists, that those in which it was brought to a saline form, by means of acetous acid, would be the mildest; and such a preparation was conjectured to be the basis of a celebrated pill, prepared and sold by Mr Keyser. It was, however, found to be a very difficult matter to imitate his pill, or to obtain a combination of mercury with the acetous acid: but not long since, the process for preparing these pills was published by authority at Paris, after being purchased by the French king. The process here described though in some particulars much less operose than that of Mr Keyser, yet nearly approaches to it, and furnishes us with the mildest of the saline mercurials.

Calcined quicksilver. L.

Take of purified quicksilver, one pound; expose the quicksilver in a flat-bottomed glass cucurbit, to an heat of about 600 degrees in a sand-bath, till it becomes a red powder.

This preparation may now be made in a shorter time than by the process formerly directed in the London pharmacopœia, which in general required several months: for the access of air, without which calcination cannot be performed, was then very much excluded. Still, however, the process is a tedious one, and might perhaps be improved. A vessel might be so contrived, as to occasion a continual flux of air over the surface of the mercury. Preparations and Compositions.

This preparation is highly esteemed in venereal cases, and supposed to be the most efficacious and certain of all the mercurials. It may be advantageously given in conjunction with opiates: a bolus or pill, containing from half a grain to two grains of this calx, and a quarter or half a grain or more of opium, with the addition of some warm aromatic ingredient, may be taken every night. Thus managed, it acts mildly, though powerfully, as an alterative and diaphoretic: given by itself in larger doses, as four or five grains, it proves a rough emetic and cathartic.

Ash-coloured powder of mercury. E.

Take of quicksilver, weak nitrous acid, equal weights. 287
Mix them so as to dissolve the quicksilver; dilute the solution with pure water, and add spirit of sal ammoniac as much as is sufficient to separate the mercury perfectly from the acid; then wash the powder in pure water, and dry it.

In this process the mercurial nitre is decomposed; the precipitate, therefore, is a calx of mercury, and the clear liquor a solution of nitrous ammoniac. From the great attraction which the nitrous acid has for phlogiston, or from its ready disposition to part with pure air, the precipitates of mercury from its solution in this acid are more completely in the state of a calx than those from any other menstruum. There are, however, several niceties to be observed in conducting this process. If we employ too small a proportion of acid, and assist the solution by heat, the solution will contain an excess of calx capable of being separated by the water; and the whole precipitate from such a solution would be of a white colour. If, on the other hand, we employ too large a proportion of acid, the mercury is then so far calcined as to be capable of being dissolved by the volatile alkali; and this might happen in proportion as the quantity should be superabundant to the neutralization of the acid. The use of the water is to dissolve the nitrous ammoniac as fast as it is formed, and thereby prevent it from falling down and mixing with the precipitate. It is necessary to employ the purest water. If such be used as contains a nitrous selenite, not only a part of the mercury may be precipitated by the base of the selenite, but this last might also be deposited by the succeeding addition of the alkali.

The ash-coloured powder of mercury has of late years been much celebrated for the cure of venereal affections. It was first proposed by Dr Saunders to be made by precipitating the mercury from calomel, as the best substitute for the tedious and expensive process of the precipitate *per se*, and of the grey powder produced by triture with gum arabic. From the testimony of Dr Home, and several other practitioners, we have no doubt of its being a very valuable preparation of mercury. It may be given in a bolus or wafer, in the quantity of from one to six or seven grains: the dose being gradually increased according to its effects upon the person.

Preparations and Compositions.

Quickſilver with chalk. L.

288 Take of purified quickſilver, three ounces; powdered chalk, five ounces. Rub them together until the globules diſappear.

In this preparation, as well as the two former, we have alſo the mercury in a ſtate of calx; but in place of being brought to that ſtate by the aid of fire or of acids, what may here be conſidered as calcination is effected by triture.

This preparation had no place in the former editions of the London pharmacopœia. A preparation nearly ſimilar indeed, under the title of *mercurius alkaliſatus*, in which crabs eyes were employed inſtead of chalk, had a place in the old editions of the Edinburgh pharmacopœia, but was rejected from the edition of 1744, and has never again been reſtored. One reaſon for rejecting it was its being liable to groſs abuſe in the preparation, by the addition of ſome intermedium, facilitating the union of mercury with the abſorbent earth, but diminiſhing or altering its power. The preſent preparation is liable to the ſame objection. Some, however, are of opinion, that when duly prepared, it is an uſeful alterative. But there can be little doubt, that the abſorbent earth, by deſtroying acid in the alimentary canal, will diminiſh the activity of the mercurial calx.

Muriated quickſilver. L.

289 Take of purified quickſilver, vitriolic acid, each two pounds; dried ſea-ſalt, three pounds and an half. Mix the quickſilver with the acid in a glaſs veſſel, and boil in a ſand-heat until the matter be dried. Mix it, when cold, with the ſea-ſalt, in a glaſs veſſel; then ſublime in a glaſs cucurbit, with a heat gradually raiſed. Laſtly, let the ſublimed matter be ſeparated from the ſcoriæ.

Sublimate corroſive mercury. E.

290 Take of quickſilver, weak nitrous acid, each four ounces; calcined ſea-ſalt, calcined vitriol, of each five ounces. Diſſolve the quickſilver in the nitrous acid, and evaporate the ſolution to a white and thoroughly dry maſs: then add the ſea-ſalt and vitriol. Having ground and mixed them well together, put the whole into a phial, one half of which they ought to fill; then ſublime in ſand, firſt with a gentle, but afterwards with an increaſed, heat.

The ſublimate prepared by either of theſe methods is the ſame, they both conſiſt only of mercury and the acid of the ſea-ſalt united together. In the proceſs directed by the Edinburgh college, the materials being mixed and expoſed to the fire, firſt the vitriol parts with its acid, which, diſlodging thoſe of the nitre and marine ſalt, takes their place. The marine acid, reſolved into fume and aſſiſted by the nitrous, diſſolves the mercury, now alſo ſtrongly heated. This acid, though it very difficultly acts on mercury, yet when thus once united with it, is more ſtrongly retained thereby than any other acid. The nitrous ſpirit, therefore, having nothing to retain it (for its own baſis and that of the ſea-ſalt are both occupied by the vitriolic, and that which the vitriolic forſook to unite with theſe, is now ſcarcely combinable with it), ariſes; leaving the mercury and marine acid to ſublime together when the heat ſhall be ſtrong enough to elevate them. Some ſmall portion of the marine ſpirit ariſes along with the nitrous: and hence this compound acid has been uſually employed inſtead of the *compound aqua-fortis*, to which it is ſimilar, for making the red corroſive.

It appears, therefore, that the vitriol, and the baſes of the nitre and ſea-ſalt, are of no farther uſe in this proceſs, than as convenient intermediums for facilitating the union of the mercury with the marine acids. They likewiſe ſerve to afford a ſupport for the ſublimate to reſt upon, which thus aſſumes the form of a placenta or cake.

The proceſs, however, now adopted by the London college, is a better and more ſimple one. There the mercury, corroded by the vitriolic acid into a white maſs, is mixed with about an equal quantity of ſea-ſalt, and ſet to ſublime; the vitriolic acid quits the mercury to unite with the baſis of the ſea ſalt; and the acid of the ſea-ſalt, now ſet at liberty, unites with the mercury, and ſublimes with it into the compound required. The diſcovery of this method is generally attributed to Boulduc; though it is found alſo in Kunckel's *Laboratorium Chymicum*. When the proceſs is conducted in this way, the reſiduous matter is a pure Glauber's ſalt, and the ſublimate is alſo free of ferruginous matter; a greater or leſs quantity of which is very generally carried up along with the mercury when vitriol of iron is employed. Boulduc's method has therefore the advantage in this, that the proportion of mercury in a given quantity of ſublimate muſt be leſs liable to variation.

If the mercury be corroded by the nitrous acid inſtead of the vitriolic, the event will be the ſame; that acid equally quitting the mercury, and ſetting looſe the marine; and the ſublimate made by this method is the ſame with the foregoing; but as the quantity of fixed matter is ſmaller, it more difficultly aſſumes the form of a cake. It requires indeed ſome ſkill in the operator to give it this appearance when either proceſs is followed. When large quantities are made, this form may be eaſily obtained, by placing the matraſs no deeper in the ſand than the ſurface of the matter contained in it; and removing a little of the ſand from the ſides of the glaſs, as ſoon as the flowers begin to appear in the neck; when the heat ſhould likewiſe be ſomewhat lowered, and not at all raiſed during the whole proceſs. The ſublimation is known to be completed by the edges of the cryſtalline cake, which will form on the ſurface of the caput mortuum, appearing ſmooth and even, and a little removed from it.

Our apothecaries rarely, and few even of the chemiſts, attempt the making of this preparation themſelves; greateſt part of what is uſed among us comes from Venice and Holland. This foreign ſublimate has been reported to be adulterated with arſenic. Some affirm, that this dangerous fraud may be diſcovered by the ſublimate turning black on being moiſtened with alkaline ley; which by others is denied. As this point ſeemed of ſome importance to be determined, ſundry experiments have been made with this view, which prove the inſufficiency of alkalis for diſcovering arſenic. Alkaline ley, poured into a ſolution of pure arſenic, and into a mixture of the two ſolutions in different proportions, produced no blackneſs in any: and though

though the pure ſublimate, and the mixtures of it with arſenic, exhibited ſome differences in theſe trials, yet theſe differences were neither ſo conſtant nor ſo ſtrongly marked, as to be laid down univerſally for criteria of the preſence or abſence of arſenic: different ſpecimens of ſublimate, known to be pure, have been found to differ conſiderably in this reſpect; probably from their holding a little more or leſs mercury in proportion to the acid, or from their retaining ſome ſmall portion of thoſe acids which were employed in the preparation as intermedia.

Some chemiſts deny the practicability of this adulteration. There is a proceſs common in books of chemiſtry, wherein ſublimate and arſenic being mixed together, and ſet to ſublime, do not ariſe in one maſs, or yield any thing ſimilar to the preparation here intended: the arſenic abſorbs the acid of the ſublimate, and is reduced thereby into a liquid or butyraceous conſiſtence; while the mercury, thus freed from the acid, diſtils in its fluid form: if the quantity of arſenic be inſufficient to decompound the whole of the ſublimate, the remainder of the ſublimate concretes diſtinct from the arſenical butter. From whence they conclude, that arſenic and ſublimate cannot be united together into a cryſtalline cake, the form in which this preparation is brought to us.

The above experiment is not altogether deciſive; for though arſenic and ſulphur do not aſſume the required form by the common proceſs, it is poſſible they may by ſome other management. It will therefore be proper to point out means for the ſatisfaction of thoſe who may be deſirous of convincing themſelves of the genuineneſs of this important preparation. Let ſome of the ſublimate, powdered in a glaſs mortar, be well mixed with twice its weight of black flux, and a little filings or ſhavings of iron; put the mixture into a crucible capable of holding four or five times as much; give a gradual fire till the ebullition ceaſes, and then haſtily increaſe it to a white heat. If no fumes of a garlic ſmell can be perceived during the proceſs, and if the particles of iron retain their form without any of them being melted, we may be ſure that the mixture contained no arſenic.

Sublimate is a moſt violent corroſive, ſoon corrupting and deſtroying all the parts of the body it touches. A ſolution of it in water, in the proportion of about a dram to a quart, is uſed for keeping down proud fleſh, and cleanſing foul ulcers; and a more diluted ſolution as a coſmetic, and for deſtroying cutaneous inſects. But a great deal of caution is requiſite even in theſe external uſes of it.

Some have nevertheleſs ventured to give it internally, in the doſe of one-tenth or one-eighth of a grain. Boerhaave relates, that if a grain of it be diſſolved in an ounce or more of water, and a dram of this ſolution, ſweetened with ſyrup of violets, be taken twice or thrice a day, it will prove efficacious in many diſtempers thought incurable; but he particularly cautions us not to venture upon it, unleſs the method of managing it be well known.

Sublimate diſſolved in vinous ſpirit has of late been given internally in larger doſes; from a quarter of a grain to half a grain. This method of uſing it was brought into repute by Baron Van Swieten at Vienna, eſpecially for venereal maladies; and ſeveral trials of it have alſo been made in this kingdom with ſucceſs. Eight grains of the ſublimate are diſſolved in ſixteen ounces of rectified ſpirit of wine or proof-ſpirit; the rectified ſpirit diſſolves it more perfectly, and ſeems to make the medicine milder in its operation than the proof-ſpirit of the original preſcription of Van Swieten. Of this ſolution, from one to two ſpoonfuls, that is, from half an ounce to an ounce, are given twice a-day, and continued till all the ſymptoms are removed; obſerving to uſe a low diet, with plentiful dilution, otherwiſe the ſublimate is apt to purge, and gripe ſeverely. It generally purges more or leſs at the beginning, but afterwards ſeems to operate chiefly by urine and perſpiration. Preparations and Compoſitions.

Sublimate conſiſts of mercury united with a large quantity of marine acid. There are two general methods of deſtroying its corroſive quality, and rendering it mild; the one is, combining with it as much freſh mercury as the acid is capable of taking up; and the other, by ſeparating a part of the acid by means of alkaline ſalts and earths. On the firſt principle ſweet mercury is formed; on the latter, white precipitate. But before entering on theſe, it is proper to give the following formula.

Solution of corroſive ſublimate mercury. E.

291 Take of corroſive ſublimate mercury, ſix grains; ſal ammoniac, twelve grains. Diſſolve in a pound of diſtilled water. If hard water be uſed for this purpoſe, the ſolution ſuffers a kind of decompoſition from the nitrous ſelenite of the water.

The ſolution of corroſive ſublimate in water is very much aſſiſted by ſal ammoniac. There was a practice ſome years ago, of mixing up this ſolution with wheat flour into the conſiſtence of pills for internal uſe; and the quantity of ſublimate in each pill was eaſily aſcertained.

This ſolution may alſo be uſed for waſhing venereal and other ſores; but in many inſtances it will be found too acrid for that purpoſe, and will require to be weakened by the addition of a portion of water.

Calomel. L.

292 Take of muriated quickſilver, one pound; purified quickſilver, nine ounces. Rub them together till the globules diſappear, and then ſublime the maſs. In the ſame manner repeat the ſublimation four times. Afterwards rub the matter into a very fine powder, and waſh it by pouring on boiling diſtilled water.

Sweet mercury. E.

293 Take of corroſive mercury ſublimate, reduced to a powder in a glaſs mortar, four ounces; pure quickſilver, three ounces and a half. Mix them well together, by long trituration in a glaſs or marble mortar, until the quickſilver ceaſes to appear. Put the powder into an oblong phial, of ſuch a ſize that only one-third of it may be filled; and ſet the glaſs in ſand, that the maſs may ſublime. After the ſublimation, break the glaſs; and the red powder which is found in its bottom, with the whitiſh one that ſticks about the neck, being thrown away, let the white mercury be ſublimed again three or four times, and reduced to a very fine powder.

Preparations and Compositions.

The trituration of corrosive sublimate with quicksilver is a very noxious operation: for it is almost impossible, by any care, to prevent the lighter particles of the former from rising so as to affect the operator's eyes and mouth. It is nevertheless of the utmost consequence, that the ingredients be perfectly united before the sublimation is begun. It is necessary to pulverize the sublimate before the mercury is added to it: but this may be safely performed with a little caution; especially if during the pulverization the matter be now and then sprinkled with a little spirit of wine: this addition does not at all impede the union of the ingredients, or prejudice the sublimation: it will be convenient not to close the top of the subliming vessel with a cap of paper at first (as is usually practised), but to defer this till the mixture begins to sublime, that the spirit may escape.

The rationale of this process deserves particular attention; and the more so, as a mistaken theory herein has been productive of several errors with regard to the operation of mercurials in general. It is supposed, that the *dulcification*, as it is called, of the corrosive mercury is owing to the spiculæ or sharp points, on which its corrosivenes depends, being broken and worn off by the frequent sublimations. If this opinion were just, the corrosive would become mild, without any addition, barely by repeating the sublimation; but this is contrary to all experience. The abatement of the corrosive quality of the sublimate is entirely owing to the combination of as much fresh mercury as is capable of being united with it; and by whatever means this combination be effected, the preparation will be sufficiently dulcified. Triture and digestion promote the union of the two, while sublimation tends rather to disunite them. The prudent operator, therefore, will not be solicitous about separating such mercurial globules as appear distinct after the first sublimation: he will endeavour rather to combine them with the rest, by repeating the triture and digestion.

The college of Wirtemberg require their sweet mercury to be only twice sublimed, and the Augustan but once; and Neumann proposes making it directly by a single sublimation from the ingredients of the corrosive sublimate, by only taking the quicksilver in a larger proportion.

Mr Selle of Berlin has lately proposed a method of making sweet mercury nearly similar to that of Neumann. He directs, that to four ounces of pure quicksilver there should be added as much strong vitriolic acid. These are to be mixed over a strong fire till they become a solid hard mass. This mass is to be triturated in a stone mortar with two ounces and an half of quicksilver and four ounces and an half of dried common salt. And by a single, or at most two, sublimations, he assures us an excellent sweet mercury is obtained.

If the medicine made after either of these methods should prove in any degree acrid, water boiled on it for some time will dissolve and separate that part in which its acrimony consists. The marks of the preparation being sufficiently dulcified are, its being perfectly insipid to the taste, and indissoluble by long boiling in water. Whether the water in which it has been boiled has taken up any part of it, may be known by dropping into the liquor a ley of any fixed alkaline salt, or any volatile alkaline spirit. If the decoction has any mercurial impregnation, it will grow turbid on this addition; if otherwise, it will continue limpid. But here care must be taken not to be deceived by any extraneous saline matter in the water itself. Most of the common spring waters turn milky on the addition of alkalis; and therefore, for experiments of this kind, distilled water or rain water ought to be used.

Prep tions Com tions

This name of *calomel*, though for a considerable time banished from our best pharmacopœias, is again restored by the London college. But we cannot help thinking, that they might easily have invented a name better expressing the constituent parts and nature of the preparation.

Calomel, or sweet mercury, may be considered as one of the most useful of the mercurial preparations; and it may be estimated as holding an intermediate place between the acetated quicksilver, one of the mildest of the saline preparations, and the muriated quicksilver, or corrosive sublimate, one of the most acrid of them.

Mild muriated quicksilver. L.

Take purified quicksilver, diluted nitrous acid, of each half a pound. Mix in a glass vessel, and set it aside until the quicksilver be dissolved. Let them boil, that the salt may be dissolved. Pour out the boiling liquor into a glass vessel into which another boiling liquor has been put before, consisting of sea-salt, four ounces; distilled water, eight pints. After a white powder has subsided to the bottom of the vessel, let the liquor swimming at the top be poured off, and the remaining powder be washed till it becomes insipid, with frequent affusions of hot water; then dried on blotting paper with a gentle heat. 2

This preparation had a place in former editions of the London and Edinburgh pharmacopœias under the name of *mercurius dulcis precipitatus*. But the process as now given is somewhat altered, being that of Mr Scheele of Sweden, who has recommended this as an easy and expeditious method of preparing sweet mercury or calomel.

It appears from several tests that this precipitate is equal in every respect to that prepared by the preceding processes. It is less troublesome and expensive, and the operator is not exposed to the noxious dust arising from the triture of the quicksilver with the corrosive sublimate, which necessarily happens by the common method. The powder is also finer than can be made from the common sublimed sweet mercury by any trituration whatever. The clear liquor standing over the precipitate is a solution of cubic or rhomboidal nitre.

Sweet mercury, which may be considered as precisely the same with the calomel and mild muriated quicksilver, appears to be one of the best and safest preparations of this mineral, when intended to act as a quick and general stimulant. Many of the more elaborate processes are no other than attempts to produce from mercury such a medicine as this really is. The dose, recommended by some for raising a salivation, is ten or fifteen grains taken in the form of a bolus or pill, every night or oftener, till the ptyalism begins. As an alterant and diaphoretic, it has been given in doses of five or six grains; a purgative being occasionally

Preparations and Compositions.

sionally interposed, to prevent its affecting the mouth. It answers, however, much better when given in smaller quantities, as one, two, or three grains every morning and evening, in conjunction with such substances as determine its action to the skin, as the extract or resin of guaiacum; the patient at the same time keeping warm, and drinking liberally of warm diluent liquors. By this method of managing it, obstinate cutaneous and venereal distempers have been successfully cured without any remarkable increase of the sensible evacuations. It is sometimes, however, difficult to measure its effects in this way; and it is so very apt to run off by the intestines, that we can seldom administer it in such a manner as to produce those permanent effects which are often required, and which we are able to do by other preparations. It has been lately proposed to rub the gums and inside of the mouth with this preparation, as a ready and effectual method of producing salivation. This practice has been particularly recommended in the internal hydrocephalus, where it is exceedingly difficult to excite a salivation by other means. The advantages of this practice are not fully confirmed by experience; and when mercury is attended with advantage in hydrocephalus, this is not probably the consequence of any discharge under the form of salivation, but merely of the mercury being introduced into the system in an active state, and thus promoting absorption. And salivation, when it arises from the internal use of mercury, may be considered as the strongest test of this; but this is by no means the case when salivation arises from a topical action on the excretories of saliva.

Red nitrated quicksilver. L.

295 Take of purified quicksilver, nitrous acid, each one pound; muriatic acid, one dram. Mix in a glass vessel, and dissolve the quicksilver in a sand bath; then raise the fire until the matter be formed into red crystals.

Red corrosive, commonly called *red precipitated mercury.* E.

296 Take of quicksilver, weak nitrous acid, each one pound. Let the quicksilver be dissolved in the acid, and then let the solution be evaporated to a white dry mass. This being beat into a powder, must be put into a glass retort, and subjected to a fire gradually increased, till a small quantity of it, taken out in a glass spoon, and allowed to cool, assumes the form of shining red squamæ. Let the vessel be then removed from the fire. During the process the matter must be carefully agitated by a glass rod, that it may be equally heated.

The marine acid, in the menstruum ordered in the first process, disposes the mercurial calx to assume the bright sparkling look admired in it; which, though perhaps no advantage to it as a medicine, ought nevertheless to be insisted on by the buyer as a mark of its goodness and strength. As soon as the matter has gained this appearance, it should be immediately removed from the fire, otherwise it will soon lose it again. The preparation of this red precipitate, as it is called, in perfection, is supposed by some to be a secret not known to our chemists, insomuch that we are under the necessity of importing it from abroad. This reflection seems to be founded on misinformation. We sometimes indeed receive considerable quantities of it from Holland; but this depends on the ingredients being commonly cheaper there than with us, and not on any secret in the manner of the preparation.

Preparations and Compositions.

This precipitate is, as its title imports, an escharotic; and with this intention is frequently employed by the surgeons with basilicum and other dressings, for consuming fungous flesh in ulcers and the like purposes. It is subject to great uncertainty in point of strength, more or less of the acid exhaling according to the degree and continuance of the fire. The best criterion of its strength, as already observed, is its brilliant appearance; which is also the mark of its genuineness: if mixed with minium, which it is sometimes said to be, the duller hue will discover the abuse. This admixture may be more certainly detected by means of fire: the mercurial part will totally evaporate, leaving the minium behind.

Some have ventured to give this medicine internally in venereal, scrophulous, and other obstinate chronic disorders, in doses of two or three grains or more. But certainly the milder mercurials, properly managed, are capable of answering all that can be expected from this; without occasioning violent anxieties, tormina of the bowels, and similar ill consequences, which the best management can scarcely prevent this corrosive preparation from sometimes inducing. The chemists have contrived sundry methods of correcting and rendering it milder, by divesting it of a portion of the acid; but to no very good purpose, as they either leave the medicine still too corrosive, or render it similar to others which are procurable at an easier rate.

White calx of quicksilver. L.

297 Take of muriated quicksilver, sal ammoniac, water of kali, each half a pound. Dissolve first the sal ammoniac, afterwards the muriatic quicksilver, in distilled water, and add the water of kali. Wash the precipitated powder until it becomes insipid.

White precipitate of mercury. E.

298 Dissolve corrosive sublimate mercury in a sufficient quantity of hot water, and gradually drop into the solution some spirit of sal ammoniac as long as any precipitation ensues. Wash the precipitated powder with several fresh quantities of warm water.

These preparations are used chiefly in ointments, with which intention their fine white colour is no small recommendation to them. For internal purposes they are rarely employed, nor is it at all wanted: they are nearly similar to sweet mercury, but less certain in their effects.

Though the processes directed by the London and Edinburgh colleges be here somewhat different, yet the preparations are ultimately the same. The process described by the Edinburgh college is the most simple; but is liable to some objections.

Corrosive sublimate, as we have already seen, consists of mercury united with a large portion of acid. It is there dulcified by adding as much fresh mercury as is sufficient to saturate all the acid; here, by separating all the acid that is not saturated. This last way seems an unfrugal one, on account not only of the loss of the acid, but of the volatile spirit necessary for absorbing it. The operator may, however, if it should be thought

Preparations and Compositions.

thought worth while, recover the volatile ſalt from the liquor, by adding to it, after the precipitate has been ſeparated, a proper quantity of potaſh, and diſtilling with a gentle heat, in the ſame manner as for the ſpirit or volatile ſalt of ſal ammoniac; for a true ſal ammoniac is regenerated, in the precipitation, from the union of the volatile ſpirit with the marine acid of the ſublimate. It is by no means adviſable to uſe the liquor itſelf as a ſolution of ſal ammoniac, or to ſeparate the ſal ammoniac from it by evaporation and cryſtallization, as a part of the mercury might be retained, and communicate dangerous qualities: but the volatile ſalt ſeparated by diſtillation may be uſed without fear of its containing any mercury; none of which will ariſe with the heat by which the volatile ſalts are diſtilled.

Fixed alkalia anſwer as effectually for precipitating ſolutions of ſublimate as the volatile; but the precipitate obtained by means of the former, inſtead of being white, as with the latter, is generally of a reddiſh yellow or orange colour. If ſal ammoniac be diſſolved along with the ſublimate, the addition of fixed alkalis will, by extricating the volatile alkali of the ſal ammoniac, occaſion as white a precipitation as if the volatile ſalt had been previouſly ſeparated and employed in its pure ſtate; and this compendium is now allowed by the London college in the proceſs which they have adopted.

There the ſal ammoniac, beſides its uſe in the capital intention, to make a white precipitation, promotes the ſolution of the ſublimate; which of itſelf is difficultly, and ſcarcely at all totally, ſoluble by repeated boiling in water: for however ſkilfully it be prepared, ſome part of it will have an under-proportion of acid, and conſequently approach to the ſtate of ſweet mercury. A good deal of care is requiſite in the precipitation; for if too large a quantity of the fixed alkaline ſolution be imprudently added, the precipitate will loſe the elegant white colour for which it is valued.

Quickſilver with ſulphur. L.

299 Take of purified quickſilver, flowers of ſulphur, each one pound. Rub them together until the globules diſappear.

Æthiops mineral. E.

300 Take of quickſilver, flowers of ſulphur, each equal weights. Grind them together in a glaſs or ſtone mortar, with a glaſs peſtle, till the mercurial globules totally diſappear.

An æthiops is made alſo with a double quantity of mercury.

We need hardly remark, that theſe preparations, though now differing in name, are in reality the ſame. Nor need we add, that the direction given by the Edinburgh college, of uſing a glaſs or ſtone mortar and peſtle, is neceſſary and proper.

The union of the mercury and ſulphur might be much facilitated by the aſſiſtance of a little warmth. Some are accuſtomed to make this preparation in a very expeditious manner, by melting the ſulphur in an iron ladle, then adding the quickſilver, and ſtirring them together till the mixture be completed. The ſmall degree of heat here ſufficient cannot reaſonably be ſuppoſed to do any injury to ſubſtances which have already undergone much greater fires, not only in the extraction from their ores, but likewiſe in the purifications of them directed in the pharmacopœia. In the following proceſs they are expoſed in conjunction to a ſtrong fire, without ſuſpicion of the compound receiving any ill quality from it. This much is certain, that the ingredients are more perfectly united by heat than by the degree of triture uſually beſtowed on them. From the æthiops prepared by triture, part of the mercury is apt to be ſqueezed out on making it into an electuary or pills; from that made by fire no ſeparation is obſerved to happen.

Æthiops mineral is one of the moſt inactive of the mercurial preparations. Some practitioners, however, have repreſented it as poſſeſſing extraordinary virtues; and moſt people imagine it a medicine of ſome efficacy. But what benefit is to be expected from it in the common doſes of eight or ten grains, or a ſcruple, may be judged from hence, that it has been taken in doſes of ſeveral drams, and continued for a conſiderable time, without producing any remarkable effect. Sulphur eminently abates the power of all the more active minerals, and ſeems to be at the ſame time reſtrained by them from operating in the body itſelf. Boerhaave, who is in general ſufficiently liberal in the commendation of medicines, diſapproves of the æthiops in very ſtrong terms. "It cannot enter the abſorbent veſſels, the lacteals, or lymphaties, but paſſes directly through the inteſtinal tube, where it may happen to deſtroy worms, if it operates luckily. They are deceived who expect any other effects from it; at leaſt I myſelf could never find them. I am afraid it is unwarily given, in ſuch large quantities, to children and perſons of tender conſtitutions, as being a foreign maſs, unconquerable by the body; the more to be ſuſpected as it there continues long ſluggiſh and inactive. It does not raiſe a ſalivation, becauſe it cannot come into the blood. Who knows the effects of a ſubſtance, which, ſo long as it remains compounded, ſeems no more active than any ponderous inſipid earth?" The æthiops, with a double proportion of mercury, now received into our pharmacopœias, has a greater chance for operating as a mercurial; and probably the quantity of mercury might be ſtill further increaſed to advantage.

Red ſulphurated quickſilver. L.

Take of quickſilver, purified, forty ounces; ſulphur, eight ounces. Mix the quickſilver with the melted ſulphur; and if the mixture takes fire, extinguiſh it by covering the veſſel; afterwards reduce the maſs to powder, and ſublime it. 301

It has been cuſtomary to order a larger quantity of ſulphur than here directed; but ſmaller proportions anſwer better, for the leſs ſulphur the finer coloured is the cinnabar.

As ſoon as the mercury and ſulphur begin to unite, a conſiderable exploſion frequently happens, and the mixture is very apt to take fire, eſpecially if the proceſs be ſomewhat haſtily conducted. This accident the operator will have previous notice of, from the matter ſwelling up, and growing ſuddenly conſiſtent: as ſoon as this happens, the veſſel muſt be immediately cloſe covered.

During the ſublimation, care muſt be had that the

matter rise not into the neck of the vessel, so as to block up and burst the glass. To prevent this, a wide-necked bolt head, or rather an oval earthen jar, coated, should be chosen for the subliming vessel. If the former be employed, it will be convenient to introduce at times an iron wire, somewhat heated, in order to be the better assured that the passage is not blocking up; the danger of which may be prevented by cautiously raising the vessel higher from the fire.

If the ingredients were pure, no feces will remain: in such cases, the sublimation may be known to be over by introducing a wire as before, and feeling therewith the bottom of the vessel, which will then be perfectly smooth: if any roughness or inequalities are perceived, either the mixture was impure, or the sublimation is not completed: if the latter be the case, the wire will soon be covered over with the rising cinnabar.

The preparers of cinnabar in large quantity employ earthen jars, which in shape pretty much resemble an egg. These are of different sizes, according to the quantity intended to be made at one sublimation, which sometimes amounts to two hundred weight. The jar is usually coated from the small end almost to the middle, to prevent its breaking by the vehemence or irregularity of the fire. The greater part, which is placed uppermost, not being received within the furnace, has no occasion for this defence. The whole secret with regard to this process, is the management of the fire, which should be so strong as to keep the matter continually subliming to the upper part of the jar, without coming out at its mouth, which is covered with an iron plate; care should also be taken to put into the subliming vessel only small quantities of the mixture at a time.

The principal use of cinnabar is as a pigment. It was formerly held in great esteem as a medicine in cutaneous foulnesses, gouty and rheumatic pains, epileptic cases, &c. but of late it has lost much of its reputation. It appears to be nearly similar to the æthiops already spoken of. Cartheuser relates, that having given cinnabar in large quantities to a dog, it produced no sensible effect, but was partly voided along with the feces unaltered, and partly found entire in the stomach and intestines on opening the animal. The celebrated Frederic Hoffman, after bestowing high encomiums on this preparation, as having in many instances within his own knowledge perfectly cured epilepsies and vertigoes from contusions of the head (where it is probable, however, that the cure did not so much depend on the cinnabar as on the spontaneous recovery of the parts from the external injury), observes, that the large repeated doses, necessary for having any effect, can be borne only where the first passages are strong; and that if the fibres of the stomach and intestines are lax and flaccid, the cinnabar, accumulated and concreting with the mucous matter of the parts, occasions great oppression; which seems to be an acknowledgement that the cinnabar is not subdued by the powers of digestion, and has no proper medicinal activity. There are indeed some instances of the daily use of cinnabar having brought on a salivation; perhaps from the cinnabar, used in those cases, having contained a less proportion of sulphur than the sorts commonly met with. The regulus of antimony, and even white arsenic, when combined with a certain quantity of common sulphur, seem to have their deleterious power destroyed: on separating more and more of the sulphur, they exert more and more of their proper virulence. It does not seem unreasonable to presume, that mercury may have its activity varied in the same manner; that when perfectly satiated with sulphur, it may be inert; and that when the quantity of sulphur is more and more lessened, the compound may have greater and greater degrees of the proper efficacy of mercurials.

Preparations and Compositions.

Cinnabar is sometimes used in fumigations against venereal ulcers in the nose, mouth, and throat. Half a dram of it burnt, the fume being imbibed with the breath, has occasioned a violent salivation. This effect is by no means owing to the medicine as cinnabar: when set on fire, it is no longer a mixture of mercury and sulphur, but mercury resolved into fume, and blended in part with the volatile vitriolic acids; in either of which circumstances this mineral, as we have already observed, has very powerful effects.

Vitriolated quicksilver. L.

Take of quicksilver, purified, vitriolic acid, each one pound. Mix in a glass vessel, and heat them by degrees until they unite into a white mass, which is to be perfectly dried with a strong fire. This matter, on the affusion of a large quantity of hot distilled water, immediately becomes yellow, and falls to powder. Rub the powder carefully with this water in a glass mortar. After the powder has subsided, pour off the water; and, adding more distilled water several times, wash the matter till it become insipid. 302

Yellow mercury, commonly called *Turbith mineral.* E.

Take of quicksilver, four ounces; vitriolic acid, eight ounces. Cautiously mix them together, and distil in a retort, placed in a sand furnace, to dryness: the white calx, which is left at the bottom, being ground to powder, must be thrown into warm water. It immediately assumes a yellow colour, but must afterwards be purified by repeated ablutions. 305

The quantity of oil of vitriol, formerly directed, was double to that now employed by the Edinburgh college. The reduction made in this article greatly facilitates the process; and the proportions of the London college are perhaps preferable.

Boerhaave directs this preparation to be made in an open glass, slowly heated, and then placed immediately on burning coals; care being taken to avoid the fumes, which are extremely noxious. This method will succeed very well with a little address when the ingredients are in small quantity; but where the mixture is large, it is better to use a retort, placed in a sand-furnace, with a recipient, containing a small quantity of water, luted to it. Great care should be taken, when the oil of vitriol begins to bubble, that the heat be steadily kept up, without at all increasing it, till the ebullition ceases, when the fire should be augmented to the utmost degree, that as much as possible of the redundant acid may be expelled.

If the matter be but barely exsiccated, it proves a caustic salt, which in the ablution with water will almost all dissolve, leaving only a little quantity of turbith:

Preparations and Compositions.

bith: the more of the acid that has been diſſipated, the leſs of the remaining mercury will diſſolve, and conſequently the yield of turbith will be greater; fire expelling only ſuch part of the acid as is not completely ſatiated with mercury, while water takes up always, along with the acid, a proportional quantity of the mercury itſelf. Even when the matter has been ſtrongly calcined, a part will ſtill be ſoluble; this evidently appears on pouring into the waſhings a little ſolution of fixed alkaline ſalt, which will throw down a conſiderable quantity of yellow precipitate, greatly reſembling the turbith, except that it is leſs violent in operation.

From this experiment it appears, that the beſt method of edulcorating this powder is, by impregnating the water, intended to be uſed in its ablution, with a determined proportion of fixed alkaline ſalt; for by this means, the waſhed turbith will not only turn out greater in quantity, but, what is of more conſequence, will have an equal degree of ſtrength; a circumſtance which deſerves particularly to be conſidered, eſpecially in making ſuch preparations as, from an error in the proceſs, may prove too violently corroſive to be uſed with any tolerable degree of ſafety. It is neceſſary to employ warm water if we are anxious for a fine colour. If cold water be uſed, the precipitate will be white.

It is obſervable, that though the ſuperfluous acid be here abſorbed from the mercury by the alkaline ſalt; yet in ſome circumſtances this acid forſakes that ſalt to unite with mercury. If vitriolated tartar, or *vitriolated kali*, as it is now called, which is a combination of vitriolic acid with fixed alkali, be diſſolved in water, and the ſolution added to a ſolution of mercury in aquafortis, the vitriolic acid will unite with the mercury, and form with it a turbith, which falls to the bottom; leaving only the alkali diſſolved in the aquafortis, and united with its acid into a regenerated nitre. On this principle depends the preparation deſcribed by Wilſon under the title of *an excellent precipitate of mercury*; which is no other than a true turbith, though not generally known to be ſuch. It is made by diſſolving four ounces of vitriolated kali in ſixteen ounces of ſpirit of nitre; diſſolving in this compound liquor four ounces of mercury; abſtracting the menſtruum by a ſand heat; and edulcorating with water the gold coloured maſs which remains.

Turbith mineral is a ſtrong emetic, and with this intention operates the moſt powerfully of all the mercurials that can be ſafely given internally. Its action, however, is not confined to the primæ viæ; it will ſometimes excite a ſalivation, if a purgative be not taken ſoon after it. This medicine is uſed chiefly in virulent gonorrhœas, and other venereal caſes, where there is a great flux of humours to the parts. Its chief uſe at preſent is in ſwellings of the teſticle from a venereal affection; and it ſeems not only to act as a mercurial, but alſo, by the ſevere vomiting it occaſions, to perform the office of a diſcutient, by accelerating the motion of the blood in the parts affected. It is ſaid likewiſe to have been employed with ſucceſs, in robuſt conſtitutions, againſt leprous diſorders and obſtinate glandular obſtructions: the doſe is from two grains to ſix or eight. It may be given in doſes of a grain or two as an alterative and diaphoretic, in the ſame manner as the calcined mercury already ſpoken of. Dr Hope has found that the turbith mineral is the moſt convenient errhine he has had occaſion to employ. Preparations and Compoſitions

This medicine was lately recommended as the moſt effectual preſervative againſt the hydrophobia. It has been alleged there are ſeveral examples of its preventing madneſs in dogs which had been bitten; and ſome of its performing a cure after the madneſs was begun: from ſix or ſeven grains to a ſcruple may be given every day, or every ſecond day, for a little time, and repeated at the two or three ſucceeding fulls and changes of the moon. Some few trials have likewiſe been made on human ſubjects bitten by mad dogs; and in theſe alſo the turbith, uſed either as an emetic or alterative, ſeemed to have good effects.

The waſhings of turbith mineral are uſed by ſome externally for the cure of the itch and other cutaneous foulneſſes. In ſome caſes mercurial lotions may be proper, but they are always to be uſed with great caution: this is by no means an eligible one, as being extremely unequal in point of ſtrength, more or leſs of the mercury being diſſolved, as has been obſerved above, according to the degree of calcination. The pharmacopœia of Paris directs a mercurial waſh free from this inconvenience, under the title of *Aqua mercurialis*, or *Mercurius liquidus*. It is compoſed of one ounce of mercury, diſſolved in a ſufficient quantity of ſpirit of nitre, and diluted with 30 ounces of diſtilled water. In want of diſtilled water, rain water may be uſed; but of ſpring waters there are very few which will mix with the mercurial ſolution without growing turbid and precipitating a part of the mercury.

Simple mercurial ſolution. Joſ. Jac. Plenck.

Take of pureſt quickſilver, one dram; gum arabic, two drams. Beat them in a ſtone mortar, adding by little and little diſtilled water of fumitory till the mercury thoroughly diſappear in the mucilage. Having beat and mixed them thoroughly, add by degrees, and at the ſame time rubbing the whole together, ſyrup of kermes, half an ounce, diſtilled water of fumitory, eight ounces. 304

This mixture was much celebrated by its author as an effectual preparation of mercury, unattended with the inconvenience of producing a ſalivation; and he imagined that this depended on a peculiar affinity exiſting between mercury and mucilage. Hence ſuch a conjunction, the gummy quickſilver, as it has been ſtyled, has been the foundation of mixtures, pills, ſyrups, and ſeveral other formulæ, which it is unneceſſary to dwell upon in this place.

By a long continued triture, mercury ſeems to undergo a degree of calcination; at leaſt its globular appearance is not to be diſcerned by the beſt microſcope; its colour is converted into that of a greyiſh powder; and from the inactive ſubſtance in its globular form, it is now become one of the moſt powerful preparations of this metallic body. The uſe of the gum ſeems to be nothing more than to afford the interpoſition of a viſcid ſubſtance to keep the particles at a diſtance from each other, till the triture requiſite to produce this change be performed. Dr Saunders has clearly proved, that no real ſolution takes place in

this proceſs, and that though a quantity of mercurial particles are ſtill retained in the mixture after the globular parts have been depoſited by dilution with water, yet that this ſuſpended mercurial matter is only diffuſed in the liquor, and capable of being perfectly ſeparated by filtration. That long triture is capable of effecting the above change on mercury, is fully evinced from the well known experiment of Dr Boerhaave, in producing a kind of calcined mercury by expoſing quickſilver incloſed in a phial to the agitation produced by keeping the phial tied to a windmill for 14 years. By incloſing a pound of quickſilver in an iron box, with a quantity of iron nails and a ſmall quantity of water, by the addition of which a greater degree of inteſtine motion is given to the particles of the mercury, and fixing the box to the wheel of a carriage, Dr Saunders obtained, during a journey of 400 miles, two ounces of a greyiſh powder, or calx of mercury.

On the above accounts we are not to aſcribe the effects of Plenck's ſolution to an intimate diviſion of the globules of mercury, nor to any affinity, nor elective attraction, between gum-arabic and mercury; which laſt Mr Plenck has very unphiloſophically ſuppoſed. The ſame thing can be done by means of gum-tragacanth, by honey, and by ſundry balſams. It is evidently owing to the converſion of the quickſilver to a calciform nature; but as this will be accompliſhed more or leſs completely according to the different circumſtances during the triture, it is certainly preferable, inſtead of Plenck's ſolution, to diffuſe in mucilage, or other viſcid matters, a determinate quantity of the aſh coloured powder, or other calx of mercury.

It is proper to take notice, that there is in many inſtances a real advantage in employing mucilaginous matters along with mercurials, theſe being found to prevent diarrhœa and ſalivation to a remarkable degree. So far, then, Mr Plenck's ſolution is a good preparation of mercury, though his chemical rationale is perhaps erroneous. The diſtilled water and ſyrup are of no conſequence to the preparation, either as facilitating the proceſs, or for medicinal uſe.

It is always moſt expeditious to triturate the mercury with the gum in the ſtate of mucilage. Dr Saunders found that the addition of honey was an excellent auxiliary; and the mucilage of gum-tragacanth ſeems better ſuited for this purpoſe than gum-arabic.

Chap. XIV. *Preparations of Lead.*

Lead readily melts in the fire, and calcines into a duſky powder: which, if the flame is reverberated on it, becomes at firſt yellow, then red, and at length melts in a vitreous maſs. This metal diſſolves eaſily in the nitrous acid, difficultly in the vitriolic, and in ſmall quantity in the vegetable acids; it is alſo ſoluble in expreſſed oil, eſpecially when calcined.

Lead and its calces, while undiſſolved, have no conſiderable effects as medicines. Diſſolved in oils, they are ſuppoſed to be (when externally applied) anti-inflammatory and deſiccative. Combined with vegetable acids, they are remarkably ſo; and, taken internally, prove a powerful though dangerous ſtyptic.

There are two preparations of lead, *red* and *white lead*, as they are commonly called, which are much more extenſively employed in other arts than in medicine, and of courſe they are prepared in large quantities. Theſe formerly ſtood among the preparations in our pharmacopœias; but they are now referred to the materia medica. We ſhall not therefore, on the preſent occaſion, make any farther obſervations with reſpect to them, but ſhall here inſert from the old editions of the Edinburgh pharmacopœia the directions there given for preparing them. Preparations and Compoſitions.

Red lead.

Let any quantity of lead be melted in an unglazed earthen veſſel, and kept ſtirring with an iron ſpatula till it falls into powder, at firſt blackiſh, afterwards yellow, and at length of a deep red colour, in which laſt ſtate it is called *minium*; taking care not to raiſe the fire ſo high as to run the calx into a vitreous maſs. 306

The preparation of red lead is ſo troubleſome and tedious, as ſcarce ever to be attempted by the apothecary or chemiſt; nor indeed is this commodity expected to be made by them, the preparation of it being a diſtinct branch of buſineſs. The makers melt large quantities of lead at once, upon the bottom of a reverberatory furnace built for this purpoſe, and ſo contrived that the flame acts on a large ſurface of the metal, which is continually changed by means of iron rakes drawn backwards and forwards, till the fluidity of the lead is deſtroyed; after which, the calx is only now and then turned. By barely ſtirring the calx, as above directed, in a veſſel over the fire, it acquires no redneſs; the reverberation of flame on the ſurface being abſolutely neceſſary for this effect. It is ſaid, that 20 pounds of lead gain, in this proceſs, five pounds; and that the calx, being reduced into lead again, is found one pound leſs than the original weight of the metal.

Theſe calces are employed in external applications, for abating inflammations, cleanſing and healing ulcers, and the like. Their effects, however, are not very conſiderable; nor are they perhaps of much farther real uſe, than as they give conſiſtence to the plaſter, unguent, &c.

Ceruſe or white lead.

Put ſome vinegar into the bottom of an earthen veſſel, and ſuſpend over the vinegar very thin plates of lead, in ſuch a manner that the vapour which ariſes from the acid may circulate about the plates. Set the containing veſſel in the heat of horſe-dung for three weeks; if at the end of this time the plates be not totally calcined, ſcrape off the white powder, and expoſe them again to the ſteam of vinegar, till all the lead be thus corroded into powder. 307

The making of white lead is alſo become a trade by itſelf, and confined to a few perſons, who have large conveniences for this purpoſe. The general method which they follow is nearly the ſame with that above deſcribed. See the Philoſophical Tranſactions, n° 137.

In this preparation, the lead is ſo far opened by the acid, as to diſcover, when taken internally, the

Preparations and Compositions.

malignant quality of the metal; and to prove externally, when ſprinkled on running ſores, or ulcers, moderately cooling, drying, and aſtrictive.

Acetated ceruſe. L.

308 Take of ceruſe, one pound; diſtilled vinegar, one gallon and an half. Boil the ceruſe with the vinegar until the vinegar is ſaturated: then filter thro' paper; and, after proper evaporation, ſet it aſide to cryſtallize.

Salt, commonly called *ſugar of lead.* E.

309 Put any quantity of ceruſe into a cucurbit, and pour upon it ten times its quantity of diſtilled vinegar. Let the mixture ſtand upon warm ſand till the vinegar becomes ſweet; when it is to be poured off, and freſh vinegar added as often as it comes off ſweet. Then let all the vinegar be evaporated in a glaſs-veſſel to the conſiſtence of pretty thin honey, and ſet it aſide in a cold place, that cryſtals may be formed, which are to be afterwards dried in the ſhade. The remaining liquor is again to be evaporated, that new cryſtals may be formed; the evaporation of the reſiduous liquor is to be repeated till no more cryſtals concrete.

Ceruſe (eſpecially that ſort called *flake lead*, which is not, like the others, ſubject to adulteration) is much preferable either to minium or litharge, for making the ſugar of lead: for the corroſion which it has undergone from the ſteam of the vinegar diſpoſes it to diſſolve more readily. It ſhould be finely powdered before the vinegar be put to it; and during the digeſtion, or boiling, every now and then ſtirred up with a wooden ſpatula, to promote its diſſolution, and prevent its concreting into a hard maſs at the bottom. The ſtrong acid obtained from the *caput mortuum* of vinegar may be employed for this purpoſe to better advantage than the weaker, though purer acid, above directed. If a ſmall quantity of rectified ſpirit of wine be prudently added to the ſolution as ſoon as it is duly exhaled, and the mixture ſuffered to grow cold by ſlow degrees, the ſugar will concrete into very large and tranſparent cryſtals, which are ſcarcely to be obtained by any other method.

If the cryſtals be dried in ſunſhine, they acquire a blackiſh or livid colour. This ſeems to happen from the abſorption of light and its converſion into phlogiſton. If it be owing to the eſcape of pure air, why are the rays of the ſun neceſſary to this diſcharge? On whatever principles we account for it, the fact is the ſame; that the cryſtals ſoon loſe their ſaline condition, and the lead gradually reaſſumes its metallic form. From this property of lead readily abſorbing phlogiſton, or parting with pure air, a ſolution of the ſugar of lead becomes a very convenient ſympathetic ink; on the ſame grounds it is alſo uſed for a more important purpoſe. As lead communicates a ſweetneſs and aſtringency very ſimilar to the product of the vinous fermentation, a practice formerly prevailed among fraudulent dealers, of correcting the too great ſharpneſs of acid wines by adulterating them with this metal. The abuſe may be detected in two different ways: a piece of paper may be moiſtened with the liquor to be examined, and then expoſed to the vapours of liver of ſulphur: the moiſtened paper will become of a livid colour, and this will happen though 200 or 300 leaves of a book were interpoſed between the paper and the vapours; by this method, then, we make a kind of ſympathetic ink. But the beſt way of making the teſt is, to drop a ſmall quantity of a ſolution of the liver of ſulphur into the ſuſpected liquor: if there be any lead preſent, this addition will inſtantly occaſion the precipitation of a livid or dark coloured cloud.

The ſugar of lead is much more efficacious than the foregoing preparations, in anſwering the ſeveral intentions to which they are applied. Some have ventured upon it internally, in doſes of a few grains, as a ſtyptic in hæmorrhagies, profuſe colliquative ſweats, ſeminal fluxes, the fluor albus, &c. nor has it failed their expectations. It very powerfully reſtrains the diſcharge; but almoſt as certainly as it does this, it occaſions ſymptoms of another kind, often more dangerous than thoſe removed by it, and ſometimes fatal. Violent pains in the bowels or through the whole body, and obſtinate conſtipations, ſometimes immediately follow, eſpecially if the doſe has been conſiderable: cramps, tremors, and weakneſs of the nerves, generally ſooner or later enſue.

Boerhaave is of opinion, that this preparation proves malignant only as far as its acid happens to be *abſorbed* in the body; for in ſuch caſe, he ſays, "it returns again into ceruſe, which is violently poiſonous." On this principle it would follow, that in habits where acidities abound, the ſugar of lead would be innocent. But this is far from being the caſe. Lead and its preparations act in the body only when they are *combined* with acid: ceruſe poſſeſſes the qualities of the ſaccharum only in a low degree; and either of them freed from the acid has little, if any, effect at all. For the ſame reaſons, the ſalt of lead is preferable to the pompous *extract* and *vegeto-mineral water* of Goulard, in which the lead is much leſs perfectly combined in a ſaline ſtate. It is ſometimes convenient to aſſiſt the ſolution of the ſugar of lead in water, by adding a portion of vinegar. The effects of the external application of lead ſeems to differ from the ſtrength of the ſolution: thus a very weak ſolution ſeems to diminiſh directly the action of the veſſels, and is therefore more peculiarly proper in active inflammations, as of the eyes; whereas a ſtrong ſolution operates as a direct ſtimulant, and is therefore more ſucceſsful in paſſive ophthalmia.

Water of acetated litharge. L.

Take of litharge, two pounds and four ounces; diſtilled vinegar, one gallon. Mix, and boil to ſix pints, conſtantly ſtirring; then ſet it aſide. After the feces have ſubſided, ſtrain. 310

This preparation may be conſidered as nearly the ſame with the extract and vegeto-mineral water of Mr Goulard. And it is probably from the circumſtances of his preparations having come into a common uſe, that the London college have given this article a place in their pharmacopœia. It may, however, be a matter of doubt whether it be really intitled to a place. For, as we have already obſerved, every purpoſe to be anſwered by it may be better obtained from the employment

ployment of a ſolution of the acetated ceruſe in ſimple water. The acetated water of litharge is intended for external uſe only.

Chap. XV. *Preparations of tin.*

311 Tin eaſily melts in the fire, and calcines into a duſky powder; which, by a farther continuance of the heat, becomes white. A maſs of tin heated till it be juſt ready to melt, proves extremely brittle, ſo as to fall in pieces from a blow; and by dexterous agitation, into powder. Its proper menſtruum is aqua-regia; though the other mineral acids may alſo be made to diſſolve it, and the vegetable ones in ſmall quantity. It cryſtallizes with the vegetable and vitriolic acids; but with the others, deliquates.

The virtues of this metal are little known. It has been recommended as an antihyſteric, antihectic, &c. At preſent it is chiefly uſed as an anthelmintic.

Powdered tin. L.

312 Take of tin, ſix pounds. Melt it in an iron veſſel, and ſtir it with an iron rod until a powder floats on the ſurface. Take off the powder, and, when cold, paſs it through a ſieve.

This preparation may be conſidered as nearly the ſame with the calx Jovis, which had a place in the former editions of the Edinburgh pharmacopœia; but from the late editions the calx has been expunged, and the filings or powder of tin, has a place only in their liſt of the materia medica. But although ſeldom prepared by the apothecary himſelf, it is not unfrequently employed as a remedy againſt worms, particularly the flat kinds, which too often elude the force of other medicines. The general doſe is from a ſcruple to a dram; ſome confine it to a few grains. But Dr Alſton aſſures us, in the Edinburgh Eſſays, that its ſucceſs chiefly depends on its being given in much larger quantities: he directs an ounce of the powder on an empty ſtomach, mixed with four ounces of molaſſes; next day, half an ounce; and the day following, half an ounce more; after which a cathartic is adminiſtered: he ſays the worms are uſually voided during the operation of the purge, but that pains in the ſtomach occaſioned by them are removed almoſt immediately upon taking the firſt doſe of the tin.

This practice is ſometimes ſucceſsful in the expulſion of tænia, but by no means ſo frequently as Dr Alſton's obſervations would lead us to hope.

Amalgama of tin. Dan.

313 Take of ſhavings of pure tin, two ounces; pure quickſilver, three drams. Let them be rubbed to a powder in a ſtone mortar.

Some have imagined that tin thus acted on by mercury is in a more active condition than when exhibited in a ſtate of powder: and accordingly it has been given in worm caſes. But as both are equally inſoluble in the animal fluids, this is not to be expected; and to obtain any peculiar properties which tin may poſſeſs to their full extent, it will probably be neceſſary to exhibit it in ſome ſaline ſtate.

Chap. XVI. *Preparations of zinc and copper.*

Preparations and Compositions.

Calcined zinc. L.

314 Take of zinc, broken into ſmall pieces, eight ounces. Caſt the pieces of zinc, at ſeveral times, into an ignited, large, and deep crucible, placed leaning, or half-upright, putting on it another crucible in ſuch a manner that the air may have free acceſs to the burning zinc. Take out the calx as ſoon as it appears, and ſeparate its white and lighter part by a fine ſieve.

Flowers of zinc. E.

315 Let a large crucible be placed in a furnace, in an inclined ſituation, only half-upright; when the bottom of the veſſel is moderately red, put a ſmall piece of zinc, about the weight of two drams, into it. The zinc ſoon flames, and is at the ſame time converted into a ſpongy calx, which is to be raked from the ſurface of the metal with an iron ſpatula, that the combuſtion may proceed the more ſpeedily: when the zinc ceaſes to flame, take the calx out of the crucible. Having put in another piece of zinc, the operation may be repeated as often as you pleaſe. Laſtly, the calx is to be prepared like antimony.

Theſe flowers, as uſed externally, are preferable for medicinal purpoſes to tutty, and the more impure ſublimates of zinc, which are obtained in the braſs works; and likewiſe to calamine, the natural ore of this metal, which contains a large quantity of earth, and frequently a portion of heterogeneous metallic matter. But beſides being applied externally, they have alſo of late been uſed internally. The flowers of zinc, in doſes from one to ſeven or eight grains, have been much celebrated of late years in the cure of epilepſy and ſeveral ſpaſmodic affections: and there are ſufficient teſtimonies of their good effects, where tonic remedies in thoſe affections are proper.

White vitriol. E.

316 Take of zinc, cut into ſmall pieces, three ounces; vitriolic acid, five ounces; water, twenty ounces; having mixed the acid and water, add the zinc, and when the ebullition is finiſhed ſtrain the liquor; then after proper evaporation ſet it apart in a cold place, that it may ſhoot into cryſtals.

This ſalt is an elegant white vitriol. It differs from the common white vitriol, and the ſalt of vitriol of the ſhops, only in being purer, and perfectly free from any admixture of copper, or ſuch other foreign metallic bodies as the others generally contain.

Purified vitriolated zinc. L.

317 Take of white vitriol, one pound; vitriolic acid, one dram; boiling diſtilled water, three pints. Mix, and filter through paper. After a proper evaporation, ſet it aſide in a cold place to cryſtallize.

Although the Edinburgh college have given a formula for the preparations of white vitriol, yet their direction is very rarely followed by any of the apothecaries or chemiſts, who in general purchaſe it as obtained from the Goſlar mines. When, however, it is got in this way, it is often a very impure ſalt, and requires

Preparations and Compositions.

quires that purification which is here directed, and which is by no means neceſſary for the white vitriol artificially prepared, in the manner above directed. But by this proceſs, the ordinary white vitriol, in its common ſtate of impurity, will be freed from thoſe impregnations of earth and other matters which it often contains. And in this purified ſtate it anſwers many uſeful purpoſes, not only externally but internally; and particularly in doſes from ten grains to half a dram, it operates almoſt inſtantly as an emetic, and is at the ſame time perfectly ſafe. By employing it internally, in ſmaller doſes, we may obtain, and perhaps even more effectually, all the tonic power of the zinc; and ſome think it in every caſe preferable to the calx of zinc.

Ammoniacal copper. E.

219 Take of blue vitriol, two parts; volatile ſal ammoniac, three parts; rub them together in a glaſs mortar, until they unite, after the effervescence ceaſes, into a uniform violet colored maſs, which muſt be firſt dried on blotting paper, and afterwards by a gentle heat. The product muſt be kept in a glaſs phial, well cloſed with a glaſs ſtopper.

This preparation has been thought ſerviceable in epilepſies; but from its frequent want of ſucceſs, and the diſagreeable conſequences with which its uſe is ſometimes attended, it has not lately been much preſcribed. It is employed by beginning with doſes of half a grain, twice a day, and increaſing them gradually to as much as the ſtomach will bear. Dr Cullen ſometimes increaſed the doſe to five grains.

Chap. XVII. *Simple diſtilled waters.* L. E.

319 The effluvia which exhale into the air from many vegetables, particularly from thoſe of the odorous kind, conſiſt apparently of principles of great ſubtility and activity, capable of ſtrongly and ſuddenly affecting the brain and nervous ſyſtem, eſpecially in thoſe whoſe nerves are of great ſenſibility; and likewiſe of operating in a ſlower manner on the ſyſtem of the groſſer veſſels. Thus Boerhaave obſerves, that in hyſterical and hypochondriacal perſons, the fragrant odour of the Indian hyacinth excites ſpaſms, which the ſtrong ſcent of rue relieves; that the effluvia of the walnut-tree occaſion headachs, and make the body coſtive; that thoſe of poppies procure ſleep; and that the ſmell of bean-bloſſoms, long continued, diſorders the ſenſes. Lemery relates, from his own knowledge, that ſeveral perſons were purged by ſtaying long in a room where damaſk roſes were drying.

Some of the chemiſts have indulged themſelves in the pleaſing ſurvey of theſe preſiding ſpirits, as they are called, of vegetables; their peculiar nature in the different ſpecies of plants; their exhalation into the atmoſphere by the ſun's heat, and diſperſion by winds; their rendering the air of particular places medicinal, or otherwiſe, according to the nature of the plants that abound. They have contrived alſo different means for collecting theſe fugitive emanations, and concentrating and condenſing them into a liquid form; employing either the native moiſture of the ſubject, or an addition of water, as a vehicle or matrix for retaining them.

Preparations and Compositions.

The proceſs which has been judged moſt analogous to that of nature, is the following. The ſubject freſh gathered at the ſeaſon of its greateſt vigour, with the morning dew on it, is laid lightly and unbruiſed in a ſhallow veſſel, to which is adapted a low head with a recipient; under the veſſel a live coal is placed, and occaſionally renewed, ſo as to keep up an uniform heat, no greater than that which obtains in the atmoſphere in ſummer, viz. about 85 degrees of Fahrenheit's thermometer. In this degree of heat there ariſes exceeding ſlowly an inviſible vapour, which condenſes in the head into dewy drops, and falls down into the receiver; and which has been ſuppoſed to be the very ſubſtance that the plant would have ſpontaneouſly emitted in the open air.

But on ſubmitting many kinds of odoriferous vegetables to this proceſs, the liquors obtained by it have been found to be very different from the natural effluvia of the reſpective ſubjects: they have had very little ſmell, and no remarkable taſte. It appeared that a heat, equal to that of the atmoſphere, is incapable of raiſing in cloſe veſſels thoſe parts of vegetables which they emit in the open air. It may therefore be preſumed, that in this laſt caſe ſome other cauſe concurs to the effect: that it is not the ſun's heat alone which raiſes and impregnates the air with the odorous principles of vegetables, but that the air itſelf, or the watery humidity with which it abounds, acting as a true ſolvent, extracts and imbibes them; ſo that the natural effluvia of a plant may be conſidered as an infuſion of the plant made in air. The purgative virtue of the damaſk roſe, and the aſtringency of the walnut-tree, which, as above obſerved, are in ſome degree communicated to the air, may be totally extracted by infuſion both in watery and ſpirituous menſtrua, but never riſe in diſtillation with any degree of heat: and the volatile odours of aromatic herbs, which are diffuſed through the atmoſphere in the loweſt warmth, cannot be made to diſtil without a heat much greater than is ever found to obtain in a ſhaded air.

We apprehend, that the effluvia ariſing from growing vegetables are chiefly exhaled by the living energy of the plant: the odorous matter is a real ſecretion, which cannot be performed independent of active veſſels; and it is as reaſonable to allow the ſame powers for the exhalation of theſe effluvia, as for the tranſpiration of their watery parts.

The above proceſs, therefore, and the theory on which it is built, appear to be faulty in two points; 1. In ſuppoſing that all theſe principles, which naturally exhale from vegetables, may be collected by diſtillation; whereas there are many which the air extracts in virtue of its ſolvent power: ſome are alſo incapable of being collected in a viſible and inelaſtic form; and ſome are artificially ſeparable by ſolvents only: 2. In employing a degree of heat inſufficient for ſeparating even thoſe parts which are truly exhalable by heat.

The foregoing method of diſtillation is commonly called *diſtillation by the cold ſtill;* but thoſe who have practiſed it have generally employed a conſiderable heat. A ſhallow leaden veſſel is filled with the freſh herbs, flowers, &c. which are heaped above it; ſo that when the head is fitted on, this alſo may be filled a conſiderable way. A little fire is made under the veſſel,

Preparations and Compositions.

fel, ſufficient to make the bottom much hotter than the hand can bear, care being only taken not to heat it ſo far as to endanger ſcorching any part of the ſubject. If the bottom of the veſſel be not made ſo hot as to have this effect on the part contiguous to it, it is not to be feared that the heat communicated to the reſt of the included matter will be ſo great as to do it any injury. By this management, the volatile parts of ſeveral odorous plants, as mint, are effectually forced over; and if the proceſs has been ſkilfully managed, the diſtilled liquor proves richly impregnated with the native odour and flavour of the ſubject, without having received any kind of diſagreeable impreſſion from the heat uſed.

This proceſs has been chiefly practiſed in private families; the ſlowneſs of the diſtillation, and the attendance and care neceſſary for preventing the ſcorching of ſome part of the plant, ſo as to communicate an ungrateful burnt flavour to the liquor, rendering it inconſiſtent with the diſpatch requiſite in the larger way of buſineſs.

Another method has therefore been had recourſe to, viz. by the common ſtill, called, in diſtinction from the foregoing, the *hot ſtill*. Here a quantity of water is added to the plant to prevent its burning; and the liquor is kept nearly of a boiling heat, or made to boil fully, ſo that the vapour riſes plentifully into the head, and paſſing thence into a ſpiral pipe or worm placed in a veſſel of cold water, is there condenſed, and runs out in drops quickly ſucceeding each other, or in a continued ſtream. The additional water does not at all weaken the produce; for the moſt volatile parts of the ſubject riſe firſt, and impregnate the liquor that firſt diſtils: as ſoon as the plant has given over its virtue ſufficiently, which is known by examining from time to time the liquor that runs from the noſe of the worm, the diſtillation is to be ſtopped.

This is the method of diſtillation commonly practiſed for the officinal waters. It is accompanied with one imperfection, affecting chiefly thoſe waters whoſe principal value conſiſts in the delicacy of their flavour; this being not a little injured by the boiling heat uſually employed, and by the agitation of the odorous particles of the ſubject with the water. Sometimes alſo a part of the plant ſticks to the ſides of the ſtill, and is ſo far ſcorched as to give an ungrateful taint to the liquor.

There is another method of managing this operation, which has been recommended for the diſtillation of the more volatile eſſential oils, and which is equally applicable to that of the waters. In this way, the advantages of the foregoing methods are united, and their inconveniences obviated. A quantity of water being poured into the ſtill, and the herbs or flowers placed in a baſket over it, there can be no poſſibility of burning; the water may be made to boil, but ſo as not to riſe up into the baſket, which would defeat the intention of this contrivance. The hot vapour of the water paſſing lightly through all the interſtices of the ſubject matter, imbibes and carries over the volatile parts unaltered in their native flavour. By this means the diſtilled waters of all thoſe ſubſtances whoſe oils are of the moſt volatile kind, are obtained in the utmoſt perfection, and with ſufficient diſpatch; for which laſt intention the ſtill may be filled quite up to the head.

Preparations and Compositions.

In the diſtillation of eſſential oils, the water, as was obſerved in the foregoing ſection, imbibes always a part of the oil. The diſtilled liquors here treated of, are no other than water thus impregnated with the eſſential oil of the ſubject; whatever ſmell, taſte, or virtue is here communicated to the water, or obtained in the form of a watery liquor, being found in a concentrated ſtate in the oil. The eſſential oil, or ſome part of it, more attenuated and ſubtilized than the reſt, is the direct principle on which the title of *ſpiritus rector*, or preſiding ſpirit, has been beſtowed.

All thoſe vegetables therefore which contain an eſſential oil, will give over ſome virtue to water by diſtillation: but the degree of the impregnation of the water which a plant is capable of ſaturating with its virtue, are by no means in proportion to the quantity of its oil. The oil ſaturates only the water that comes over at the ſame time with it: if there be more oil than is ſufficient for this ſaturation, the ſurplus ſeparates, and concretes in its proper form, not miſcible with the water that ariſes afterwards. Some odoriferous flowers, whoſe oil is in ſo ſmall quantity, that ſcarcely any viſible mark of it appears, unleſs fifty or an hundred pounds or more are diſtilled at once, give nevertheleſs as ſtrong an impregnation to water as thoſe plants which abound moſt with oil.

Many have been of opinion, that diſtilled waters may be more and more impregnated with the virtues of the ſubject, and their ſtrength increaſed to any aſſigned degree, by *cohobation*, that is, by rediſtilling them a number of times from freſh parcels of the plant. Experience, however, ſhows the contrary; a water ſkilfully drawn in the firſt diſtillation, proves on every repeated one not ſtronger but more diſagreeable. Aqueous liquors are not capable of imbibing above a certain quantity of the volatile oil of vegetables; and this they may be made to take up by one as well as by any number of diſtillations: the oftener the proceſs is repeated, the ungrateful impreſſion which they generally receive from the fire, even at the firſt time, becomes greater and greater. Thoſe plants, which do not yield at firſt waters ſufficiently ſtrong, are not proper ſubjects for this proceſs, ſince their virtue may be obtained much more advantageouſly by others.

General rules for the DISTILLATION *of the* OFFICINAL SIMPLE WATERS.

1. Where they are directed freſh, ſuch only muſt be employed: but ſome are allowed to be uſed dry, as being eaſily procurable in this ſtate at all times of the year, though rather more elegant waters might be obtained from them while green. 523

When freſh and juicy herbs are to be diſtilled, thrice their weight of water will be fully ſufficient; but dry ones require a much larger quantity. In general, there ſhould be ſo much water, that after all intended to be diſtilled has come over, there may be liquor enough left to prevent the matter from burning to the ſtill.

Plants differ ſo much, according to the ſoil and ſeaſon of which they are the produce, and likewiſe according to their own age, that it is impoſſible to fix the

Preparations and Compositions

the quantity of water to be drawn from a certain weight of them to any invariable ſtandard. The diſtillation may always be continued as long as the liquor runs well flavoured off the ſubject, and no longer.

2. The diſtillation may be performed in an alembic with a refrigeratory, the junctures being luted.
3. If the herbs are of prime goodneſs, they muſt be taken in the weights preſcribed: but when freſh ones are ſubſtituted for dry, or when the plants themſelves are the produce of unfavourable ſeaſons, and weaker than ordinary, the quantities are to be varied according to the diſcretion of the artiſt.

After the odorous water, alone intended for uſe, has come over, an acidulous liquor ariſes, which has ſometimes extracted ſo much from the copper head of the ſtill as to prove emetic. To this are owing the anthelmintic virtues attributed to certain diſtilled waters.

4. In a preceding edition of the Edinburgh pharmacopœia, ſome vegetables were ordered to be ſlightly fermented with the addition of yeſt previouſly to the diſtillation.

The principle on which this management is founded, is certainly juſt; for the fermentation ſomewhat opens and unlocks their texture, ſo as to make them part with more in the ſubſequent diſtillation than could be drawn over from them without ſome aſſiſtance of this kind. Thoſe plants, however, which require this treatment, are not proper ſubjects for ſimple waters to be drawn from, their virtues being obtainable to better advantage by other proceſſes.

5. If any drops of oil ſwim on the ſurface of the water, they are to be carefully taken off.
6. That the waters may keep the better, about a 20th part their weight of proof-ſpirit may be added to each after they are diſtilled.

A great number of diſtilled waters were formerly kept in the ſhops, and are ſtill retained in foreign pharmacopœias. The faculty of Paris direct, in the laſt edition of their *Codex Medicamentarius*, no leſs than 125 different waters, and 130 different ingredients in one ſingle water. Nearly one half of theſe preparations have ſcarcely any virtue or flavour from the ſubject, and many of the others are inſignificant.

The colleges of London and Edinburgh have rejected theſe oſtentatious ſuperfluities, and given an elegant and compendious ſet of waters, ſufficient for anſwering ſuch purpoſes as theſe kinds of preparations are applied to in practice. Diſtilled waters are employed chiefly as grateful diluents, as ſuitable vehicles for medicines of greater efficacy, or for rendering diſguſtful ones more acceptable to the palate and ſtomach; few are depended on, with any intention of conſequence, by themſelves.

Diſtilled water. L.

321 Take of ſpring-water, 10 gallons. Draw off by diſtillation, firſt, four pints; which being thrown away, draw off four gallons. This water is to be kept in a glaſs or earthen bottle with a glaſs ſtopper.

Diſtilled water. E.

Let well or river water be diſtilled in very clean veſſels till about two thirds are drawn off.

Native water is ſeldom or never found pure, and generally contains earthy, ſaline, metallic, or other matters. Diſtillation is therefore employed as a means of freeing it from theſe heterogeneous parts. For ſome pharmaceutical purpoſes diſtilled water is abſolutely neceſſary: thus, if we employ hard undiſtilled water for diſſolving ſugar of lead, inſtead of a perfect ſolution, we produce a milky-like cloud, owing to a real decompoſition of parts.

Preparations and Compoſitions.

Diſtilled water is now employed by the London college for a great variety of purpoſes; and there can be no doubt, that in many chemical and pharmaceutical proceſſes, the employment of a heterogeneous fluid, in place of the pure element, may produce an eſſential alteration of qualities, or fruſtrate the intention in view. While the London college have made more uſe of diſtilled water than any other, their directions for preparing it ſeem to be the beſt. For as ſome impregnations may be more volatile than pure water, the water may be freed from them by throwing away what comes firſt over; and by keeping it afterwards in a cloſe veſſel, abſorption from the air is prevented.

Dill-water. L.

Take of dill-ſeed, bruiſed, one pound; water, ſufficient to prevent an empyreuma. Draw off one gallon. 322

Simple dill-ſeed water. E.

Take of dill ſeeds, one pound; pour on as much water as when ten pounds have been drawn off by diſtillation there may remain as much as is ſufficient to prevent an empyreuma. After proper maceration, let ten pounds be drawn off.

Although the dill water holds a place, not only in the London and Edinburgh pharmacopœias, but alſo in moſt of the foreign ones; yet it is not much employed in practice. It obtains, indeed, a pretty ſtrong impregnation from the ſeeds, and is ſometimes employed as a carminative, particularly as the baſis of mixtures and juleps; but it is leſs powerful and leſs agreeable than that of peppermint, cinnamon, and ſome others.

Cinnamon-water. L. E.

Take of cinnamon, bruiſed, one pound; water, ſufficient to prevent an empyreuma. Macerate for 24 hours, and draw off one gallon. 323

From one pound of cinnamon the Edinburgh college direct 10 pounds of water to be drawn off; and if the cinnamon employed be of good quality, it may yield that quantity with a ſtrong impregnation; but what comes over firſt is unqueſtionably the ſtrongeſt.

This is a very grateful and uſeful water, poſſeſſing in an eminent degree the fragrance and aromatic cordial virtues of the ſpice. Where real cinnamon water is wanted, care ſhould be had in the choice of the cinnamon, to avoid the too common impoſition of caſſia being ſubſtituted in its room. The two drugs may be eaſily diſtinguiſhed from each other by a variety of marks, which it is needleſs to introduce in this place. See CASSIA and CINNAMON. But the eſſential oils of the two approach ſo near, that after diſtillation it is perhaps impoſſible to diſtinguiſh the waters; and it is ſtill more doubtful how far the one is in any degree preferable to the other.

The oil of cinnamon is very ponderous, and arifes more difficultly than that of any other of the vegetable matters from which fimple waters are ordered to be drawn. This obfervation directs us, in the diftillation of this water, to ufe a quick fire and a low veffel. For the fame reafon, the water does not keep fo well as might be wifhed; the ponderous oil parting from it in time, and falling to the bottom, when the liquor lofes its milky hue, its fragrant fmell, and aromatic tafte. Some recommend a fmall proportion of fugar to be added, in order to keep the oil united with the water.

Caffia-water. E.

324 From a pound and a half of the caffia bark, ten pounds of water are directed to be drawn off in the fame manner as the dill-water.

This diftilled water, as we have already obferved, when properly prepared, approaches fo near to that of cinnamon, that it is almoft, if not altogether, impoffible to diftinguifh the difference between the two. And although the London college has given it no place in their pharmacopœia, yet we may venture to affert, that it is no ftranger to the fhops of the apothecaries. Nay, fo great is the difference of price, and the fenfible qualities fo nearly alike, that what is fold under the name of cinnamon-water is almoft entirely prepared from caffia alone; and not even prepared from the caffia bark, as directed by the Edinburgh college, but from the caffia buds, which may be had at a ftill cheaper rate, and which yield precifely the fame effential oil, although in lefs quantity. When caffia-water is prepared precifely according to the directions of the Edinburgh college, from containing a larger proportion of the fubject, it has in general a ftronger impregnation than their genuine cinnamon-water, and is probably in no degree inferior in its virtues.

Fennel-water. L.

325 Take of fweet fennel feeds, bruifed, one pound; water, fufficient to prevent an empyreuma. Draw off one gallon.

The water of fennel feeds is not unpleafant. A water has alfo been diftilled from the leaves. When thefe are employed, they fhould be taken before the plant has run into flower; for after this time they are much weaker and lefs agreeable. Some have obferved, that the upper leaves and tops, before the flowers appear, yield a more elegant water, and a remarkably finer effential oil than the lower ones; and that the oil obtained from the one fwims on water, while that of the other finks. No part of the herb, however, is equal in flavour to the feeds.

Peppermint-water.

326 Take of herb of peppermint, dried, one pound and an half; water, fufficient to prevent an empyreuma. Draw off one gallon. *L.*

From three pounds of the leaves of peppermint, ten pounds of water are to be drawn off. *E.*

This is a very elegant and ufeful water. It has a warm pungent tafte, exactly refembling that of the peppermint itfelf. A fpoonful or two taken at a time warm the ftomach, and give great relief in cold flatulent colics. Some have fubftituted a plain infufion of the dried leaves of the plant, which is not greatly different in virtue from the diftilled water.

In the diftillation of this water, a confiderable quantity of effential oil generally comes over in its pure ftate. And it is not uncommon to employ this for impregnating other water, with which it may be readily mixed by the aid of a little fugar.

Spearmint-water. L.

Take of fpearmint, dried, one pound and an half; water, fufficient to prevent an empyreuma. Draw off one gallon. 327

The Edinburgh college directs this water to be made in the fame proportion as the preceding. But probably three pounds of the freſh herb will not give a ftronger impregnation than a pound and a half of the dried: fo that the water of the London college may be confidered to be as ftrongly impregnated as that of the Edinburgh college.

This water fmells and tafles very ftrongly of the mint; and proves in many cafes an ufeful ftomachic. Boerhaave commends it (cohobated) as a pleafant and incomparable remedy for ftrengthening a weak ftomach, and curing vomiting proceeding from cold vifcous phlegm, and alfo in lienteries.

All-fpice water. L. E.

Take of all-fpice, bruifed, half a pound; water, fufficient to prevent an empyreuma. Macerate for 24 hours, and draw off one gallon. 328

From half a pound of the pimento the Edinburgh college directs ten pounds of water to be drawn off; fo that the impregnation is there fomewhat weaker than the above.

This diftilled water is a very elegant one, and has of late come pretty much into ufe; the hofpitals employ it as a fuccedaneum to the more coftly fpice-waters. It is, however, inferior in gratefulnefs to the fpirituous water of the fame fpice hereafter directed.

Pennyroyal-water. L. E.

Take of dried herb pennyroyal, one pound and an half; water, fufficient to prevent an empyreuma. Draw off one gallon. 329

The pennyroyal-water is directed to be prepared by the Edinburgh college in the fame proportions as the mint and peppermint. Whether prepared from the recent or dried plant, it poffeffes in a confiderable degree the fmell, tafte, and virtues, of the pennyroyal. It is not unfrequently employed in hyfterical cafes, and fometimes with a good effect.

Rofe-water. L. E.

Take of freſh petals of the damaſk rofe, the white heels being cut off, fix pounds; water, fufficient to prevent an empyreuma. Draw off one gallon. 330

From the fame quantity the Edinburgh college direct ten pounds to be drawn off.

This water is principally valued on account of its fine flavour, which approaches to that generally admired in the rofe itfelf. The purgative virtue of the rofes remains entire in the liquor left in the ftill, which has therefore been generally employed for making the folutive honey and fyrup, inftead of a decoction or infufion of freſh rofes prepared on purpofe; and this

piece

Preparations and Compositions.

piece of frugality the college have now admitted. A diſtilled water of red roſes has been ſometimes called for in the ſhops, and ſupplied by that of damaſk roſes diluted with common water. This is a very venial ſubſtitution; for the water drawn from the red roſe has no quality which that of the damaſk does not poſſeſs in a far ſuperior degree; neither the purgative virtue of the one nor the aſtringency of the other ariſing in diſtillation.

Lemon-peel-water. E.

331 From two pounds of recent lemon peel ten pounds of water are to be drawn off by diſtillation.

Orange-peel-water. E.

332 From two pounds of orange peel ten pounds of water are directed to be drawn off.

Neither of theſe diſtilled waters are now to be met with in the London pharmacopœia; and it is probable that no great loſs ariſes from the want of them, for both the one and the other contain only a very weak impregnation. They are chiefly employed as diluents in fevers and other diſorders where the ſtomach and palate are very apt to be diſguſted. And perhaps the only circumſtance for which they are valuable is the ſlightneſs of the impregnation; for in ſuch affections, any flavour, however agreeable at other times, often becomes highly diſguſtful to patients.

The diſtilled waters above noticed are the whole that have now a place in the pharmacopœias of the London and Edinburgh colleges; and perhaps this ſelection is ſufficiently large for anſwering every uſeful purpoſe. But beſides theſe, a conſiderable number of others are ſtill retained even in the modern foreign pharmacopœias; ſome of which at leaſt it may not be improper to mention.

Alexiterial water. Brun.

333 Take of elder flowers, moderately dried, three pounds; angelica leaves, freſh gathered, two pounds; ſpring water, forty pounds. Draw off, by diſtillation, thirty pounds.

This water is ſufficiently elegant with regard to taſte and ſmell; though few expect from it ſuch virtues as its title ſeems to imply. It is uſed occaſionally for vehicles of alexipharmac medicines, or in juleps to be drank after them, as coinciding in the intention; but in general is not ſuppoſed to be itſelf of any conſiderable efficacy.

Camphor-water. Brun.

334 Take of camphor, an ounce and an half. Let it be diſſolved in half an ounce of the ſpirit of roſemary, then pour on it two pounds of ſpring water, and draw off by diſtillation a pound and an half.

This diſtilled water, which has no place in our pharmacopœias, is introduced into ſome of the foreign ones. And ſince camphor may be conſidered as a concrete eſſential oil, it naturally occurs as a form under which that medicine may be introduced with advantage in a diluted ſtate.

Caſtor-water. Brun.

335 Take of Ruſſia caſtor, one ounce; water, as much as will prevent burning. Draw off two pints.

Caſtor yields almoſt all its flavour in diſtillation to water, but treated in the ſame manner with ſpirit of wine gives over nothing. The ſpirit of caſtor formerly kept in the ſhops had none of the ſmell or virtues of the drug; while the water here directed proves, when freſh drawn, very ſtrong of it. Preparations and Compoſitions

It is remarkable, that the virtues of this animal ſubſtance reſide in a volatile oil, analogous to the eſſential oils of vegetables. Some are reported to have obtained, in diſtilling large quantities of this drug, a ſmall portion of oil, which ſmelt extremely ſtrong of the caſtor, and diffuſed its ungrateful ſcent to a great diſtance.

This water is uſed in hyſteric caſes, and ſome nervous complaints, though it has not been found to anſwer what many people expect from it. It loſes greatly of its flavour in keeping.

And it is probably from this circumſtance that it has no place either in our pharmacopœias or in the modern foreign ones; but at the ſame time, as poſſeſſing in a high degree the ſenſible qualities of the caſtor, it may be conſidered as juſtly deſerving future attention.

Chervil-water. Gen.

Take of freſh leaves of chervil, one pound; ſpring water, as much as is ſufficient for allowing eight pounds to be drawn off by diſtillation, at the ſame time avoiding empyreuma. 336

Although the chervil be but little employed in Britain, yet among ſome of the foreigners it is held in high eſteem; and the diſtilled water is perhaps one of the moſt elegant forms under which its active parts can be introduced. But there is reaſon to believe that thoſe diuretic powers, for which it has been chiefly celebrated, will be moſt certainly obtained from exhibiting it in ſubſtance, or under the form of the expreſſed juice of the recent plant.

Black cherry-water. Suec.

Take of ripe black cherries bruiſed with the kernels, 20 pounds; pure water, as much as is ſufficient for avoiding empyreuma. Draw off 20 pounds by diſtillation. 337

This water, although now baniſhed from our pharmacopœias, has long maintained a place in the foreign ones, and even in Britain it is not unfrequently to be met with in the ſhops. It has often been employed by phyſicians as a vehicle, in preference to the other diſtilled waters; and among nurſes who have the care of young children has been the firſt remedy againſt the convulſive diſorders to which infants are ſo often ſubject.

This water has nevertheleſs of late been brought into diſrepute, and has been eſteemed poiſonous. They obſerve, that it receives its flavour principally from the cherry ſtones; and that theſe kernels, like many others, bear a reſemblance in taſte to the leaves of the lauro cerafus, which have been diſcovered to yield, by infuſion or diſtillation, the moſt ſudden poiſon known. Some phyſicians of Worceſter have lately found, by trial purpoſely made, that a diſtilled water very ſtrongly impregnated with the flavour of the cherry kernels (no more than two pints being diſtilled from fourteen pounds of the cherry ſtones) proved in like manner

Preparations and Compositions.

poiſonous to brutes. The London college repeated the ſame experiment, and found the effects agreeable to thoſe gentlemens report.

It by no means follows from theſe trials, nor after ſuch long experience can it be imagined, that black-cherry-water, when no ſtronger than the ſhops have been accuſtomed to prepare it, is unſafe. Theſe kernels plainly reſemble opium, and ſome other things, which poiſon only when taken in too great a quantity. The water from the very laurel leaves is harmleſs when duly diluted; and even ſpirit of wine proves a poiſon of its kind not greatly different, if drank to a certain degree of exceſs. Nor can it be concluded, from the trials with the ſtrong black-cherry water on dogs, &c. that even this will have the ſame effects in the human body; the kernels of many ſorts of fruits being in ſubſtance poiſonous to brutes, though innocent to man.

It is poſſible, however, that this water in any degree of ſtrength may not be altogether ſafe to the tender age of infants, where the principles of life are but juſt beginning as it were to move. It is poſſible that it may there have had pernicious effects without being ſuſpected; the ſymptoms it would produce, if it ſhould prove hurtful, being ſuch as children are often thrown into from the diſeaſe which it is imagined to relieve. On theſe conſiderations, both the London and Edinburgh colleges have choſen to lay it aſide; more eſpecially as it has been too often counterfeited with a water diſtilled from bitter almonds, which are known to communicate a poiſonous quality. It is, however, one of thoſe active articles which may perhaps be conſidered as deſerving farther attention.

Camomile-flower water. Dan.

338 Take of camomile flowers, dried in the ſhade, eight pounds; water, 72 pounds. Draw off by gentle diſtillation 48 pounds.

Camomile flowers were formerly ordered to be fermented previouſly to the diſtillation, a treatment which they do not need; for they give over, without any fermentation, as much as that proceſs is capable of enabling them to do. In either caſe the ſmell and peculiar flavour of the flowers ariſe without any of the bitterneſs, this remaining behind in the decoction; which, if duly depurated and inſpiſſated, yields an extract ſimilar to that prepared from the flowers in the common manner. The diſtilled water has been uſed in flatulent colics and the like, but is at preſent held in no great eſteem.

Strawberry-water. Succ.

339 From 20 pounds of ſtrawberries 20 pounds of diſtilled water are drawn off, according to the ſame directions given for the preparation of the black cherry water.

Water thus impregnated with the eſſential oil of the ſtrawberries ſome people will think of a very agreeable flavour, but any conſiderable medical power is not to be expected from it.

Hyſſop-water. Succ.

340 From four pounds of the freſh leaves of hyſſop ſix pounds of water are drawn off.

Hyſſop-water has been held by ſome in conſiderable eſteem as an uterine and pectoral medicine. It was directed in a former edition of the Edinburgh pharmacopœia for making up the black pectoral troches, but is now exchanged for common water. Few at preſent expect any ſingular virtues from it, nor is it often to be met with in our ſhops, being now expunged from our pharmacopœias. It holds a place, however, in moſt of the foreign ones, and among ourſelves there are ſtill ſome practitioners who frequently employ it. But there can be no doubt that thoſe medical properties which the hyſſop contains may be more readily and effectually extracted by ſimple infuſion.

White-lily water. Brun.
Lily-of-the-valley water. Brun.

341 To any quantity of theſe flowers four times their weight of water is to be added, and water drawn off by diſtillation in the proportion of two pounds to each pound of the flowers.

Theſe waters muſt obtain ſome impregnation of that elegant eſſential oil on which the odour of flowers in their growing ſtate depends. But they do not poſſeſs any remarkable medical properties.

Balm-water. Brun.

342 The green leaves of the balm are to be macerated with double their weight of water; and from each pound of the plant a pound and an half of water is to be drawn off.

This water contains a conſiderable impregnation from the balm, which yields its eſſential oil pretty freely on diſtillation. Though now baniſhed from our pharmacopœias, it has ſtill a place in moſt of the foreign ones. In the old editions of the Edinburgh pharmacopœia, this water was ordered to be cohobated or rediſtilled from freſh quantities of the herb. This management ſeems to have been taken from Boerhaave, who has a very high opinion of the water thus prepared: he ſays, he has experienced in himſelf extraordinary effects from it taken on an empty ſtomach; that it has ſcarce its equal in hypochondriacal and hyſterical caſes, the chlorоſis, and palpitation of the heart, as often as thoſe diſeaſes proceed from a diſorder of the ſpirits, rather than from any collection of morbific matter.

But whatever virtues are lodged in balm, they may be much more perfectly and advantageouſly extracted by cold infuſion in aqueous or ſpirituous menſtrua: in this laſt proceſs, the liquor ſuffers no injury from being returned on freſh parcels of the herb; a few repetitions will load it with the virtues of the ſubject, and render it very rich. The impregnation here is almoſt unlimited; but in diſtilled waters it is far otherwiſe.

Rue water. Roſſ.

343 From each pound of rue, with a ſufficient quantity of ſpring-water to prevent empyreuma, two pounds of diſtilled water are to be drawn.

Rue gives over in this proceſs the whole of its ſmell, and great part of its pungency. The diſtilled water ſtands recommended in epileptic caſes, the hyſteric paſſion, for promoting perſpiration, and other natural ſecretions. But though it is a good deal employed abroad, it is with us falling into diſrepute.

Preparations and Compositions.

Savin-water.

This is distilled from the fresh leaves of savin, after the same manner as the other already mentioned.

344 This water is by some held in considerable esteem for the same purposes as the distilled oil of savin. Boerhaave relates, that he has found it (when prepared by cohobation) to give an almost incredible motion to the whole nervous system; and that, when properly used, it proves eminently serviceable for promoting the menses and the hæmorrhoidal flux.

It has now, however, fallen so much into disrepute as to have no place either in our pharmacopœias or in the best modern foreign ones: But at the same time, when we reflect how readily savin yields a large proportion of active essential oil on distillation, it may perhaps be considered as better intitled to attention than some other distilled waters which are still retained.

Elder-flower water. Brun.

345 This is distilled from fresh elder flowers, after the same manner as the white-lily water.

This water smells considerably of the flowers; but is rarely used among us.

Sage-water. Brun.

346 This is directed to be prepared from the green leaves of the sage in the same manner as the balm water.

Sage leaves contain a considerable proportion of essential oil, which they yield pretty freely on distillation. But their whole medical properties may with still greater ease and advantage be extracted by simple infusion.

To the simple distilled waters the London college have annexed the following remarks.

We have ordered the waters to be distilled from the dried herbs, because fresh are not ready at all times of the year. Whenever the fresh are used, the weights are to be increased. But, whether the fresh or dried herbs be employed, the operator may vary the weight according to the season in which they have been produced and collected.

Herbs and seeds kept beyond the space of a year are less proper for the distillation of waters.

To every gallon of these waters add five ounces, by measure, of proof-spirit.

Chap. XVIII. *Distilled Spirits.*

347 The flavours and virtues of distilled waters are owing, as was observed in the preceding chapter, to their being impregnated with a portion of the essential oil of the subject from which they are drawn. Spirit of wine, considered as a vehicle for these oils, has this advantage above water, that it is their proper menstruum, and keeps all the oil that rises with it perfectly dissolved into an uniform limpid liquor.

Nevertheless, many substances, which, on being distilled with water, impart to it their virtues in great perfection; if treated in the same manner with spirit of wine, scarcely give it any smell or taste. This difference proceeds from hence, that spirit is not susceptible of so great a degree of heat as water. Liquids in general, when made to boil, have received as great a heat as they are capable of sustaining: now, if the extent of heat between freezing and boiling water, as measured by thermometers, be taken for a standard, spirit of wine will be found to boil with less than four-fifths of that heat, or above one-fifth less than the heat of boiling water. It is obvious, therefore, that substances may be volatile enough to rise with the heat of boiling water, but not with that of boiling spirit.

Preparations and Compositions.

Thus, if cinnamon, for instance, be committed to distillation with a mixture of spirit of wine and water, or with a pure proof-spirit, which is no other than a mixture of about equal parts of the two; the spirit will rise first, clear, colourless, and transparent, and almost without any taste of the spice; but as soon as the more ponderous watery fluid begins to rise, the oil comes over freely with it, so as to render the liquor highly odorous, sapid, and of a milky hue.

The proof-spirits usually met with in the shops are accompanied with a degree of ill flavour; which, though concealed by means of certain additions, plainly discovers itself in distillation. This nauseous relish does not begin to rise till after the purer spirituous part has come over; which is the very time that the virtues of the ingredients begin also most plentifully to distil: and hence the liquor receives an ungrateful taint. To this cause principally is owing the general complaint, that the cordials of the apothecary are less agreeable than those of the same kind prepared by the distiller; the latter being extremely curious in rectifying or purifying the spirits (when designed for what he calls fine goods) from all ill flavour.

Ardent spirit. L.

Take of rectified spirit of wine, one gallon; kali, made hot, one pound and an half; pure kali, one ounce. Mix the spirit of wine with the pure kali, and afterwards add one pound of the hot kali; shake them, and digest for twenty-four hours. Pour off the spirit, to which add the rest of the kali, and distil in a water bath. It is to be kept in a vessel well stopped. The specific gravity of the alcohol is to that of distilled water as 815 to 1000. 348.

We have already offered some observations on spirit of wine both in the state of what is called *rectified* and *proof-spirit*. But in the present formula we have ardent spirit still more freed from an admixture of water than even the former of these. And in this state it is unquestionably best fitted for answering some purposes. It may therefore be justly considered as an omission in the present edition of the Edinburgh pharmacopœia, that they have no analogous form. In former editions of this work, alcohol was directed to be prepared from French brandy. But this is rather too dear an article in this country for distillation; nor is the spirit obtained from it anywise preferable to one procurable from cheaper liquors. The coarser inflammable spirits may be rendered perfectly pure, and fit for the nicest purposes, by the following method.

If the spirit be exceedingly foul, mix it with about an equal quantity of water, and distil with a slow fire; discontinuing the operation as soon as the liquor begins to run milky, and discovers by its nauseous taste that the impure and phlegmatic part is rising. By this

Preparations and Compositions.

treatment, the ſpirit leaves a conſiderable portion of its foul oily matter behind it in the water, which now appears milky and turbid, and proves highly diſagreeable to the taſte. If the ſpirit be not very foul at firſt, this ablution is not neceſſary; if extremely ſo, it will be needful to repeat it once, twice, or oftener.

As vinous ſpirits ariſe with a leſs degree of fire than watery liquors, we are hence directed to employ, in the diſtillation of them, a heat leſs than that in which water boils; and if due regard be had to this circumſtance, very weak ſpirits may, by one or two wary diſtillations, be tolerably well freed from their aqueous phlegm; eſpecially if the diſtilling veſſels are of ſuch a height, that the ſpirit, by the heat of a water-bath, may but juſt paſs over them: in this caſe, the phlegmatic vapours which riſe for a little way along with the ſpirit, will condenſe and fall back again before they can come to the head. Very pompous inſtruments have been contrived for this purpoſe, and carried in a ſpiral or ſerpentine form to an extraordinary height. The ſpirit aſcending through theſe, was to leave all the watery parts it contained in its paſſage, and come over perfectly pure and free from phlegm. But theſe inſtruments are built upon erroneous principles, their extravagant height defeating the end it was deſigned to anſwer: if the liquor be made to boil, a conſiderable quantity of mere phlegm will come over along with the ſpirit; and if the heat be not raiſed to this pitch, neither phlegm nor ſpirit will diſtil. The moſt convenient inſtrument is the common ſtill; between the body of which and its head an adopter or copper tube may be fixed.

The ſpirit being waſhed, as above directed, from its foul oil, and freed from the greateſt part of the phlegm by gentle diſtillation in a water-bath, add to every gallon of it a pound or two of pure dry fixed alkaline ſalt. Upon digeſting theſe together for a little time, the alkali, from its known property of attracting water and oils, will imbibe the remaining phlegm, and ſuch part of the diſagreeable unctuous matter as may ſtill be left in the ſpirit, and will ſink with them to the bottom of the veſſel. If the ſpirit be now again gently drawn over, it will riſe entirely free from its phlegm and nauſeous flavour; but ſome particles of the alkaline ſalt are apt to be carried up with it, and give what the workmen call an *urinous reliſh*: this may be prevented by adding, previous to the laſt diſtillation, a ſmall proportion of calcined vitriol, alum, or bitter cathartic ſalt; the acids of theſe ſalts will unite with and neutralize the alkali, and effectually prevent it from riſing; while no more of the acid of the ſalts is extricated than what the alkali abſorbs.

The ſpirit obtained by this means is extremely pure, limpid, perfectly flavourleſs, and fit for the fineſt purpoſes. It may be reduced to the ſtrength commonly underſtood by proof, by mixing twenty ounces of it with ſeventeen ounces of water. The diſtilled cordials made with theſe ſpirits prove much more elegant and agreeable, than when the common rectified or proof-ſpirits of the ſhops are uſed.

If the rectified ſpirit be diſtilled afreſh from dry alkaline ſalt with a quick fire, it brings over a conſiderable quantity of the ſalt; and in this ſtate it is ſuppoſed to be a more powerful menſtruum for certain ſubſtances than the pure ſpirit. This alkalized ſpirit is called *tartarized ſpirit of wine*.

Preparations and Compoſitions.

The proceſs here deſcribed, which was long ſince recommended by Dr Lewis, will ſufficiently explain the intention of the London college, in the directions they have now given for the preparation of alcohol. And there can be no doubt, that by their proceſs a very pure alcohol may be obtained. Of this we have a ſufficient teſt in the ſpecific gravity of the fluid which comes over, which is to that of diſtilled water only as 815 to 1000, while the ſpecific gravity of proper rectified ſpirit is as 835 to 1000.

Spirit of vitriolic æther. L.

Take of rectified ſpirit of wine, vitriolic acid, each one pound. Pour by a little at a time the acid on the ſpirit, and mix them by ſhaking; then from a retort through a tubulated receiver, to which another recipient is fitted, diſtil the ſpirit of vitriolic æther till ſulphureous vapours begin to riſe. 342

Vinous vitriolic acid, commonly called *dulcified ſpirit of vitriol.* E.

Take of vitriolic ethereal liquor, one part; rectified ſpirit of wine, two parts. Mix them.

The laſt of theſe proceſſes is a very ready and convenient method of preparing the dulcified ſpirit of vitriol, which only differs from æther by the acid being more predominant, and leſs intimately combined.

In the firſt proceſs, a good deal of caution is requiſite in mixing the two liquors. Some direct the ſpirit of wine to be put firſt into the retort, and the oil of vitriol to be poured upon it all at once; a method of procedure by no means adviſable, as a violent heat and ebullition always enſue, which not only diſſipate a part of the mixture, but hazard alſo the breaking of the veſſel, to the great danger of the operator. Others put the oil of vitriol into the retort firſt: then by means of a funnel, with a long pipe that may reach down juſt to the ſurface of the acid, pour in the ſpirit of wine; if this be done with ſufficient caution, the vinous ſpirit ſpreads itſelf on the ſurface of the oil of vitriol, and the two liquors appear diſtinct. On ſtanding for a week or two, the vinous ſpirit is gradually imbibed, without any commotion, and the veſſel may then be ſafely ſhaken to complete the mixture: but if the ſpirit be poured in too haſtily at firſt, or if the veſſel be moved before the two liquors have in ſome degree incorporated, the ſame effect enſues as in the foregoing caſe. The only ſecure way is, to add the oil of vitriol to the ſpirit of wine by a little quantity at a time, waiting till the firſt addition be incorporated before another quantity is put in: by this management, the heat that enſues is inconſiderable, and the mixture is effected without any inconvenience.

The diſtillation ſhould be performed with an equable and very gentle heat, and not continued ſo long as till a black froth begins to appear: for before this time a liquor will ariſe of a very different nature from the ſpirits here intended. The ſeveral products are moſt commodiouſly kept apart by uſing a tubulated receiver, ſo placed, that its pipe may convey the matter which ſhall come over into a vial ſet underneath. The juncture of the retort and recipient is to be luted with a

Preparations and Compositions.

paſte made of lintſeed meal, and further ſecured by a piece of wet bladder; the lower juncture may be cloſed only with ſome ſoft wax, that the vial may be occaſionally removed with eaſe.

The true dulcified ſpirit ariſes in thin ſubtile vapours, which condenſe on the ſides of the recipient in ſtraight ſtriæ. It is colourleſs as water, very volatile, inflammable, of an extremely fragrant ſmell, in taſte ſomewhat aromatic.

After the fire has been kept up for ſome time, white fumes ariſe; which either form irregular ſtriæ, or are collected into large round drops like oil: On the firſt appearance of theſe, the vial, or the receiver, if a common one is uſed, muſt be taken away. If another be ſubſtituted, and the diſtillation continued, an acid liquor comes over, of an exceeding pungent ſmell, like the fumes of burning brimſtone. At length a black froth begins haſtily to ariſe, and prevents carrying the proceſs further.

On the ſurface of the ſulphureous ſpirit is found ſwimming a ſmall quantity of oil, of a light yellow colour, a ſtrong, penetrating, and very agreeable ſmell. This oil ſeems to be nearly of the ſame nature with the eſſential oils of vegetables. It readily and totally diſſolves in rectified ſpirit of wine, and communicates to a large quantity of that menſtruum the taſte and ſmell of the aromatic or dulcified ſpirit.

The matter remaining after the diſtillation is of a dark blackiſh colour, and ſtill highly acid. Treated with freſh ſpirit of wine, in the ſame manner as before, it yields the ſame production; till at length all the acid that remains unvolatilized being ſaturated with the inflammable oily matter of the ſpirit, the compound proves a bituminous ſulphureous maſs; which, expoſed to the fire in open veſſels, readily burns, leaving a conſiderable quantity of fixed aſhes; but in cloſe ones it explodes with violence; with fixed alkaline ſalts it forms a compound nearly ſimilar to one compoſed of alkalis and ſulphur.

The new names adopted by the London and Edinburgh colleges for this fluid, are expreſſive of its compoſition; the one employing the term of *ſpiritus ætheris vitriolici*, the other of *acidum vitriolicum vinoſum*: the old term of *ſpiritus vitrioli dulcis* is leſs properly fitted to diſtinguiſh it from other fluids, and to convey a juſt idea of its nature.

Dulcified ſpirit of vitriol has been for ſome time greatly eſteemed, both as a menſtruum and a medicine. It diſſolves ſome reſinous and bituminous ſubſtances more readily than ſpirit of wine alone, and extracts elegant tinctures from ſundry vegetables. As a medicine, it promotes perſpiration and the urinary ſecretion, expels flatulencies, and in many caſes abates ſpaſmodic ſtrictures, eaſes pains, and procures ſleep. The doſe is from ten to eighty or ninety drops in any convenient vehicle. It is not eſſentially different from the celebrated anodyne liquor of Hoffman; to which it is, by the author himſelf, not unfrequently directed as a ſuccedaneum.

Of this fluid, however, or at leaſt of an article ſtill more nearly reſembling it, we ſhall afterwards have occaſion to ſpeak, when we treat of the vinous ſpirit of vitriolic æther.

Vitriolic æther. L.

350 Take of the ſpirit of vitriolic ether, two pounds; water of pure kali, one ounce. Shake them together, and diſtil, with a gentle heat, fourteen ounces by meaſure.

Preparations and Compositions.

Vitriolic ethereal liquor. E.

Take of rectified ſpirit of wine, vitriolic acid, each thirty two ounces. Pour the ſpirit into a glaſs retort fit for ſuſtaining a ſudden heat, and add to it the acid in an uniform ſtream. Mix them by degrees, frequently ſhaking them moderately; this done, inſtantly diſtil from ſand previouſly heated for that purpoſe, into a receiver kept cool with water or ſnow. But the heat is to be ſo managed, that the liquor ſhall boil at firſt, and continue to boil till 16 ounces are drawn off; then let the retort be raiſed out of the ſand

To the diſtilled liquor add two drams of the common bitter cauſtic; then diſtil again in a very high retort with a very gentle heat, into a cool receiver, until ten ounces have been drawn off.

If ſixteen ounces of rectified ſpirit of wine be poured upon the acid remaining in the retort after the firſt diſtillation, an ethereal liquor may be obtained by repeating the diſtillation. This may be done pretty often.

The preparation of this ſingular fluid, now received into public pharmacopœias, was formerly confined to a few hands; for though ſeveral proceſſes have been publiſhed for obtaining it, the ſucceſs of moſt of them is precarious, and ſome of them are accompanied alſo with danger to the operator. The principal difficulty conſiſts in the firſt part of the diſtillation.

It has been uſual to direct the heat to be kept up till a black froth begins to appear: but if it is managed in the manner here directed, the quantity of æther which the liquor can afford will be formed and drawn off before this ſulphureous froth appears. The uſe of the cauſtic alkali is to engage any uncombined vitriolic acid which may be preſent in the firſt diſtilled liquor. If a mild alkali were employed for this purpoſe, the ſeparation of its air by the acid might endanger the burſting of the veſſels. This laſt is indeed an inconvenience which attends the whole of this proceſs. It might in a great meaſure be obviated by employing a range of receivers ſuch as the alopter deſcribed in the firſt part of this work.

The æther, or ethereal ſpirit, is the lighteſt, moſt volatile and inflammable of all known liquids. It is lighter than the moſt highly rectified ſpirit of wine, in the proportion of about 7 to 8: a drop, let fall on the hand, evaporates almoſt in an inſtant, ſcarcely rendering the part moiſt. It does not mix, or only in a ſmall quantity, with water, ſpirit of wine, alkaline lixivia, volatile alkaline ſpirits, or acids; but is a powerful diſſolvent for oils, balſams, reſins, and other analogous ſubſtances: it is the only known ſubſtance capable of diſſolving the elaſtic gum; it has a fragrant odour, which, in conſequence of the volatility of the fluid, is diffuſed through a large ſpace. It has often been found to give eaſe in violent headachs, by being applied externally to the part; and to relieve the toothach, by being laid on the afflicted jaw. It has been given alſo internally, with benefit, in hooping coughs, hyſterical caſes, in aſthma, and indeed in almoſt every ſpaſmodic affection, from a few drops to the

Preparations and Compositions.

the quantity of half an ounce, in a glaſs of wine or water; which ſhould be ſwallowed as quickly as poſſible, as the æther ſo ſpeedily exhales.

Spirit of nitrous æther. L.

351 Take of rectified ſpirit of wine, two pints; nitrous acid, half a pound. Mix them, by pouring in the acid on the ſpirit, and diſtil with a gentle heat one pound ten ounces.

Vinous acid of nitre, commonly called *dulcified ſpirit of nitre.* E.

Take of rectified ſpirit of wine, three pounds: nitrous acid, one pound. Pour the ſpirit into a capacious phial, placed in a veſſel full of cold water, and add the acid by degrees, conſtantly agitating them. Let the phial be ſlightly covered, and laid by for ſeven days in a cool place; then diſtil the liquor with the heat of boiling water, into a receiver kept cool with water or ſnow, till no more ſpirit comes over.

By allowing the acid and rectified ſpirit to ſtand for ſome time, the union of the two is not only more complete, but the danger alſo of the veſſels giving way to the ebullition and heat conſequent on their being mixed, is in a great meaſure prevented. By fixing the degree of heat to the boiling point, the ſuperabundant acid matter is left in the retort, being too ponderous to be raiſed by that degree of heat

Here the operator muſt take care not to invert the order of mixing the two liquors, by pouring the vinous ſpirit into the acid; for if he ſhould, a violent effervescence and heat would enſue, and the matter be diſperſed in highly noxious red fumes. The moſt convenient and ſafe method of performing the mixture ſeems to be, to put the inflammable ſpirit into a large glaſs bottle with a narrow mouth, placed under a chimney, and to pour into it the acid, by means of a glaſs funnel, in very ſmall quantities at a time; ſhaking the veſſel as ſoon as the effervescence enſuing upon each addition ceaſes, before a freſh quantity is put in: by this means the glaſs will be heated equally, and be prevented from breaking. During the action of the two ſpirits upon each other, the veſſel ſhould be lightly covered: if cloſe ſtopped, it will burſt; and if left entirely open, ſome of the more valuable parts will exhale. Lemery directs the mixture to be made in an open veſſel; by which unſcientifical procedure, he uſually loſt, as he himſelf obſerves, half his liquor; and we may preſume, that the remainder was not the medicine here intended.

Several methods have been contrived for obviating the inconveniences ariſing from the elaſtic fluid and violent exploſions produced on the mixture of the nitrous acid and rectified ſpirit of wine: for preparing the nitrous æther they are abſolutely neceſſary, and might perhaps be conveniently uſed for making the dulcified ſpirit. The method we judge to be the beſt, is that employed by Dr Black. On two ounces of the ſtrong acid put into a phial, the doctor pours, ſlowly and gradually, about an equal quantity of water; which, by being made to trickle down the ſides of the phial, floats on the ſurface of the acid without mixing with it: he then adds, in the ſame cautious manner, three ounces of highly rectified ſpirit of wine, which in its turn floats on the ſurface of the water. By this means the three fluids are kept ſeparate on account of their different ſpecific gravities, and a ſtratum of water is interpoſed between the acid and ſpirit. The phial is now ſet in a cool place: the acid gradually aſcends, and the ſpirit deſcends through the water, this laſt acting as a boundary to reſtrain their violent action on each other. By this method a quantity of nitrous æther is formed, without the danger of producing elaſtic vapours or exploſion.

For the preparation of the dulcified ſpirit, the liquors, when mixed together, ſhould be ſuffered to reſt for ſome time, as above directed, that the fumes may entirely ſubſide, and the union be in ſome meaſure completed. The diſtillation ſhould be performed with a very ſlow and well regulated fire; otherwiſe the vapour will expand with ſo much force as to burſt the veſſels. Wilſon ſeems to have experienced the juſtneſs of this obſervation, and hence directs the juncture of the retort and receiver not to be luted, or but ſlightly: if a tubulated recipient, with a ſufficiently long pipe, be uſed, and the diſtillation performed with the heat of a water-bath, the veſſels may be luted without any danger: this method has likewiſe another advantage, as it aſcertains the time when the operation is finiſhed: examining the diſtilled ſpirit every now and then with alkaline ſalts, as directed above, is ſufficiently troubleſome; while in a water-bath we may ſafely draw over all that will riſe; for this heat will elevate no more of the acid than what is dulcified by the vinous ſpirit.

Dulcified ſpirit of nitre has been long held, and not undeſervedly, in great eſteem. It quenches thirſt, promotes the natural ſecretions, expels flatulencies, and moderately ſtrengthens the ſtomach: it may be given from 20 drops to a dram, in any convenient vehicle. Mixed with a ſmall quantity of ſpirit of hartſhorn, the volatile aromatic ſpirit, or any other alkaline ſpirit, it proves a mild, yet efficacious, diaphoretic, and often remarkably diuretic; eſpecially in ſome febrile caſes, where ſuch a ſalutary evacuation is wanted. A ſmall proportion of this ſpirit added to malt ſpirits, gives them a flavour approaching to that of French brandy.

Spirit of ammonia. L.

352 Take of proof-ſpirit, three pints; ſal ammoniac, four ounces: pot-aſh, ſix ounces. Mix and diſtil with a ſlow fire one pint and an half.

Vinous ſpirit of ſal ammoniac. E.

Take of quicklime, 16 ounces; ſal ammoniac, eight ounces; rectified ſpirit of wine, 32 ounces. Having ſlightly bruiſed and mixed the quicklime and ammoniacal ſalt, put them into a glaſs retort; then add the ſpirit, and diſtil in the manner directed for the volatile cauſtic alkali, till all the ſpirit has paſſed over.

This ſpirit has lately come much into eſteem, both as a medicine and a menſtruum. It is a ſolution of volatile ſalt in rectified ſpirit of wine; for though proof-ſpirit be uſed, its phlegmatic part does not riſe in the diſtillation, and ſerves only to facilitate the action of the pure ſpirit upon the ammoniacal ſalt.

Rectified

Rectified ſpirit of wine does not diſſolve volatile alkaline ſalts by ſimple mixture: on the contrary, it precipitates them, as has been already obſerved, when they are previouſly diſſolved in water: but by the preſent proceſs, a conſiderable proportion of the volatile alkali is combined with the ſpirit. It might perhaps, for ſome purpoſes, be more adviſable to uſe with this intention the volatile ſpirit made with quicklime; for this may be mixed at once with rectified ſpirit of wine, in any proportion, without the leaſt danger of any ſeparation of the volatile alkali.

The name here employed by the London college, particularly when put in contradiſtinction to the water of ammonia, conveys a clear idea of the article, and is, we think, preferable to that employed by the Edinburgh college.

As a menſtruum, the ſpirit of ammonia is employed to diſſolve eſſential oils, thus forming the volatile aromatic ſpirit, or *compound ſpirit of ammonia*, as it is now called by the London college, which again is employed in making the tinctures of guaiac, valerian, &c.

The chief medical virtues which the ſpirit of ammonia poſſeſſes, when exhibited by itſelf, are thoſe of the volatile alkali.

Fetid ſpirit of ammonia.

353 Take of proof-ſpirit, ſix pints; ſal ammoniac, one pound; aſafœtida, four ounces; pot-aſh, one pound and a half. Mix them, and draw off by diſtillation five pints, with a ſlow fire. *L.*

Take of vinous ſpirit of ſal ammoniac, eight ounces; aſafœtida, half an ounce. Digeſt in a cloſe veſſel 12 hours; then diſtil off with the heat of boiling water eight ounces. *E.*

This ſpirit, the laſt formula of which is in our opinion the beſt, as being moſt eaſily prepared without any riſk of being injured in the preparation, is deſigned as an antihyſteric, and is undoubtedly a very elegant one. Volatile ſpirits, impregnated for theſe purpoſes with different fetids, have been uſually kept in the ſhops; the ingredient here made choice of, is the beſt calculated of any for general uſe, and equivalent in virtue to them all. The ſpirit is pale when newly diſtilled, but acquires a conſiderable tinge in keeping.

Compound ſpirit of aniſeed. L.

354 Take aniſeed, angelica-ſeed, of each, bruiſed, half a pound; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon by diſtillation.

This compound ſpirit is now directed to be prepared by the London college in the ſame manner as in their former edition. It has no place in the Edinburgh pharmacopœia; but it may juſtly be conſidered as a very elegant aniſeed water. The angelica ſeeds greatly improve the flavour of the aniſe. It is often employed with advantage, particularly in caſes of flatulent cholic; but it has been alleged to be ſometimes too frequently uſed with this intention as a domeſtic medicine, eſpecially by old ladies: for unleſs it be prudently and cautiouſly employed, it may ſoon be attended with all the pernicious conſequences of dram-drinking.

Spirit of caraway. L.

Take of caraway ſeeds, bruiſed, half a pound; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon. 355

Spirituous caraway-water. E.

Take of caraway-ſeeds, half a pound; proof-ſpirit, nine pounds. Macerate two days in a cloſe veſſel; then pour on as much water as will prevent an empyreuma, and draw off by diſtillation nine pounds.

By this proceſs the ſpirit obtains in great perfection the flavour of the caraway-ſeeds; and with ſome it is a cordial not uncommonly in uſe.

Spirit of cinnamon. L.

Take of bruiſed cinnamon one pound; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon. 356

Spirituous cinnamon-water. E.

From one pound of cinnamon, nine pounds of ſpirit are to be drawn off, in the ſame manner as in the caraway ſpirit.

This is a very agreeable and uſeful cordial, but not ſo ſtrong of the cinnamon as might be expected; for very little of the virtues of the ſpice ariſes till after the pure ſpirituous part has diſtilled. Hence, in the former editions of the London pharmacopœia, the diſtillation was ordered to be protracted till two pints more than here directed were come over. By this means, the whole virtue of the cinnamon was more frugally than judiciouſly obtained; for the diſagreeable flavour of the feints of proof ſpirits, and the acidulous liquor ariſing from cinnamon as well as other vegetables when their diſtillation is long continued, give an ill reliſh to the whole; at the ſame time that the oil which was extracted from the ſpice was by this acid thrown down.

In the Pharmacopœia Reformata, it is propoſed to make this ſpirit by mixing the ſimple cinnamon water with ſomewhat leſs than an equal quantity of rectified ſpirit: on ſhaking them together, the liquor loſes its milky hue, ſoon becomes clear, and more elegant than the water diſtilled as above: it is equally ſtrong of the cinnamon, and free from the nauſeous taint with which the common proof-ſpirits are impregnated.

Compound ſpirit of juniper. L.

Take of juniper-berries, bruiſed, one pound; caraway-ſeeds, bruiſed, ſweet-fennel ſeeds, of each one ounce and an half; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon. 357

Compound juniper-water. E.

Take of juniper-berries, well bruiſed, one pound; ſeeds of caraway, ſweet-fennel, each one ounce and a half; proof-ſpirit, nine pounds; macerate two days; and having added as much water as will prevent an empyreuma, draw off by diſtillation nine pounds.

This water, mixed with about an equal quantity of the rob of juniper-berries, proves an uſeful medicine

cine in catarrhs, debility of the ſtomach and inteſtines, and ſcarcity of urine. The water by itſelf is a good cordial and carminative: the ſervice which this and other ſpirituous water do with theſe intentions is commonly known; though the ill conſequences that follow from their conſtant uſe are too little regarded.

Spirit of lavender. L.

Take of freſh flowers of lavender, one pound and a half; proof-ſpirit, one gallon. Draw off by diſtillation in a water-bath, five pints.

Simple ſpirit of lavender. E.

Take of flowering ſpikes of lavender, freſh gathered, two pounds; rectified ſpirit of wine, eight pounds. Draw off by the heat of boiling water ſeven pounds.

This ſpirit, when made in perfection, is very grateful and fragrant: It is frequently rubbed on the temples, &c. under the notion of refreſhing and comforting the nerves; and it probably operates as a powerful ſtimulus to their ſenſible extremities: it is likewiſe taken internally, to the quantity of a teaſpoonful, as a warm cordial.

Spirit of peppermint. L.

Take of the herb peppermint, dried, one pound and an half; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon.

Spirituous peppermint-water. E.

From a pound and a half of theſe leaves nine pounds of ſpirit are drawn off, as from the caraway-ſeeds.

This ſpirit receives a ſtrong impregnation from the peppermint. It is employed in flatulent colics and ſimilar diſorders; and in theſe it ſometimes gives immediate relief: but where it is indicated, there are few caſes in which the peppermint-water is not preferable.

Spirit of ſpearmint. L.

Take of ſpearmint, dried, one pound and an half; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon.

This ſpirit has no place in the Edinburgh pharmacopœia. It, however, turns out a very elegant one, and preferable, in weakneſs of the ſtomach, retching to vomit, and the like, to many more elaborate preparations. Where the diſorder is not accompanied with heat or inflammation, half an ounce of this water may be given diluted with ſome agreeable aqueous liquor: but, as was already obſerved with regard to the preceding article, there are many caſes in which the prudent practitioner will be diſpoſed to give the preference to the ſimple diſtilled water.

Spirit of nutmeg. L.

Take of bruiſed nutmegs, two ounces; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon.

Spirituous nutmeg-water. E.

By two ounces of the nutmeg, well bruiſed, nine pounds of ſpirit are impregnated.

This is an agreeable ſpirituous liquor, highly impregnated with the nutmeg flavour. It was formerly celebrated in nephritic diſorders, and when combined with a few hawthorn flowers, it had even the title of *nephritic water*. At preſent it is employed only as a cordial liquor, and is not even very frequently in uſe. Preparations and Compoſitions.

Spirit of pimento, or *all-ſpice.* L.

Take of all-ſpice, bruiſed, two ounces; proof-ſpirit, one gallon; water, ſufficient to prevent an empyreuma. Draw off one gallon. 362

Spirituous Jamaica-pepper water. E.

By half a pound of pimento nine pounds of ſpirit are to be impregnated.

This water is far more agreeable than a ſimple water drawn from the ſame ſpice; and had long a place among the cordials of the diſtiller before it was received into any public pharmacopœia: but although now adopted both by the London and Edinburgh colleges, it is not very frequently ordered from the ſhops of the apothecary.

Spirit of pennyroyal. L.

Take of the herb pennyroyal, dried, one pound and an half; proof-ſpirit, one gallon; water ſufficient to prevent an empyreuma. Draw off one gallon. 363

This ſpirit has no place in the Edinburgh pharmacopœia. It poſſeſſes, however, a conſiderable ſhare of the flavour of the pennyroyal, and very frequently it is employed as a carminative and antihyſteric.

Compound ſpirit of horſe-radiſh. L.

Take of freſh horſe-radiſh root, dried outer-rind of Seville oranges, each two pounds; freſh herb of garden ſcurvy-graſs, four pounds; bruiſed nutmegs, one ounce; proof-ſpirit, two gallons; water, ſufficient to prevent an empyreuma. Draw off two gallons. 364

This ſpirit has long been conſidered as an elegant one, and is perhaps as well adapted for the purpoſes of an antiſcorbutic as any thing that can be contrived in this form. It has been alleged, that the horſe-radiſh and ſcurvy-graſs join very well together, giving a ſimilar flavour, though not a little diſagreeable; that the nutmeg ſuppreſſes this flavour very ſucceſsfully, without ſuperadding any of its own; and that to this, orange-peel adds a flavour very agreeable. Arum root had formerly a place in this water, but is here deſervedly thrown out; for it gives nothing of its pungency over the helm, notwithſtanding what is aſſerted by ſome pharmaceutical writers to the contrary. Muſtard-ſeed, though not hitherto employed in theſe kinds of compoſitions, would ſeem to be an excellent ingredient; it gives over the whole of its pungency, and is likewiſe leſs periſhable than moſt of the other ſubſtances of this claſs: this ſeed wants no addition, excepting ſome aromatic material to furniſh an agreeable flavour.

But although this proceſs may furniſh an agreeable compound ſpirit, yet it is much to be doubted, whether it poſſeſs thoſe antiſcorbutic powers for which it was once celebrated. And with this intention the Edinburgh college place ſo little confidence in it, that they have now rejected it from their pharmacopœia.

Spirit

Preparations and Compositions.

Spirit of roſemary.

Take of freſh tops of roſemary, one pound and a half; proof-ſpirit, one gallon. Diſtil in a water-bath, five pints. *L.*

365 Take of flowering tops of roſemary, freſh gathered, two pounds; rectified ſpirit of wine, eight pounds. Diſtil in the heat of boiling water till ſeven pounds come over. *E.*

A ſpirit ſimilar to this is generally brought to us from abroad, under the name of *Hungary-water*.

This ſpirit is very fragrant, ſo as to be in common uſe as a perfume: that brought from abroad is ſuperior in fragrance to ſuch as is generally made among us. In order to prepare it in perfection, the vinous ſpirit ſhould be extremely pure; the roſemary tops gathered when the flowers are full blown upon them, and committed immediately to diſtillation, care being taken not to bruiſe or preſs them. The beſt method of managing the diſtillation, is that which was formerly recommended for the diſtillation of the more volatile eſſential oils and ſimple waters, viz. firſt to place the ſpirit in the ſtill, and then ſet in, above the liquor, either an iron hoop, with a hair-cloth ſtretched over it, upon which the flowers are to be lightly ſpread, or rather a baſket, ſupported on three pins, reaching down to the bottom. A gentle heat being applied, juſt ſufficient to raiſe the ſpirit, its vapour lightly percolating through the flowers, will imbibe their finer parts, without making that diſagreeable alteration, which liquors applied to ſuch tender ſubjects, in their groſſer form, generally do. Probably the ſuperiority of the French Hungary-water, to that prepared among us, is owing to ſome ſkilful management of this kind, or to employing a perfectly pure ſpirit.

In the Wirtemberg pharmacopœia, ſome ſage and ginger are added, in the proportion of half a pound of the former, and two ounces of the latter, to four pounds of the roſemary.

But the peculiar agreeable flavour of this water in all probability depends on the roſemary alone.

Carmelite water, or compound balm-water. Dan.

366 Take of freſh gathered leaves of balm, a pound and a half; the recent yellow rind of lemons four ounces; nutmeg, coriander, each two ounces; cloves, cinnamon, each one ounce. The ingredients being ſliced and bruiſed, pour upon them rectified ſpirit of wine, ſix pounds; balm-water, three pounds. Digeſt for three days, then draw off ſix pounds by diſtillation.

This ſpirit has been a good deal celebrated, particularly among the French, under the title of *Eau de Carmes*. Mr Beaumé, in his *Elemens de Pharmacie*, propoſes ſome improvements on the proceſs. After the ſpirit added to the ingredients has been drawn off in the heat of a water-bath, he orders the diſtilled liquor to be rectified by a ſecond diſtillation, drawing off ſomewhat leſs than nine-tenths of it. He recommends, that all the aromatic ſpirits ſhould be prepared in the ſame manner. When the common ſpirits of this kind are rubbed on the hands, &c. they leave, after the more volatile parts have exhaled, a diſagreeable empyreumatic ſmell; and when diluted with water, and taken medicinally, they leave, in like manner, a nauſeous flavour in the mouth. To remedy theſe imperfections, he made many experiments, which ſhowed, that in order to obtain theſe liquors of the deſirable qualities, the ſpirit muſt not only be perfectly pure at firſt, but that the liquor ought alſo to be rectified after it has been diſtilled from the ſubjects. In this rectification, only the more volatile, ſubtile, aromatic parts of the ingredients ariſe: there remains behind a white liquor, acrid, bitter, loaded only with the groſſer oil, and deprived of all the ſpecific flavour of the ſubjects. Indeed the very imperfection complained of naturally points out this ſecond diſtillation as the remedy; for it ſhows the ſpirit to contain a grateful and ungrateful matter; the firſt of which exhales, while the other is left behind. The author ſays, that when the *aqua meliſſæ* is prepared as above directed, it has ſomething in it more perfect than any of the odoriferous ſpirits, whoſe excellence is cried up, and which have the reputation of being the beſt.

Aromatic ſpirituous liquors have in general leſs ſmell, when newly diſtilled, than after they have been kept about ſix months. M. Beaumé ſuſpects that the preparations of this kind which have been moſt in vogue, were ſuch as have been thus improved by keeping; and found that the good effects of age might be produced in a ſhort time by means of cold. He plunges quart bottles of the liquor into a mixture of pounded ice and ſea-ſalt; the ſpirit, after having ſuffered, for ſix or eight hours, the cold thence reſulting, proves as grateful as that which has been kept for ſeveral years. Simple waters alſo, after being frozen, prove far more agreeable than they were before, though they are always leſs ſo than thoſe which have been drawn with ſpirit, and expoſed to a like degree of cold. This melioration of diſtilled waters by froſt was taken notice of by Geoffroy.

Spirit of ſcurvy-graſs. Suec.

Take of freſh ſcurvy-graſs, bruiſed, 10 pounds; rectified ſpirit of wine, eight pints. With the heat of a water-bath, diſtil off four pints. 367

This ſpirit is very ſtrong of the ſcurvy-graſs; and has been given, in thoſe caſes where the uſe of this herb is proper, from 20 to 100 drops. The virtues of ſcurvy-graſs reſide in a very ſubtile, volatile oil, which ariſes in diſtillation both with water and pure ſpirit; and if the liquors are expoſed to the air, ſoon exhales from both. The ſpirit, newly diſtilled, is extremely pungent; but if long kept, even in cloſe veſſels, it becomes remarkably leſs ſo: but it is not probable, that with ſuch a pungent vehicle we can uſe a ſufficient quantity of the herb to produce any permanent or conſiderable effect; it has been much recommended as a diuretic in dropſies.

The makers of this ſpirit have frequently added to the ſcurvy-graſs a quantity of horſe radiſh root, and ſometimes ſubſtituted for it one drawn entirely from the horſe-radiſh: the flavour of theſe two ſimples being ſo much alike, that their diſtilled ſpirits are ſcarcely diſtinguiſhable from each other. Here it may be obſerved, that though *arum* and *dracunculus* are uſually ranked in the ſame claſs with the two foregoing vegetables, and conſidered as ſimilar to them; this proceſs diſcovers a remarkable difference: while the former

Preparations and Compositions.

yield all their pungency in diſtillation both to water and ſpirit; the latter give over nothing to either, and yet their virtues are deſtroyed in the operation.

Orange-peel water. Suec.

368 Take of recent orange ſkins, one pound; proof-ſpirit, three pounds. Draw off two pounds by the heat of a water-bath.

This ſpirit, which is now rejected from our pharmacopœias, had formerly a place in them under the title of *aqua corticum aurantiorum ſpirituoſa*. It is conſiderably ſtronger of the orange-peel than the ſimple water; and it is uſed as an uſeful cordial, ſtomachic, and carminative.

Aromatic ſpirit. Suec.

369 Take of the tops of roſemary, a pound and an half; tops of milfoil, thyme, each half a pound; proof ſpirit, 16 pounds; macerate for two days, and draw off by diſtillation eight pounds. If before diſtillation eight pounds of vinegar be added, it forms the acetated aromatic ſpirit.

Theſe preparations do not differ materially from the ſpirit of roſemary or Hungary water; for on the eſſential oil of the roſemary their medicinal properties may be conſidered as chiefly depending. They are often employed, particularly for external purpoſes, and for impregnating the air with their vapours, to deſtroy the influence of febrile contagions.

Antiſceric ſpirit. Gen.

370 Take of ſpirit of turpentine, an ounce and an half; rectified ſpirit of wine, half a pound. Diſtil with a gentle heat. Let the oil ſwimming above in the receiver be ſeparated from the ſaturated ſpirit, which is to be preſerved for uſe.

It has been imagined, that this combination of oil of turpentine with ardent ſpirit will furniſh an effectual ſolvent for biliary calculi. Hence the origin of the name here given it; but although it may have ſuch an effect when copiouſly applied to the calculi in a glaſs veſſel; yet this is not to be expected when it is taken into the ſtomach, and can only reach them in the courſe of circulation.

Chap. XIX. *Decoctions and infuſions.*

371 Water, the direct menſtruum of gums and ſalts, extracts readily the gummy and ſaline parts of vegetables. Its action, however, is not limited to theſe; the reſinous and oily principles being, in moſt vegetables, ſo intimately blended with the gummy and ſaline, as to be in part taken up along with them: ſome of the reſinous cathartics, and moſt of the aromatic herbs, as well as bitters and aſtringents, yield to water the greateſt part of their ſmell, taſte, and medicinal virtue. Even of the pure eſſential oils, and odorous reſins of vegetables, ſeparated from the other principles, water imbibes a part of the flavour; and by the artificial admixture of gummy or ſaline matter, the whole ſubſtance of the oil or reſin is made ſoluble in water.

Of pure ſalts, water diſſolves only certain determinate quantities: by applying heat, it is generally enabled to take up more than it can do in the cold, and this in proportion to the degree of heat; but as the liquor cools, this additional quantity ſeparates, and the water retains no more than it would have diſſolved without heat. With gummy ſubſtances, on the other hand, it unites unlimitedly, diſſolving more and more of them till it loſes its fluidity. Heat expedites the action of the water, but cannot enable it to take up more than it would do by allowing it longer time in the cold. The active parts extracted from moſt vegetables by water, and oils and reſins made ſoluble in water by the artificial admixture of gum, partake of this property of pure gums, being ſoluble without ſaturation.

Preparations and Compositions.

It has been imagined, that vegetables in a freſh ſtate, while their oily, reſinous, and other active parts are already blended with a watery fluid, would yield their virtues to water more freely and more plentifully than when their native moiſture has been diſſipated by drying. Experience, however, ſhows, that dry vegetables in general give out more than freſh ones, water ſeeming to have little action upon them in their recent ſtate. If, of two equal quantities of mint, one be infuſed freſh in water, and the other dried, and then infuſed in the like quantity of water for the ſame length of time, the infuſion of the dry herb will be remarkably the ſtrongeſt: and the caſe appears to be the ſame in all the vegetables that have been tried.

In all the preparations deſcribed in this chapter, it is to be underſtood that the ſubjects muſt be moderately and newly dried, unleſs when they are expreſsly ordered to be taken freſh; in which caſe it is to be judged that their virtues are deſtroyed or impaired by drying.

The native colours of many vegetables are communicated to water along with their medicinal matter; many impart a colour different from their own; and others, though of a beautiful and deep colour themſelves, give ſcarcely any to the menſtruum. Of the firſt kind are the yellow and red flowers; of the ſecond, the leaves of moſt plants; of the third, ſome of the blue flowers, as thoſe of cyanus and larkſpur. Acid liquors change the infuſions of moſt flowers, the yellow ones excepted, to a red; and alkalis, both fixed and volatile, to a green.

From animal ſubſtances water extracts the gelatinous and nutritious parts; whence glues, jellies, broths, &c.; and along with theſe, it takes up principles of more activity, as the acrid matter of cantharides. It diſſolves alſo ſome portion of calcined calcareous earths, both of the animal and of the mineral kingdom, but has no action on any other kind of earthy matter.

The effect of boiling differs from that of infuſion in ſome material particulars. One of the moſt obvious differences is, that as the eſſential oils of vegetables, in which their ſpecific odours reſide, are volatile in the heat of boiling water, they exhale in the boiling along with the watery ſteam, and thus are loſt to the remaining decoction; whereas both in cold, and ſometimes in hot infuſions, they are preſerved; although in the latter they are by no means perfectly ſo. Odorous ſubſtances, and thoſe in general whoſe virtues depend on their volatile parts, are therefore unfit for this treatment. The ſoluble parts of theſe may, nevertheleſs, be united in this form with thoſe bodies of a more fixed nature, by boiling the latter till their virtues

Preparations and Compositions.

tues be sufficiently extracted, and then infusing the former in this decoction.

The extraction of the virtue of the subject is usually promoted or accelerated by a boiling heat; but this rule is less general than it is commonly supposed to be. We have already observed, that Peruvian bark gives out its virtue more perfectly by cold infusion than by coction. In some cases, boiling occasions a manifest disunion of the principles of the subject: thus, when almonds are triturated with cold water, their oil, blended with the mucilaginous or other soluble matter of the almond, unites with the water into a milky liquor called *an emulsion*: but on boiling them in water, the oil separates and rises to the surface; and if the most perfect emulsion be made to boil, a like separation happens.

This also appears to take place, though in a less evident manner, in boiling sundry other vegetables; thus tobacco, asarum, and ipecacuanha, lose their active powers by boiling: nor does it appear that this change is effected merely by the discharge of volatile parts. From some late experiments, it has been found, that the distilled water of ipecacuanha was infinitely less emetic than the infusion from which it was distilled, and that the boiling liquor gradually assumes a black colour, indicating some kind of decomposition of parts: the same circumstances probably take place in boiling tobacco, asarum, and perhaps all vegetables whatever, though from their not producing such sensible operations on the living body, they cannot be so clearly discovered as in ipecacuanha, tobacco, or asarum. The experiments we allude to were made by Dr Irving, when a student in the college of Edinburgh; and they gained him the prize given by the Harveian Society of that place, for the best experimental inquiry concerning ipecacuanha.

It is for the above-mentioned reasons that we think many of the infusions should be made with cold water: it is, however, to be acknowledged, that this is not always absolutely necessary, and in extemporaneous practice it may be often very inconvenient; it is, however, proper to point out the advantages to be expected from this more tedious, but much more complete and elegant, method.

Vinegar extracts the virtues of several medicinal substances in tolerable perfection: but at the same time its acidity makes a remarkable alteration in them, or superadds a virtue of a different kind; and hence it is more rarely employed with this intention than purely aqueous or spirituous menstrua. Some drugs, however, for particular purposes, vinegar excellently assists, or coincides with, as squills, garlic, ammoniac, and others: and in many cases where this acid is itself principally depended on, it may be advantageously impregnated with the flavour of certain vegetables; most of the odoriferous flowers impart to it their fragrance, together with a fine purplish or red colour; violets, for instance, if fresh parcels of them are infused in vinegar in the cold for a little time, communicate to the liquor a pleasant flavour, and deep purplish red colour. Vinegar, like other acids, added to watery infusions or decoctions, generally precipitates a part of what the water had dissolved.

Decoction of marshmallows. E.

Preparations and Compositions.

Take of dried marshmallow roots, four ounces; raisins of the sun, stoned, two ounces; water, seven pounds. Boil to five pounds; place apart the strained liquor till the feces have subsided, then pour out the clear liquor. 372

The Edinburgh college have substituted this for the more complicated formula of the *Decoctum ad Nephriticos* of their former pharmacopœia, and it fully answers the intentions of that preparation: it is intended chiefly as an emollient, to be liberally drunk of in nephritic paroxysms; in which cases, by softening and relaxing the parts, it frequently relieves the pain, and procures an easy passage for the sabulous matter. This medicine is now made more simple than before, without any diminution of its virtue, by the rejection of wild carrot seed, restharrow root, figs, linseed, and liquorice. The carrot seeds were indeed unfit for this form, as they give out little of their virtue to watery liquors.

Decoction of hartshorn. L.

Take of burnt and prepared hartshorn, two ounces; gum arabic, six drams; distilled water, three pints. Boil, constantly stirring, to two pints, and strain. 373

This decoction is used as common drink in acute diseases attended with a looseness, and where acrimonious humours abound in the primæ viæ. The gum is added, in order to render the liquor lightly glutinous, and thus enable it to sustain more of the calx; which is the ingredient on which the colour, but probably not the virtue, of the medicine depends. Calcined hartshorn has no quality from which it seems capable either of constringing and strengthening the vessels, giving a greater degree of consistency to thin fluids, or obtunding acrimonious humours. It blunts and absorbs acid juices; but acrimony and acidity are very different; there are few (perhaps none of the acute) disorders of adults attended with the latter; and few of infants are unaccompanied therewith. Some have proposed starch as an ingredient in these kinds of decoctions; a small quantity of this soft, gelatinous, farinaceous substance would seem to be greatly preferable to the earthy calx. It may be observed, that the water is not enabled by the boiling to dissolve any part of the calx; and that in the decoction, the earth is only diffused in substance through the water, as it would be by agitation.

For these reasons, this formula is now rejected by the Edinburgh college, notwithstanding the reputation in which it was held by Dr Sydenham, and other names of the first eminence. But as an absorbent of a similar nature, the Edinburgh college have introduced the following formula.

Chalk julep. E.

Take of prepared chalk, one ounce; purest refined sugar, half an ounce; mucilage of gum arabic, two ounces; rub them together; and add by degrees, water, two pounds and a half; spirituous cinnamon water, two ounces. Mix them. 374

In the former edition of the Edinburgh pharmacopœia,

poeia, a preparation of this kind had the title of *decoctum cretaceum*, and the chalk was directed to be boiled with the water and gum. In the present formula, the chalk is much more completely suspended by the mucilage and sugar, which last gives also to the mixture an agreeable taste; it is proper to employ the finest sugar, as the redundant acid in the coarser kinds might form with the chalk a kind of salt. It would perhaps have been more proper to have added an aromatic, by suspending the entire powder of cinnamon, or its oil, by means of the mucilage and sugar: the method here directed is, however, less exceptionable in this than in many other preparations, as the precipitated matter of the spirituous water will probably be invisceated in the saccharine and mucilaginous matter. This is a very elegant form of exhibiting chalk, and is an useful remedy in diseases arising from, or accompanied with, acidity in the primæ viæ. It has been most frequently employed in fluxes proceeding from that cause. At the same time that the mucilage serves to keep the chalk uniformly diffused, it also considerably improves its virtues by sheathing the internal surface of the intestines so often abraded in these affections. It is indeed probable, that chalk, as being somewhat astringent, is in some of these complaints preferable to magnesia; both, however, are improper in dysentery, or other fluxes attended with putrescent matter in the primæ viæ, or a general tendency to a putrefaction of the fluids.

Decoction of Peruvian bark. L.

375 Take of Peruvian bark, powdered, one ounce; distilled water, one pint and three ounces. Boil, for ten minutes, in a covered vessel, and strain the liquor while hot.

Although a cold watery infusion of bark is in general preferable to any decoction, yet this form has at least the advantage of being more quickly prepared. And the decoction here directed, which is boiled only for a short time, and strained while hot, is preferable to any other.

This decoction should be passed only through a coarse strainer, and drank while turbid: if suffered to stand till clear, the more efficacious parts of the bark will subside. We have formerly observed, that the virtues of this drug consist chiefly in its resinous substance, which, though it may be totally melted out by the heat of boiling water, remains only partially suspended in that menstruum.

Decoction for a clyster. L.

376 Take of the dried leaves of mallow, one ounce; dried camomile-flowers, half an ounce; water, one pint. Boil, and strain.

The title of this decoction sufficiently expresses its use, as the basis of glysters. The ingredients should be very lightly boiled, or at least the camomile flowers should not be put in till towards the end, a part of their virtue being soon lost by boiling.

Decoction for fomentation. L.

377 Take of the dried leaves of southernwood, the dried tops of sea wormwood, dried camomile flowers, each one ounce; dried bay-leaves, half an ounce; distilled water, six pints. Boil them a little, and strain.

Common decoction. E.

Take of camomile flowers, one ounce; carvy seeds, half an ounce; water, five pounds. Boil for a quarter of an hour, and strain. 378

This decoction is intended to answer the purposes of both the foregoing. It is less loaded with ingredients than either, but not perhaps for that reason the less useful.

It is indeed to be acknowledged, that these impregnations are for the most part unnecessary for the purpose of glysters; and in ordinary cases the weight of the water usually solicits a discharge before these medicines can produce any effect.

As to fomentations, their virtues in our opinion are totally to be ascribed to the influence of the warm water. And when the herbs themselves are applied, they act only as retaining heat and moisture for a longer time.

Decoction of hellebore. L.

Take of the root of white hellebore, powdered, one ounce; distilled water, two pints; rectified spirit of wine, two ounces. Boil the water with the root to one pint; and, the liquor being cold and strained, add to it the spirit. 379

White hellebore, as we formerly observed, is now very rarely employed internally; and the present formula is entirely intended for external use. Recourse is sometimes had to it with advantage in cutaneous eruptions, particularly in tinea capitis. But where the incrustations are entirely removed, leaving a very tender skin, it is necessary that the decoction should be diluted previous to its employment.

Decoction of barley. L.

Take of pearl-barley, two ounces; distilled water, four pints. The barley being first washed with cold water from the adhering impurities, pour upon it about half a pint of water, and boil the barley a little time. This water being thrown away, add the distilled water, boiling, to the barley; boil it to two pints, and strain. 380

Compound decoction of barley. L.

Take of the decoction of barley, two pints; raisins, stoned, figs, sliced, each two ounces; liquorice-root, sliced and bruised, half an ounce; distilled water, one pint. Boil to two pints, and strain. 381

Barley-water. E.

Take of pearl barley, two ounces; water, five pints. First wash the barley from the mealy matter that adheres to it with some cold water; then boil it a little with about half a pint of fresh water, which will acquire a considerable tinge from it. Throw away this tinged water; put the barley into the five pints of boiling water prescribed; and continue the boiling till half the water be wasted. 382

These liquors are to be drank freely as a diluter, in fevers and other disorders; hence it is of consequence that they should be prepared so as to be as elegant and agreeable as possible; for this reason they are inserted in the pharmacopœia, and the several circumstances which contribute to their elegance set down; if any one of them be omitted, the beverage will be less grateful,

Preparations and Compositions.

ful. However trivial medicines of this claſs may appear to be, they are of greater importance in the cure of acute diſeaſes than many more elaborate preparations.

Barley-water, however, is much more frequently prepared by nurſes than apothecaries, particularly in its ſimple ſtate. The compound decoction contains a large proportion of ſaccharine and mucilaginous matter, and may be employed for the ſame purpoſes as the decoction of marſhmallows of the Edinburgh pharmacopœia.

Decoction of the woods. E.

383 Take of guaiacum ſaw-duſt, three ounces; raiſins of the ſun, ſtoned, two ounces; ſaſſafras wood, ſhaved, liquorice, ſliced, each one ounce; water, ten pounds. Boil the guaiacum and raiſins with the water, over a gentle fire, to the conſumption of one half; adding, towards the end the ſaſſafras and liquorice. Strain out the liquor; and having ſuffered it to reſt for ſome time, pour off the clear from the feces without expreſſion

This decoction is very well contrived; and if its uſe be duly continued, it will do great ſervice in ſome cutaneous diſeaſes, in what has been called foulneſs of the blood and juices, and in ſome diſorders of the breaſt; particularly in phlegmatic habits. It may be taken by itſelf to the quantity of a quarter of a pint two or three times a day, or uſed as an aſſiſtant in a courſe of mercurial or antimonial alteratives; the patient in either caſe keeping warm, in order to promote the operation of the medicine. The ſaw-duſt expoſes a larger ſurface to the action of the water than the ſhavings, directed in the former edition of the pharmacopœia.

Decoction of ſarſaparilla. L.

384 Take of the root of ſarſaparilla, ſliced, ſix ounces; diſtilled water, eight pints. Macerate for two hours, with an heat of about 195; then take out the root, and bruiſe it; return the bruiſed root to the liquor, and again macerate it for two hours. Then, the liquor being boiled to four pints, preſs it out, and ſtrain.

This decoction is an article in very common uſe, particularly in venereal affections. And there can be little doubt, that by this proceſs the medical powers of the ſarſaparilla are fully extracted. But it has of late been much queſtioned, whether this article be in any degree intitled to the high character which was once given of it. Some, as we have already obſerved, are even diſpoſed to deny its poſſeſſing any medical property whatever: but the general opinion is, that it has ſomewhat of a diaphoretic effect; and this effect is more readily obtained when it is exhibited under the form of decoction than under any other.

Compound decoction of ſarſaparilla. L.

385 Take of the root of ſarſaparilla, ſliced and bruiſed, ſix ounces; bark of the root of ſaſſafras, raſpings of guaiacum-wood, liquorice root, bruiſed, of each one ounce; bark of the root of mezereon, three drams; diſtilled water, ten pints. Macerate, with a gentle heat, for ſix hours; then boil it down to five pints, adding, towards the end, the bark of the root of mezereon, and ſtrain the liquor.

This compound decoction is an elegant mode of preparing an article once highly celebrated under the title of the *Liſbon diet drink*. That formula, for a long time after its firſt introduction into Britain, was kept a ſecret; but an account of the method of preparation was at length publiſhed in the Phyſical and Literary Eſſays of Edinburgh, by Dr Donald Monro. And of the formula there given, which is in many reſpects an unchemical one, the preſent may juſtly be conſidered as an improvement. Even in its original form, but ſtill more in the preſent ſtate, there can be no doubt, that it furniſhes us with a very uſeful medicine, particularly in thoſe obſtinate ulcers originating from venereal infection, which reſiſt the power of mercury. And it is highly probable, that its good effects principally depend on the impregnation it receives from the mezereon. Perhaps, however, even thus improved, it is more complicated and expenſive than is neceſſary: at leaſt we are inclined to think, that every advantage derived from it may with equal eaſe and certainty be obtained from impregnating with the mezereon, in the manner here directed, a ſimple decoction of the guaiacum, bardana, or althæa, without having recourſe to ſeveral articles, or employing one ſo expenſive as the ſarſaparilla.

Decoction of ſeneka. E.

386 Take of ſeneka, or rattleſnake root, one ounce; water, two pounds. Boil to ſixteen ounces, and ſtrain

The virtues of this decoction will be eaſily underſtood from thoſe of the root from which it is prepared. The doſe, in hydropic caſes, and rheumatic, or arthritic complaints, is two ounces, to be repeated three or four times a-day, according to its effect.

Decoction of elm. L.

387 Take of the freſh inner bark of elm, bruiſed, four ounces; diſtilled water, four pints. Boil to two pints, and ſtrain.

It has been chiefly, if not entirely, under this form of decoction, that the elm-bark has been employed for combating thoſe cutaneous eruptions againſt which it has of late been ſo highly celebrated. Any experience which we have had of it, however, in actual practice, by no means confirms the very favourable account which ſome have given of its uſe.

Mucilage of ſtarch. L.

388 Take of ſtarch, three drams; diſtilled water, one pint. Rub the ſtarch, by degrees adding the diſtilled water; then boil it a little time.

The mucilage thus formed of ſtarch is very uſeful for anſwering theſe purpoſes where a glutinous ſubſtance is required, and in particular it is often ſucceſsfully employed under the form of glyſter.

Mucilage of gum arabic.

389 Take of gum arabic, powdered, four ounces; boiling diſtilled water, eight ounces. Rub the gum with the water until it be diſſolved. *L.*

Take of gum arabic, beat into powder, and warm water, each equal weights. Digeſt, and frequently ſtir them till the gum be diſſolved, then preſs the ſolution through linen. *E.*

It

Preparations and Compositions.

It is very neceſſary to paſs the mucilage through linen, in order to free it from pieces of wood and other impurities, which always adhere to the gum; the linen may be placed in a funnel.

Mucilage of gum arabic is very uſeful in many operations in pharmacy: it is alſo much uſed for properties peculiar to thoſe ſubſtances of its own claſs, and of all the gums it ſeems to be the pureſt.

Mucilage of gum tragacanth. E.

390 Take of gum tragacanth, powdered, one ounce; hot water, eight ounces. Macerate twenty-four hours; then mix them, by rubbing briſkly, that the gum may be diſſolved; and preſs the mucilage through linen cloth.

This gum is more difficultly ſoluble in water than gum arabic, and ſeems to be conſiderably more adheſive; it is therefore fitter for forming troches, and ſuch like purpoſes. It has been thought to be more peculiarly what has been called a *pectoral*, than the other gums; but this does not ſeem to be certainly founded. This mucilage is perhaps preferable to the foregoing in thoſe operations in pharmacy where much tenacity is required; as in the ſuſpenſion of mercury, or other ponderous bodies.

Mucilage of quince-ſeed. L.

391 Take of ſeeds of the quince, one dram; diſtilled water, eight ounces, by meaſure. Boil with a ſlow fire until the water thickens; then paſs it through linen.

This is a pleaſant ſoft mucilage, of a ſomewhat ſweetiſh taſte, and a light agreeable ſmell: in theſe reſpects, and in its eaſy ſolubility in water, it differs from the mucilage of gum tragacanth, to which ſome have ſuppoſed it ſimilar: it has another difference, to its diſadvantage, being apt to grow mouldy in keeping.

Compound infuſion of gentian. L.

392 Take of the root of gentian, one dram; freſh outer-rind of lemons, half an ounce; dried outer rind of Seville oranges, one dram and an half. Boiling water, 12 ounces, by meaſure. Macerate for an hour, and ſtrain.

Bitter infuſion. E.

Take of gentian root, half an ounce; dried peel of Seville oranges, one dram; coriander ſeeds, half a dram; proof-ſpirit, four ounces, water, one pound. Firſt pour on the ſpirit, and three hours thereafter add the water; then macerate without heat for a night, and ſtrain.

Theſe formulæ do not materially differ. That of the London college is the moſt expeditious mode of preparation; but that of the Edinburgh college poſſeſſes other advantages, which are in our opinion more than ſufficient to outweigh that circumſtance.

In the former edition of the Edinburgh pharmacopœia the water was directed to be boiling: this was at leaſt unneceſſary, and was probably liable to the objections obſerved againſt decoctions. The proof-ſpirit is alſo an uſeful addition to the bitter infuſion, as it now ſtands in the Edinburgh pharmacopœia: beſides that it aſſiſts in extracting the reſinous parts, and preſerving the infuſion from fermentation, it communicates an agreeable pungency to the liquor. To anſwer in ſome meaſure theſe intentions, it was formerly directed to add to the filtrated liquor a quantity of aromatic water. This was certainly a piece of very bad pharmacy; for, beſides that the ſpirit in this preparation, when diluted with the water of the infuſion was now no longer able to retain the ſuſpended matter, it would alſo diſpoſe the infuſion to part with its proper extractive matter; and in this way the reſinous matter of the aromatic water, and the gummy parts of the bitter infuſion, would both in ſome degree ſeparate to the bottom of the veſſel. By the formula now laid down, the infuſion contains the different principles of the ingredients in a manner more nearly approaching to their natural and entire ſtate.

Preparations and Compoſitions.

Simple infuſion of ſenna. L.

Take of ſenna, an ounce and a half; ginger, powdered, one dram; boiling diſtilled water, one pint. Macerate them for an hour in a covered veſſel; and the liquor being cold, ſtrain it. 393

This, although a ſimple, is a very elegant infuſion of ſenna, the ginger acting as an uſeful corrigent. But if the ſenna were employed to the quantity of a dram and an half or two drams only, with the ſame menſtruum, in place of the quantity here ordered, it would be a no leſs uſeful medicine, and might be employed for one doſe, as it is beſt when freſh. Of the preſent infuſion, an ounce or two is a ſufficient doſe.

Tartarized infuſion of ſenna. L.

Take of ſenna, one ounce and a half; coriander ſeeds, bruiſed, half an ounce; cryſtals of tartar, two drams; diſtilled water, one pint. Diſſolve the cryſtals of tartar by boiling in the water, then pour the water, as yet boiling, on the ſenna and ſeeds. Macerate for an hour in a covered veſſel, and ſtrain when cold. 394

In the laſt edition of the London pharmacopœia this had the name of *infuſum ſennæ commune*.

Formerly an alkaline ſalt was uſed in the infuſion of ſenna inſtead of the acid one here directed. The firſt was ſuppoſed to promote the operation of the medicine, by ſuperadding a degree of purgative virtue of its own, and by enabling the water to extract ſomewhat more from the capital ingredient than it would be capable of doing by itſelf; while acids were alleged to have rather a contrary effect. Experience, however, has ſufficiently ſhown, that alkaline ſalts increaſe the offenſiveneſs of the ſenna, while cryſtals of tartar conſiderably improve the colour of the infuſion, and likewiſe render the taſte to ſome perſons leſs diſagreeable. Soluble tartar ſhould ſeem a good ingredient to theſe kinds of compoſitions, as it not only improves the taſte, but promotes the purgative virtue of the medicine: this addition alſo renders the infuſion leſs apt to gripe, or occaſion flatulencies.

Infuſion of tamarinds with ſenna. E.

Take of tamarinds, ſix drams; cryſtals of tartar, ſenna, each one dram; coriander ſeeds, half a dram; brown ſugarcandy, half an ounce; boiling water, eight ounces. Macerate in a cloſe earthen veſſel which has not been vitrified with lead; ſtir the liquor now 395

and

Preparations and Compositions.

and then, and after it has ſtood four hours ſtrain it. It may alſo be made with double, triple, &c. the quantity of ſenna.

Both this and the former infuſions might be made with cold water. By this means the aromatic quality of the coriander ſeeds would probably be extracted in a more perfect ſtate; but the cryſtals of tartar are ſo difficultly ſoluble in cold water, that for extemporaneous uſe it is in ſome meaſure neceſſary to prepare them in the manner here directed. It is not indeed probable, that when ſuch ſoluble matters as acids and ſugar are preſented to water, the water ſhall be able to extract ſuch a quantity of the finer volatile part of aromatics as to afford any conſiderable flavour to the liquor. Where an aromatic is required, we would therefore propoſe, that ſome agreeable aromatic water ſhould be mixed with the liquor immediately before ſwallowing it; or that a quantity of aromatic oil ſhould be incorporated with the cold infuſion by means of gum, or a part of the ſugar which might be reſerved for that purpoſe. It is a very neceſſary caution not to make this infuſion in veſſels glazed with lead, otherwiſe the acid might corrode the lead, and communicate its poiſonous effects to the infuſion.

Both theſe infuſions are mild and uſeful purges; the latter in particular is exactlently ſuited for delicate ſtomachs, at the ſame time that it is very much calculated for febrile and other acute diſeaſes. It is obſervable, that ſugar added to neutral ſalts rather increaſes than diminiſhes their nauſeouſneſs; but when uſed along with an acid, ſuch as tamarinds, or a ſalt wherein the acid predominates, as in cryſtals of tartar, it is found very much to improve their taſte. The acid in this infuſion, or rather the combination of acid and ſweet, are found to cover the taſte of the ſenna very effectually: the aromatic ſerves alſo the ſame purpoſe, but would perhaps be better applied in the way above propoſed.

Infuſion of the roſe. L.

296 Take of red roſe-buds, the heels being cut off, half an ounce; vitriolic acid, diluted, three drams; boiling diſtilled water, two pints and a half; double-refined ſugar, one ounce and a half. To the water, firſt poured on the petals in a glaſs veſſel, add the diluted vitriolic acid, and macerate for half an hour. Strain the liquor when cold, and add the ſugar.

Infuſion, commonly called *tincture of roſes.* E.

Take of red roſes, dried, one ounce; boiling water, five pounds; vitriolic acid, one dram; white ſugar, two ounces. Macerate the roſes with the boiling water in an unglazed veſſel four hours; then having poured on the acid, ſtrain the liquor, and add the ſugar.

Some have directed the vitriolic acid to be dropped upon the roſes before the water is put to them: but this method is certainly faulty; for ſuch of the roſes as this cauſtic liquor falls on undiluted will be burnt up by it, and have their texture deſtroyed. Others have made an infuſion of the roſes in water firſt, and then added the acid, from an apprehenſion, that if this acid be added to the water, it would weaken its power as a menſtruum; but whatever the acid ſpirit will hinder the water from extracting, it muſt precipitate if added afterwards; though, in this preparation, the vitriolic acid bears ſo ſmall a proportion to the water, that its effects in this reſpect will be very little; and it appears to be of little conſequence which of the two ways be followed, only that by the above formula the veſſels are expoſed a ſhorter time to the action of the acid. The infuſion ſhould be made in a glaſs or ſtone-ware veſſel, rather than a glazed earthen one; for the acid will be apt to corrode the glazing of the latter. Preparations and Compoſitions.

This infuſion is of an elegant red colour, and makes a very grateful addition to julops in hæmorrhagies, and in all caſes which require mild coolers and ſubaſtringents. It is ſometimes taken with boluſes or electuaries of the bark, and likewiſe makes a good gargle. But although in our pharmacopœias it has its name from the roſes, yet its virtues are to be aſcribed chiefly, or perhaps ſolely, to the vitriolic acid.

Infuſion of rhubarb. E.

Take of rhubarb, half an ounce; boiling water, eight ounces; ſpirituous cinnamon water, one ounce. Macerate the rhubarb in a glaſs veſſel with the boiling water for a night; then having added the cinnamon water, ſtrain the liquor. 397

In this infuſion cold water might perhaps be employed with advantage; we alſo object to the ſpirituous cinnamon-water on the ſame grounds as we did before to the aromatic water in the bitter infuſion of the former edition of the Edinburgh pharmacopœia. This, however, appears to be one of the beſt preparations of rhubarb when deſigned as a purgative; water extracting its virtue more effectually than either vinous or ſpirituous menſtrua. In this reſpect rhubarb differs from moſt of the other vegetable cathartics; and we think the London college might have given it a place in their pharmacopœia as well as the wine or tincture of rhubarb.

Lime-water.

Take of quicklime, half a pound; boiling diſtilled water, twelve pints. Mix, and ſet it aſide in a covered veſſel for an hour; then pour off the liquor, which keep in a cloſe veſſel. *L.* 398

Take half a pound of freſh-burnt quicklime, put it into an earthen veſſel, and gradually ſprinkle on it four ounces of water, keeping the veſſel ſhut while the lime grows hot and falls into powder; then pour on it twelve pounds of water, and mix the lime thoroughly with the water by ſtirring. After the lime has ſubſided renew the ſtirring; and let this be done about ten times, always keeping the veſſel ſhut (during the ebullition), that the acceſs of the air may be the more effectually prevented. Laſtly, let the water be filtered through paper placed in a funnel cloſe ſhut at its top; and it muſt be kept in very cloſe veſſels. *E.*

The reaſon of adding the water by degrees to the lime is, that when poured on at once it reduces the external part to a kind of muddy ſubſtance, or ſoft paſte, which in ſome meaſure defends the internal part from being acted on by the water. It does not appear that the different proportions of water in the two above preſcriptions occaſion any ſenſible difference in the ſtrength of the product: the quicklime is far from yielding all its ſoluble parts to either proportion; the remainder

remainder giving a ſtrong impregnation to many freſh quantities of water, though not ſo ſtrong as to the firſt. The caution of keeping the water in cloſe-ſtopped veſſels ought to be ſtrictly attended to; for in open ones the calcareous matter diſſolved in the liquor ſoon begins to ſeparate, and forms a white cruſt on the ſurface. This cruſt is not of a ſaline nature, as ſome have imagined; but an inſipid earth, no longer miſcible with watery liquors. The theory of the production of this earth will be eaſily underſtood from what we have ſaid on the article FIXED AIR. The ſeparation firſt takes place at the ſurface, as being the part immediately applied to the common air. As long as the cruſt remains entire, the cloſeneſs of its texture ſo excludes the air, that the reſt of the matter ſtill remains impregnated with lime; but when this pellicle is broken by any means, it ſoon ſinks to the bottom, and expoſes a new ſurface for the ſeparation of the lime. In this way a ſucceſſion of cruſts and precipitations are formed, till the whole of the once cauſtic and ſoluble quicklime is now found at the bottom of the veſſel in the ſtate of a mild inſoluble earth, leaving the water perfectly inſipid.

The formation of theſe cruſts, and their ſucceſſive precipitations, are owing to the abſorption of fixed air, or aerial acid, from the atmoſphere; and the mild inſoluble ſtate of theſe precipitations is alſo owing to the ſame cauſe.

The diſtilled water recommended by the London college is certainly preferable to common fountain water; the purity of which can rarely be depended on.

Lime-water has been thought of great ſervice in ſcrofulous complaints; but perhaps on no very good foundation. It has alſo been uſed both internally and externally for various affections of the ſkin. It ſeems to be very conſiderably aſtringent, and has been uſeful in ſome kinds of alvine fluxes, in diabetes, leucorrhœa, and in ſundry other diſorders proceeding from a laxity or debility of the ſolids.

Its more common uſe is in affections of the ſtomach accompanied with acidity and flatulence. For which laſt complaint, the mild or aerated earths are leſs proper, on account of the ſeparation of air on their meeting with an acid in the ſtomach. Lime-water is alſo capable of diſſolving mucus; and may therefore be uſed where a redundance of the inteſtinal mucus affords a neſtus for worms, or gives riſe to other complaints. It has alſo been found, that lime-water injected into the anus immediately kills aſcarides. The lithontriptic powers of lime-water ſeem at preſent to be much doubted. Lime-water is given in doſes proportioned to the nature of the complaints; in ſome caſes, as in diabetes, it may be given in divided portions to the extent of two quarts a-day. It is uſed externally for waſhing what are called *foul* or *ill-conditioned ulcers*; it is alſo injected into the vagina and other parts affected with preternatural diſcharges from laxity.

The uſe of lime-water in ſcurvy is very doubtful.

Vinegar of ſquills.

399 Take of ſquills, dried, one pound; vinegar, ſix pints; proof-ſpirit, half a pint. Macerate the ſquills in the vinegar, with a gentle heat, in a glaſs veſſel, for four-and-twenty hours; then preſs out the liquor, and ſet it by that the feces may ſubſide: laſtly, pour off the liquor, and add to it the ſpirit. *L.* Preparations and Compoſitions.

Take of dried root of ſquills, two ounces; diſtilled vinegar, two pounds and a half; rectified ſpirit of wine, three ounces. Macerate the ſquills with the vinegar eight days; then preſs out the vinegar, to which add the ſpirit; and when the feces have ſubſided, pour off the clear liquor. *E.*

Vinegar of ſquills is a medicine of great antiquity; we find in a treatiſe attributed to Galen, an account of its preparation, and of many particular virtues then aſcribed to it. It is a very powerful ſtimulant, aperient, and what is called an attenuant of tenacious juices; and hence it is frequently uſed, with great ſucceſs, in diſorders of the breaſt occaſioned by a load of thick phlegm, and for promoting urine in hydropic caſes. The doſe of this medicine is from a dram to half an ounce: where crudities abound in the firſt paſſages, it may be given at firſt in a larger doſe, to evacuate them by vomiting. It is moſt conveniently exhibited along with cinnamon, or other agreeable aromatic waters, which prevent the nauſea it would otherwiſe, even in ſmall doſes, be apt to occaſion.

Aromatic vinegar. Succ.

400 Take of tops of roſemary, leaves of ſage, each four ounces; flowers of lavender, two ounces; cloves two drams; vinegar, eight pounds. Macerate for four days, expreſs the liquor, and ſtrain it.

This may be conſidered as an elegant improvement of what had formerly a place in the foreign pharmacopœias, under the title of *acetum prophylacticum*, which contained not only the preſent articles, but alſo a confuſed farrago of others, as wormwood, rue, garlic, cinnamon, &c.

It is ſaid, that during the plague at Marſeilles, four perſons, by the uſe of the acetum prophylacticum as a preſervative, attended, unhurt, multitudes of thoſe who were infected: that under colour of thoſe ſervices, they robbed both the ſick and the dead: and that one of them being afterwards apprehended, ſaved himſelf from the gallows by diſcovering the remedy. The preparation was hence called *Vinaigre des quatre voleurs*; "The vinegar of the four thieves." It is not to be doubted that vinegar, impregnated with antiſeptic vegetables, will contribute greatly to prevent the effects of contagious air. And in the preſent aromatic vinegar we have a ſtronger and better impregnation, than from the numerous articles which were before employed. We are far, however, from imagining that it will be able to counteract the contagion of the plague: but it may on different occaſions be more powerful than vinegar in its ſimple ſtate, for impregnating with antiſeptic vapours the chambers of the ſick.

Vinegar of roſes. Succ.

402 Take of the flowers of red roſes dried, any quantity; add to them twelve times their weight of vinegar. Macerate for four days, and ſtrain through paper.

This has been chiefly uſed for embrocating the head and temples in ſome kinds of headach, &c. in which it has now and then been of ſervice. It has alſo been uſed for certain caſes of ophthalmia. But before it

Preparations and Compositions.

can be applied to the eyes, it will in general require to be diluted with water.

Vinegar of lead. Succ.

402 Take of litharge, triturated, half a pound; vinegar, two pounds. Digeſt them together, frequently ſtirring the mixture with a wooden rod, till the colour of blue paper be not changed by the vinegar; preſerve for uſe the clear liquor which is above the ſediment.

This liquor is of the ſame nature with ſolutions of ſugar of lead, or acetated ceruſe, as it is now called. It is only uſed externally againſt cutaneous eruptions, redneſs, inflammations, &c. But even in theſe caſes ſome think it is not void of danger: and it is alleged, that there are examples of its continued uſe having occaſioned ſundry ill conſequences. Of this, however, we are very doubtful. But by means of the acetated ceruſe every purpoſe to be anſwered by this may be accompliſhed. This liquor differs only in the proportions from the water of acetated litharge of the London pharmacopœia.

Vinegar of colchicum. Roſs.

403 Take of the recent root of colchicum cut into ſlices, one ounce; vinegar, one pound. Macerate with a gentle heat for two days: then ſtrain after ſlight expreſſion.

Although in our pharmacopœias a place be given to the oxymel and ſyrup of colchicum, both of which are formed from the vinegar, yet the vinegar itſelf is not directed to be kept in its ſeparate ſtate: under this form, however, it may often be employed with advantage.

Infuſion of Peruvian bark. Succ.

404 Take of Peruvian bark, bruiſed, an ounce and a half; river water, boiling, a pound and a half. Digeſt for two hours, ſhaking the veſſel frequently; then ſtrain the liquor with expreſſion.

The Peruvian bark, as we have already had occaſion to obſerve, gives out its medical properties to water not leſs readily in the way of infuſion than of decoction. And in the former, the extractive matter is even more in a ſtate of ſolution. An infuſion, however, not only more elegant, but ſtronger than the preſent, might be obtained, from employing cold inſtead of boiling water, and from continuing the maceration for a greater length of time. But in whatever manner it be formed, an infuſion will often ſit on the ſtomach, when the bark either in ſubſtance or decoction cannot be retained.

Tar-water. Succ.

405 Take of tar two pounds; water, one gallon. Stir them ſtrongly together with a wooden rod; and after ſtanding to ſettle for twelve hours, pour off the water for uſe.

Tar-water has lately been recommended to the world as a certain and ſafe medicine in almoſt all diſeaſes; a ſlow yet effectual alterative in cahexies, ſcurvies, chlorotic, hyſterical, hypochondriacal, and other chronical complaints; and a ſudden remedy in acute diſtempers which demand immediate relief, as pleuriſies, peripneumonies, the ſmall-pox, and all kinds of fevers in general. The medicine, though certainly far inferior to the character that has been given of it, is doubtleſs in many caſes of conſiderable utility: it ſenſibly raiſes the pulſe; and occaſions ſome conſiderable evacuation, generally by perſpiration or urine, though ſometimes by ſtool or vomit. Hence it is ſuppoſed to act by increaſing the vis vitæ, and enabling nature to expel the morbific humours.

Preparations and Compositions.

We ſhall here inſert, from the firſt public recommender of this liquor (Biſhop Berkeley), ſome obſervations on the manner of uſing it. "Tar-water, when right, is not paler than French, nor deeper coloured than Spaniſh, white wine, and full as clear; if there be not a ſpirit very ſenſibly perceived, in drinking, you may conclude the tar water is not good. It may be drank either cold or warm. In colics, I take it to be beſt warm. As to the quantity, in common chronical indiſpoſitions, a pint a-day may ſuffice, taken on an empty ſtomach, at two or four times, *viz.* night and morning, and about two hours after dinner and breakfaſt: more may be taken by ſtronger ſtomachs. But thoſe who labour under great and inveterate maladies, muſt drink a greater quantity, at leaſt a quart every twenty-four hours. All of this claſs muſt have much patience and perſeverance in the uſe of this, as well as of all other medicines, which, though ſure, muſt yet in the nature of things be ſlow in the cure of inveterate chronical diſorders. In acute caſes, fevers of all kinds, it muſt be drank in bed warm, and in great quantity (the fever ſtill enabling the patient to drink), perhaps a pint every hour, which I have known to work ſurpriſing cures. But it works ſo quick, and gives ſuch ſpirits, that the patients often think themſelves cured before the fever has quite left them."

Notwithſtanding theſe encomiums, tar-water ſeems to be faſt loſing its reputation. It is not probable that water can take up any of the more active principles of the tar; and it would perhaps be more convenient to ſeparate its acid by diſtillation, and mix it with water occaſionally: for it is pretty certain, that the water can only take up the acid of the tar, perhaps charged with a very ſmall quantity of oily matter in the ſtate of an acid ſoap.

Decoction of catechu. Gen.

406 Take of catechu, three drams; ſpring-water, two pounds: boil it to one pound; and add to the ſtrained liquor, of ſyrup of quinces, three ounces.

This decoction may be conſidered as nearly ſimilar to the decoctum japonicum, and decoctum terræ japonicæ of the former editions of our pharmacopœia: and like theſe it will be found a very agreeable and uſeful medicine in fluxes that are not critical or ſymptomatic, and in a weak lax ſtate of the inteſtines. A ſpoonful or two may be taken every hour, or oftener: thus managed, it produces much better effects than if larger doſes are given at once. But for extracting the powers of the catechu, boiling is not requiſite. By ſimple infuſion in warm water, all its active parts are readily and completely diſſolved. It may in this manner alſo be readily united with cinnamon or other aromatics. And an infuſum japonicum is, we think, a formula juſtly intitled to a place in our pharmacopœias.

Preparations and Compositions.

Chap. XX. *Medicated Wines.*

407 The original intention of medicated wines was, that medicines, which were to be continued for a length of time, might be taken in the moſt familiar and agreeable form; by this means a courſe of remedies was complied with, notwithſtanding the repugnance and averſion which the ſick often manifeſt to thoſe directly furniſhed from the ſhops; and hence the inferior ſort of people had their medicated ales. Nevertheleſs, as vinous liquors excellently extract the virtues of ſeveral ſimples, and are not ill fitted for keeping, they have been employed as officinal menſtrua alſo; and ſubſtances of the greateſt efficacy are truſted in this form. As compounds of water and inflammable ſpirit, they take up ſuch parts of vegetables and animals as are ſoluble in thoſe liquors; though moſt of them abound at the ſame time with a mucilaginous or viſcous ſubſtance, which renders them leſs effectual menſtrua than purer mixtures of water and ſpirit. They contain likewiſe a ſubtile acid, which ſomewhat further obſtructs their action on certain vegetable and animal matters; but enables them, in proportion to its quantity, to diſſolve ſome bodies of the metallic kind, and thus impregnate themſelves with the corroborating virtues of ſteel, the alterative and emetic powers of antimony, and the noxious qualities of lead.

To all the medicated wines, after they have been ſtrained, you may add about one-twentieth their quantity of proof ſpirit, to preſerve them from fermentation. They may be conveniently kept in the ſame kind of glaſs bottles that wines generally are for common uſes, which ſhould likewiſe be corked with the ſame care.

Wine of aloes. L.

408 Take of ſocotorine aloes, eight ounces; white canella, commonly called *winter's bark*, two ounces; Spaniſh white wine, ſix pints; proof-ſpirit, two pints. Powder the aloes and white canella ſeparately; when mixed, pour on them the wine and ſpirit: afterwards digeſt for fourteen days, now and then ſhaking them; laſtly, ſtrain. It will not be amiſs to mix white ſand, cleanſed from impurities, with the powder, in order to prevent the moiſtened aloes from getting into lumps.

Aloetic wine, or *ſacred tincture.* E.

Take of ſocotorine aloes, one ounce; leſſer cardamom ſeeds, ginger, each one dram; Spaniſh white wine, two pounds. Digeſt for ſeven days, ſtirring now and then, and afterwards ſtrain.

This medicine has long been in great eſteem, not only as a cathartic, but likewiſe as a ſtimulus; the wine diſſolving all that part of the aloes in which theſe qualities reſide, a portion only of the leſs active reſinous matter being left. The aromatic ingredients are added to warm the medicine, and ſomewhat alleviate the ill flavour of the aloes: white canella, or cloves, are ſaid, among numerous materials that have been tried, to anſwer this end the moſt ſucceſsfully; hence the introduction of the former of theſe into the formula of the London college.

The ſacred tincture appears from long experience to be a medicine of excellent ſervice in languid, phlegmatic habits, not only for cleanſing the primæ viæ, but likewiſe for ſtimulating the ſolids, warming the habit, promoting or exciting the uterine purgations, and the hæmorrhoidal flux. The doſe, as a purgative, is from one to two ounces or more. It may be introduced into the habit, ſo as to be productive of excellent effects, as an alterant, by giving it in ſmall doſes, at proper intervals: thus managed, it does not for a conſiderable time operate remarkably by ſtool; but at length proves purgative, and occaſions a lax habit of much longer continuance than that produced by the other common cathartics.

Bitter wine. E.

Take of root of gentian, half an ounce; Peruvian bark, one ounce; Seville orange-peel, dried, two drams; white canella, one dram; proof ſpirit, four ounces; Spaniſh white wine, two pounds and a half. Firſt pour on the ſpirit, after twenty-four hours add the wine; then macerate for three days, and ſtrain. 409

This wine is intended to ſupply the place of the ſtomachic tincture, as it was formerly called. The wine is a menſtruum fully capable of extracting the active powers of the different ingredients; and it ſupplies us with a very uſeful and elegant ſtomachic medicine, anſwering the purpoſes intended much better than the celebrated elixir of Van Helmont, and other unchemical and uncertain preparations, which had formerly a place in our pharmacopœias.

Wine of antimony. L.

Take of vitrified antimony, powdered, one ounce; Spaniſh white wine, a pint and an half. Digeſt for twelve days, frequently ſhaking the veſſel, and filter the wine through paper.

Antimonial wine. E.

Take of glaſs of antimony, finely powdered, one ounce; Spaniſh white wine, fifteen ounces. Macerate for three days, ſtirring them now and then, and afterwards ſtrain the liquor through paper. 410

However carefully the ſettling and decantation are performed, the filtration of the wine through paper appears to be neceſſary, leſt ſome of the finer parts of the glaſs ſhould chance to remain ſuſpended in ſubſtance. It is not here, as in moſt other wines and tinctures, where the matter left undiſſolved by the menſtruum is of little conſequence; the antimonial glaſs, after the action of the wine, continues as virulent as ever, and capable of impregnating freſh parcels of the liquor as ſtrongly as the firſt, and this, in appearance, inexhauſtibly. After thirty repeated infuſions, it has been found ſcarce ſenſibly diminiſhed in weight.

The antimonial wine poſſeſſes the whole virtues of that mineral, and may be ſo doſed and managed as to perform all that can be effected by any antimonial preparation; with this advantage, that as the active part of the antimony is here already diſſolved and rendered miſcible with the animal fluids, its operation is more certain. Given from ten to fifty or ſixty drops, it generally acts as an alterative and diaphoretic; in larger doſes, as a diuretic and cathartic; while three or four drams prove for the moſt part violently emetic.

Preparations and Compositions.

It has been chiefly uſed with this laſt intention, in ſome maniacal and apoplectic caſes; and hence it gained the name of *emetic wine*.

The quantity of the reguline part muſt, however, vary according to the proportions of the acid matter in different wines, and the operation of the medicine muſt be thereby leſs certain in degree; the vitrum is preferable to the crocus for making this preparation. See the different preparations of *Antimony*.

Wine of tartarized antimony. L.

411 Take of tartarized antimony, two ſcruples; boiling diſtilled water, two ounces; Spaniſh white wine, eight ounces; diſſolve the tartarized antimony in the boiling diſtilled water, and add the wine.

Wine of antimonial tartar. E.

Take of antimonial tartar, commonly called *emetic tartar*, twenty four grains; and diſſolve it in a pound of Spaniſh white wine.

Watery ſolutions of emetic tartar, on ſtanding, precipitate a part which is leſs completely in a ſaline ſtate; by this means, and eſpecially if the ſolution be not ſhaken before uſing it, the doſe of that medicine is ſomewhat ambiguous: in the above formula, the acid matter of the wine increaſes the ſaline ſtate of the antimony, and therefore its ſolubility, whereby the operation of the medicine is more certain, and in many caſes more powerful. From the certainty of its effects, this preparation might be very convenient in large hoſpitals or armies, where great numbers of the ſick, and inaccurate nurſing, frequently occaſion an uncertain or dangerous practice.

In the formula employed by the Edinburgh college, each ounce of the wine contains two grains of the tartarized antimony; but in that of the London college, each ounce of the menſtruum contains four grains: hence, while an ounce of the one may be employed for exciting full vomiting, the ſame quantity of the other would be too ſtrong a doſe. It is much to be regretted, that, in articles of this active nature, the proportions employed by the two colleges ſhould differ ſo conſiderably: and it would perhaps have been better, had the London college adopted the proportions employed by that of Edinburgh, as they have followed them in adopting this formula.

Wine of iron. L.

412 Take of filings of iron, four ounces; Spaniſh white wine, four pints. Digeſt for a month, often ſhaking the veſſel, and then ſtrain.

This formula of the London pharmacopœia is now not only ſimplified, but improved, when compared with their former *vinum chalybeatum*: for the cinnamon and other articles which were then conjoined with the iron, were certainly rather prejudicial than otherwiſe; but at the ſame time, Rheniſh wine, formerly employed, is perhaps to be conſidered as a better menſtruum than the Spaniſh wine now directed. It may ſtill, however, be juſtly conſidered as a good chalybeate; and we think the Edinburgh college have done wrong in rejecting the formula from their pharmacopœia.

By the London college it was formerly prepared by maceration, without heat; now, however, they direct digeſtion for the ſpace of a month. Some have objected to the uſe of heat, that it impregnated the wine more ſtrongly with the metal, and thus rendered it more unpleaſant to the taſte: but if this was the only inconvenience, the remedy would be eaſy, diluting it with more wine. Heat has another effect, much leſs deſirable, and which art cannot remedy; making a diſagreeable alteration in the quality of the wine itſelf: hence it is neceſſary that it ſhould be very moderate.

Steel-wine is a very uſeful preparation of this metal, and frequently exhibited in chlorotic and other indiſpoſitions where chalybeates are proper. Boerhaave recommends it as one of the nobleſt medicines he was acquainted with for promoting that power in the body by which blood is made, when weakened by a bare debility of the over-relaxed ſolids, and an indolent, cold, aqueous indiſpoſition of the juices: for in this caſe, ſays he, no virtue of any vegetable or animal ſubſtance, no diet, nor regimen, can effect that which is effected by iron: but it proves hurtful where the vital powers are already too ſtrong, whether this proceeds from the fluids or the ſolids. The doſe is from a dram to half an ounce; which may be repeated two or three times a-day.

Some direct ſolutions of iron, made in wine or other vegetable acids, to be evaporated to the conſiſtence of an extract, under the title of *extractum martis*. Theſe preparations have no advantage, in point of virtue, above the common chalybeates: though in ſome forms, that of pills in particular, they may be rather more commodiouſly exhibited than moſt of the officinal chalybeates of equal efficacy. They may be made into pills by themſelves; and are tenacious enough to reduce other ſubſtances into that form.

Wine of ipecacuanha. L.

413 Take of the root of ipecacuanha, bruiſed, two ounces; Spaniſh white wine, two pints. Digeſt for ten days, and ſtrain.

Wine, or tincture, of ipecacuanha. E.

Take of ipecacuanha, in powder, one ounce; Spaniſh white wine, fifteen ounces. After three days maceration, let the tincture be filtrated for uſe.

Both theſe wines are very mild and ſafe emetics, and equally ſerviceable in dyſenteries alſo with the ipecacuanha in ſubſtance; this root yielding nearly all its virtues to the Spaniſh white wine here ordered, as it does a good ſhare of them even to aqueous liquors. The common doſe is an ounce, more or leſs, according to the age and ſtrength of the patient. The college of Edinburgh added formerly a ſcruple of cochineal, which imparts a fine red colour to the liquor: this article is now omitted, on a complaint that the red colour of the matters evacuated ſometimes alarmed the patient, as if it proceeded from a diſcharge of blood.

Wine of millepeds. E.

414 Take of live millepeds, bruiſed, one ounce; Rheniſh wine, eight ounces. Infuſe them together for twelve hours, and afterwards preſs the liquor through a ſtrainer.

This wine has been commended as an admirable cleanſer of all the viſcera, yielding to nothing in the jaundice and obſtructions of the kidneys or urinary

passages, of excellent service in almost all chronical distempers, even in scrofulous and strumous swellings, and in defluxions of rheum upon the eyes. But those who expected these extraordinary virtues from it have often been deceived; and at present there are few who have any great dependence on it; and hence it is omitted by the London college, probably without any loss. It is directed to be given from half an ounce to two ounces.

Wine of rhubarb. L.

415 Take of sliced rhubarb, two ounces and an half; lesser cardamom seeds, bruised and husked, half an ounce; saffron, two drams; Spanish white wine, two pints; proof-spirit, eight ounces. Digest for ten days, and strain.

Rhubarb-wine. E.

Take of rhubarb, two ounces; white canella, one dram; proof-spirit, two ounces; Spanish white wine, fifteen ounces. Macerate for seven days, and strain.

By assisting the solvent power of the menstruum, the proof-spirit in the above formulæ is a very useful addition. This is a warm, cordial, laxative medicine. It is used chiefly in weakness of the stomach and bowels, and some kinds of looseneſſes, for evacuating the offending matter, and strengthening the tone of the viscera. It may be given from half a spoonful to three or four spoonfuls or more, according to the circumstances of the disorder, and the purposes it is intended to answer.

Tobacco-wine.

416 Take of the dried leaves of the best Virginian tobacco, one ounce; Spanish white wine, one pound. Macerate for four days, and then strain the liquor.

We have already, under the article NICOTIANA, offered some observations on its late introduction into practice by Dr Fowler, as a very useful remedy in the cure of dropsies and dysuries. From his treatise on that subject the present formula is taken; and we may observe, that while in practice we have frequently experienced from the tobacco those good effects for which Dr Fowler recommends it, we are inclined to give the present formula the preference to every other which he has proposed. It seems to extract more fully the active principles of the tobacco than either water or spirit taken separately. For further observations on the medical virtues of tobacco, see the article NICOTIANA.

Squill-wine. Suec.

417 Take of dried squill, sliced, one ounce; ginger, one dram; French white wine, two pounds. Macerate for three days, and then strain.

By the wine employed as a menstruum, the active properties of the squills may be readily extracted; and in some cases at least the present formula may justly be considered as intitled to a preference over either the vinegar or oxymel of squills, which have a place in our pharmacopœias. The ginger here added to the squills operates as an useful corrigent; and on this account the present formula is preferable to the squill-wine of some other pharmacopœias, where the squills alone are used: For it is chiefly used in those cases where it is intended that the squills should exert their effects, not on the alimentary canal, but on the kidneys or other excretories.

418

Zedoary wine. Dan.

Take of the root of zedoary, gently bruised, two pounds; spirit of wine, eight pounds. Let them be macerated for a month; then add spring water, eight pounds. Distil from thence twelve pounds.

Though this formula has the name of a wine, yet it is in reality a distilled spirit, nothing from the zedoary but a portion of its essential oil being united with the ardent spirit: and we are inclined to think, that the active powers of this article, both as depending on aroma and bitterness, might be better obtained by a simple infusion in Spanish white wine.

CHAP. XXI. *Tinctures.*

RECTIFIED spirit of wine is the direct menstruum of the resins and essential oils of vegetables, and totally extracts these active principles from sundry vegetable matters, which yield them to water either not at all, or only in part. It dissolves likewise the sweet saccharine matter of vegetables; and generally those parts of animal bodies in which their peculiar smell and taste reside. 419

The virtues of many vegetables are extracted almost equally by water and rectified spirit; but in the watery and spirituous tinctures of them there is this difference, that the active parts in the watery extractions are blended with a large proportion of inert gummy matter, on which their solubility in this menstruum in a great measure depends, while rectified spirit extracts them almost pure from gum. Hence, when the spirituous tinctures are mixed with watery liquors, a part of what the spirit had taken up from the subject generally separates and subsides, on account of its having been freed from that matter which, being blended with it in the original vegetable, made it soluble in water. This, however, is not universal; for the active parts of some vegetables, when extracted by rectified spirit, are not precipitated by water, being almost equally soluble in both menstrua.

Rectified spirit may be tinged by vegetables of all colours except blue: the leaves of plants in general, which give out but little of their natural colour to watery liquors, communicate to spirit the whole of their green tincture, which for the most part proves elegant, though not very durable.

Fixed alkaline salts deepen the colour of spirituous tinctures; and hence they have been supposed to promote the dissolving power of the menstruum, though this does not appear from experience: in the trials that have been made to determine this affair, no more was found to be taken up in the deep-coloured tinctures than in the paler ones, and often not so much: if the alkali be added after the extraction of the tincture, it will heighten the colour as much as when mixed with the ingredients at first. Nor does the addition of these salts make tinctures useless only, but likewise prejudicial, as they in general injure the flavour of aromatics, and superadd a quality, sometimes contrary to the intention of the medicine. Volatile alkaline salts, in many cases, promote the action of the spirits. A-

Preparations and Compositions.

cifs generally weaken it; unleſs when the acid has been previouſly combined with the vinous ſpirit into a compound of new qualities, called *dulcified ſpirit.*

Tincture of wormwood. E.

420 Take of the flowering tops of wormwood, properly dried, four ounces; rectified ſpirit of wine, two pounds. Macerate for two days; then preſs out the ſpirit, and pour it on two ounces of wormwood. Macerate again for four days; then preſs the tincture through a cloth, and afterwards ſtrain it through paper.

The aromatic parts of wormwood are more eſpecially found in the flowering tops, and its bitterneſs in the leaves: but as the latter are replete with a mucilaginous matter, which might impede the action of the menſtruum on the aromatic parts in this very elegant formula the flowering tops are infuſed firſt, and their tincture made to extract the bitter parts of the leaves and ſtalks. This preparation may therefore be conſidered as containing the whole virtues of the plant.

In the tincture of wormwood we have one of the ſtrongeſt of the vegetable bitters. It is ſometimes uſed as an anthelmintic, and ſtill more frequently in ſtomach ailments: But to moſt people it is a very diſagreeable medicine.

Tincture of aloes. L.

421 Take of ſocotorine aloes, powdered, half an ounce; extract of liquorice, an ounce and an half; diſtilled water, proof-ſpirit, of each eight ounces. Digeſt in a ſand-bath, now and then ſhaking the veſſel, until the extract be diſſolved, and then ſtrain.

In this ſimple tincture all the active parts of the aloes, whether of a gummy or reſinous nature, are ſuſpended in the menſtruum. The extract of liquorice ſerves both to promote the ſuſpenſion and to cover the taſte of the aloes; and in theſe caſes where we wiſh for the operation of the aloes alone, without the aid either of an adjuvans or corrigens, this is perhaps one of the beſt formulæ under which aloes can be exhibited in a fluid ſtate.

Compound tincture of aloes. L.

422 Take of tincture of myrrh, two pints; ſaffron, ſocotorine aloes, of each three ounces. Digeſt for eight days, and ſtrain.

Elixir of aloes, commonly called *elixir proprietatis.* E.

Take of myrrh in powder, two ounces; ſocotorine aloes, an ounce and a half; Engliſh ſaffron, one ounce; rectified ſpirit of wine, proof-ſpirit, of each one pound. Digeſt the myrrh with the ſpirit for the ſpace of four days; then add the aloes in powder, and the ſaffron; continue the digeſtion for two days longer, ſuffer the feces to ſubſide, and pour off the clear elixir.

Theſe two formulæ, though the mode of preparation be ſomewhat varied, do not materially differ from each other; and both may be conſidered as being the *elixir proprietatis* of Paracelſus, improved with regard to the manner of preparation. The myrrh, ſaffron, and aloes, have been uſually directed to be digeſted in the ſpirit together: by this method, the menſtruum ſoon loads itſelf with the latter, ſo as ſcarcely to take up any of the myrrh; while a tincture, extracted firſt from the myrrh, readily diſſolves a large quantity of the others. The alkaline ſalt, commonly ordered in theſe preparations with a view to promote the diſſolution of the myrrh, we have already obſerved to be uſeleſs; and accordingly it is now omitted. Inſtead of employing the rectified ſpirit alone, the Edinburgh college have uſed an equal portion of proof-ſpirit, which is not only a more complete menſtruum, but alſo renders the medicine leſs heating.

Preparations and Compositions.

This medicine is highly recommended, and not undeſervedly, as a warm ſtimulant and aperient. It ſtrengthens the ſtomach and other viſcera, cleanſes the firſt paſſages from tenacious phlegm, and promotes the natural ſecretions in general. Its continued uſe has frequently done much ſervice in cachectic and icteric caſes, uterine obſtructions, and other ſimilar diſorders; particularly in cold pale phlegmatic habits. Where the patient is of a hot bilious conſtitution and florid complexion, this warm ſtimulating medicine is leſs proper, and ſometimes prejudicial. The doſe may be from twenty drops to a tea-ſpoonful or more, two or three times a-day, according to the purpoſes which it is intended to anſwer.

Vitriolic elixir of aloes, or *proprietatis.* E.

Take of myrrh, ſocotorine aloes, each an ounce and a half; Engliſh ſaffron, one ounce; dulcified ſpirit of vitriol, one pound. Digeſt the myrrh with the ſpirit for four days in a cloſe veſſel; then add the ſaffron and aloes. Digeſt again four days; and when the feces have ſubſided pour off the elixir. 423

The Edinburgh college have reformed this preparation conſiderably; and eſpecially by directing the myrrh to be digeſted firſt, for the ſame reaſons as were obſerved on the preceding article. Here the dulcified ſpirit of vitriol is very judiciouſly ſubſtituted for the ſpirit of ſulphur, ordered in other books of pharmacy to be added to the foregoing preparation; for that ſtrong acid precipitates from the liquor great part of what it had before taken up from the other ingredients; whereas, when the acid is previouſly combined with the vinous ſpirit, and thereby dulcified, as it is called, it does not impede its diſſolving power. This elixir poſſeſſes the general virtues of the preceding, and is, in virtue of the menſtruum, preferred to it in hot conſtitutions and weakneſſes of the ſtomach.

Aromatic tincture. E.

Take of cinnamon, ſix drams: leſſer cardamom ſeeds, one ounce; garden-angelica root, three drams; long pepper, two drams; proof ſpirit, two pounds and an half. Macerate for ſeven days, and filter the tincture. 424

This preparation is improved from the preceding editions by the omiſſion of ſome articles, either ſuperfluous or foreign to the intention; galangal, gentian, zedoary, bay-berries, and calamus aromaticus. As now reformed, it is a ſufficiently elegant warm aromatic.

This very warm aromatic is too hot to be given without dilution. A tea ſpoonful or two may be taken in wine or any other convenient vehicle, in languors,

Preparations and Compositions.

weakneſs of the ſtomach, flatulencies, and other ſimilar complaints; and in theſe caſes it is often employed with advantage.

Tincture of aſafœtida. L.

425 Take of aſafœtida, four ounces; rectified ſpirit of wine, two pints. Digeſt with a gentle heat for ſix days, and ſtrain.

Fetid tincture. E.

Take of aſafœtida, two ounces; vinous ſpirit of ſal ammoniac one pound. Macerate for ſix days in a cloſe ſhut veſſel, and ſtrain.

Of theſe two formulæ, the laſt is perhaps moſt generally uſeful: The vinous ſpirit of ſal ammoniac is not only a more powerful menſtruum than the rectified ſpirit of wine, but alſo coincides with the general virtues of the remedy.

This tincture poſſeſſes the virtues of the aſafœtida itſelf; and may be given from ten drops to fifty or ſixty. It was firſt propoſed to be made with proof-ſpirit; this diſſolves more of the aſafœtida than a rectified one; but the tincture proves turbid; and therefore rectified ſpirit, which extracts a tranſparent one, is very juſtly preferred where ardent ſpirit is to be employed: and with this menſtruum we can at leaſt exhibit the aſafœtida in a liquid form to a greater extent.

Tincture of balſam of Peru. L.

426 Take of balſam of Peru, four ounces; rectified ſpirit of wine, one pint. Digeſt until the balſam be diſſolved.

The whole of the Peruvian balſam is diſſolved by ſpirit of wine: this therefore may be conſidered as a good method of freeing it from its impurities; while at the ſame time it is thus reduced to a ſtate under which it may be readily exhibited: but at preſent it is very little employed, unleſs in compoſition, either under this or any other form.

Tincture of balſam of Tolu.

427 Take of balſam of Tolu, one ounce and an half; rectified ſpirit of wine, one pint. Digeſt until the balſam be diſſolved, and ſtrain. *L.*

Take of balſam of Tolu, an ounce and an half; rectified ſpirit of wine, one pound. Digeſt until the balſam be diſſolved, and then ſtrain the tincture. *E.*

This ſolution of balſam of Tolu poſſeſſes all the virtues of the balſam itſelf. It may be taken internally, with the ſeveral intentions for which that valuable balſam is proper, to the quantity of a tea-ſpoonful or two, in any convenient vehicle. Mixed with the plain ſyrup of ſugar, it forms an elegant balſamic ſyrup.

Compound tincture of benzoin. L.

428 Take of benzoin, three ounces; ſtorax ſtrained, two ounces; balſam of Tolu, one ounce; ſoccotorine aloes, half an ounce; rectified ſpirit of wine, two pints. Digeſt with a gentle heat for three days, and ſtrain.

Traumatic balſam. E.

Take of benzoin, three ounces; balſam of Peru, two ounces; hepatic aloes, half an ounce; rectified ſpirit of wine, two pounds. Digeſt them in a ſand heat for the ſpace of ten days, and then ſtrain the balſam.

Preparations and Compositions.

Although the London college have changed the name of this compoſition, yet they have made very little alteration on the formula which, in their laſt edition, had the name of *Traumatic balſam*; a name which it ſtill retains in the Edinburgh pharmacopœia; and both may be conſidered as elegant contractions of ſome very complicated compoſitions, which were celebrated under different names; ſuch as Baume de Commandeur, Wade's balſam, Friar's balſam, Jeſuit's drops, &c. Theſe, in general, conſiſted of a confuſed jarrago of diſcordant ſubſtances. They, however, derived conſiderable activity from the benzoin and aloes; and every thing to be expected from them may readily be obtained from the preſent formulæ.

The compound tincture of benzoin, or traumatic balſam, ſtands highly recommended, externally, for cleanſing and healing wounds and ulcers, for diſcuſſing cold tumors, allaying gouty, rheumatic, and other old pains and aches; and likewiſe internally, for warming and ſtrengthening the ſtomach and inteſtines, expelling flatulencies, and relieving colic complaints. Outwardly, it is applied cold on the part with a feather; inwardly, a few drops are taken at a time, in wine or any other convenient vehicle.

There is, however, reaſon to think that its virtues have been conſiderably over-rated; and at preſent it is much leſs employed than formerly, recourſe being chiefly had to it in caſes of recent wounds, with the view of ſtopping hæmorrhagies, and of promoting healing by the firſt intention, as it is called.

Tincture of the Spaniſh fly.

Take of bruiſed cantharides, two drams; cochineal, powdered, half a dram; proof-ſpirit, one pint and an half. Digeſt for eight days, and ſtrain. *L.* 429

Take of cantharides, one dram; proof ſpirit, one pound. Digeſt for four days, and ſtrain through paper. *E.*

Theſe tinctures poſſeſs the whole virtues of the fly, and are the only preparations of it deſigned for internal uſe: tinctures being by far the moſt commodious and ſafe form for the exhibition of this active drug. The two tinctures are ſcarcely different in virtue from each other. The cochineal is uſed only as a colouring ingredient: the gum-guaiacum, camphor, and eſſential oil of juniper-berries, which were formerly added, however well adapted to the intentions of cure, could be of little conſequence in a medicine limited to ſo ſmall a doſe. If any additional ſubſtances ſhould be thought requiſite for promoting the effect of the cantharides, whether as a diuretic, as a detergent in ulcerations of the urinary paſſages, or as a ſpecific reſtringent of ſeminal gleets and the fluor albus, they are more advantageouſly joined extemporaneouſly to the tincture, or interpoſed by themſelves at proper intervals. The uſual doſe of theſe tinctures is from ten to twenty drops; which may be taken in a glaſs of water, or any other more agreeable liquor, twice a day; and increaſed by two or three drops at a time, according to the effect.

The tincture of cantharides has of late been highly celebrated as a ſucceſsful remedy in diabetic caſes; and

Preparations and Compositions.

and in ſome inſtances of this kind, its uſe has been puſhed to a very conſiderable extent, without giving riſe to any ſtrangurious affections: But we have not found it productive of a change for the better in any of thoſe caſes of diabetes in which we have tried it.

Tincture of cardamom.

430 Take of leſſer cardamom ſeeds, huſked and bruiſed, three ounces; proof-ſpirit, two pints. Digeſt for eight days, and ſtrain. *L.*

Take of leſſer cardamom-ſeeds, ſix ounces; proof-ſpirit, two pounds and a half. Macerate for eight days, and ſtrain through paper. *E.*

Tincture of cardamom has been in uſe for a conſiderable time. It is a pleaſant, warm cordial; and may be taken, along with any proper vehicle, from a dram to a ſpoonful or two.

Compound tincture of cardamom. L.

431 Take of leſſer cardamom ſeeds, huſked, caraway-ſeeds, cochineal, each, powdered, two drams; cinnamon, bruiſed, half an ounce; raiſins, ſtoned, four ounces; proof-ſpirit, two pints. Digeſt for fourteen days, and ſtrain.

This tincture contains ſo ſmall a proportion of cardamoms as to be hardly intitled to derive its name from that article; and from the large proportion of raiſins which it contains, the influence of the aromatics muſt be almoſt entirely prevented, while, at the ſame time, from theſe it cannot be ſuppoſed to obtain any active impregnation.

Tincture of caſcarilla. L.

432 Take of the bark of caſcarilla, powdered, four ounces; proof-ſpirit, two pints. Digeſt with a gentle heat for eight days, and ſtrain.

Proof-ſpirit readily extracts the active powers of the caſcarilla; and the tincture may be employed to anſwer moſt of thoſe purpoſes for which the bark itſelf is recommended: But in the cure of intermittents, it in general requires to be exhibited in ſubſtance.

Tincture of caſtor.

433 Take of Ruſſia caſtor, powdered, two ounces; proof-ſpirit, two pints. Digeſt for ten days, and ſtrain. *L.*

Take of Ruſſia caſtor, an ounce and a half; rectified ſpirit of wine, one pound; digeſt them with a gentle heat for ſix days, and afterwards ſtrain off the liquor. *E.*

An alkaline ſalt was formerly added in this laſt preſcription, which is here judiciouſly rejected, as being at leaſt an uſeleſs, if not a prejudicial, ingredient. It has been diſputed, whether a weak or rectified ſpirit, and whether cold or warm digeſtion, are preferable for making this tincture. To determine this point, the following experiment has been mentioned. "Some fine Siberia caſtor having been infuſed in good French brandy, without heat, for twenty days, the tincture proved very weak: On the ſame individual caſtor (the magma or reſiduum of the former tincture) the ſame quantity of rectified ſpirit was poured as before of brandy; and after a few hours warm digeſtion, a tincture was extracted much ſtronger than the other." But this experiment is not ſatisfactory: the effects of the two menſtrua, and of heat, having been reſpectively compared in very different circumſtances.

Preparations and Compoſitions.

From other trials, it appears that caſtor, macerated without heat, gives out its finer and moſt grateful parts to either ſpirit, but moſt perfectly to the rectified. That heat enables both menſtrua to extract greateſt part of its groſſer, and more naufeous matter; and proof-ſpirit extracts this laſt more readily than rectified.

The tincture of caſtor is recommended in moſt kinds of nervous complaints and hyſteric diſorders: In the latter it ſometimes does ſervice, though many have complained of its proving ineffectual. The doſe is from twenty drops to forty, fifty, or more.

Compound tincture of caſtor. E.

Take of Ruſſia caſtor, one ounce; aſafœtida, half an ounce; vinous ſpirit of ſal ammoniac, one pound. Digeſt for ſix days in a cloſe ſtopped phial, frequently ſhaking the veſſel; and then ſtrain the tincture. 434

This compoſition is a medicine of real efficacy, particularly in hyſterical diſorders, and the ſeveral ſymptoms which accompany them. The ſpirit here uſed is an excellent menſtruum, both for the caſtor and the aſafœtida, and greatly adds to their virtues.

Tincture of catechu. L.

Take of catechu, three ounces; cinnamon, bruiſed, two ounces; proof-ſpirit, two pints. Digeſt for three days, and ſtrain. 435

Japonic tincture. E.

Take of Japan earth, three ounces; cinnamon, two ounces; proof-ſpirit, two pounds and a half. After digeſtion for eight days, let the tincture be paſſed through a ſtrainer.

A tincture of this kind, with the addition of Peruvian bark, ambergris, and muſk, to the ingredients above directed, was formerly kept in the ſhops. The tincture here received is preferable for general uſe: where any other ingredients are required, tinctures of them may be occaſionally mixed with this in extemporaneous preſcription. The cinnamon is a very uſeful addition to the catechu, not only as it warms the ſtomach, &c. but likewiſe as it improves the roughneſs and aſtringency of the other.

The tincture is of ſervice in all kinds of defluxions, catarrhs, looſeneſſes, uterine fluors, and other diſorders, where mild aſtringent medicines are indicated. Two or three tea-ſpoonfuls may be taken every now and then in red wine, or any other proper vehicle.

Tincture of cinnamon.

Take of cinnamon, bruiſed, one ounce and an half; proof-ſpirit, one pint. Digeſt for ten days, and ſtrain. *L.* 436

Take of cinnamon, three ounces; proof-ſpirit, two pounds and a half. Macerate for eight days, and ſtrain. *E.*

The tincture of cinnamon poſſeſſes the reſtringent virtues of the cinnamon, as well as its aromatic cordial ones; and in this reſpect it differs from the diſtilled waters of that ſpice.

Compound

Compound tincture of cinnamon. L.

Take of cinnamon, bruiſed, ſix drams; leſſer cardamom-ſeeds, huſked, three drams; long pepper, ginger, of each, in powder, two drams; proof-ſpirit, two pints. Digeſt for eight days and ſtrain.

From the different articles which this tincture contains, it muſt neceſſarily be of a more hot and fiery nature than the former, though much leſs ſtrongly impregnated with the cinnamon.

Tincture of colomba. L.

Take of colomba-root, powdered, two ounces and an half; proof-ſpirit, two pints. Digeſt for eight days, and ſtrain.

The colomba readily yields its active qualities to the menſtruum here employed; and accordingly, under this form, it may be advantageouſly employed againſt bilious vomitings, and thoſe different ſtomach ailments, in which the colomba has been found uſeful; but where there does not occur ſome objection to its uſe in ſubſtance, that form is in general preferable to the tincture, which is now for the firſt time introduced into the London pharmacopœia.

Tincture of orange peel. L.

Take of the freſh exterior peel of Seville oranges, three ounces; proof-ſpirit, two pints. Digeſt for three days, and ſtrain.

By this menſtruum, both the bitter quality of the orange ſkins, and likewiſe their peculiar eſſential oil, are extracted: hence it may be employed for any purpoſe in medicine which theſe are capable of anſwering. It is, however, but rarely uſed; and, as well as the former, has now only for the firſt time a place in the London pharmacopœia.

Tincture of Peruvian bark.

Take of Peruvian bark, powdered, four ounces; proof-ſpirit, two pints. Digeſt with a gentle heat for eight days, and ſtrain. *L.*

Take of Peruvian bark, four ounces; proof-ſpirit, two pounds and a half. Digeſt for ten days, and ſtrain. *E.*

A medicine of this kind has been for a long time pretty much in eſteem, and uſually kept in the ſhops, though but lately received into the pharmacopœias. Some have employed highly-rectified ſpirit of wine as a menſtruum; which they have taken care fully to ſaturate, by digeſtion on a large quantity of the bark. Others have thought of aſſiſting the action of the ſpirit by the addition of a little fixed alkaline ſalt, which does not however appear to be of any advantage; and others have given the preference to the vitriolic acid, which was ſuppoſed, by giving a greater conſiſtence to the ſpirit, to enable it to ſuſtain more than it would be capable of doing by itſelf; at the ſame time that the acid improves the medicine by increaſing the roughneſs of the bark. This laſt tincture, and that made with rectified ſpirit, have their advantages; though, for general uſe, that above directed is the moſt convenient of any, the proof-ſpirit extracting nearly all the virtues of the bark. It may be given from a tea ſpoonful to half an ounce, or an ounce, according to the different purpoſes it is intended to anſwer.

Compound tincture of Peruvian bark. L.

Take of Peruvian bark, powdered, two ounces; exterior peel of Seville oranges, dried, one ounce and an half; Virginian ſnake-root, bruiſed, three drams; ſaffron, one dram; cochineal, powdered, two ſcruples; proof-ſpirit, twenty ounces. Digeſt for fourteen days, and ſtrain.

This has been for a conſiderable time celebrated under the title of *Huxham's tincture of bark.*

The ſubſtances here joined to the bark, in ſome caſes, promote its efficacy in the cure of intermittents, and not unfrequently are abſolutely neceſſary. In ſome ill habits, particularly where the viſcera and abdominal glands are obſtructed, the bark, by itſelf, proves unſucceſsful, if not injurious; while given in conjunction with ſtimulating ſtomachics and deobſtruents, it more rarely fails of the due effect. Orange-peel and Virginian ſnake-root are among the beſt additions for this purpoſe; to which it is thought by ſome neceſſary to join chalybeate medicines alſo.

Aaa corroborant and ſtomachic, it is given in doſes of two or three drams; but when employed for the cure of intermittents, it muſt be taken to a greater extent. For this purpoſe, however, it is rarely employed, unleſs with thoſe who are averſe to the uſe of the bark in ſubſtance, or whoſe ſtomachs will not retain it under that form.

Tincture of ſaffron. E.

Take of Engliſh ſaffron, one ounce; proof-ſpirit, fifteen ounces. After digeſting them for five days, let the tincture be ſtrained through paper.

This tincture is ſimilar in virtue to the ſaffron wine. A ſpirituous menſtruum is here preferred to the wine, as a tincture drawn with the former retains its elegant colour longer, and is not apt to depoſite in keeping any part of what it had taken up from the ſaffron. The ſhops have been accuſtomed to employ treacle water as a menſtruum for ſaffron, with a view to the promoting its efficacy with the intention of operating as an alexipharmac; but the acid in that compound water ſoon deſtroys the colour of the tincture.

Tincture of muriated iron. L.

Take of the ruſt of iron, half a pound; muriatic acid, three pounds; rectified ſpirit of wine, three pints. Pour the muriatic acid on the ruſt of iron in a glaſs veſſel; and ſhake the mixture now and then during three days. Set it by that the feces may ſubſide; then pour off the liquor: evaporate this to one pint, and, when cold, add to it the vinous ſpirit.

Tincture of iron. E.

Take of the ſcales of iron, purified and powdered, three ounces; muriatic acid, as much as is ſufficient to diſſolve the powder. Digeſt with a gentle heat; and the powder being diſſolved, add of rectified ſpirit of wine as much as will make up of the whole liquor two pounds and a half.

Of theſe two formulæ, that of the Edinburgh college is, in our opinion, in ſeveral reſpects intitled to the

Preparations and Compositions.

the preference. The ſcales are much fitter for giving a proper ſolution than the ruſt. The ſtrength of the muriatic acid is ſo variable, that the quantity is left to the judgment of the operator. If the acid be ſuperabundant, the ſolution is of a green colour; if it be fully ſaturated with the iron, it is more or leſs of a reddiſh or yellow colour; and this ſerves as a pretty accurate criterion. As the muriatic acid combines leſs intimately with rectified ſpirit than any of the foſſil acids, ſo the after-proceſs of dulcification ſcarcely, if at all, impairs the ſolvent power of the acid; though, when the dulcification happens to be more than uſually complete, a ſmall quantity of ferruginous matter is ſometimes precipitated on adding the rectified ſpirit to the ſolution. But as the rectified ſpirit increaſes the volatility of the acid, ſo if it was added at firſt, we ſhould loſe much more of the menſtruum by the heat employed during the digeſtion. When this tincture is well prepared, it is of a yellowiſh-red colour; if the acid be ſuperabundant, it is more or leſs of a greeniſh hue; and if the rectified ſpirit has been impregnated with the aſtringent matter of oak caſks, it aſſumes an inky colour.

All the tinctures of iron are no other than real ſolutions of the metal made in acids, and combined with vinous ſpirits. The tinctures here directed differ from each other only in ſtrength, the acid being the ſame in both. In our former pharmacopœias, there was a tincture from the matter which remains after the ſublimation of the martial flowers; which, though it appears to be a good one, is now expunged as ſuperfluous. Some have recommended dulcified ſpirit of nitre as a menſtruum; but though this readily diſſolves the metal, it does not keep it ſuſpended. The marine is the only acid that can be employed for this purpoſe.

Theſe tinctures are greatly preferable to the calces or croci of iron, as being not only more ſpeedy, but likewiſe more certain in their operation. The latter, in ſome caſes, paſs off through the inteſtinal tube with little effect; while the tinctures ſcarce ever fail. From ten to twenty drops of either of the tinctures may be taken two or three times a-day, in any proper vehicle; though it is ſeldom adviſable to extend the doſe of any tinctures of iron ſo far as the laſt of theſe quantities, eſpecially with the tincture in ſpirit of ſalt, which is exceedingly ſtrong of the iron.

Tincture of ſoot. E.

444 Take of ſhining wood-ſoot, one ounce; aſafœtida, half an ounce; rectified ſpirit of wine, proof-ſpirit, of each half a pound. Digeſt for ſix days, and ſtrain.

The proof-ſpirit is not liable to any objection here, as giving a turbid tincture; for when ſoot is added, whatever ſpirit be employed, the tincture will not prove tranſparent. Fuller, in his Pharmacopœia Domeſtica, has a medicine under the title of *hyſteric tincture*, ſimilar to this, only with a little myrrh, which is no very material addition to aſafœtida and ſoot. Theſe medicines are found ſerviceable, not only in hyſteric caſes, but likewiſe in other nervous diſorders. They may be given from a tea-ſpoonful to a table-ſpoonful twice a-day.

This medicine has by ſome been thought ſerviceable in obſtructions of the menſes; but its activity may be conſidered as depending much more on the aſafœtida than on the ſoot.

Preparations and Compoſitions.

Tincture of galbanum. L.

445 Take of galbanum, cut into ſmall pieces, two ounces; proof-ſpirit, two pints. Digeſt with a gentle heat for eight days, and ſtrain.

This tincture is now for the firſt time introduced by the London college, and may be uſefully employed for anſwering ſeveral purpoſes in medicine. Galbanum is one of the ſtrongeſt of the fetid gums; and although leſs active, yet much leſs diſagreeable than aſafœtida: and under the form of tincture it may be ſucceſsfully employed in caſes of flatulence and hyſteria, where its effects are immediately required, particularly with thoſe who cannot bear aſafœtida.

Compound tincture of gentian. L.

446 Take of gentian root, ſliced and bruiſed, two ounces; exterior dried peel of Seville oranges, one ounce; leſſer cardamom ſeeds, huſked and bruiſed, half an ounce; proof-ſpirit, two pints. Digeſt for eight days, and ſtrain.

Bitter tincture, or ſtomachic elixir. E.

Take of gentian-root, two ounces; Seville orange-peel, dried, one ounce; white canella, half an ounce; cochineal, half a dram; proof-ſpirit, two pounds and a half. Macerate for four days, and ſtrain through paper.

Theſe are very elegant ſpirituous bitters. As the preparations are deſigned for keeping, lemon-peel, an excellent ingredient in the watery bitter infuſions, has, on account of the periſhableneſs of its flavour, no place in theſe. The aromatics are here a very commodious ingredient, as in this ſpirituous menſtruum they are free from the inconvenience with which they are attended in other liquors, of rendering them untranſparent.

Elixir of guaiacum. E.

447 Take of gum-guaiacum, one pound; balſam of Peru, three drams; rectified ſpirit of wine, two pounds and a half. Digeſt for ten days, and ſtrain.

This tincture may be conſidered as nearly agreeing in medical virtues with the two following. It is, however, leſs in uſe; but it may be employed with advantage in thoſe caſes where an objection occurs to the menſtruum uſed in forming the others.

Tincture of gum-guaiacum. L.

448 Take of gum-guaiacum, four ounces; compound ſpirit of ammonia, a pint and a half. Digeſt for three days, and ſtrain.

Volatile elixir of guaiacum. E.

Take of gum-guaiacum, four ounces; balſam of Peru, two drams; diſtilled oil of ſaſſafras, half a dram; vinous ſpirit of ſal ammoniac, a pound and an half. Macerate for ſix days in a cloſe veſſel, and ſtrain.

In the laſt of theſe formulæ, the vinous ſpirit of ſal ammoniac is leſs acrimonious than the menſtruum directed by the London college; and the balſam of Peru, and diſtilled oil of ſaſſafras, are uſeful additions, by

by increasing the permanence of its operation as a general ſtimulant, or more particularly as a diaphoretic.

Theſe are very elegant and efficacious tinctures; the volatile ſpirit excellently diſſolving the gum, and at the ſame time promoting its medicinal virtue. In rheumatic caſes, a tea or even table ſpoonful, taken every morning and evening in any convenient vehicle, particularly in milk, has proved of ſingular ſervice.

Tincture of black hellebore. L.

Take of black hellebore root, in coarſe powder, four ounces; cochineal, powdered, two ſcruples; proof-ſpirit, two pints. Digeſt with a gentle heat for eight days, and ſtrain.

Tincture of melampodium, or black hellebore. E.

Take of black hellebore root, four ounces; cochineal, half a dram; proof-ſpirit two pounds and a half. Digeſt them together for eight days, and afterwards filter the tincture through paper.

This is perhaps the beſt preparation of hellebore, when deſigned for an alterative, the menſtruum here employed extracting the whole of its virtues. It has been found, from experience, particularly ſerviceable in uterine obſtructions; in ſanguine conſtitutions, where chalybeates are hurtful, it has been ſaid that it ſeldom fails of exciting the menſtrual evacuations, and removing the ill conſequences of their ſuppreſſion. So great, according to ſome, is the power of this medicine, that wherever, from an ill conformation of the parts, or other cauſes, the expected diſcharge does not ſucceed on the uſe of it, the blood, as Dr Mead has obſerved, is ſo forcibly propelled, as to make its way through other paſſages. A tea ſpoonful of the tincture may be taken twice in a day in warm water or any other convenient vehicle.

The college of Edinburgh had formerly a tincture of this root with wine. Proof ſpirit is undoubtedly preferable, both as a menſtruum, and as being better fitted for keeping.

Tincture of jalap.

Take of powdered jalap root, eight ounces; proof-ſpirit, two pints. Digeſt with a gentle heat for eight days, and ſtrain. *L.*

Take of jalap, in coarſe powder, three ounces; proof-ſpirit, fifteen ounces. Digeſt them for eight days, and ſtrain the tincture. *E.*

Rectified ſpirit of wine was formerly ordered for the preparation of this tincture; but rectified ſpirit diſſolving little more than the pure reſinous parts of the jalap, rendered the uſe of the medicine ſomewhat leſs commodious than that of the tincture prepared with proof-ſpirit. Moſt of the tinctures made in rectified ſpirit, diluted with water, ſo as to be fit for taking, form a turbid white mixture. Many of them are ſafely taken in this form, without any further addition: but the cathartic ones are never to be ventured on without an admixture of ſyrup or mucilage to keep the reſin united with the liquor; for if it ſeparates in its pure undivided ſtate, it never fails to produce violent gripes.

Some have preferred to the tinctures of jalap, a ſolution in ſpirit of wine of a known quantity of the reſin extracted from the root; and obſerve, that this ſolution is more certain in ſtrength than any tincture that can be drawn from the root directly. For, as the purgative virtue of jalap reſides in its reſin, and as all jalap appears from experiment not to be equally reſinous, ſome ſorts yielding five, and others not three, ounces of reſin from ſixteen; it follows, that although the root be always taken in the ſame proportion to the menſtruum, and the menſtruum always exactly of the ſame ſtrength, it may, nevertheleſs, according to the degree of goodneſs of the jalap, be impregnated with different quantities of reſin, and conſequently prove different in degree of efficacy. Though this objection againſt the tincture does not reach ſo far as ſome ſeem to ſuppoſe, it certainly behoves the apothecary to be careful in the choice of the root. The inferior ſorts may be employed for making reſin of jalap, which they yield in as great perfection, though not in ſo large quantity, as the beſt. Neumann thinks even the worm-eaten jalap as good for that purpoſe as any other.

Preparations and Compoſitions.

Tincture of gum-kino. E.

Take of gum-kino, two ounces; proof-ſpirit, a pound and an half. Digeſt eight days, and ſtrain. 451

The ſubſtance called *gum-kino* ſeems to be really a gum-reſin; on which account proof-ſpirit is the moſt proper menſtruum. This preparation muſt therefore poſſeſs the virtues of the ſubſtance; and it is perhaps one of the beſt forms under which it can be exhibited in obſtinate diarrhœas, and in caſes of lienteria: but in hemorrhagies, it is in general proper to exhibit it either in ſubſtance or diffuſed; yet we cannot help thinking that the want of this tincture is an omiſſion in the London pharmacopœia.

Compound tincture of lavender. L.

Take of ſpirit of lavender, three pints; roſemary, one pint; cinnamon bruiſed, nutmegs bruiſed, of each half an ounce; red ſaunders, one ounce. Digeſt for ten days, and ſtrain. 452

Compound ſpirit of lavender. E.

Take of ſimple ſpirit of lavender, three pounds; ſimple ſpirit of roſemary, one pound; cinnamon, one ounce; cloves, two drams; nutmeg, half an ounce; red ſaunders, three drams. Macerate ſeven days, and ſtrain.

Theſe two compoſitions, although varying a little from each other, both with reſpect to their ingredients and names, may yet be conſidered as preciſely the ſame. Although the London college, in the preſent edition of their pharmacopœia, have made many uſeful alterations with reſpect to names, yet the propriety of the change here adopted may perhaps be doubted: For it cannot with juſtice be ſtyled a tincture of lavender, when the diſtilled ſpirit of that plant is employed only as a menſtruum. If, therefore, it ſeemed neceſſary to refer it to the head of tinctures, it ought to have been denominated from the cinnamon or nutmegs; but ſince the activity of this article very much depends on the ſpirit of la-

Preparations and Compositions.

vender, the old name is in our opinion justly preferable to the new one.

The red saunders is of no farther use in these compositions than as a colouring ingredient. If a yellow spirit was liked, the yellow saunders would be an excellent article, as it not only communicates a fine colour, but likewise a considerable share of medicinal virtue. A spirit distilled from the flowers of lavender and sage, in due proportion, and digested in the cold for a little time with some cinnamon, nutmeg, and yellow saunders, proves a very elegant and grateful one. Where essential oils are employed, particular care must be had in the choice of them; for on their goodness that of the medicine depends. The digestion of the spirit with the spices, &c. should be performed without heat, otherwise the flavour of the medicine will be injured. These spirits are grateful reviving cordials: though considerably more simple, they are not less elegant or valuable than many other more elaborate preparations. This medicine has long been held in great esteem, under the name of *Palsy drops*, in all kinds of languors, weakness of the nerves, and decays of age. It may be conveniently taken on sugar, from ten to eighty or a hundred drops.

Tincture of musk. E.

453 Take of musk, two drams; rectified spirit of wine, one pound. Digest for ten days, and strain.

Rectified spirit is the most complete menstruum for musk; but in this form it is often impossible to give such a quantity of the musk as is necessary for our purpose; and hence this article is more frequently employed under the form of julep or bolus.

Tincture of myrrh.

454 Take of myrrh, bruised, three ounces; proof-spirit, a pint and an half; rectified spirit of wine, half a pint. Digest with a gentle heat for eight days, and strain. *L.*

Take of myrrh, three ounces; proof spirit, two pounds and a half. After digestion for ten days, strain off the tincture. *E.*

The pharmaceutical writers in general have been of opinion, that no good tincture can be drawn from myrrh by spirit of wine alone, without the assistance of fixed alkaline salts. But it appears from proper experiments, that these salts only heighten the colour of the tincture, without enabling the menstruum to dissolve any more than it would by itself. Rectified spirit extracts, without any addition, all that part of the myrrh in which its peculiar smell and taste reside, viz. the resin: and proof-spirit dissolves almost the whole of the drug, except its impurities: hence the combination of these two directed by the London college is perhaps preferable to either by itself.

Tincture of myrrh is recommended internally for warming the habit, attenuating viscid juices, strengthening the solids, opening obstructions, particularly those of the uterine vessels, and resisting putrefaction. Boerhaave greatly esteems it in all languid cases proceeding from simple inactivity; in those female disorders which are occasioned by an aqueous, mucous, sluggish indisposition of the humours, and a relaxation of the vessels; in the fluor albus, and all diseases arising from a like cause. The dose is from fifteen drops to forty or more. The medicine may doubtless be given in these cases to advantage; though with us, it is more commonly used externally for cleansing foul ulcers and promoting the exfoliation of carious bones.

Preparations and Compositions.

Tincture of opium. L.

455 Take of hard purified opium, powdered, ten drams; proof-spirit, one pint. Digest for ten days, and strain.

Tincture of opium, commonly called *liquid laudanum.* E.

Take of opium, two ounces; spirituous cinnamon-water, one pound and a half. Digest four days, and strain off the tincture.

These are very elegant liquid opiates, the menstruum in the last dissolves nearly the whole substance of the opium, and effectually covers its ill flavour. It were to be wished that the shops were furnished with a liquid opiate, in which the proportion of menstruum was still much larger, so as to admit of the dose being determined by weight or measure; the method by drops seeming too precarious for a medicine of so powerful a kind. The following preparation is contrived with this view.

Take of thebaic extract, half a dram; highly rectified spirit of wine, called *alcohol*, ten ounces; simple cinnamon-water, twenty ounces. Digest them together until the opium be dissolved, and then filter the solution through paper.

This preparation is apprehended to be free from all the inconveniences attending the common opiate tinctures. The menstruum dissolves the whole of the opium except the impurities, and consequently the tincture is not liable to any uncertainty in point of strength. The dose may be ascertained to the greatest exactness; one grain of opium is contained in one ounce by measure, which is equal nearly to seven drams by weight. Neither the tinctures in wine nor proof-spirit are so well adapted for keeping as could be wished: in long standing, a part of the opium is gradually thrown off from both, and consequently the tinctures become gradually weaker: the part which thus separates, amounts sometimes, it is said, to near one-fourth of the quantity of opium at first dissolved: it floats on the surface of the vinous tincture, and in the spirituous sinks to the bottom. In the preparation here recommended, it has not been observed that any separation happens.

Instead of the cinnamon-water, pure water may be employed in the mixture: and where aromatic additions are wanted, either with a medicinal intention or for covering the ill smell of the opium, any proper tincture or distilled water may be extemporaneously joined. Saffron, an addition once employed by the Edinburgh college, has been considered as a corrector of opium; but the qualities it was supposed to correct are merely imaginary; nor indeed can that article be of much importance with any intention in the small quantity that enters a dose of the tincture; a grain of opium being accompanied with only half a grain of saffron.

A preparation in some respects similar to that here recommended was introduced into the Edinburgh phar-

Preparations and Compositions.

pharmacopœia published in 1774, under the title of *tinctura meconii*. Each ounce of this tincture contained four grains of opium; and it was proposed that the doses of it should be measured, not by drops, but by weight: but as modern physicians are much more bold in giving opium than their predecessors, such a scrupulous accuracy in the dose is not thought at all necessary; and it is not probable that any dangerous consequence will ever arise, merely from a difference in the size of drops. This, however, might be the case, where the thebaic tincture is by accident taken for the tincture of meconium. To such mistakes, however, it was feared that the analogy of the articles, as well as the caution necessary with respect to both, might lead; and it was on many accounts safer to have but one liquid laudanum only. It is, however, much to be regretted, that the liquid laudanum of the London and Edinburgh colleges, which by the former is now styled *tinctura opii*, by the latter *tinctura thebaica*, should differ so much from each other in point of strength.

Camphorated tincture of opium. L.

456 Take of hard purified opium, flowers of benzoin, each one dram; camphor, two scruples; essential oil of aniseed, one dram; proof-spirit, two pints. Digest for three days.

Paregoric elixir. E.

Take of flowers of benzoin, English saffron, each three drams; opium, two drams; essential oil of aniseeds, half a dram; vinous spirit of sal ammoniac, sixteen ounces. Digest for four days in a close vessel, and strain.

These two, though differing not merely in name, may yet be considered as agreeing very nearly in their nature.

The most material differences in the last formula from the first are the substitution of the vinous spirit of sal ammoniac for the proof-spirit, and a larger proportion of opium; the vinous spirit of sal ammoniac is not only, perhaps, a more powerful menstruum, but in most instances coincides with the virtues of the preparation; but as the opium is the ingredient on which we place the principal dependence, so its proportion is increased, in order that we may give it in such a dose as that the acrimony of the menstruum shall not prove hurtful to the stomach.

The London formula is taken from Le Mort, with the omission of three unnecessary ingredients, honey, liquorice, and alkaline salt. It was originally called *elixir asthmaticum*, which name it does not ill deserve. It contributes to allay the tickling which provokes frequent coughing; and at the same time is supposed to open the breast, and give greater liberty of breathing: the opium procures (as it does by itself) a temporary relief from the symptoms; while the other ingredients tend to remove the cause, and prevent their return. It is given to children against the chincough, &c. from five drops to twenty; to adults, from twenty to an hundred. In the London formula, half an ounce by measure contains about a grain of opium; but in the Edinburgh formula the proportion of opium is larger.

Tincture of rhubarb.

457 Take of rhubarb, sliced, two ounces; lesser cardamom seeds, husked and bruised, half an ounce; saffron, two drams; proof-spirit, two pints. Digest for eight days, and strain. L.

Take of rhubarb, three ounces; lesser cardamom seeds, half an ounce; proof-spirit two pounds and a half. Digest for seven days, and strain. E.

Compound tincture of rhubarb. L.

Take of rhubarb sliced, two ounces; ginger powdered, saffron, each two drams; liquorice-root, bruised, half an ounce; distilled water, one pint; proof-spirit, twelve ounces. Digest for fourteen days, and strain.

Bitter tincture of rhubarb. E.

Take of rhubarb two ounces; gentian-root, half an ounce; Virginian snake-root, one dram; proof spirit, two pounds and a half. Digest for seven days, and then strain the tincture.

Sweet tincture of rhubarb. E.

It is made by adding to two pounds and a half of the strained tincture of rhubarb, four ounces of sugar-candy.

The last of these preparations is improved from the former editions. Two ounces of liquorice and one of raisins are supplied, by an increase of the sugar-candy.

All the foregoing tinctures of rhubarb are designed as stomachics and corroborants, as well as purgatives: spirituous liquors excellently extract those parts of the rhubarb in which the two first qualities reside, and the additional ingredients considerably promote their efficacy. In weakness of the stomach, indigestion, laxity of the intestines, diarrhœas, colic, and other similar complaints, these medicines are frequently of great service: the second is also, in many cases, an useful addition to the Peruvian bark, in the cure of intermittents, particularly in cachectic habits, where the viscera are obstructed; with these intentions, a spoonful or two may be taken for a dose, and occasionally repeated.

Elixir of aloes and rhubarb, commonly called *sacred elixir*. E.

458 Take of rhubarb, cut small, ten drams; socotorine aloes, in powder, six drams; lesser cardamom seeds, half an ounce; proof-spirit, two pounds and a half. Digest for seven days, and then strain the elixir.

This preparation is very much employed as a warming cordial purge, and for the general purposes of aloetics; with which, however, it combines the medical properties of rhubarb.

Compound tincture of savin. L.

459 Take of extract of savin, one ounce; tincture of castor, one pint; myrrh, half a pint. Digest till the extract of savin be dissolved, and then strain.

This preparation had a place in the last edition of our pharmacopœia, under the title of *Elixir myrrhæ compositum*.

This preparation is improved from one deſcribed in ſome former diſpenſaries under the name of *uterine elixir*. It is a medicine of great importance in uterine obſtructions, and in hypochondriacal caſes; though, poſſibly, means might be contrived of ſuperadding more effectually the virtues of ſavin to a tincture of myrrh and caſtor. It may be given from five drops to twenty or thirty, or more, in pennyroyal water, or any other ſuitable vehicle.

Tincture of ſquill. L.

460 Take of ſquills, freſh dried, four ounces; proof-ſpirit, two pints. Digeſt for eight days, and pour off the liquor.

For extracting the virtues of ſquills, the menſtruum which has hitherto been almoſt ſolely employed is vinegar. There are, however, caſes in which ardent ſpirit may be more proper; and by the menſtruum here directed its virtues are fully extracted. Hence it is with propriety that the London college have introduced this form, as well as the vinegar and oxymel. But, in general, the purpoſes to be anſwered by ſquills may be better obtained by employing it in ſubſtance than in any other form.

Antiphthiſical tincture. E.

461 Take of ſugar of lead, an ounce and a half; vitriol of iron, one ounce; rectified ſpirit of wine, one pound. Let a tincture be extracted without heat.

The reducing of the ſalts *ſeparately* into powder, and performing the digeſtion *without heat*, are very neceſſary circumſtances: for if the ingredients be attempted to be pulverized together, they will grow ſoft and almoſt liquid; and if heat be uſed, ſcarce any tincture will be obtained.

This tincture is ſometimes given in doſes of twenty or thirty drops for reſtraining immoderate ſecretions, particularly the colliquative ſweats attending hectic fevers and phthiſical diſorders; whence the name *antiphthiſical* tincture. It is undoubtedly a medicine of great efficacy in theſe caſes, but too dangerous to be raſhly ventured on. Some have ſuppoſed that it does not contain any of the ſugar of lead; but experiments made for that purpoſe have ſhown the contrary.

We muſt, however, conſider the above preparation as unſcientific. Both the acetous and vitriolic acid have a greater attraction for iron than for lead: and though the vitriolic be capable of diſcharging the acetous acid, yet it makes not only in its entire ſtate a leſs perfect union with lead than the acetous acid, but it is now alſo combined with iron, for which it has a greater attraction, and can therefore only act on the ſalt of lead in proportion as it is ſuperabundant in the ſalt of copperas; but in proportion as the vitriolic diſengages the acetous acid from the lead, the laſt, in its turn, will attach itſelf to the iron. On the whole, it is difficult to aſcertain the preciſe nature of this preparation; it ſeems always, however, to contain a quantity of lead in a ſaline ſtate ſufficient to expunge it from prudent practice: or, at leaſt, if in theſe caſes in which it has hitherto been employed, lead be thought neceſſary, the ſalt of lead may with more ſafety and advantage be given in its ſolid ſtate, particularly when combined with opium: and it is probably on this account that the preſent formula has now no place in the London pharmacopœia.

Tincture of ſenna. L.

462 Take of ſenna, one pound; caraway ſeeds, bruiſed, one ounce and an half; leſſer cardamom-ſeeds, huſked and bruiſed, half an ounce; raiſins, ſtoned, ſixteen ounces; proof-ſpirit, one gallon. Digeſt for fourteen days, and ſtrain.

Compound tincture of ſenna, commonly called *Elixir of health.* E.

Take of ſenna leaves, two ounces; jalap root, one ounce; coriander ſeeds, half an ounce; proof ſpirit, two pounds and a half. Digeſt for ſeven days, and to the ſtrained liquor add four ounces of ſugarcandy.

Both theſe tinctures are uſeful carminatives and cathartics, eſpecially to thoſe who have accuſtomed themſelves to the uſe of ſpirituous liquors; they oftentimes relieve flatulent complaints and colics, where the common cordials have little effect: the doſe is from one to two ounces. Several preparations of this kind have been offered to the public under the name of *Daffy's elixir:* the two above are equal to any, and ſuperior to moſt of them. The laſt in particular is a very uſeful addition to the caſtor oil, in order to take off its mawkiſh taſte: and as coinciding with the virtues of the oil, it is therefore much preferable to brandy, ſhrub, and ſuch like liquors, which otherwiſe are often found neceſſary to make the oil ſit on the ſtomach.

Tincture of ſnake root.

Take of Virginian ſnake-root, three ounces; proof-ſpirit, two pints. Digeſt for eight days, and ſtrain. *L.* 463

Take of Virginian ſnake-root, two ounces; cochineal, one dram; proof-ſpirit, two pounds and a half. Digeſt in a gentle heat for four days, and then ſtrain the tincture. *E.*

The tincture of ſnake-root was in a former pharmacopœia directed to be prepared with the tincture of ſalt of tartar, which being now expunged, it was propoſed to the college to employ rectified ſpirit; but as the heat of this ſpirit prevents the medicine from being taken in ſo large a doſe as it might otherwiſe be, a weaker ſpirit was choſen. The tincture made in this menſtruum, which extracts the whole virtues of the root, may be taken to the quantity of a ſpoonful or more every five or ſix hours; and to this extent it often operates as an uſeful diaphoretic.

Tincture of valerian. L.

464 Take of the root of wild valerian, in coarſe powder, four ounces; proof-ſpirit, two pints. Digeſt with a gentle heat for eight days, and ſtrain.

The valerian root ought to be reduced to a pretty fine powder, otherwiſe the ſpirit will not ſufficiently extract its virtues. The tincture proves of a deep colour, and conſiderably ſtrong of the valerian; though it has not been found to anſwer ſo well in the cure of epileptic diſorders as the root in ſubſtance, exhibited in the form of powder, or bolus. The doſe of the tincture is, from half a ſpoonful to a ſpoonful or more, two or three times a-day.

Volatile

Volatile tincture of valerian.

465 Take of the root of wild valerian, four ounces; compound ſpirit of ammonia, two pints. Digeſt for eight days, and ſtrain. *L.*

Take of wild valerian root, two ounces; vinous ſpirit of ſal ammoniac, one pound. Macerate for ſix days in a cloſe veſſel, and ſtrain. *E.*

Both the compound and vinous ſpirit of ſal ammoniac are here excellent menſtrua, and at the ſame time conſiderably promote the virtues of the valerian, which in ſome caſes wants an aſſiſtance of this kind. The doſe may be a tea ſpoonful or two.

Tincture of veratrum, or white hellebore. E.

466 Take of white hellebore root, eight ounces; proof-ſpirit, two pounds and a half. Digeſt them together for ten days, and filter the tincture through paper.

This tincture is ſometimes uſed for acuating cathartics, &c. and as an emetic in apoplectic and maniacal diſorders. It may likewiſe be ſo managed as to prove a powerful alterative and deobſtruent in caſes where milder remedies have little effect. But a great deal of caution is requiſite in its uſe: the doſe, at firſt, ought to be only a few drops; if conſiderable, it proves violently emetic or cathartic.

Acid elixir of vitriol. E.

467 Take of rectified ſpirit of wine, two pounds; drop into it by little and little ſix ounces of vitriolic acid; digeſt the mixture with a very gentle heat in a cloſe veſſel for three days, and then add of cinnamon, an ounce and a half; ginger, one ounce. Digeſt again in a cloſe veſſel for ſix days, and then filter the tincture through paper placed in a glaſs funnel.

The intention in this proceſs is, to obtain a tincture of aromatic vegetables, in ſpirit of wine, combined with a conſiderable proportion of vitriolic acid. When the tincture is firſt drawn with vinous ſpirit, and the acid added afterwards, the acid precipitates great part of what the ſpirit had before taken up: and on the other hand, when the acid is mixed with the ſpirit immediately before the extraction, it prevents the diſſolution of all that it would have precipitated by the former way of treatment: by previouſly uniting the acid and the vinous ſpirit together by digeſtion, the inconvenience is ſomewhat leſſened.

This is a valuable medicine in weakneſs and relaxations of the ſtomach and decays of conſtitution, particularly in thoſe which proceed from irregularities, which are accompanied with ſlow febrile ſymptoms, or which follow the ſuppreſſion of intermittents. It frequently ſucceeds after bitters and aromatics by themſelves had availed nothing; and indeed great part of its virtues depend on the vitriolic acid; which, barely diluted with water, has, in thoſe caſes where the ſtomach could bear the acidity, produced happy effects.

Fuller relates (in his *Medicina Gymnaſtica*) that he was recovered by Mynſicht's elixir, from an extreme decay of conſtitution, and continual retchings to vomit. It may be given from 10 to 30 or 40 drops or more, according to the quantity of acid, twice or thrice a-day, at ſuch times as the ſtomach is moſt empty. It is very uſefully conjoined with the bark, both as covering its diſagreeable taſte and coinciding with its virtues.

Sweet elixir of vitriol. E.

468 This is made of the ſame aromatics, and in the ſame manner as the aromatic tincture; except that, in place of the vinous, the dulcified ſpirit of vitriol is employed.

This is deſigned for perſons whoſe ſtomachs are too weak to bear the foregoing acid elixir; to the taſte, it is gratefully aromatic, without any perceptible acidity. The dulcified ſpirit of vitriol, here directed, occaſions little or no precipitation on adding it to the tincture.

A medicine of this kind was formerly in great eſteem under the title of *Vigani's volatile elixir of vitriol*; the compoſition of which was firſt communicated to the public in the *Pharmacopœia reformata*. It is prepared by digeſting ſome volatile ſpirits of vitriol upon a ſmall quantity of mint leaves curiouſly dried, till the liquor has acquired a fine green colour. If the ſpirit, as it frequently does, partakes too much of the acid, this colour will not ſucceed: in ſuch caſe, it ſhould be rectified from a little fixed alkaline ſalt.

Camphorated ſpirit of wine. E.

469 Take of camphor, one ounce; rectified ſpirit of wine, one pound. Mix them together, that the camphor may be diſſolved. It may alſo be made with a double, triple, &c. proportion of camphor.

This ſolution of camphor is employed chiefly for external uſes, againſt rheumatic pains, paralytic numbneſſes, inflammations, for diſcuſſing tumours, preventing gangrenes, or reſtraining their progreſs. It is too pungent to be exhibited internally, even when diluted, nor does the dilution ſucceed well; for on the admixture of aqueous liquors, the camphor gradually ſeparates and runs together into little maſſes.

Hoffman, Rothen, and others, mention a camphorated ſpirit not ſubject to this inconvenience. It is prepared by grinding the camphor with ſomewhat more than an equal weight of fixed alkaline ſalt, then adding a proper quantity of proof-ſpirit, and drawing off one half of it by diſtillation. This ſpirit was propoſed to be received into our pharmacopœias, under the title of *Spiritus camphoræ tartarizatus*. But on trial, it did not anſwer expectation: ſome of the camphor riſes with the ſpirit in diſtillation, though but a ſmall quantity; whence, mixed with a large portion of water, it does not ſenſibly render it turbid; but in a proper quantity, it exhibits the ſame appearance as the more common camphorated ſpirit: it did not appear, that ſpirit diſtilled from camphor, with or without the alkaline ſalt, differed at all in this reſpect.

The moſt convenient method of uniting camphor with aqueous liquors, for internal uſe, ſeems to be by the mediation of almonds, or of mucilages; triturated with theſe, it readily mingles with water into the form of an emulſion, at the ſame time that its pungency is conſiderably abated. It may alſo be commodiouſly exhibited in the form of an oily draught, expreſſed oils totally diſſolving it.

The anodyne liniment, commonly called *Anodyne balſam*. E.

470 Take of opium, one ounce; white Caſtile ſoap, four ounces;

Preparations and Compositions.

ounces; camphor, two ounces; eſſential oil of roſemary, half an ounce; rectified ſpirit of wine, two pounds. Digeſt the opium and ſoap in the ſpirit for three days; then to the ſtrained liquor add the camphor and oil, diligently ſhaking the veſſel.

The ſeveral ingredients in this formula are exceedingly well ſuited for the purpoſes expreſſed in the title of this preparation; the anodyne balſam has accordingly been uſed with much ſucceſs to allay pains in ſtrained limbs, and ſuch like topical affections.

Saponaceous balſam or liniment. E.

471 This is made in the ſame manner and of the ſame ingredients as the anodyne balſam, only omitting the opium.

It is intended as a ſimplification and improvement of what had formerly the name of *Opodeldock*, and is employed with the ſame intentions as the two preceding.

Tincture of antimony. Raſſ.

472 Take of antimony, in powder, half a pound; ſalt of tartar, one pound; rectified ſpirit, three pints. Mix the antimony with the ſalt of tartar, and inject them by little and little into a crucible placed in a ſtrong fire. Let the mixture melt thin, and continue in this ſtate for half an hour; after which it is to be poured out into a hot and dry iron mortar. Powder the maſs while hot, put it into a heated matraſs, and pour the ſpirit on it. Digeſt them together for three days, and then ſtrain the tincture.

In this proceſs, the alkaline ſalt unites with the ſulphur of the antimony into a hepar; which communicates to the ſpirit a tincture ſimilar to the tincture of ſulphur. This antimonial tincture is ſuppoſed to contain likewiſe ſome of the reguline parts of the mineral, and is ſaid to have ſometimes provoked a puke when taken on an empty ſtomach, even in a ſmall doſe. It ſtands recommended in doſes from ten to ſixty drops or more, as a deobſtruent, promoter of urine, and purifier of the blood. But there is probably no purpoſe to be anſwered by it, which may not be more effectually obtained by other antimonial preparations, particularly the wine of tartar of antimony.

Tincture of colocynth. Suec.

473 Take of colocynth, cut ſmall, and freed from the ſeeds, one ounce; aniſeed, one dram; proof-ſpirit, fourteen ounces. Macerate for three days, and ſtrain through paper.

In this tincture we have the active purgative power of the colocynth. And although it be ſeldom uſed as a cathartic by itſelf, yet even in ſmall quantity it may be advantageouſly employed to promote the operation of others.

Volatile tincture of copper. Gen.

474 Take of filings of copper, one dram; ſpirit of ſal ammoniac, an ounce and a half. Mix them, and keep them in a veſſel cloſely ſtopped, which is to be frequently agitated, till the liquor becomes of a beautiful violet colour.

In this formula the copper is brought to a ſaline ſtate by means of the volatile alkali. It may therefore be conſidered as very analogous to the ammoniacal copper. And where recourſe is had to it in practice, it is employed with the ſame intentions.

Preparations and Compoſitions.

Tincture of quaſſia. Suec.

475 Take of quaſſia, bruiſed, two ounces; proof-ſpirit, two pounds and an half. Digeſt for three days, and then ſtrain through paper.

By proof-ſpirit the medical properties, as well as the ſenſible qualities of the quaſſia, are readily extracted. And under this form it may be advantageouſly employed for anſwering different purpoſes in medicine.

Tincture of lac. Suec.

476 Take of gum lac, powdered, one ounce; myrrh, three drams; ſpirit of ſcurvy-graſs, a pint and an half. Digeſt in a ſand heat for three days; after which, ſtrain off the tincture for uſe.

This tincture is principally employed for ſtrengthening the gums, and in bleedings and ſcorbutic exulcerations of them: it may be fitted for uſe with theſe intentions, by mixing it with honey of roſes, or the like. Some recommend it internally againſt ſcorbutic complaints, and as a corroborant in gleets, female weakneſſes, &c. Its warmth, pungency, and manifeſtly aſtringent bitteriſh taſte, point out its virtues in theſe caſes to be conſiderable, though common practice among us has not yet received it.

Tincture of nux vomica. Roſſ.

477 Take of nux vomica, an ounce and a half; proof-ſpirit, two pounds. Digeſt for ſome days, and then ſtrain it.

The nux vomica, a very active vegetable, has of late, as we have already had occaſion to obſerve, been introduced into practice as taken internally, for the cure of intermittents and of contagious dyſentery. In theſe affections it may be employed under the form of tincture as well as in ſubſtance; and in this way it moſt readily admits of being combined with other articles, either as adjuvantia or corrigentia.

Tincture of amber. Suec.

478 Take of yellow amber, powdered, one ounce; vitriolic æther, four ounces. Digeſt for three days in a veſſel accurately cloſed, frequently ſhaking the veſſel, and after this ſtrain through paper.

The tincture of amber was formerly prepared with rectified ſpirit of wine: but the menſtruum here directed gives a more complete ſolution, and forms a more elegant and active tincture. It poſſeſſes the whole virtues of the concrete; and although it has no place in our pharmacopœia, yet it is perhaps to be conſidered as one of the moſt valuable preparations of amber. It has been recommended in a variety of affections, particularly thoſe of the nervous kind, as hyſterical and epileptic complaints. It may be taken from a few drops to the extent of a tea ſpoonful in a glaſs of wine or any ſimilar vehicle.

Chap. XXII. *Mixtures.*

Camphorated mixture. L.

479 Take of camphor, one dram; rectified ſpirit of wine, ten drops; double-refined ſugar, half an ounce; boiling diſtilled water, one pint. Rub the camphor firſt with the ſpirit of wine, then with the ſugar; laſtly, add the water by degrees, and ſtrain the mixture.

While camphor is often exhibited in a ſolid ſtate, it is frequently alſo advantageous to employ it as diffuſed in watery fluids. And with this intention the preſent formula is perhaps one of the moſt ſimple, the union being affected merely by the aid of a ſmall quantity of ſpirit of wine and a little ſugar. But perhaps the more common form of emulſion in which the union is effected, by triturating the camphor with a few almonds, is not to be conſidered as inferior to this. For the unctuous quality of the almonds ſerves in a conſiderable degree to cover the pungency of the camphor without diminiſhing its activity. Camphor under the preſent form as well as that of emulſion, is very often uſeful in fevers, taken to the extent of a table ſpoonful every three or four hours.

Chalk mixture. L.

480 Take of prepared chalk, one ounce; double-refined ſugar, ſix drams; gum arabic, powdered, two ounces; diſtilled water, two pints. Mix them.

Chalk-drink. E.

Take of prepared chalk, one ounce; pureſt refined ſugar, half an ounce; mucilage of gum-arabic, two ounces. Rub them together, and add by degrees, water, two pounds and an half; ſpirituous cinnamon water, two ounces.

Theſe two preparations agree pretty much both in their name and in their nature. But of the two formulæ that of the Edinburgh college is moſt agreeable to the palate, from containing a proportion of cinnamon-water, by which the diſagreeable taſte of the chalk is taken off.

In the former edition of the Edinburgh pharmacopœia, a preparation of this kind ſtood among the decoctions, and the chalk was directed to be boiled with the water and gum: by the preſent formula, the chalk is much more completely ſuſpended by the mucilage and ſugar; which laſt gives alſo to the mixture an agreeable taſte. It is proper to employ the fineſt ſugar, as the redundant acid in the coarſer kinds might form with the chalk a kind of earthy ſalt. It would perhaps have been more proper to have added an aromatic, by ſuſpending the entire powder of cinnamon, or its oil, by means of the mucilage and ſugar: The method here directed is, however, leſs exceptionable in this than many other preparations, as the precipitated matter of the ſpirituous water will probably be inveſtigated in the ſaccharine and mucilaginous matter. This is a very elegant form of exhibiting chalk, and is an uſeful remedy in diſeaſes ariſing from, or accompanied with, acidity in the primæ viæ. It is frequently employed in diarrhœa proceeding from that cauſe. The mucilage not only ſerves to keep the chalk uniformly diffuſed, but alſo improves its virtues by ſheathing the internal ſurface of the inteſtines. The doſe of this medicine requires no nicety. It may be taken to the extent of a pound or two in the courſe of a day.

Muſk mixture. L.

Take of muſk, two ſcruples; gum-arabic, powdered, double-refined ſugar, of each one dram; roſe-water, ſix ounces by meaſure. Rub the muſk firſt with the ſugar, then with the gum, and add the roſe-water by degrees. 481

This had formerly the name of *julepum e moſcho*, and was intended as an improvement upon the hyſteric julep with muſk of Bates. Orange-flower-water is directed by that author; and indeed this more perfectly coincides with the muſk than roſe-water: but as the former is difficultly procurable in perfection, the latter is here preferred. The julep appears turbid at firſt: on ſtanding a little time, it depoſites a brown powder, and becomes clear, but at the ſame time loſes great part of its virtue. This inconvenience may be prevented by thoroughly grinding the muſk with gum-arabic before the addition of the water: by means of the gum, the whole ſubſtance of the muſk is made to remain ſuſpended in the water. Volatile ſpirits are in many caſes an uſeful addition to muſk, and likewiſe enable water to keep ſomewhat more of the muſk diſſolved than it would otherwiſe retain.

Almond milk. L.

Take of ſweet almonds, one ounce and an half; double-refined ſugar, half an ounce; diſtilled water, two pints. Beat the almonds with the ſugar; then, rubbing them together, add by degrees the water, and ſtrain the liquor. 482

Common emulſion. E.

Take of ſweet almonds, one ounce; bitter almonds, one dram; common-water, two pounds and a half. Beat the blanched almonds in a ſtone mortar, and gradually pour on them the common water, working the whole well together, then ſtrain off the liquor.

Arabic emulſion. E.

This is made in the ſame manner as the preceding; only adding, while beating the almonds, of mucilage of gum arabic two ounces. 483

All theſe may be conſidered as poſſeſſing nearly the ſame qualities. But of the three the laſt is the moſt powerful demulcent.

Great care ſhould be taken, that the almonds be not become rancid by keeping; which will not only render the emulſion extremely unpleaſant, a circumſtance of great conſequence in a medicine that requires to be taken in large quantities, but likewiſe give it injurious qualities little expected from preparations of this kind. The addition of the bitter almonds now ordered by the Edinburgh college in preparing theſe emulſions may perhaps preſerve them in ſome degree from running the above changes; but it is much more uſeful in giving the emulſion an agreeable flavour. Although the ſubſtance of bitter almonds be of a

Preparations and Compositions.

rious nature, yet nothing is to be apprehended from the quantity here employed.

Theſe liquors are principally uſed for diluting and obtunding acrimonious humours; particularly in heat of urine and ſtranguries ariſing either from a natural ſharpneſs of the juices, or from the operation of cantharides and other irritating medicines: in theſe caſes, they are to be drank frequently, to the quantity of half a pint or more at a time.

Some have ordered emulſions to be boiled, with a view to deprive them of ſome imaginary crudity; but by this proceſs they quickly ceaſe to be emulſions, the oil ſeparating from the water, and floating diſtinctly on the ſurface. Acids and vinous ſpirits produce a like decompoſition. On ſtanding alſo for ſome days, without addition, the oily matter ſeparates and riſes to the top, not in a pure form, but like thick cream. Theſe experiments prove the compoſition of the emulſions made from the oily ſeeds of kernels, and at the ſame time point out ſome cautions to be attended to in their preparation and uſe.

Ammoniacum milk. L.

484 Take of ammoniacum, two drams; diſtilled water, half a pint. Rub the gum-reſin with the water, gradually poured on, until it becomes a milk. In the ſame manner may be made a milk of aſafœtida, and of the reſt of the gum reſins.

The ammoniacum milk is uſed for attenuating tough phlegm, and promoting expectoration, in humoural aſthmas, coughs, and obſtructions of the viſcera. It may be given to the quantity of two ſpoonfuls twice a-day.

The lac aſafœtida is employed in ſpaſmodical, hyſterical, and other nervous affections. And it is alſo not unfrequently uſed under the form of injection. It anſwers the ſame purpoſes as aſafœtida in ſubſtance.

Compound ſpirit of vitriolic æther. L.

485 Take of ſpirit of vitriolic æther, two pounds; oil of wine, three drams. Mix them.

This is ſuppoſed to be, if not preciſely the ſame, at leaſt very nearly, the celebrated mineral anodyne liquor of Hoffman; as we learn from his own writings, that the liquor which he thus denominated was formed of dulcified ſpirit of vitriol and the aromatic oil which ariſes after it, but he does not tell us in what proportions theſe were combined. It has been highly extolled as an anodyne and antiſpaſmodic medicine; and with theſe intentions it is not unfrequently employed in practice.

Compound ſpirit of ammonia. L.

486 Take of ſpirit of ammonia, two pints; eſſential oil of lemon, nutmeg, of each two drams. Mix them.

This differs almoſt only in name from the following.

Volatile aromatic ſpirit, commonly called *volatile oily ſpirit*, and *ſaline aromatic ſpirit.* E.

Take of vinous ſpirit of ſal ammoniac, eight ounces; diſtilled oil of roſemary, one dram and a half; diſtilled oil of lemon-peel, one dram. Mix them that the oils may be diſſolved.

By the method here directed, the oils are as completely diſſolved as when diſtillation is employed.

Preparations and Compositions.

Volatile ſalts, thus united with aromatics, are not only more agreeable in flavour, but likewiſe more acceptable to the ſtomach, and leſs acrimonious than in their pure ſtate. Both the foregoing compoſitions turn out excellent ones, provided the oils are good, and the diſtillation ſkilfully performed. The doſe is from five or ſix drops to ſixty or more.

Medicines of this kind might be prepared extemporaneouſly, by dropping any proper eſſential oil into the dulcified ſpirit of ſal ammoniac, which will readily diſſolve the oil without the aſſiſtance of diſtillation. But it is perhaps preferable that they ſhould be kept in the ſhops ready mixed.

Succinated ſpirit of ammonia. L.

Take of alcohol, one ounce; water of pure ammonia, four ounces by meaſure; rectified oil of amber, one ſcruple; ſoap, ten grains. Digeſt the ſoap and oil of amber in the alcohol till they be diſſolved; then add the water of pure ammonia, and mix them by ſhaking. 487

This compoſition is extremely penetrating, and has lately come into eſteem, particularly for ſmelling to in lowneſſes and faintings, under the name of *eau de luce*. It has been hitherto brought from France. It is not quite limpid, for the oil of amber diſſolves only imperfectly in the ſpirit: if the volatile ſpirit be not exceedingly ſtrong, ſcarcely any of the oil will be imbibed.

The *eau de luce* is not only uſed with the view of making an impreſſion on the noſe, but is taken internally in the ſame caſes. It has likewiſe of late been celebrated as a remedy for the bite of the rattleſnake, when uſed internally, and applied externally to the wounded part.

Camphorated ſpirit. L.

Take of camphor, four ounces; rectified ſpirit of wine, two pints: Mix them, ſo that the camphor may be diſſolved. 488

Of this we have already had occaſion to ſpeak in the preceding chapter under the title given to it by the Edinburgh college.

Simple oily emulſion. Gen.

Take of almond oil, one ounce; ſyrup of althea, an ounce and a half; gum arabic, half an ounce; ſpring water, ſix ounces, Mix, and make an emulſion according to art. 489

Volatile oily emulſion. Gen.

Take of almond oil, an ounce and a half; ſyrup of althea, one ounce; gum-arabic, half an ounce; volatile alkaline ſalt, one dram; ſpring-water, ſeven ounces. Mix them according to art.

Both theſe are elegant and convenient modes of exhibiting oil internally. And under theſe forms it is often advantageouſly employed in caſes of cough, hoarſeneſs, and ſimilar affections. By means of the alkali, a more intimate union of oil with water is obtained than can be had with the intermedium either of ſyrup or vegetable mucilage; and in ſome caſes,

the alkali both contributes to anſwer the intention in view, and prevents the oil from exciting ſickneſs at ſtomach: But in other inſtances, the pungency which it imparts is diſagreeable to the patient and unfavourable to the diſeaſe. According to theſe circumſtances, therefore, where an oily mixture is to be employed, the practitioner will be determined in his choice to have recourſe either to the one or the other formula.

Acid julep. Gen.

490 Take of weak vitriolic acid, three drams; ſimple ſyrup, three ounces; ſpring-water, two pounds. Mix them.

In this ſtate, the vitriolic acid is ſufficiently diluted to be taken with eaſe in conſiderable doſes. And it may thus be advantageouſly employed in various affections: concerning which we have already had occaſion to make a few remarks in CHEMISTRY, n° 617. (ſee *CHEMISTRY-Index*), and which are to be anſwered, either by its action on the ſtomach, or on the ſyſtem in general.

Æther julep. Gen.

491 Take of pure vitriolic æther, two ſcruples; ſpring-water, ſix ounces; refined ſugar, half an ounce. Mix them according to art.

Although it is in general proper that æther ſhould be diluted only when it is to be immediately uſed, yet it is ſometimes neceſſary that it ſhould be put into the hands of the patient in the ſtate in which it is to be taken. In ſuch inſtances the preſent formula is a very proper one; for the addition of a little mucilage tends both to cover the pungency of the æther in the mouth, and to retain it in a ſtate or mixture with the water.

Amber julep. Gen.

492 Take of tincture of amber, two drams; refined ſugar, half an ounce; ſpring-water, ſix ounces. Mix them according to art.

Under this form the tincture of amber is ſo far diluted and ſweetened, as to form an agreeable mixture; and in this manner it may often be advantageouſly employed for counteracting nervous affections, and anſwering thoſe other purpoſes for which we have already mentioned that this article is had recourſe to in practice.

Saline mixture, or julep. Succ.

493 Take of fixed vegetable alkali, three drams; river-water, half a pound. To this lixivium add, lemon-juice, half a pound, or as much as is ſufficient to ſaturate the alkali; ſyrup of black currants, one ounce.

This mixture is frequently preſcribed in febrile diſeaſes as a means of promoting a ſlight diſcharge by the ſurface: For where the ſkin is parched with great increaſed heat, it generally operates as a gentle diaphoretic. It often alſo promotes a diſcharge by the kidneys, and is not unfrequently employed to reſtrain vomiting. With theſe intentions it is in daily uſe among Britiſh practitioners, although it has no place in our pharmacopœias, from its being entirely an extemporaneous preſcription.

Mineral ſolution of arſenic.

494 Take of white arſenic, reduced to a ſubtile powder, fixed vegetable alkali, each ſixty-four grains; diſtilled water, half a pint. Put them into a florentine flaſk, and let this be placed in a ſand heat, ſo that the water may boil gently till the arſenic be completely diſſolved; then add to the ſolution when cold half an ounce of ſpirit of lavender, and as much diſtilled water as to make the ſolution amount to a pint by meaſure, or fifteen ounces and an half by weight.

For the introduction of this remedy we are indebted to Dr Fowler of Stafford. We have already had occaſion to mention it in our article ARSENIC, n° 14; ſee alſo CHEMISTRY, n° 1266, &c. In the former of theſe places we have obſerved, that if it be not preciſely the ſame, it is at leaſt ſuppoſed to be very analogous to a remedy which has had a very extenſive ſale in ſome parts of England under the name of the *taſteleſs ague drop*; and which has been employed with very great ſucceſs in the cure of obſtinate intermittents. But whether the preſent formula in any degree approaches to the taſteleſs ague drop or not, there can be no doubt, from the concurring teſtimony of many eminent practitioners, that it is equally ſucceſsful in combating intermittents. For this purpoſe it is given according to the age and other circumſtances of the patient in doſes from two to twenty drops, once, twice, or oftener in the courſe of the day: And its uſe has been found to be attended with remarkable ſucceſs, although with ſome patients even very ſmall doſes have been found to excite ſevere vomiting. Beſides diſtinctly marked intermittents, this ſolution has alſo been ſometimes ſucceſsful in obſtinate periodical headaches, and in cutaneous affections of the leprous kind, reſiſting every other mode of cure. And perhaps in every caſe where arſenic can be employed with ſafety or advantage internally, this preparation is preferable to any other with which we are yet acquainted.

CHAP XXIII. *Syrups.*

SYRUPS are ſaturated ſolutions of ſugar, made in 495
water, or watery or vinous infuſions, or in juices. They were formerly conſidered as medicines of much greater importance than they are thought to be at preſent. Syrups and diſtilled waters were for ſome ages uſed as the great alteratives; inſomuch that the evacuation of any peccant humour was never attempted till by a due courſe of theſe it had firſt been ſuppoſed to be regularly prepared for expulſion. Hence roſe the exuberant collection of both, which we meet with in pharmacopœias, and like errors have prevailed in each. As multitudes of diſtilled waters have been compounded from materials unfit to give any virtue over the helm; ſo numbers of ſyrups have been prepared from ingredients, which in this form cannot be taken in ſufficient doſes to exert their virtues; for two-thirds of a ſyrup conſiſt of ſugar, and greateſt part of the remaining third is an aqueous fluid.

Syrups are at preſent chiefly regarded as convenient vehicles for medicines of greater efficacy; and uſed

Preparations and Compositions

for ſweetening draughts and juleps, for reducing the lighter powders into boluſes, pills, or electuaries, and other ſimilar purpoſes. Some likewiſe may not improperly be conſidered as medicines themſelves; as thoſe of ſaffron, buckthorn-berries, and ſome others.

To the chapter on *Syrups* the London college in their pharmacopœia have premiſed the following general obſervations.

In the making of ſyrups, where we have not directed either the weight of the ſugar, or the manner in which it ſhould be diſſolved, this is to be the rule:

Take of double-refined ſugar, twenty-nine ounces; any kind of liquor, one pint. Diſſolve the ſugar in the liquor in a water-bath; then ſet it aſide for twenty-four hours; take off the ſcum, and pour off the ſyrup from the feces if there be any.

The following are the general rules which have commonly been given with reſpect to the preparation of ſyrups.

I. All the rules laid down for making decoctions are likewiſe to be obſerved in the decoctions for ſyrups. Vegetables, both for decoctions and infuſions, ought to be dry, unleſs they are expreſsly ordered otherwiſe.

II. In both the London and Edinburgh pharmacopœias, only the pureſt or double refined ſugar is allowed.

In the ſyrups prepared by boiling, it has been cuſtomary to perform the clarification with whites of eggs after the ſugar had been diſſolved in the decoction of the vegetable. This method is apparently injurious to the preparation; ſince not only the impurities of the ſugar are thus diſcharged, but a conſiderable part likewiſe of the medicinal matter, which the water had before taken up from the ingredients, is ſeparated along with them. Nor indeed is the clarification and deſpumation of the ſugar, by itſelf, very adviſable; for its purification by this proceſs is not ſo perfect as might be expected: after it has undergone this proceſs, the refiners ſtill ſeparate from it a quantity of oily matter, which is diſagreeable to weak ſtomachs. It appears therefore moſt eligible to employ fine ſugar for all the ſyrups; even the purgative ones (which have been uſually made with coarſe ſugar, as ſomewhat coinciding with their intention) not excepted: for, as purgative medicines are in general ungrateful to the ſtomach, it is certainly improper to employ an addition which increaſes their offenſiveneſs.

III. Where the weight of the ſugar is not expreſſed, twenty-nine ounces are to be taken in every pint of liquor. The ſugar is to be reduced into powder, and diſſolved in the liquor by the heat of a water-bath, unleſs ordered otherwiſe.

Although in the formula of ſeveral of the ſyrups, a double weight of ſugar to that of the liquor is directed, yet leſs will generally be ſufficient. Firſt, therefore, diſſolve in the liquor an equal weight of ſugar, then gradually add ſome more in powder, till a little remains undiſſolved at the bottom, which is to be afterwards incorporated by ſetting the ſyrup in a water-bath.

The quantity of ſugar ſhould be as much as the liquor is capable of keeping diſſolved in the cold: if there is more, a part of it will ſeparate, and concrete into cryſtals or candy; if leſs, the ſyrup will be ſubject to ferment, eſpecially in warm weather, and change into a vinous or ſour liquor. If in crystallizing, only the ſuperfluous ſugar be ſeparated, it would be of no inconvenience; but when part of the ſugar has candied, the remaining ſyrup is found to have an under proportion, and is as ſubject to fermentation as if it had wanted ſugar at firſt.

IV. Copper-veſſels, unleſs they be well tinned, ſhould not be employed in the making of acid ſyrups, or ſuch as are compoſed of the juices of fruits.

The confectioners, who are the moſt dexterous people at theſe kinds of preparations, to avoid the expence of frequently new tinning their veſſels, rarely make uſe of any other than copper ones untinned, in the preparation even of the moſt acid ſyrups, as of oranges and lemons. Nevertheleſs, by taking due care that their coppers be well ſcoured and perfectly clean, and that the ſyrup remain no longer in them than is abſolutely neceſſary, they avoid giving it any ill taſte or quality from the metal. This practice, however, is by no means to be recommended to the apothecary.

V. The ſyrup, when made, is to be ſet by till next day; if any ſaccharine cruſt appears upon the ſurface it is to be taken off.

Preparations and Compoſitions

Syrup of vinegar. E.

Take of vinegar, two pounds and an half; refined ſugar, three pounds and an half. Boil them till a ſyrup be formed. 496

This is to be conſidered as ſimple ſyrup merely acidulated, and is by no means unpleaſant. It is often employed in mucilaginous mixtures and the like; and on account of its cheapneſs it is often preferred to ſyrup of lemons.

Syrup of marſhmallow.

Take of freſh root of marſhmallow, bruiſed, one pound; double-refined ſugar, four pounds; diſtilled water, one gallon. Boil the water with the marſhmallow root to one half, and preſs out the liquor when cold. Set it by twelve hours; and, after the feces have ſubſided, pour off the liquor. Add the ſugar, and boil it to the weight of ſix pounds. *L.* 497

Take of marſhmallow roots, ſomewhat dried, nine ounces; water, ten pounds; pureſt ſugar, four pounds. Boil the water with the roots to the conſumption of one half, and ſtrain the liquor, ſtrongly expreſſing it. Suffer the ſtrained liquor to reſt till the feces have ſubſided; and when it is free from the dregs, add the ſugar; then boil ſo as to make a ſyrup. *E.*

The ſyrup of marſhmallows ſeems to have been a ſort of favourite among diſpenſatory writers, who have taken great pains to alter and amend it, but have been wonderfully tender in retrenching any of its articles. In the laſt preſcription, it is lopt of its ſuperfluities, without any injury to its virtues. It is uſed chiefly in nephritic caſes, for ſweetening emollient decoctions, and the like: of itſelf it can do little ſervice, notwithſtanding the high opinion which ſome have entertained of it; for what can be expected from two or three ſpoonfuls of the ſyrup, when the decoction, from which two or three pounds are made, may be taken at a draught or two? It is ſometimes uſeful in tickling coughs,

coughs, by inviſcating irritating matter diſtilling in the fauces: in this way it ſometimes affords conſiderable relief.

Syrup of clove July flower.

498 Take of freſh clove July flowers, the heels being cut off, two pounds; boiling diſtilled water, ſix pints. Macerate the flowers for twelve hours in a glaſs veſſel; and in the ſtrained liquor diſſolve the double-refined ſugar, that it may be made a ſyrup. *L.*

Take of clove July flowers, freſh gathered and freed from the heels, one pound; pureſt ſugar, ſeven pounds and a quarter; boiling water, four pounds. Macerate the flowers in the water for a night; then to the ſtrained liquor add the ſugar previouſly beat, and diſſolve it by a gentle heat, to make the whole into a ſyrup. *E.*

This ſyrup is of an agreeable flavour, and a fine red colour; and for theſe it is chiefly valued. Some have ſubſtituted for it one eaſily preparable at ſeaſons when the flowers are not to be procured: an ounce of clove ſpice is infuſed for ſome days in twelve ounces of white wine, the liquor ſtrained, and, with the addition of twenty ounces of ſugar, boiled to a proper conſiſtence; a little cochineal renders the colour of this ſyrup exactly ſimilar to that prepared from the clove July-flower; and its flavour is of the ſame kind, though not ſo pleaſant. The abuſe may be readily detected by adding to a little of the ſyrup ſome alkaline ſalt or ley; which will change the genuine ſyrup to a green colour; but in the counterfeit, it will make no ſuch alteration, only varying the ſhade of the red.

As the beauty of the colour is a principal quality in this ſyrup, no force in the way of expreſſion ſhould be uſed in ſeparating the liquor from the flowers.

Syrup of colchicum. E.

499 Take of colchicum root, freſh and ſucculent, cut into ſmall pieces, one ounce; vinegar, ſixteen ounces; pureſt ſugar, twenty-ſix ounces. Macerate the root in the vinegar two days, now and then ſhaking the veſſel; then ſtrain it with a gentle preſſure. To the ſtrained liquor add the ſugar, and boil a little, ſo as to form a ſyrup.

This ſyrup ſeems to be the beſt preparation of the colchicum; great care is required to take up this root in the proper ſeaſon: and from errors of this kind we are to aſcribe the uncertainty in the effects of this medicine as found in the ſhops.

The ſyrup of colchicum is often ſucceſsfully employed as a diuretic, and may be taken from a dram or two to the extent of an ounce or more.

Syrup of orange-peel.

500 Take of freſh outer-rind of Seville-oranges, eight ounces; boiling diſtilled water, five pints. Macerate for twelve hours in a cloſe veſſel; and in the ſtrained liquor diſſolve double-refined ſugar to make a ſyrup. *L.*

Take of yellow rind of Seville orange-peel freſh, ſix ounces; boiling water, three pounds. Infuſe them for a night in a cloſe veſſel; then ſtrain the liquor; let it ſtand to ſettle; and having poured it off clear from the ſediment, diſſolve in it four pounds and a quarter of white ſugar, ſo as to make it into a ſyrup with a gentle heat. *E.*

Preparations and Compoſitions.

In making this ſyrup, it is particularly neceſſary that the ſugar be previouſly powdered, and diſſolved in the infuſion with as gentle a heat as poſſible, to prevent the exhalation of the volatile parts of the peel. With theſe cautions, the ſyrup proves a very elegant and agreeable one, poſſeſſing great ſhare of the fine flavour of the orange-peel.

Syrup of ſaffron. L.

501 Take of ſaffron, one ounce; boiling diſtilled water, one pint. Macerate the ſaffron, in the water, for twelve hours, in a cloſe veſſel; and diſſolve double-refined ſugar in the ſtrained liquor, that it may be made a ſyrup.

Saffron is very well fitted for making a ſyrup, as in this form a ſufficient doſe of it is contained in a reaſonable compaſs. This ſyrup is at preſent frequently preſcribed; it is a pleaſant cordial, and gives a fine colour to juleps.

Syrup of lemon-juice.

502 Take of lemon-juice, ſtrained, after the feces have ſubſided, two pints; double refined ſugar, fifty ounces. Diſſolve the ſugar, that it may be made a ſyrup. *L.*

Take of juice of lemons, ſuffered to ſtand till the feces have ſubſided, and afterwards ſtrained, two pounds and a half; double-refined ſugar, fifty ounces. Diſſolve the ſugar in the juice, ſo as to make a ſyrup. *E.*

Syrup of mulberry-juice. L.

Syrup of raſpberry-juice. L.

Syrup of black currants. L.

Theſe three are directed by the London college to be prepared in the ſame manner as ſyrup of lemons, which immediately precedes them.

All theſe four are very pleaſant cooling ſyrups; and with this intention they are occaſionally uſed in draughts and juleps, for quenching thirſt, abating heat, &c. in bilious or inflammatory diſtempers. They are ſometimes likewiſe employed in gargariſms for inflammations of the mouth and tonſils.

Syrup of the white poppy. L.

503 Take of the heads of white poppies, dried, and the ſeeds taken out, three pounds and an half; double-refined ſugar, ſix pounds; diſtilled water, eight gallons. Slice and bruiſe the heads, then boil them in the water, to three gallons, in a water-bath ſaturated with ſea-ſalt, and preſs out the liquor. Reduce this by boiling to about the meaſure of four pints, and ſtrain it while hot, firſt through a ſieve, then through a thin woollen cloth, and ſet it aſide for twelve hours, that the feces may ſubſide. Boil the liquor, poured off from the feces, to three pints, and diſſolve the ſugar in it that it may be made a ſyrup.

Syrup of white poppies, or of *meconium*, commonly called *diacodium*. E.

Take of white poppy heads, dried, and freed from the

Preparations and Compositions

feeds, two pounds; boiling-water, thirty pounds; pureſt ſugar, four pounds. Macerate the bruiſed heads in the water for a night; next boil till only one third part of the liquor remain; then ſtrain it, expreſſing it ſtrongly. Boil the ſtrained liquor to the conſumption of one half, and ſtrain again; laſtly, add the ſugar, and boil to a ſyrup. It may alſo be made by diſſolving in two pounds and a half of ſimple ſyrup, one dram of the extract of white poppies.

This ſyrup, impregnated with the opiate matter of the poppy heads, is given to children in doſes of two or three drams; to adults from half an ounce to an ounce and upwards, for eaſing pain, procuring reſt, and anſwering the other intentions of mild opiates. Particular care is requiſite in its preparation, that it may be always made, as nearly as poſſible, of the ſame ſtrength; and accordingly the colleges have been very minute in their deſcription of the proceſs.

Syrup of the red poppy. L.

504 Take of the freſh flowers of the wild or red poppy, four pounds; boiling diſtilled water, four pints and an half. Put the flowers by degrees into the boiling water in a water bath, conſtantly ſtirring them. After this, the veſſel being taken out of the bath, macerate for twelve hours; then preſs out the liquor, and ſet it apart, that the feces may ſubſide. Laſtly, make it into a ſyrup, with double-refined ſugar.

The deſign of putting the flowers into boiling water in a water bath is, that they may be a little ſcalded, ſo as to ſhrink enough to be all immerged in the water; without this artifice they can ſcarcely be all got in: but they are no longer to be continued over the fire than till this effect is produced, leſt the liquor become too thick, and the ſyrup be rendered ropy.

This ſyrup has been recommended in diſorders of the breaſt, coughs, ſpitting of blood, pleuriſies, and other diſeaſes, both as an emollient and as an opiate. It is one of the lighteſt of the opiate medicines; and in this reſpect ſo weak, that ſome have doubted of its having any anodyne quality. We indeed preſume, that it might be very ſafely ſuperſeded altogether; and accordingly it has now no place either in the Edinburgh pharmacopœia, or ſome of the beſt foreign ones, though ſtill retained by the London college.

Roſe ſyrup. L.

505 Take of the dried leaves of the damaſk roſe, ſeven ounces; double-refined ſugar, ſix pounds; boiling diſtilled water, four pints. Macerate the roſe leaves in water for twelve hours, and ſtrain. Evaporate the ſtrained liquor to two pints and an half, and add the ſugar, that it may be made a ſyrup.

Syrup of pale roſes. E.

Take of pale roſes, freſh gathered, one pound; boiling water, four pounds; white ſugar, three pounds. Macerate the roſes in the water for a night; then to the liquor ſtrained, and freed from the dregs, add the ſugar; and boil them into a ſyrup.

This ſyrup may likewiſe be made from the liquor remaining after the diſtillation of roſe-water depurated from its feces.

The liquor remaining after the diſtillation of roſes (provided the ſtill has been perfectly clean) is as proper for making this ſyrup as a freſh infuſion; for the diſtillation only collects thoſe volatile parts which are diſſipated in the air while the infuſion is boiling to its conſiſtence. This ſyrup is an agreeable and mild purgative for children, in the doſe of half a ſpoonful or a ſpoonful. It likewiſe proves gently laxative to adults; and with this intention may be of ſervice in coſtive habits. Its principle uſe is in ſolutive glyſters.

Syrup of dry roſes. E.

Take of red roſes, dried, ſeven ounces; white ſugar, ſix pounds; boiling water, five pounds. Infuſe the roſes in the water for a night, then boil them a little; ſtrain out the liquor, and adding to it the ſugar, boil them to the conſiſtence of a ſyrup. 506

This ſyrup is ſuppoſed to be mildly aſtringent; but is principally valued on account of its red colour. The London college have omitted it, having retained others at leaſt equal to it in that reſpect.

Syrup of ſquills. E.

Take of vinegar of ſquills, two pounds; white ſugar, three pounds and a half. Make them into a ſyrup with a gentle heat. 507

This ſyrup was formerly prepared with ſome ſpices, intended to alleviate the offenſiveneſs of the ſquills. But while they had not this effect, they often counteracted the intention in view, and are therefore omitted. It is uſed chiefly in doſes of a ſpoonful or two, for promoting expectoration, which it does very powerfully.

Simple or common ſyrup. E.

Take of pureſt ſugar, fifteen parts; water, eight parts. Let the ſugar be diſſolved by a gentle heat. 508

This preparation is a plain liquid ſweet, void of flavour or colour. It is convenient for ſundry purpoſes where theſe qualities are not wanted, or would be exceptionable.

Syrup of buckthorn.

Take of the juice of ripe and freſh buckthorn berries, one gallon; ginger, bruiſed, one ounce; all ſpice, powdered, one ounce and an half; double-refined ſugar, ſeven pounds. Set by the juice for ſome days, that the feces may ſubſide, and ſtrain. Macerate the ginger and all-ſpice in a pint of the ſtrained juice for four hours, and ſtrain. Boil away the reſt of the juice to three pints; then add that part of the juice in which the ginger and all-ſpice have been macerated; and, laſtly, the ſugar, that it may be made a ſyrup. *L.* 509

Take of juice of the ripe buckthorn berries, depurated, ſeven pounds and a half; white ſugar, three pounds and a half. Boil them to the conſiſtence of a ſyrup. *E.*

Both theſe preparations, in doſes of three or four ſpoonfuls, operate as briſk cathartics. The principal inconveniences attending them are, their being very unpleaſant, and their occaſioning a thirſt and dryneſs of the mouth and fauces, and ſometimes violent gripes. Theſe effects may be prevented by drinking freely of water-

Preparations and Compositions.

water-gruel, or other warm liquids, during the operation. The ungratefulness of the buckthorn is endeavoured to be remedied in the first of the above prescriptions by the addition of aromatics, which, however, are scarcely sufficient for that purpose. The second also had formerly an aromatic material for the same intention, a dram of the essential oil of cloves; which being found ineffectual, is now rejected.

Syrup of balsam of Tolu. L.

510 Take of the balsam of Tolu, eight ounces; distilled water, three pints. Boil for two hours. Mix with the liquor, strained after it is cold, the double-refined sugar, that it may be made a syrup.

Balsamic syrup. E.

Take of simple syrup, just made, and warm from the fire, two pounds; tincture of balsam of Tolu, one ounce. When the syrup has grown almost cold, stir into it the tincture, by little at a time, agitating them well together till perfectly united.

This last method of making the balsamic syrup was dropt in one of the preceding editions of the Edinburgh pharmacopœia, on a complaint that the spirit spoiled the taste of the syrup; which it did in a great degree when the tincture was drawn with malt spirits, the nauseous oil which all the common malt spirits are accompanied with communicating that quality; and this was particularly the case when the spirituous part was evaporated from the syrup, as was directed in the former edition of the Edinburgh pharmacopœia. Particular care therefore should be taken that the spirit employed for making the tincture be perfectly clean, and well rectified from all ill flavour.

The intention of the contrivers of the two foregoing processes seems to have been somewhat different. In the first, the more subtile and fragrant parts of the balsam are extracted from the grosser resinous matter, and alone retained in the syrup: the other syrup contains the whole substance of the balsam in larger quantity. They are both moderately impregnated with the agreeable flavour of the balsam.

In some pharmacopœias a syrup of this kind is prepared from a tincture of balsam of Peru, with rose-water, and a proper quantity of sugar.

Syrup of violets.

511 Take of the fresh petals of the violet, two pounds; boiling distilled water, five pints. Macerate for 24 hours; afterwards strain the liquor, without pressing, through thin linen. Add refined sugar, that it may be made a syrup. *L.*

Take of fresh violets, one pound; boiling water, four pounds; purest sugar, seven pounds and a half. Macerate the violets in the water for 24 hours in a glass, or at least a glazed earthen vessel, close covered; then strain without expression, and to the strained liquor add the sugar powdered, and make into a syrup. *E.*

This syrup is of a very agreeable flavour; and in the quantity of a spoonful or two proves to children gently laxative. It is apt to lose, in keeping, the elegant blue colour, for which it is chiefly valued; and hence some have been induced to counterfeit it with materials whose colour is more permanent. This abuse may be readily discovered, by adding to a little of the suspected syrup any acid or alkaline liquor. If the syrup be genuine, the acid will change its blue colour to a red, and the alkali will change it to a green; but if counterfeit, these changes will not happen. It is obvious, from this mutability of the colour of the violet, that the prescriber would be deceived if he should expect to give any blue tinge to acidulated or alkalized juleps or mixtures by the addition of the blue syrup.

Preparations and Compositions.

Syrup of ginger.

Take of ginger, bruised, four ounces; boiling distilled water, three pints. Macerate for four hours, and strain; then add refined sugar, that it may be made a syrup. *L.* 512

Take of powdered ginger, three ounces; boiling water, four pounds; purest sugar, seven pounds and a half. Macerate the ginger in the water in a close vessel for 24 hours; then to the liquor, strained and freed from the feces, add the powdered sugar, and make them into a syrup. *E.*

These are agreeable and moderately aromatic syrups, lightly impregnated with the flavour and virtues of the ginger.

Acid of syrup. Gen.

Take of weak spirit of vitriol, two drams; syrup of lemons, six ounces. Mix them. 513

Where we wish to obtain a syrup, not only strongly acidulated, but also powerfully astringent, this formula may be considered as well suited to answer the purpose.

Alkaline syrup. Gen.

Take of salt of tartar, three drams; simple syrup, six ounces. Mix them. 514

In this syrup we have in some degree the converse of the preceding; and it may be usefully employed either for the destruction of acid in the stomach, or for the formation of neutral or effervescent mixtures.

Syrup of garlic. Suec.

Take of the fresh root of garlic, sliced, one pound; boiling water, two pounds. Macerate them in a close vessel for an hour. Add to the strained liquor, refined sugar, two pounds. Boil them to a syrup. 515

This syrup formerly held a place in our pharmacopœias, and was recommended for promoting expectoration in cases of chronic catarrh and other affections of the breast: but, as well as the oxymel of garlic, it is now banished from them; and there can be little doubt that the same intentions may in general be answered by less disagreeable medicines. Yet where we wish to employ garlic in a watery menstruum, this formula is perhaps one of the best under which it can be exhibited.

Syrup of almonds. Suec.

Take of sweet almonds, one pound; bitter almonds, two drams. Let the almonds be blanched and beat in a stone mortar with a wooden pestle; then by degrees add barley-water, two pounds; strain the 516

liquor,

Preparations and Compositions.

liquor, and form it into a ſyrup, with as much double refined ſugar as may be neceſſary.

The agreeable flavour of the almonds is in this formula communicated to a ſyrup, which may be advantageouſly employed to ſweeten mixtures, or to form a pleaſant drink when diffuſed in water; and the flavour is not a little improved by the addition of the proportion of bitter almonds here directed. But even theſe cannot be ſuppoſed to communicate any active quality to this ſyrup, as they are employed in ſo ſmall a quantity: and ſtill leſs is to be expected from the ſweet almonds, which can communicate little more to the ſyrup than their mild oil.

Syrup of cinnamon. Roſſ.

517 Take of cinnamon, bruiſed, five ounces; ſpirituous cinnamon water, two pounds. Digeſt them in a cloſe glaſs veſſel for 24 hours; then add to the ſtrained liquor double refined ſugar, three pounds. Boil it to a ſyrup.

This ſyrup is ſtrongly impregnated with the cinnamon; and where we wiſh to ſweeten any mixture, at the ſame time adding to it an agreeable aromatic, it is perhaps one of the beſt articles we can employ.

Emetic ſyrup. Brun.

518 Take of glaſs of antimony, finely powdered, two drams; Rheniſh wine, twelve ounces. Let them be digeſted for three days in a gentle heat; then ſtrain the liquor through paper, and mix with the ſtrained liquor 30 ounces of double-refined ſugar. Let it be formed into a ſyrup, and kept in a cloſe veſſel.

There can be no doubt of this ſyrup being ſtrongly impregnated with the emetic quality of the antimony; and it will at leaſt have ſo far the advantage of being very agreeable to the taſte, that it may be readily taken by very young people. But every good effect to be obtained from it may be had with more certainty, by adding to ſimple ſyrup any quantity that may be thought neceſſary of the antimonial tartar previouſly diſſolved in a ſmall proportion of water.

Syrup of quickſilver. Suec.

519 Take of purified quickſilver, one dram; gum arabic, three drams; roſe-water, as much as ſufficient for reducing the gum to a mucus. Let them be rubbed in a mortar till the quickſilver totally diſappears; then by degrees mix with it ſimple ſyrup, four ounces.

In this we have a preparation ſimilar to the mercurial ſolution of Dr Plenck formerly mentioned; and which, while it does not poſſeſs any other advantage than mere ſweetneſs of taſte, is liable to the objections formerly urged againſt that preparation.

Chap. XXIV. *Medicated Honeys.*

520 The more fixed parts of vegetables, diſſolved in watery liquors, may be thence transferred into honey, by mixing the honey with the watery decoction or juice of the plant, and boiling them together till the aqueous part has exhaled, and the honey remains of its original conſiſtence. Honey has not probably, however, any very peculiar advantage over ſugar, and it is liable to many inconveniences which ſugar is free from: in particular, it is much more liable to run into fermentation, and in many conſtitutions produces gripes, and often violent effects. The Edinburgh college have therefore rejected the whole of the oxymels from their laſt edition of the pharmacopœia. And the number of preparations with honey in moſt of the foreign pharmacopœias is now much diminiſhed. Still, however, there are ſeveral much employed by practitioners of eminence; and of courſe retained in the London pharmacopœia.

Preparations and Compoſitions.

Honey of roſes. L.

Take of dried red roſe-buds, with the heels cut off, four ounces; boiling diſtilled water, three pints; clarified honey, five pounds. Macerate the roſe leaves in the water for ſix hours; then mix the honey with the ſtrained liquor, and boil the mixture to the thickneſs of a ſyrup. 521

This preparation is not unfrequently uſed as a mild cooling detergent, particularly in gargariſms for ulcerations and inflammation of the mouth and tonſils. The roſe buds here uſed ſhould be haſtily dried: the deſign of doing ſo is, that they may the better preſerve their aſtringency.

Honey of ſquills. L.

Take of clarified honey, three pounds; tincture of ſquills, two pints. Boil them in a glaſs veſſel to the thickneſs of a ſyrup. 522

The honey will here be impregnated with all the active parts of the ſquills which the tincture before contained, and may be employed as an uſeful expectorant or diuretic.

Oxymel of verdigriſe. L.

Take of prepared verdegriſe, one ounce; vinegar, ſeven ounces; clarified honey, fourteen ounces. Diſſolve the verdegriſe in the vinegar, and ſtrain it through linen: then add the honey, and boil the whole to a proper thickneſs. 523

This is an improvement of what was formerly known in our pharmacopœias under the title of *Mel Ægyptiacum*; which, however, was, as often prepared, very uncertain with reſpect to ſtrength. It is uſed only externally for cleanſing foul ulcers, and keeping down fungous fleſh. It is alſo often ſerviceable in venereal ulcerations of the mouth and tonſils. But there is ſome danger from its application to places from the ſituation of which it is apt to be ſwallowed; for even a ſmall quantity of verdegriſe paſſing into the ſtomach may be productive of diſtreſſing, if not deleterious, effects.

Oxymel of meadow ſaffron. L.

Take of the freſh root of meadow-ſaffron, cut into thin ſlices, one ounce; diſtilled vinegar, one pint; clarified honey, two pounds. Macerate the root of meadow-ſaffron with the vinegar, in a glaſs veſſel, with a gentle heat, for 48 hours. Strain the liquor, preſſed out ſtrongly from the root, and add the honey. Laſtly, boil the mixture, frequently ſtirring it with a wooden ſpoon, to the thickneſs of a ſyrup. 524

This oxymel may be conſidered as very analogous to the ſyrup of colchicum, of which we have already made ſome obſervations. Under this form it was firſt introduced by Dr Stoerk. And although with certain conſtitutions the ſyrup is unqueſtionably preferable, yet it well deſerves a place in our pharmacopœias, as being an active medicine.

Oxymel of ſquills. L.

525 Take of clarified honey, three pounds; vinegar of ſquills, two pints. Boil them in a glaſs veſſel, with a ſlow fire, to the thickneſs of a ſyrup.

The honey was formerly employed for this preparation unclarified, and the ſcum, which in ſuch caſes ariſes in the boiling, taken off: by this means the impurities of the honey were diſcharged; but ſome of the medicinal parts of the ſquills, with which the vinegar was impregnated, were alſo ſeparated. For this reaſon the college of London have now judiciouſly ordered the honey for all theſe kinds of preparations to be previouſly clarified by itſelf.

Oxymel of ſquills is an uſeful aperient, detergent, and expectorant, and of great ſervice in humoral aſthmas, coughs, and other diſorders where thick phlegm abounds. It is given in doſes of two or three drams, along with ſome aromatic water, as that of cinnamon, to prevent the great nauſea which it would otherwiſe be apt to excite. In large doſes it proves emetic.

Simple oxymel. L.

526 Take of clarified honey, two pounds; diſtilled vinegar, one pint. Boil them in a glaſs veſſel, with a ſlow fire, to the thickneſs of a ſyrup.

This preparation may be conſidered as analogous to the *ſyrupus aceti* of the Edinburgh pharmacopœia. It is not inferior in efficacy to many more elaborate compoſitions. It is an agreeable, mild, cooling medicine. It is often uſed in cooling detergent gargariſms, and not unfrequently as an expectorant.

Oxymel of garlic. Dan.

527 Take of garlic, cut in ſlices, an ounce and a half; caraway ſeeds, ſweet fennel ſeeds, each two drams; clarified honey, ten ounces; vinegar, half a pint. Boil the vinegar for a little time, with the ſeeds bruiſed, in a glazed earthen veſſel; then add the garlic, and cover the veſſel cloſe; when grown cold, preſs out the liquor, and diſſolve in it the honey by the heat of a water bath.

This oxymel is recommended for attenuating viſcid juices, promoting expectoration, and the fluid ſecretions in general. It is doubtleſs a medicine of conſiderable efficacy, though very unpleaſant, the flavour of the garlic prevailing notwithſtanding the addition of the aromatic ſeeds.

Pectoral oxymel. Brun.

528 Take of elecampane roots, one ounce; orris root, half an ounce; gum ammoniac, one ounce; vinegar, half a pint; clarified honey, one pound; water, three pints. Let the roots, cut and bruiſed, be boiled in the water till one-third is waſted: then ſtrain off the liquor; let it ſtand to ſettle; and having poured it off clear from the feces, add to it the honey and the ammoniac, previouſly diſſolved in the vinegar. Mix them together, by gently boiling them.

The title of this compoſition expreſſes its medical virtues. It is deſigned for thoſe diſorders of the breaſt that proceed from a load of viſcid phlegm, and obſtructions of the pulmonary veſſels. Two or three ſpoonfuls may be taken every night and morning, and continued for ſome time.

Chap. XXV. *Powders.*

This form receives ſuch materials only as are capable of being ſufficiently dried to become pulveriſable without the loſs of their virtue. There are many ſubſtances, however, of this kind, which cannot be conveniently taken in powder: bitter, acrid, fetid drugs, are too diſagreeable; emollient and mucilaginous herbs and roots are too bulky; pure gums cohere, and become tenacious in the mouth; fixed alkaline ſalts liquefy on expoſing the compoſition to the air; and volatile alkalis exhale. Many of the aromatics, too, ſuffer a greater loſs of their odorous principle when kept in powder; as in that form they no doubt expoſe a much larger ſurface to the air. 529

The doſe of powders, in extemporaneous preſcription, is generally about half a dram: it rarely exceeds a whole dram, and is not often leſs than a ſcruple. Subſtances which produce powerful effects in ſmaller doſes are not truſted to this form, unleſs their bulk be increaſed by additions of leſs efficacy; thoſe which require to be given in larger ones are better fitted for other forms.

The uſual vehicle for taking the lighter powders is any agreeable thin liquid. The ponderous powders, particularly thoſe prepared from metallic ſubſtances, require a more conſiſtent vehicle, as ſyrups; for from thin ones they ſoon ſubſide. Reſinous ſubſtances likewiſe are moſt commodiouſly taken in thick liquors; in thin ones they are apt to run into lumps, which are not eaſily again ſoluble.

General rules for making powders.

I. Particular care ought to be taken that nothing carious, decayed, or impure, be mixed in the compoſition of powders: the ſtalks and corrupted parts of plants are to be ſeparated.

II. The dry aromatics ought to be ſprinkled, during their pulverization, with a few drops of any proper water.

III. The moiſter aromatics may be dried with a very gentle heat before they are committed to the mortar.

IV. Gums, and ſuch other ſubſtances as are difficultly pulveriſable, ſhould be pounded along with the drier ones, that they may paſs the ſieve together.

V. No part ſhould be ſeparated for uſe until the whole quantity put into the mortar has paſſed the ſieve, and the ſeveral ſiftings mixed together; for thoſe parts of the ſubject which are firſt powdered may prove different, at leaſt in degree of efficacy, from the reſt.

VI. Powders of aromatics are to be prepared only in ſmall quantities at a time, and kept in glaſs veſſels very cloſely ſtopped.

If powders are long kept, and not carefully ſecured from the air, their virtue is in a great meaſure deſtroyed, although

Preparations and Compositions

although the parts in which it consists should not in other circumstances prove volatile. Thus, though the virtues of ipecacuanha are so fixed as to remain entire even in extracts made with proper menstrua, yet if the powdered root be exposed for a long time to the air, it loses its emetic quality.

Aloetic powder. L.

530 Take of socotorine aloes, one pound; white canella, three ounces. Rub them separately to powder, and then mix them.

This composition has long been known in the shops under the title of *hiera picra*. It furnishes us with an useful aloetic purgative, the canella operating as a good corrigent for the aloes. But it is more frequently employed as the basis of electuaries or pills, or of a tincture which was for a long time distinguished by the appellation of *sacred tincture*.

Aloetic powder with iron. L.

531 Take of socotorine aloes, powdered, an ounce and an half; myrrh, powdered, two ounces; dry extract of gentian, vitriolated iron, of each, in powder, one ounce. Mix them.

In this powder we have an aloetic and chalybeate conjoined. It consists of nearly the same articles which formerly entered the composition of the *pilulæ ecphractica chalybeatæ*, as they were called; and it is perhaps more frequently employed when brought to the form of pills by means of syrups than in powder: but in either way it is an useful medicine, and is particularly employed with advantage in cases of obstructed menstruation.

Aloetic powder with guaiacum. L.

532 Take of socotorine aloes, one ounce and an half; gum guaiacum, one ounce; aromatic powder, half an ounce. Rub the aloes and gum guaiacum separately to powder; then mix all the ingredients together.

In the guaiacum, as well as the aloes, we have a warm gummi-resinous purgative: and both are corrected, as well as more minutely divided, from their combination with the aromatics. This therefore furnishes us with an useful purgative: but when taken only in small doses, its chief effect is that of promoting perspiration. It is, however, more frequently employed in the form of pills than in the state of powder; and indeed it consists of nearly the same ingredients which constituted the *pilulæ aromaticæ* of the former edition of the London pharmacopœia.

Aromatic powder. L.

533 Take of cinnamon, two ounces; smaller cardamom seeds husked, ginger, long pepper, of each one ounce. Rub them together to a powder.

Aromatic powder, or *aromatic spices.* E.

Take of nutmegs, lesser cardamom seeds, ginger, each two ounces. Beat them together into a powder, to be kept in a phial well shut.

Both these compositions are agreeable, hot, spicy medicines; and as such may be usefully taken in cold phlegmatic habits and decayed constitutions, for warming the stomach, promoting digestion, and strengthening the tone of the viscera. The dose is from ten grains to a scruple and upwards. The first is considerably the warmest. This principally arises from the quantity of long pepper which it contains. But it is perhaps to be doubted whether from this article any advantage be derived; and a powder not inferior to either might, we think, be formed, by substituting cassia for the cinnamon employed by the one college, or the nutmegs by the other.

Preparations and Compositions

Compound powder of asarabacca. L.

Take of the dry leaves of asarabacca, sweet marjoram, Syrian herb mastich, dry flowers of lavender, each one ounce. Powder them together. 534

Sternutatory or *cephalic powder.* E.

Take of the leaves of asarum, three parts; marjoram, one part. Beat them together into a powder.

Though the former of these powders be more compounded than the latter, yet they differ very little. They are both agreeable and efficacious errhines, and superior to most of those usually sold under the name of *herb snuff*. They are often employed with great advantage in cases of obstinate headach, and of ophthalmias resisting other modes of cure. Taken under the form of snuff to the extent of five or six grains at bed-time, they will operate the succeeding day as a powerful errhine, inducing frequent sneezing, but still more a large discharge from the nose. It is, however, necessary, during their operation, to avoid exposure to cold.

Powder of cerusse. L.

Take of cerusse, five ounces; sarocoll, one ounce and an half; tragacanth, half an ounce. Rub them together into powder. 535

This composition is the *tro hisci albi* of Rhazes brought back to its original simplicity with regard to the ingredients, and without the needless trouble of making it into troches. It is employed for external purposes, as in collyria, lotions, and injections, for repelling acrimonious humours, and in inflammations.

Compound powder of crabs claws. L.

Take of crabs claws, prepared, one pound; chalk, red coral, each, prepared, three ounces. Mix them. 536

These powders have lost several of their ingredients without any injury to their virtues; and possibly they would still bear a further reduction, for the crabs eyes and chalk are by themselves at least as essential as any composition of them with coral. And perhaps every purpose to be obtained from them may be accomplished by a more simple absorbent, as the chalk powder afterwards to be mentioned, or the powder of the lapilli cancrorum.

Compound powder of contrayerva. L.

Take of contrayerva, powdered, five ounces; compound powder of crabs claws, one pound and an half. Mix them. 537

This powder was formerly directed to be made up into balls with water, and was then called *lapis contrayervæ*; a piece of trouble now laid aside as needless, for it was necessary to reduce the balls into powder

Preparations and Compositions.

again before they could be uſed. Nor did that form contribute, as has been imagined, to their preſervation; for it is ſcarcely to be ſuppoſed that the powder will loſe more by being kept for a reaſonable length of time in a cloſe-ſtopt glaſs than the balls will in the humectation with water and exſiccation in the air before they are fit for being put by to keep. This medicine has much better claim to the title of an alexipharmac and ſudoriſic than the foregoing compoſitions. The contrayerva by itſelf proves very ſerviceable in low fevers, where the *vis vitæ* is weak, and a diaphoreſis to be promoted. It is poſſible that the crabs claws are of no farther ſervice than as they divide this powerful ingredient, and make it ſit more eaſily on the ſtomach.

Compound powder of chalk. L.

538 Take of prepared chalk, half a pound; cinnamon, four ounces; tormentil, gum-arabic, of each three ounces; long pepper, half an ounce. Powder them ſeparately, and mix them.

Chalk powder. E.

Take of white chalk, prepared, four ounces; nutmeg, half a dram; cinnamon, one dram. Mix and make them into a powder; which may ſupply the place of the cardialgic troches.

The addition of the aromatics in the above formula, coincides with the general intention of the remedy which is indicated for weakneſs and acidity in the ſtomach; and in looſeneſs from acidity.

Compound powder of chalk with opium. L.

Take of compound powder of chalk, eight ounces; hard purified opium, powdered, one dram and an half. Mix them.

From the addition of the opium this remedy becomes ſtill more powerful than the above in reſtraining diarrhœa.

Compound powder of ipecacuanha. L.

539 Take ipecacuanha and hard purified opium, of each, powdered, one dram; vitriolated kali, powdered, one ounce. Mix them.

Sudoriſic, or Dover's powder. E.

Take of vitriolated tartar, three drams; opium, root of ipecacuanha powdered, of each one ſcruple. Mix, and grind them accurately together, ſo as to make an uniform powder.

The vitriolated tartar, from the grittineſs of its cryſtals, is perhaps better fitted for tearing and dividing the tenacious opium than any other ſalt; this ſeems to be its only uſe in the preparation. The operator ought to be careful that the opium and ipecacuanha ſhall be equally diffuſed through the whole maſs of powder, otherwiſe different portions of the powder muſt have differences in degree of ſtrength.

The hard purified opium, directed by the London college, is, from this circumſtance, preferable to opium in its ordinary ſtate, employed by the Edinburgh college.

This powder is one of the moſt certain ſudorifics that we know of; and as ſuch, was recommended by Dr Dover as an effectual remedy in rheumatiſm. Modern practice confirms its reputation, not only in rheumatiſm, but alſo in dropſy and ſundry other diſeaſes, where it is often difficult by other means to produce a copious ſweat. The doſe is from five to ten or twelve grains, according as the patient's ſtomach and ſtrength can bear it. It is convenient to avoid much drinking immediately after taking it, otherwiſe it is very apt to be rejected by vomiting before any other effects are produced.

Compound powder of jalap. E.

Take of jalap root, one ounce; cryſtals of tartar, two ounces. Mix, and diligently grind them together for ſome time, ſo as to form a very fine powder. 540

The uſe of the cryſtals in this preparation is to break down and divide the jalap into very minute particles, whereby its operation is thought to be meliorated; and on this account the two articles are directed to be pounded together, and not ſeparately. But whether from this circumſtance any advantage ariſes or not, there can be no doubt that this combination furniſhes us with a very uſeful and active purgative, in every caſe where it is neceſſary to produce both a full evacuation of the inteſtinal canal, and a free diſcharge from the ſyſtem in general, under the form of catharſis.

Compound powder of myrrh. L.

Take of myrrh, dried ſavin, dried rue, Ruſſian caſtor, of each, one ounce. Rub them together into a powder. 541

This is a reformation of the troches of myrrh, a compoſition contrived by Rhazes againſt uterine obſtructions. It may be taken in any convenient vehicle, or made into boluſes, from a ſcruple to a dram or more, two or three times a-day.

Opiate powder. L.

Take of hard purified opium, powdered, one dram; burnt and prepared hartſhorn, nine drams. Mix them. 542

The hartſhorn is here intended merely to divide the opium, and to give it the form of powder, although it may perhaps have alſo ſome influence in rendering the opium more active from deſtroying acid in the ſtomach. But whether in this way it has any effect or not, there can be no doubt that it is a very convenient formula for the exhibition of opium in powder; which on ſome occaſions is preferable to its being given either in a liquid form or in that of pills. As ten grains of this powder contain preciſely one of the opium, the requiſite doſe may be eaſily adapted to the circumſtances of the caſe. It is often ſucceſsfully employed as a ſweating powder; and has not, like Dover's powder, the effect of inducing ſickneſs or vomiting.

Compound powder of ſcammony.

Take of ſcammony, hard extract of jalap, each two ounces; ginger, half an ounce. Powder them ſeparately, and mix them. *L.* 543

Preparations and Compositions.

Take of ſcammony, cryſtals of tartar, each two ounces; mix, and grind them diligently into a powder. *E.*

It is much to be regretted, that in the pharmacopœias publiſhed by authority in Britain, two compoſitions ſhould be diſtinguiſhed by the ſame name, differing conſiderably from each other in their nature and degree of activity.

The compound powder of ſcammony in the laſt edition of the London pharmacopœia differed conſiderably from the preſent: For there, the only addition was calcined hartſhorn, intended merely for the diviſion of the ſcammony. This purpoſe is ſtill better anſwered by the cryſtals of tartar, which at the ſame time conſpire with the operation of the ſcammony as a purgative. But the addition of jalap and ginger, according to the preſent formula of the London pharmacopœia, gives not only a purgative conſiderably different, but increaſes alſo the heating quality of the medicine, while the cream of tartar has an evident refrigerant power. Both may on occaſions be uſeful, but we think that in moſt caſes the Edinburgh formula will be found preferable.

In editions of our pharmacopœias of ſtill older date, this powder was prepared with another very active ingredient, diaphoretic antimony. It was much celebrated as diſtinguiſhed by the name of its inventor, being called from its firſt publiſher, *Cornachini's powder*. In a former edition of the Edinburgh pharmacopœia it was thus directed to be prepared:

Take of diaphoretic antimony, cream of tartar, ſcammony, each equal parts. Make them into a powder.

This may be given to the quantity of a dram or more. In other preſcriptions, the tartar and antimonial calx bear nearly the ſame proportion to the ſcammony as the calcined hartſhorn did in the London pharmacopœia. It appears probable, that neither of theſe ingredients are of any farther uſe, than as they divide the texture of the ſcammony; though Cornachini ſuppoſes very conſiderable advantage from ſome deobſtruent quality in the tartar, whereby the veſſels ſhall be opened, and the noxious humours prepared for expulſion; and from the preparation of antimony, though it have no ſenſible operation, he expects ſome ſhare of the ſame ſucceſs which ſometimes attends the rougher preparations of that mineral.

Both the preſent formulæ may, however, be conſidered as poſſeſſing all the advantages of Cornachini's powder.

Powder of ſcammony with aloes. L.

544 Take of ſcammony, ſix drams; hard extract of jalap, ſocotorine aloes, of each an ounce and an half; ginger, half an ounce. Powder them ſeparately, and mix them.

In this formula, the combination of ſcammony, jalap, and aloes, furniſhes a very active purgative, which, with ſome intentions at leaſt, may be preferable to either of the preceding. Taken from five to ten grains, it will operate as a purgative, even in caſes of obſtinate coſtiveneſs.

Powder of ſcammony with calomel. L.

545 Take of ſcammony, half an ounce; calomel, double-refined ſugar, of each two drams. Rub them ſeparately to a powder, and then mix them. Preparations and Compoſitions.

In this formula, we have the ſcammony in a more ſimple ſtate, united with ſuch a proportion of calomel as muſt very conſiderably aid its purgative power. And accordingly it may be employed with advantage, both in caſes of obſtinate coſtiveneſs and in dropſical affections, where a conſiderable diſcharge is required from the ſyſtem.

Compound powder of ſenna. L.

546 Take ſenna, cryſtals of tartar, of each two ounces; ſcammony, half an ounce; ginger, two drams. Rub the ſcammony by itſelf, rub the reſt together into a powder, and then mix them all.

This powder is given as a cathartic, in the doſe of two ſcruples or a dram. The ſpice is added, not only to divide, but to warm the medicine, and make it ſit eaſier on the ſtomach. The ſcammony is uſed as a ſtimulus to the ſenna; the quantity of the latter neceſſary for a doſe, when not aſſiſted by ſome more powerful material, being too bulky to be conveniently taken in this form.

The compoſition of this medicine is now conſiderably ſimplified by the rejection both of cinnamon and cloves, as the ginger alone is found fully to anſwer the intention in view.

Styptic powder. E.

547 Take of alum, an ounce and an half; gum-kino, three drams. Grind them together into a fine powder.

In former editions of our pharmacopœia, a powder of this kind was directed to be made with alum and dragon's blood, and was long in repute as an aſtringent, under the title of *Helvetius's ſtyptic powder*. The gum-kino is judiciouſly ſubſtituted for the dragon's blood, as being a much more powerful and certain aſtringent. The chief uſe of this powder is in hæmorrhagies, eſpecially of the uterus.

Compound powder of tragacanth. L.

548 Take of tragacanth powdered, gum-arabic, ſtarch, each an ounce and a half; double-refined ſugar, three ounces. Rub them together into a powder.

This compoſition is ſomewhat ſimplified by the rejection of the marſhmallow, and liquorice-root, which formerly entered it. But this has not probably produced any diminution of its medical properties. It operates as a mild emollient; and hence becomes ſerviceable in hectic caſes, tickling coughs, ſtrangury, ſome kinds of alvine fluxes, and other diſorders proceeding from a thin acrimonious ſtate of the humours, or an abraſion of the mucus of the inteſtines; they ſoften, and give a greater degree of conſiſtency to the former, and defend the latter from being irritated or excoriated by them. All the ingredients coincide in theſe general intentions. The doſe is from half a dram to two or three drams, which may be frequently repeated.

Anthelmintic powder. Gen.

549 Take of the flowers of tanſy, worm-ſeeds, each three drams; ſal martis, one dram. Mix them.

Both

Both the tanſy and worm-ſeed poſſeſs a conſiderable degree of anthelmintic power, which is not a little increaſed by the ſalt of ſteel. And from this combination more effect in the expulſion of worms, particularly of the lumbrici, may be expected, than from any of the articles taken by themſelves. This powder may be taken to the extent of half a dram or upwards for a doſe, proportioned to the age and circumſtances of the patient.

Powder againſt the bite of a mad dog. Brun.

550 Take of aſh-coloured ground liverwort, two ounces; black pepper, one ounce. Beat them together into a powder.

The virtue for which this medicine has been celebrated, is expreſſed in its title; the doſe is a dram and a half, to be taken in the morning faſting, in half a pint of cows milk warm, for four mornings together.

At one period it was held, on the recommendation of Dr Mead and other eminent practitioners, in very high eſteem. Now, however, it has fallen into ſuch diſrepute, as to be baniſhed from moſt of the modern pharmacopœias.

Compound powder of arum. Succ.

551 Take of arum root, freſh dried, two drams; yellow water-flag roots, burnt ſaxifrage roots, each one dram; white canella, a dram; ſalt of wormwood, one ſcruple. Beat them into a powder, which is to be kept in a cloſe veſſel.

In former editions of the London pharmacopœia, one of the ingredients in this compoſition was called *acorus vulgi* or *vulgaris*; a name which has been applied, by different writers, both to *calamus aromaticus*, and to *gladiolus luteus*, or common yellow water-flag. In this uncertainty, the compounders generally took the former. But as the medicine was firſt contrived by a German phyſician (Birkmann), and as in ſome of the German pharmacopœias, the *acorus vulgaris* is explained to be the water-flag, the Swediſh college have rather, in conformity to the original preſcription, than from any opinion of the virtues of the water-flag (which appears, when the root is dried and powdered, to be very inconſiderable), made choice of this laſt, and expreſſed it by the name which more clearly diſtinguiſhes it from the other. The caution of keeping the powder in a cloſe veſſel is very neceſſary; for if it be expoſed to the air, the alkaline ſalt, imbibing moiſture, would run into a liquid ſtate. Two alkaline ſalts have been generally directed; but as they differ from each other only in name, one of them is here juſtly omitted, and ſupplied by a proportional increaſe of the other. Crabs eyes were originally an article in this compoſition, but probably ſerved little other purpoſe than to increaſe its volume.

Agreeably to the above remark, the college of Edinburgh, in a reviſal of their pharmacopœia, had omitted the crabs-eyes, and continued the former practice of uſing calamus aromaticus for the *acorus vulgaris*. They had likewiſe exchanged the cinnamon for the white canella; and the alkaline ſalt for a neutral one, better ſuited to the form of a powder. Their formula was as follows:

Take of arum roots, newly dried, two ounces; calamus aromaticus, burnt ſaxifrage roots, each one ounce; white canella, ſix drams; vitriolated tartar, two drams. Mix and make them into a powder.

This article, which had formerly a place alſo in the London pharmacopœia, is ſtill retained in ſome of the beſt foreign ones: But it is now altogether rejected from our pharmacopœias.

The compound powder of arum was originally intended as a ſtomachic: and in weakneſſes and relaxations of the ſtomach, accompanied with a ſurcharge of viſcid humours, it is doubtleſs a very uſeful medicine. It frequently has alſo good effects in rheumatic caſes: the doſe may be from a ſcruple to a dram, two or three times a day, in any convenient liquor. It ſhould be uſed as freſh as poſſible, for its virtue ſuffers greatly in keeping: the arum root in particular, its capital ingredient, ſoon loſes the pungency, in which its efficacy principally conſiſts.

Digeſtive powder. Succ.

552 Take of bitter purging ſalts, rhubarb, each equal parts. Mix them.

In this compoſition, the ſalt will briſken the operation of the rhubarb as a cathartic, and the aſtringency of the latter will tend to increaſe the tone of the ſtomach: hence, in conſequence of evacuating, and at the ſame time ſtrengthening the alimentary canal, it may be preſumed to have conſiderable influence in promoting digeſtion.

Dyſenteric powder. Dan.

553 Take of rhubarb, one ounce; calcined hartſhorn, half an ounce; gum-arabic, three drams; caſcarilla bark, two drams. Mix them, and reduce them to a very fine powder.

Here the rhubarb is combined with another powerful tonic, the caſcarilla; and while the calcined hartshorn ſerves to neutralize acid, the gum-arabic will operate as a demulcent. This compoſition therefore may be very uſeful in dyſenteric caſes, after the violence of the diſeaſe has been overcome, and when there remains a debilitated and abraded ſtate of the inteſtinal canal.

Fumigation powder. Roſſ.

554 Take of olibanum, amber, maſtich, each three parts; ſtorax, two parts; benzoin, labdanum, each one part. Mix them into a groſs powder.

This powder is intended for the purpoſe of fumigation; and when burnt it gives out a fragrant odour: hence it may be ſucceſsfully employed for combating diſagreeable ſmells, and counteracting putrid or other noxious vapours diffuſed in the atmoſphere.

Powder for infants. Succ.

555 Take of magneſia alba, one ounce; rhubarb, reduced to a very fine powder, one dram. Let them be mixed.

This powder is very uſeful for deſtroying acid, and at the ſame time reſtoring the diminiſhed tone of the alimentary canal: hence it is often advantageouſly employed in caſes of diarrhœa, which depend on theſe

Preparations and Compositions.

morbid conditions. And it is in general a circumſtance of conſiderable advantage, that it does not tend to check looſeneſs very ſuddenly. It is particularly uſeful with infants, and hence the origin of the name here affixed to it.

Nitrous powder. Suec.

556 Take of purified nitre, three ounces; ſalt of ſorrel, one ounce; double-refined ſugar, ten ounces. Let them be mixed.

This is a very convenient and agreeable form of exhibiting nitre: for while the ſugar ſerves not only to divide and diffuſe it, but alſo to correct its taſte, the ſalt of ſorrel adds to its refrigerant power.

Purging Peruvian powder. Gen.

557 Take of the powder of Peruvian bark, one ounce; powder of rhubarb, powder of ſal ammoniac, each one dram and a half.

It has been imagined by many, that particular advantage reſulted from uniting the Peruvian bark with ſal ammoniac; and there can be no doubt, that in ſome caſes inconvenience reſults from the bark, in conſequence of its binding the belly. There are therefore circumſtances in which the combination here propoſed may perhaps be proper: but there is reaſon to believe that the benefit of the ſal ammoniac is more imaginary than real; and it not unfrequently happens, that we are diſappointed of the benefit which might otherwiſe be derived from the bark, in conſequence of its proving even of itſelf a purgative. Hence, in perhaps a majority of caſes, the exhibiting it with the additions here propoſed will be rather prejudicial than otherwiſe.

Thebaic powder. Suec.

558 Take of opium, half a ſcruple; purified nitre, five ſcruples and a half; refined ſugar, one ounce. Mix them together into a powder.

In this powder thoſe inconveniences which ſometimes reſult from opium may with certain conſtitutions be corrected, in conſequence of the refrigerant power of nitre; and hence it may prove a very uſeful ſedative powder. The ſugar is intended merely to give form to the medicine; and in its ſtate of combination, each dram of it contains a grain of opium; ſo that a practitioner has it in his power eaſily to regulate the doſe according to circumſtances.

Sponge-powder. Gen.

559 Take of burnt ſponge, powdered, common ſalt, each three drams. Mix them, and divide into twelve powders.

We have formerly noticed the manner of burning ſponge, (ſee n° 98.) It is of very conſiderable ſervice in ſcrofulous affections, and particularly in the cure of the bronchocele. It has of late been highly celebrated for theſe purpoſes by Mr Wilmer, under the title of the *Coventry remedy*. There it was ſometimes employed merely in its pure ſtate, combined with a ſufficient quantity of honey, to form it into a bolus; ſometimes it was given united with calcined cork and pumice-ſtone. What advantage, however, it could have derived from theſe additions it is difficult to conceive; nor can we readily ſee how it will be improved by the addition of common ſea-ſalt here propoſed: for this may probably lead to new combinations, materially altering the qualities of thoſe ſalts which the ſponge itſelf contains; and on which its virtues, as far as it has any, muſt depend. At the ſame time, for any experience which we ourſelves have had, we are inclined to think, that thoſe virtues which have been attributed to burnt ſponge are more imaginary than real.

Preparations and Compoſitions.

Chap. XXVI. *Troches.*

Troches and lozenges are compoſed of powders made up with glutinous ſubſtances into little cakes, and afterwards dried. This form is principally uſed for the more commodious exhibition of certain medicines, by fitting them to diſſolve ſlowly in the mouth, ſo as to paſs by degrees into the ſtomach; and hence theſe preparations have generally a conſiderable proportion of ſugar or other materials grateful to the palate. Some powders have likewiſe been reduced into troches, with a view to their preparation; though poſſibly for no very good reaſons: for the moiſtening, and afterwards drying them in the air, muſt on this account be of greater injury than any advantage accruing from this form can counterbalance. 560

General Rules for making Troches.

1. The three firſt rules laid down for making powders, are alſo to be obſerved in the powders for troches.
2. If the maſs proves ſo glutinous as to ſtick to the fingers in making up, the hands may be anointed with any convenient ſweet or aromatic oil; or elſe ſprinkled with powder of ſtarch, or of liquorice, or with flour.
3. In order to thoroughly dry the troches, put them on an inverted ſieve, in a ſhady airy place, and frequently turn them.
4. Troches are to be kept in glaſs veſſels, or in earthen ones well glazed.

Troches of ſtarch. L.

Take of ſtarch, an ounce and an half; liquorice, ſix drams; florentine orris, half an ounce; double refined ſugar, one pound and a half. Rub theſe to powder, and, by the help of tragacanth, diſſolved in water, make troches. They may be made, if ſo choſen, without the orris. 561

White pectoral troches. E.

Take of pureſt ſugar, one pound; gum arabic, four ounces; ſtarch, one ounce; flowers of benzoin, half a dram. Having beat them all into a powder, make them into a proper maſs with roſe-water, ſo as to form troches.

Theſe compoſitions are very agreeable pectorals, and may be uſed at pleaſure. They are calculated for ſoftening acrimonious humours, and allaying the tickling in the throat which provokes coughing.

Although not only the name but the compoſition alſo

also in the London and Edinburgh pharmacopœias be somewhat different, yet their effects are very much the same.

Troches of liquorice. L.

562 Take of extract of liquorice, double-refined sugar, each ten ounces; tragacanth, powdered, three ounces. Make troches by adding water.

Black pectoral troches. E.

Take of extract of liquorice, gum arabic, each four ounces; white sugar, eight ounces. Dissolve them in warm water, and strain: then evaporate the mixture over a gentle fire till it be of a proper consistence for being formed into troches.

These compositions are designed for the same purposes as the white pectoral troches above described. In foreign pharmacopœias there are some other troches of this kind, under the titles of *Trochisci bechici flavi* and *rubri*; the first are coloured with saffron, the latter with bole armenic. The dissolving and straining the extract of liquorice and gum arabic, as now ordered in the last of the above prescriptions, is a considerable improvement; not only as they are by that means more uniformly mixed than they can well be by beating, but likewise as they are thereby purified from the heterogeneous matters, of which both those drugs have commonly no small admixture.

Pectoral troches with opium. E.

563 Take of pure opium, two drams; balsam of Peru, one dram; tincture of Tolu, three drams. Grind the opium with the balsam and tincture previously mixed, till it be thoroughly dissolved; then add by degrees, of common syrup, eight ounces; extract of liquorice, softened in warm water, five ounces. While beating them diligently, gradually sprinkle upon the mixture five ounces of powdered gum arabic. Exsiccate so as to form troches, each weighing ten grains.

The directions for preparing the above troches are so full and particular, that no farther explanation is necessary. Six of the troches prepared in the manner here ordered, contain about one grain of opium. These troches are medicines of approved efficacy in tickling coughs depending on an irritation of the fauces. Besides the mechanical effect of the invisicating matters and involving acrid humours, or lining and defending the tender membranes, the opium must, no doubt, have a considerable share, by more immediately diminishing the irritability of the parts themselves.

The composition of these troches, however, would perhaps be improved by the omission of the balsam of Peru: for although here directed only in small quantity, yet it gives a taste to the troches which is to many people very disagreeable; and it is at the same time probable that it adds very little, if any thing, to the efficacy of the medicine.

Troches of nitre.

564 Take of purified nitre, powdered, four ounces; double-refined sugar, powdered, one pound; tragacanth, powdered, six ounces. With the addition of water, make troches. *L.*

Take of nitre, purified, three ounces; double-refined sugar, nine ounces. Make them into troches with mucilage of gum tragacanth. *E.*

This is a very agreeable form for the exhibition of nitre; though, when the salt is thus taken without any liquid (if the quantity be considerable), it is apt to occasion uneasiness about the stomach, which can only be prevented by large dilution with aqueous liquors. The troches of nitre have been said to be employed with success in some cases of difficult deglutition.

Troches of sulphur.

Take of washed flowers of sulphur, two ounces; double-refined sugar, four ounces. Rub them together; and, with the mucilage of quince-seeds, now and then added, make troches. *L.* 565

Take of flowers of sulphur, two ounces; flowers of benzoin, one scruple; white sugar, four ounces; factitious cinnabar, half a dram. Beat them together, and add mucilage of gum tragacanth as much as is sufficient. Mix and make them into troches according to art. *E.*

These compositions are to be considered only as agreeable forms for the exhibition of sulphur, no alteration or addition being here made to its virtues; unless that, by the flowers of benzoin in the second prescription, the medicine is supposed to be rendered more efficacious as a pectoral.

The factitious cinnabar seems chiefly intended as a colouring ingredient.

Troches of chalk. L.

Take of chalk, prepared, four ounces; crabs-claws, prepared, two ounces; cinnamon, half an ounce; double-refined sugar, three ounces. These being rubbed to powder, add mucilage of gum arabic, and make troches. 566

Troches of magnesia. L.

Take of burnt magnesia, four ounces; double-refined sugar, two ounces; ginger, powdered, one scruple. With the addition of mucilage of gum arabic make troches.

These compositions are calculated against that uneasy sensation at the stomach, improperly called the *heartburn*; in which they often give immediate relief, by absorbing and neutralizing the acid juices that occasion this disorder. The absorbent powders here used are of the most powerful kind. The former has in general the effect of binding, the latter of opening, the belly; and from this circumstance the practitioner will be determined in his choice, according to the nature of the case which he may have occasion to treat.

Red lead troches. Dan.

Take of red lead, half an ounce; corrosive sublimate mercury, one ounce; crumb of the finest bread four ounces. Make them up with rose-water into oblong troches. 567

Preparations and Compositions.

These troches are employed only for external purposes as escarotics: they are powerfully such, and require a good deal of caution in their use.

Troches of catechu. Brun.

Take of catechu, one ounce; white sugarcandy, two ounces; ambergris, musk, each ten grains; mucilage of gum tragacanth, as much as is sufficient. Make them into troches. 568

This medicine has long been in esteem as a slight restringent; and restringents thus gradually received into the stomach produce better effects than when an equal quantity is taken down at once. These troches would be more palatable, and perhaps not less serviceable, were the musk and ambergris omitted.

Chap. XXVII. *Pills.*

To this form are peculiarly adapted those drugs which operate in a small dose, and whose nauseous and offensive taste or smell require them to be concealed from the palate. 569

Pills dissolve the most difficultly in the stomach, and produce the most gradual and lasting effects of all the internal forms. This is in some cases of great advantage, in others it is a quality not at all desirable; and sometimes may even be of dangerous consequence, particularly with regard to emetics; which, if they pass the stomach undissolved, and afterwards exert themselves in the intestines, operate there as violent cathartics. Hence emetics are among us scarcely ever given in pills; and hence to the resinous and difficultly soluble substances, saponaceous ones ought to be added, in order to promote their solution.

Gummy resins, and inspissated juices, are sometimes soft enough to be made into pills without addition: where any moisture is requisite, spirit of wine is more proper than syrups or conserves, as it unites more readily with them, and does not sensibly increase their bulk. Light dry powders require syrup or mucilages; and the more ponderous, as the mercurial and other metallic preparations, thick honey, conserve or extracts.

Light powders require about half their weight of syrup, of honey, about three-fourths their weight, to reduce them into a due consistence for forming pills. Half a dram of the mass will make six or seven pills of a moderate size.

General Rules for making pills.

1. Gums and inspissated juices are to be first softened with the liquid prescribed; then add the powders, and continue beating them all together till they be perfectly mixed.
2. The masses for pills are best kept in bladders, which should be moistened now and then with some of the same kind of liquid that the mass was made up with, or with some proper aromatic oil.

Ethiopic pills. E.

Take of quicksilver, six drams; golden sulphur of antimony, resin of guaiacum, honey, each half an ounce. Grind the quicksilver with the honey, in a glass mortar, until the mercurial globules entirely disappear; then add the golden sulphur and guaiacum, with as much mucilage of gum arabic as is sufficient to make the mixture into a mass of the proper consistence for forming pills. 570

These pills are much more efficacious than those of a former edition; the ethiops mineral, there ordered, being exchanged for a more active composition. In their present form, they resemble Dr Plummer's pills, described in the Edinburgh Essays, and afterwards to be mentioned. To it they are preferable in one respect, that they are less apt to run off by stool. They are an useful alterative both in cutaneous and venereal disorders. One fourth-part of the quantity above prescribed may be made into sixty pills; of which from one to four may be taken every night and morning, the patient keeping moderately warm during the whole time that this course is continued.

Pills of aloes. L.

Take of socotorine aloes, powdered, one ounce; extract of gentian, half an ounce; syrup of ginger, as much as is sufficient. Beat them together. 571

Aloetic pills. E.

Take of socotorine aloes, in powder, thick extract of gentian, each two ounces; make them into a mass with simple syrup.

These pills were formerly directed to be made with Castile soap; from a notion which Boerhaave and some others were very fond of, that soap promoted the solution of resinous and several other substances in the stomach. This, however, seems to be a mistake; and, on the contrary, it is highly probable that the alkaline part of the soap is in most instances separated from the oily by the acid in the stomach; by which decomposition the soap may possibly retard instead of promoting the solution of the aloes. These pills have been much used as warming and stomachic laxatives: they are very well suited for the costiveness so often attendant on people of sedentary lives. Like other preparations of aloes, they are also used in jaundice, and in certain cases of obstructed menses. They are seldom used for producing full purging; but if this be required, a scruple or half a dram of the mass may be made into pills of a moderate size for one dose.

Pills of aloes with myrrh. L.

Take of socotorine aloes, two ounces; myrrh, saffron, of each one ounce; syrup of saffron, as much as is sufficient. Rub the aloes and myrrh separately to powder; afterwards beat them all together. 572

The common pills, vulgarly called *Rufus's pills.* E.

Take of socotorine aloes, two ounces; myrrh, one ounce; saffron, half an ounce. Beat them into a mass with a proper quantity of syrup.

These pills have long continued in practice, without any other alteration than in the syrup with which the mass is made up, and in the proportion of saffron. In our last pharmacopœia, the syrup of wormwood was ordered, which is here judiciously exchanged by the London college for that of saffron; this preserving and

and improving the brightneſs of colour in the medicine, which is the characteriſtic of its goodneſs. The ſaffron, in the compoſition which is attributed to Rufus, is equal in quantity to the myrrh; and in theſe proportions the pill was received in our firſt pharmacopœia. As the diminution afterwards made in the ſaffron was grounded on very abſurd reaſons, (viz. "leſt the former quantity ſhould occaſion a ſpaſmus cynicus,") the London college have now again increaſed it, and reſtored the pill to its original form. The virtues of this medicine may be eaſily underſtood from its ingredients. Theſe pills, given to the quantity of half a dram or two ſcruples, prove conſiderably cathartic, but they anſwer much better purpoſes in ſmaller doſes as laxatives or alteratives.

Colocynth pills with aloes, commonly called *Cocciæ*. E.

573 Take ſocotorine aloes, ſcammony, of each two ounces; ſal polychreſt, two drams; colocynth, one ounce; oil of cloves, two drams. Reduce the aloes and ſcammony into a powder with the ſalt; then let the colocynth, beat into a very fine powder, and the oil be added; laſtly, make it into a proper maſs with mucilage of gum arabic.

In theſe pills we have a very uſeful and active purgative; and where the ſimple aloetic pill is not ſufficient for obviating coſtiveneſs, this will often effectually anſwer the purpoſe. Little of their activity can depend upon the ſalt which enters the compoſition; but it may aſſiſt in dividing the active parts of the other articles, particularly the aloes and ſcammony. Theſe pills often produce a copious diſcharge in caſes of obſtinate coſtiveneſs, when taken to the extent only of five or ten grains; but they may be employed in much larger doſes. They are, however, ſeldom uſed with the view of producing proper catharſis. Half a dram of the maſs contains about five grains of the colocynth, ten of the aloes, and ten of the ſcammony.

Copper pills. E.

574 Take of cuprum ammoniacum, ſixteen grains; crumb of bread, four ſcruples; ſpirit of ſal ammoniac, as much as is ſufficient to form them into a maſs, which is to be divided into thirty-two equal pills.

Theſe pills had formerly the name of *Pilulæ cæruleæ*, but they are now with greater propriety denominated from the metal which is their baſis.

Each of theſe pills weigh about three grains, and contain ſomewhat more than half a grain of the cuprum ammoniacum. The above pills ſeem to be the beſt form of exhibiting this medicine. See *Cuprum Ammoniacale*, and Chemistry, no 1034.

Gum pills.

575 Take of galbanum, opopanax, myrrh, ſagapenum, each one ounce; aſafœtida, half an ounce; ſyrup of ſaffron, as much as is ſufficient. Beat them together. *L.*

Take of aſafœtida, galbanum, myrrh, each one ounce; rectified oil of amber, one dram. Beat them into a maſs with ſimple ſyrup. *E.*

Theſe pills are deſigned for antihyſterics and emmenagogues, and are very well calculated for anſwering thoſe intentions; half a ſcruple, a ſcruple, or more, may be taken every night or oftener. The fetid pills of our former pharmacopœia were conſiderably purgative: the purgative ingredients are now omitted, as the phyſician may eaſily, in extemporaneous preſcription, compound theſe pills with cathartic medicines, in ſuch proportions as particular caſes ſhall require. Preparations and Compoſitions.

Quickſilver pills. L.

576 Take purified quickſilver, extract of liquorice, having the conſiſtence of honey, of each two drams; liquorice, finely powdered, one dram. Rub the quickſilver with the extract of liquorice until the globules diſappear; then, adding the liquorice-powder, mix them together.

Mercurial pills. E.

Take of quickſilver, honey, each one ounce; crumb of bread, two ounces. Grind the quickſilver with the honey in a glaſs mortar till the globules diſappear, adding occaſionally a little ſimple ſyrup; then add the crumb of bread, and beat the whole with water into a maſs, which is to be immediately divided into four hundred and eighty equal pills.

The quickſilver was formerly directed to be ground with reſin of guaiacum and Caſtile ſoap. The former was ſuppoſed to coincide with the virtues of the mercury, and the latter was uſed chiefly to divide the globules of mercury. For this laſt intention Dr Saunders found that honey, the ſubſtance here ordered by the Edinburgh college, is of all he tried the moſt effectual: but we would ſuppoſe with this gentleman, that ſomething farther is done in this proceſs than the mere diviſion of the mercurial globules, and that part of the quickſilver is as it were amalgamated with the honey, or brought to a ſtate ſimilar to that in Plenck's ſolution. The ſame effect will take place when the pills are prepared with extract of liquorice now directed by the London college.

The mercurial pill is one of the beſt preparations of mercury, and may in general ſuperſede moſt other forms of this medicine. It is neceſſary to form the maſs immediately into pills, as the crumb ſoon becomes too hard for that purpoſe. Soap was undoubtedly a very improper medium for triturating the mercury; it is not only too hard for that purpoſe, but when the preparation entered the ſtomach, the alkaline part of the ſoap being engaged by the acid in that viſcus, the mercury would in all probability be immediately ſeparated. The honey and bread can only be changed by the natural powers of digeſtion, and can never oppreſs the ſtomach. The doſe of the pills is from two to four or ſix in the day, according to the effects we wiſh to produce.

Jalap pills. E.

Take of extract of jalap, two ounces; aromatic powder, half an ounce. Beat them into a maſs with ſimple ſyrup. 577

This is an uſeful and active purgative, either for evacuating the contents of the inteſtinal canal, or producing a diſcharge from the ſyſtem in general.

Preparations and Compositions.

One of the ſame kind, with powdered jalap in ſubſtance inſtead of the extract, is uſed in ſome of our hoſpitals, as a cheap and effectual purge.

Plummer's pill. E.

578 Take of ſweet mercury, precipitated ſulphur of antimony, each ſix drams; extract of gentian, white Spaniſh ſoap, each two drams. Let the mercury be triturated with the ſulphur till they be thoroughly mixed, then add the extract, and form a maſs with ſimple ſyrup.

Theſe pills were recommended to the attention of the public about forty years ago by Dr Plummer, whoſe name they ſtill bear. He repreſented them in a paper which he publiſhed in the Edinburgh Medical Eſſays, as a very uſeful alterative; and on his authority they were at one time much employed; but they are now leſs extenſively uſed than formerly. And although they ſtill retain a place in the Edinburgh pharmacopœia, yet it is probable that every purpoſe to be anſwered by them may be more effectually obtained from the common mercurial pill, or from calomel in a more ſimple ſtate.

Opium pills. L.

579 Take of hard purified opium, powdered, two drams; extract of liquorice, one ounce. Beat them until they are perfectly united.

Thelaic, commonly called *Pacific pills.* E.

Take of opium, half an ounce; extract of liquorice, two ounces; Caſtile ſoap, an ounce and a half; Jamaica pepper, one ounce. Soften the opium and extract ſeparately with proof-ſpirit, and having beat them into a pulp, mix them; then add the ſoap, and the pepper beat into a powder; and laſtly, having beat them well together, form the whole into a maſs.

Theſe two compoſitions, though differing in ſeveral particulars, may yet be conſidered as fundamentally very much the ſame. The firſt is a ſimple opiate, in which every five grains of the maſs contains one of opium; and in the opium alone can we ſuppoſe that the activity of the medicine depends.

Although ſome of the articles contained in the latter compoſition may perhaps be ſuppoſed to operate as corrigentia, yet the former compoſition, which is the moſt ſimple, is in general preferable.

Pills ſimilar to the ſecond were contrived by a chemical empiric, Starkey, and communicated by him to Matthews, under whoſe name they were ſome time ago greatly celebrated. The form here given differs conſiderably from the original, in omitting many ingredients of no great ſervice. Nor indeed are any of the ingredients of much conſequence, except the opium; their quantity being too inconſiderable to anſwer any uſeful purpoſe. Ten grains of the compoſition contain one of opium.

Squill-pills.

580 Take of freſh dried ſquills, powdered, one dram; ginger powdered, ſoap, of each three drams; ammoniacum, two drams; ſyrup of ginger, as much as is ſufficient. Beat them together. *E.*

Take of gum ammoniac, leſſer cardamom ſeeds, in powder, extract of liquorice, each one dram; dried root of ſquills, in fine powder, one ſcruple. Mix, and form them into a maſs with ſimple ſyrup. *E.* Preparations and Compoſitions.

Theſe are elegant and commodious forms for the exhibition of ſquills, whether for promoting expectoration, or with the other intentions to which that medicine is applied. As the virtue of the compound is chiefly from the ſquills, the other ingredients are often varied in extemporaneous preſcription: and probably no material difference takes place in the two forms here propoſed (excepting in the proportion of the ſquills, which in the former conſtitutes one ninth, in the latter one tenth, of the maſs.

Stomachic pills. E.

Take of rhubarb, one ounce; ſocotorine aloes, ſix drams; myrrh, half an ounce; vitriolated tartar, one dram; eſſential oil of mint, half a dram; ſyrup of orange peel, a ſufficient quantity. Make them into a maſs. 581

This pill is intended for moderately warming and ſtrengthening the ſtomach, and evacuating crude viſcid humours. A ſcruple of the maſs may be taken twice a-day.

Bacher's pill. Gen.

Take of extract of black hellebore, purified myrrh, each one ounce; powder of carduus benedictus, two ſcruples. Mix them into a maſs according to art, to be dried in the air till it be fit for the formation of pills, each weighing one grain. 582

Theſe pills have been ſtrongly recommended as a moſt effectual remedy in dropſical caſes, and have been alleged to unite an evacuant and tonic power. Hence they have been conſidered as particularly ſuited to thoſe caſes where remarkable weakneſs and laxity occur. Under the hands of Mr Bacher the inventor, they acquired ſo great reputation, that, after a trial in the military hoſpitals at Paris, the receipt was purchaſed by the French king, and publiſhed by authority. But like many other noſtrums ſince this publication, Bacher's pill has by no means ſupported the reputation which it had when kept a ſecret. The doſe is varied according to circumſtances, from one to thirty pills taken in the courſe of the day.

Pills of elaterium. Suec.

Take of the pureſt gum ammoniac, two ounces; ſocotorine aloes, gamboge, each two drams; elaterium, half a dram. Mix them, by means of bitter tincture, into a maſs, and let pills be formed, each weighing two grains. 583

This, as well as the former, is alſo a pill celebrated for the cure of dropſical affections. And the elaterium, from which it derives its name, is one of the moſt powerful evacuants in the way of catharſis. Here, however, it is united with ſuch active articles, particularly the gamboge, as muſt make its effect ſomewhat doubtful. And we are inclined to think that a preferable formula for making the pills of elaterium, is to form it into a maſs, with the extract of gentian. This is imagined to have ſome influence as correcting its effect,

in

in exciting ſickneſs. And when each pill is made to contain half a grain of the elaterium, the doſe may be eaſily accommodated to the circumſtances of the patient, one or two pills being taken every hour till they begin to operate.

The elaterium, whether under the form above-mentioned, or in the more ſimple ſtate which has now been ſuggeſted, operates as a very powerful cathartic, often inducing the diſcharge of ſtagnant ſerum, when other remedies are found ineffectual. But it can be exhibited only in thoſe caſes where the patient ſtill retains a conſiderable degree of ſtrength.

Fetid pills. Suec.

584 Take of aſafœtida, caſtor, each a dram and a half; ſalt of amber, half a dram; oil of hartſhorn, half a ſcruple. Make them into a maſs, with tincture of myrrh, to be divided into pills of two grains each.

Theſe, like the gum-pills formerly mentioned, are chiefly uſed as an antihyſteric and antiſpaſmodic medicine; and they are particularly uſeful in counteracting ſpaſmodic affections of the alimentary canal, eſpecially thoſe connected with flatulence. But the aſafœtida is no leſs ſucceſsful when exhibited in a more ſimple ſtate, particularly when formed into pills with an equal quantity of ſoap, by the aid of ſimple ſyrup.

Gamboge pills. Dan.

585 Take of ſocotorine aloes, extract of black hellebore, ſweet mercury, gamboge, each two drams; diſtilled oil of juniper, half a dram; ſyrup of buckthorn, as much as is ſufficient for forming a maſs of pills.

From the ingredients of which theſe pills are conſtituted, we need hardly remark, that they muſt prove a very powerful purgative. The gamboge, from which they derive their name is unqueſtionably a very active purge. But it is not more ſo than the ſweet mercury; and perhaps from an union of theſe two, as much might be expected as from the more compounded formula here adopted. Yet it is not improbable that the eſſential oil of juniper may in ſome degree operate as a corrigent.

Pills of corroſive ſublimate mercury. Suec.

586 Take of corroſive ſublimate, purified ſal ammoniac, each one ſcruple; diſtilled water, as much as is ſufficient to diſſolve them; powder of the root of althea, ſixteen ſcruples; honey, two drams. Mix them into a maſs for the formation of pills, each weighing three grains.

Corroſive ſublimate in ſubſtance was long conſidered as being ſo violent in its effects, that it could not with ſafety be taken internally; but for a conſiderable time it has been uſed with advantage under the form of ſolution, either in water or ſpirits. But to both theſe a conſiderable objection occurs from their diſagreeable braſſy taſte. This objection is however entirely obviated, by reducing the ſolution, after it is formed, to a ſolid maſs, by means of crumb of bread, or any proper powder: and by the aid of a little ſal ammoniac, the ſolution may be made in a very ſmall quantity of water; ſo that leſs of any ſolid intermedium will be ſufficient to bring it to the form of pills. The formula here directed ſeems well ſuited for the purpoſe intended. Each of the pills contains about an eighth of a grain of the corroſive; thus the doſe may be eaſily regulated according to the intention in view. And theſe pills are not unfrequently employed with advantage, both in combating venereal and cutaneous affections, and for the expulſion of worms from the alimentary canal. With the latter of theſe intentions, a ſimilar pill was particularly recommended by Dr Gardner, in a paper publiſhed in the Edinburgh Phyſical and Literary Eſſays: and although not received into our pharmacopœia, it has been frequently uſed at Edinburgh.

Tar pills. Dan.

587 Take any quantity of tar, and mix with it as much powdered elecampane root as will reduce it to a proper thickneſs for being formed into pills.

The powder here mixed with the tar, though of no great virtue, is nevertheleſs a very uſeful addition, not only for procuring it a due conſiſtence, but likewiſe as it divides the reſinous texture of the tar, and thus contributes to promote its ſolution by the animal juices. In the Edinburgh infirmary, half a dram of the maſs, made into middle-ſized pills, is given every morning and evening in diſorders of the breaſt, ſcurvies, &c.

Soap-pills. Suec.

588 Take of hard white ſoap, two ounces; extract of birch, one ounce. Let them be formed into a maſs, to be divided into pills, each containing three grains.

Although many virtues have been attributed to the birch, yet we are inclined to think, that it here ſerves little other purpoſe than to give the form of pills to the ſoap. And this article, even when taken in ſmall quantity with ſome conſtitutions, operates as a gentle laxative. But beſides this, it has alſo been ſuppoſed to be highly uſeful both in caſes of jaundice and of calculus. There can, however, be little doubt, that the theories on which it has been inferred that it may be uſeful in ſuch complaints are not well founded; and we may perhaps add, that the uſe of it, even to a great extent, is by no means attended with thoſe conſequences which were once alleged to ariſe from it.

Storax pills. Suec.

589 Take of ſtrained ſtorax, five ſcruples; extract of liquorice, three drams; opium, one dram. Let the opium, diſſolved in wine, be added to the other ingredients, ſo as to form a maſs of proper conſiſtence, to be made into pills, each weighing three grains.

Theſe pills are principally active in conſequence of the opium which they contain. And they are chiefly meant with a view to a ſlow ſolution in the ſtomach, and conſequently producing more gradual and laſting effects. One grain of opium is contained in ſeventeen grains of the maſs.

CHAP. XXVIII. *Electuaries.*

590 ELECTUARIES are compoſed chiefly of powders mixed up with ſyrups, &c. into ſuch a conſiſtence that

Preparations and Compositions.

the powders may not ſeparate in keeping, that a doſe may be eaſily taken upon the point of a knife, and not prove too ſtiff to ſwallow.

Electuaries receive chiefly the milder alterative medicines, and ſuch as are not ungrateful to the palate. The more powerful drugs, as cathartics, emetics, opiates, and the like (except in officinal electuaries to be diſpenſed by weight), are ſeldom truſted in this form, on account of the uncertainty of the doſe; diſguſtful ones, acrids, bitters, fetids, cannot be conveniently taken in it; nor is the form of an electuary well fitted for the more ponderous ſubſtances, as mercurials, theſe being apt to ſubſide in keeping, unleſs the compoſition be made very ſtiff.

The lighter powders require thrice their weight of honey, or ſyrup boiled to the thickneſs of honey, to make them into the conſiſtence of an electuary; of ſyrups of the common conſiſtence, twice the weight of the powder is ſufficient.

Where the common ſyrups are employed, it is neceſſary to add likewiſe a little conſerve, to prevent the compound from drying too ſoon; electuaries of Peruvian bark, for inſtance, made up with ſyrup alone, will often in a day or two grow too dry for taking.

Some powders, eſpecially thoſe of the leſs grateful kind, are more conveniently made up with mucilage than with ſyrup, honey, or conſerve. The three latter ſtick about the mouth and fauces, and thus occaſion the taſte of the medicine to remain for a conſiderable time; while mucilages paſs freely, without leaving any taſte in the mouth. A little ſoft extract of liquorice, joined to the mucilage, renders the compoſition ſufficiently grateful, without the inconveniences of the more adheſive ſweets.

The quantity of an electuary, directed at a time, in extemporaneous preſcription, varies much according to its conſtituent parts, but it is rarely leſs than the ſize of a nutmeg, or more than two or three ounces.

General rules for making electuaries.

I. The rules already laid down for decoctions and powders in general, are likewiſe to be obſerved in making decoctions and powders for electuaries.

II. Gums, inſpiſſated juices, and ſuch other ſubſtances as are not pulverizable, ſhould be diſſolved in the liquor preſcribed: then add the powders by little and little, and keep the whole briſkly ſtirring, ſo as to make an equable and uniform mixture.

III. Aſtringent electuaries, and ſuch as have pulps of fruit in their compoſition, ſhould be prepared only in ſmall quantities at a time: for aſtringent medicines loſe much of their virtue on being kept in this form, and the pulps of fruits are apt to become ſour.

IV. The ſuperfluous moiſture of the pulps ſhould be exhaled over a gentle fire, before the other ingredients are added to them.

V. Electuaries, if they grow dry in keeping, are to be reduced to a due conſiſtence, with the addition of a little Canary wine, and not with ſyrup or honey: by this means the doſe will be the leaſt uncertain; a circumſtance deſerving particular regard, in thoſe eſpecially which are made up with ſyrup, and contain a proportion of opium.

Preparations and Compositions.

Electuary of caſſia. L.

Take of the freſh extracted pulp of caſſia, half a pound; manna, two ounces; pulp of tamarinds, one ounce; roſe-ſyrup, half a pound. Beat the manna, and diſſolve it over a ſlow fire in the roſe-ſyrup; then add the pulps; and with a continued heat evaporate the whole to the proper thickneſs of an electuary. 591

Electuary of caſſia, commonly called *diacaſſia.* E.

Take of pulp of caſſia fiſtularis, ſix ounces; pulp of tamarinds, manna, each an ounce and a half; ſyrup of pale roſes, ſix ounces. Having beat the manna in a mortar, diſſolve it with a gentle heat in the ſyrup; then add the pulps, and evaporate them with a regularly continued heat to the conſiſtence of an electuary.

Theſe compoſitions are very convenient officinals, to ſerve as a baſis for purgative electuaries and other ſimilar purpoſes; as the pulping a ſmall quantity of the fruits, for extemporaneous preſcription, is very troubleſome. The tamarinds give them a pleaſant taſte, and do not ſubject them, as might be expected, to turn ſour. After ſtanding for four months, the compoſition has been found no ſourer than when firſt made. This electuary likewiſe is uſefully taken by itſelf, to the quantity of two or three drams occaſionally, for gently looſening the belly in coſtive habits.

Electuary of ſcammony. L.

Take of ſcammony, in powder, one ounce and an half; cloves, ginger, of each ſix drams; eſſential oil of caraway, half a dram; ſyrup of roſes, as much as is ſufficient. Mix the ſpices, powdered together, with the ſyrup; then add the ſcammony, and laſtly the oil of caraway. 592

This electuary is a warm briſk purgative. It is a reform of the *electuarium caryocoſtinum* of our preceding diſpenſatories; a compoſition which was greatly complained of, as being inconvenient to take on account of the largeneſs of its doſe. A dram and a half of this, which contains fifteen grains of ſcammony, is equivalent to half an ounce of the other.

Electuary of ſenna. L.

Take of ſenna, eight ounces; figs, one pound; pulp of tamarinds, of caſſia, of prunes, each half a pound; coriander ſeeds, four ounces; liquorice, three ounces; double-refined ſugar, two pounds and an half. Powder the ſenna with the coriander ſeeds, and ſift out ten ounces of the mixed powder. Boil the remainder with the figs and liquorice, in four pints of diſtilled water, to one half; then preſs out and ſtrain the liquor. Evaporate this ſtrained liquor to the weight of about a pound and an half; then add the ſugar, and make a ſyrup; add this ſyrup by degrees to the pulps, and laſtly mix in the powder. 593

Lenitive electuary. E.

Take of pulp of French prunes, one pound; pulp of caſſia, pulp of tamarinds, each two ounces and a half; black ſyrup of ſugar, commonly called *molaſſes*, one pound and a half; ſenna leaves, in fine powder, four

Preparations and Compositions.

four ounces; coriander ſeeds, in fine powder, half an ounce. Having boiled the pulps with the ſyrup to the conſiſtence of honey, add the powders, and beat the whole into an electuary.

This electuary, the name of which is with propriety changed by the London college, is now freed from ſome ſuperfluous ingredients which were left in it at former reviſals, *viz.* polypody root, French mercury leaves, fenugreek ſeeds, and linſeed. Molaſſes is preferable to either honey or ſugar, as it coincides with the intention, and is not only of itſelf inapt to ferment, but likewiſe prevents ſuch ſubſtances as are this way diſpoſed from running into fermentation.

It is a very convenient laxative, and has long been in common uſe among practitioners. Taken to the quantity of a nutmeg or more, as occaſion may require, it is an excellent laxative for looſening the belly in coſtive habits.

Japonic electuary, commonly called *Japonic confection*. E.

594 Take of Japan earth, four ounces; gum-kino, three ounces; cinnamon, nutmeg, each one ounce; opium diffuſed in a ſufficient quantity of Spaniſh white wine, one dram and a half; ſyrup of dried roſes, boiled to the conſiſtence of honey, two pounds and a quarter. Mix and form them into an electuary.

The ingredients in this electuary ſeem extremely well choſen, and are ſo proportioned to one another, that the quantity of opium is the ſame as in the diaſcordium of the former pharmacopœias of Edinburgh, *viz.* one grain in ten ſcruples. The gum-kino, now ſubſtituted for the tormentil root, is an excellent improvement in the formula.

Tin electuary. Brun.

595 Take of pure tin, quickſilver, each one ounce. Let them be formed into an amalgam; oyſter-ſhells, prepared, one ounce. Reduce the whole to a powder. Take of this powder, conſerve of wormwood, each one ounce, and form an electuary with ſyrup of mint.

Tin, as we have already had occaſion to obſerve above (n° 312.), has long been celebrated for the expulſion of tænia; and it is alſo well known, that in mercury we have one of the moſt powerful anthelmintics. Such a combination as the preſent, then, might be ſuppoſed well ſuited for the removal of that animal from the alimentary canal; and accordingly it has been alleged, that this electuary has ſometimes ſucceeded after other remedies have failed. It may be taken twice a-day, to the extent of two or three drams for a doſe.

Electuary for the gums. Suec.

596 Take of powdered myrrh, three drams; cream of tartar, cochineal, each a dram and a half. Grind them together in a glaſs mortar; then add melted honey, four ounces; cloves, in powder, one dram.

Myrrh, particularly under the form of tincture, has long been a favourite application to the gums, when in a ſpongy or ulcerated ſtate. But the ſpirituous menſtruum there employed, although ſometimes favouring the intention in view, in other inſtances occurs as an objection to its uſe. In theſe caſes, the benefit to be derived from the myrrh may be obtained from this electuary, which may always be applied with ſafety, and ſometimes with advantage.

Preparations and Compositions.

Electuary of manna. Suec.

Take of manna, refined ſugar pounded, fennel-water, each two ounces. Strain the mixture, uſing expreſſion; then add fine powder of the root of florentine orris, one dram; freſh drawn almond oil, one ounce. 597

In this electuary we have a gently emollient laxative, which is very uſeful in thoſe caſes where obſtipation either ariſes from indurated feces, or is ſupported by that cauſe. But its cathartic powers are by no means conſiderable.

Nitrous electuary. Gen.

Take of purified nitre, half an ounce; conſerve of roſes, four ounces. Mix them. 598

Under this formula nitre may be introduced to a conſiderable extent, without giving uneaſineſs at ſtomach, while at the ſame time its refrigerant power is combined with the aſtringency of the roſes. From theſe circumſtances it may be advantageouſly employed in different caſes, but particularly in inſtances of hæmoptyſis.

Terebinthinate electuary. Suec.

Take of ſpirit of turpentine, half an ounce; honey, one ounce; powder of liquorice, as much as is ſufficient for the formation of an electuary. 599

Under this form, the oil of turpentine may be introduced with leſs uneaſineſs than perhaps under almoſt any other. And it may thus be employed for different purpoſes, but particularly with a view to its diuretic power. But it has been eſpecially celebrated for the cure of obſtinate rheumatiſms, and above all, for that modification of rheumatiſm which has the name of *iſchias*, and which is found in many inſtances obſtinately to reſiſt other modes of cure.

Lenient linctus. Suec.

Take of gum-arabic, bruiſed, two drams; cherry-water, half an ounce. By trituration in a mortar, mix with them almond oil, freſh drawn, ſyrup of almonds, each ſeven ounces. 600

In this we have a very agreeable emollient linctus, highly uſeful in recent catarrhal affections, for lubricating the throat and fauces. It may be taken at pleaſure to any extent that the ſtomach may eaſily bear.

Chap. XXIX. *Confections.*

Although the London college have ſeparated theſe from electuaries, yet they differ ſo little, that in moſt pharmacopœias they are ranked under the ſame head. And in that of Edinburgh, there are ſeveral articles which have promiſcuouſly the name either of *confection* or *electuary*. But as no inconvenience ariſes from the ſeparation, and as we have followed the order of the London pharmacopœia in other particulars, it would be improper to deviate from it in this. 601

Preparations and Compositions.

Aromatic confection. L.

602 Take of zedoary, in coarſe powder, ſaffron, of each half a pound; diſtilled water, three pints. Macerate for twenty-four hours; then preſs and ſtrain. Reduce the ſtrained liquor, by evaporation, to a pint and a half, to which add the following, rubbed to a very fine powder; compound-powder of crabs-claws, ſixteen ounces; cinnamon, nutmegs, of each two ounces; cloves, one ounce; ſmaller cardamom-ſeeds, huſked, half an ounce; double-refined ſugar, two pounds. Make a confection.

This confection is compoſed of the more unexceptionable ingredients of a compoſition formerly held in great eſteem, and which was called, from its author, *confectio Raleighana*. The original confection was compoſed of no leſs than five and twenty particulars; each of which were examined apart, except one, moor-graſs, the flower of which is too ſmall to be gathered in ſufficient quantity for the general uſe of the medicine, and the plant is poſſeſſed of hurtful qualities, as is experienced in cattle that feed where it grows. In this examination, many of the extracts came out ſo very naufeous, that it was impoſſible to retain them, conſiſtent with any regard to the taſte of the compoſition. But ſome few, of equal efficacy with any of the reſt, being of a tolerable taſte and flavour, were compounded in different proportions; and when, after many trials, a compoſition was approved, the quantity of each material, that would yield the proportion of extract which entered that compoſition, was calculated, and from thence the proportions were collected as now ſet down: after which the compound extract was made, and found to anſwer expectation. The London college, in the preſent edition of their pharmacopœia, have ſtill farther ſimplified this formula, by rejecting the roſemary, juniper, and cardamoms, which formerly entered it.

The confection, as now reformed, is a ſufficiently grateful and moderately warm cordial; and frequently given with that intention, from eight or ten grains to a ſcruple or upwards, in boluſes or draughts. The formula might perhaps be ſtill more ſimplified without any loſs. The crabs-claw powder does not appear to be very neceſſary, and is inſerted rather in compliance with the original formula, than from its contributing any thing to the intention of the medicine; and the following formula of the Edinburgh pharmacopœia ſeems to us preferable to that of the London, even in its preſent improved ſtate.

Cordial electuary, commonly called *cordial confection.* E.

603 Take of conſerve of orange-peel, three ounces; preſerved nutmegs, an ounce and a half; preſerved ginger, ſix drams; cinnamon, in fine powder, half an ounce; ſyrup of orange peel, as much as will form the whole into an electuary.

In the above ſimple and elegant formula, a number of trifling ingredients are rejected, and thoſe ſubſtituted in their place are medicines of approved efficacy. We therefore conſider this preparation as an uſeful remedy for the purpoſes expreſſed in its title.

Confection of opium. L.

604 Take of hard purified opium, powdered, ſix drams; long pepper, ginger, caraway-ſeeds, of each two ounces; ſyrup of white poppy, boiled to the conſiſtence of honey, three times the weight of the whole. Mix the purified opium carefully with ſyrup gently heated; then add the reſt, rubbed to powder.

Preparations and Compoſitions.

Thebaic electuary. E.

Take of aromatic powder, ſix ounces; Virginian ſnake-root, in fine powder, three ounces; opium diffuſed in a ſufficient quantity of Spaniſh white wine, three drams; clarified honey, thrice the weight of the powders. Mix them, and form an electuary.

Theſe compoſitions conſiſt of very powerful ingredients, and are doubtleſs capable of anſwering every end that can be reaſonably expected from the more voluminous *Theriaca* of Andromachus. The London college alſo had formerly their *Theriaca* compoſed of the leſs exceptionable ingredients of Andromachus's. But as theſe medicines have for a long time been chiefly employed for external purpoſes, by the way of cataplaſm, the London theriaca is now omitted, and its place ſupplied by a cataplaſm compoſed of a few well-choſen articles, under the name of *cataplaſm of cummin*; of which hereafter. For internal uſe, none of the theriacas are at preſent ſo much regarded as they have been heretofore; practitioners having introduced in their room extemporaneous boluſes of Virginian ſnake-root, camphor, contrayerva, and the like; which anſwer all their intentions, with this advantage, that they may be given either with or without opium; an ingredient which renders the others prejudicial in caſes where they might otherwiſe be proper.

With regard to the quantity of opium in the foregoing compoſitions, one grain thereof is contained in thirty-ſix grains of the confection of opium, and in five ſcruples of the thebaic electuary. The proportion of opium will vary a little, according to the time that they have been kept; their moiſture by degrees exhaling, ſo as to leave the remainder ſtronger of the opium than an equal weight was at firſt. A change of this kind is taken notice of by many writers, but falſely attributed to an imaginary fermentative quality of the ingredients; by which they were ſuppoſed, from their multiplicity and contrariety, to be continually exalting and improving the virtues of each other.

A good deal of care is requiſite in making theſe compoſitions, to prevent the waſte which is apt to happen in the pounding, and which would render the proportion of opium to the other ingredients precarious. The intention of diſſolving the opium in wine, for theſe and other electuaries, is, that it may be more uniformly mixed with the reſt.

Theſe compoſitions fully ſupply the place of two articles, which, though long baniſhed from the ſhops, we ſhall here ſubjoin, as examples of the amazing height to which compoſition in medicine had at one time proceeded.

Mithridate, or the *confection of Democrates.*

605 Take of cinnamon, fourteen drams; myrrh, eleven drams; agaric, Indian nard, ginger, ſaffron, ſeeds of mithridate muſtard, frankincenſe, chio turpentine, each ten drams; camels hay, cnſtus, or in its ſtead zedoary, Indian leaf, or in its ſtead mace, ſtechas long

long pepper, hartwort ſeeds, hypociſtis, ſtorax ſtrained, opoponax, galbanum ſtrained, opobalſam, or in its ſtead expreſſed oil of nutmegs, Ruſſian caſtor, each one ounce; Poley mountain, ſcordium, carpobalſam, or in its ſtead cubebs, white pepper, candy-carrot ſeed, bdellium ſtrained, each ſeven drams; Celtic nard, gentian root, dittany of Crete, red roſes, Macedonian parſley ſeed, leſſer cardamom ſeeds huſked, ſweet fennel ſeed, gum arabic, opium ſtrained, each five drams; calamus aromaticus, wild valerian root, aniſeed, ſagapenum ſtrained, each three drams; meum athamanticum, St John's wort, acacia, or in its ſtead terra Japonica, bellies of ſkinks, each two drams and a half; clariſied honey, thrice the weight of all the other ingredients. Warm the honey, and mix with it the opium diſſolved in wine; melt the ſtorax, galbanum, turpentine, and opobalſam (or expreſſed oil of nutmegs), together in another veſſel, continually ſtirring them about, to prevent their burning; with theſe ſo melted, mix the hot honey, at firſt by ſpoonfuls, and afterwards in larger quantities at a time; when the whole is grown almoſt cold, add by degrees the other ſpices reduced into powder.

Theriaca of Andromachus, or *Venice treacle.*

Take of troches of ſquills, half a pound; long pepper, opium ſtrained, vipers dried, each three ounces; cinnamon, opobalſam, or in its ſtead expreſſed oil of nutmegs, each two ounces; agaric, Florence orris root, ſcordium, red roſes, navew ſeeds, extract of liquorice, each an ounce and a half; Indian nard, ſaffron, amomum, myrrh, coſtus, or in its ſtead zedoary, camel's hay, each one ounce; cinquefoil root, rhubarb, ginger, Indian leaf, or in its ſtead mace, dittany of Crete, horehound leaves, calamint leaves, ſtechas, black pepper, Macedonian parſley ſeed, olibanum, chio turpentine, wild valerian root, each ſix drams; gentian root, Celtic nard, ſpignel, leaves of Poley mountain, of St John's wort, and of groundpine, germander tops with the ſeed, carpobalſam, or in its ſtead cubebs, aniſeed, ſweet fennel ſeed, leſſer cardamom ſeeds, huſked, ſeeds of biſhop's weed, of hartwort, and of treacle muſtard, hypociſtis, acacia, or in its ſtead Japan earth, gum arabic, ſtorax ſtrained, ſagapenum ſtrained, terra Lemnia, or in its ſtead bole armenic, or French bole, green vitriol calcined, each half an ounce; ſmall (or in its ſtead the long) birthwort root, leſſer centaury tops, candy-carrot ſeed, opopanax, galbanum, ſtrained, Ruſſia caſtor, Jews pitch, or in its ſtead white amber prepared, calamus aromaticus, each two drams; clariſied honey, thrice the weight of all the other ingredients. Let theſe ingredients be mixed together, after the ſame manner as directed in making the mithridate.

Theſe celebrated electuaries are often mentioned by medical writers, and may ſerve as examples of the wild exuberance of compoſition which the ſuperſtition of former ages brought into vogue. The theriaca is a re formation of mithridate made by Andromachus phyſician to Nero. The mithridate itſelf is ſaid to have been found in the cabinet of Mithridates king of Pontus. The firſt publiſhers of this pompous arcanum were very extravagant in their commendations of its virtues; the principal of which was made to conſiſt in its being a moſt powerful preſervative againſt all kinds of venom; whoever took a proper quantity in a morning was inſured from being poiſoned during that whole day. This was confirmed by the example of its ſuppoſed inventor, who, as Celſus informs us, was by its conſtant uſe ſo fortified againſt the commonly reputed poiſons, that none of them would have any effect upon him when he wanted their aſſiſtance. But the notions of poiſons which prevailed in thoſe ruder ages were manifeſtly erroneous. Before experience had furniſhed mankind with a competent knowledge of the powers of ſimples, they were under perpetual alarms from an apprehenſion of poiſons, and buſied themſelves in contriving compoſitions which ſhould counteract their effects, accumulating together all thoſe ſubſtances which they imagined to be poſſeſſed of any degree of alexipharmac power. Hence proceed the voluminous antidotes which we meet with in the writings of the ancient phyſicians; yet it does not appear that they were acquainted with any real poiſon except the cicuta, aconitum, and bites of venomous animals; and for theſe they knew of no antidote whatever. Even admitting the reality of the poiſons, and the efficacy of the ſeveral antidotes ſeparately, the compoſitions could no more anſwer the purpoſes expected from them, than the accumulating of all the medicinal ſimples into one form could make a remedy againſt all diſeaſes.

Yet notwithſtanding the abſurdity in the original intention of theſe medicines, and their enormity in point of compoſition, as they contain ſeveral powerful materials, whoſe virtues, though greatly prejudiced, yet are not deſtroyed, by their multiplicity and contrariety; the compounds have been found, from repeated experience, to produce very conſiderable effects as warm opiate diaphoretics.

Theſe compoſitions might without doubt be lopt of numerous ſuperfluities without any diminution of their virtues; yet as the effects of them, in their preſent form, are ſo well known, ſo much regard has been paid to ancient authority as not to attempt a reformation of that kind. Although theſe forms were originally complex, yet ſubſequent additions had crept into them. Neither the deſcription in verſe of the elder Andromachus, nor the proſe explanation of the younger, make any mention of the white pepper afterwards added to the theriaca; and the orris root, in the mithridate of our former pharmacopœias, is alſo a ſupernumerary ingredient, not warranted by the original: theſe therefore are rejected. Nor is the aſarum in the mithridate grounded on any good authority: the verſe it is taken from is mutilated and corrupt; and the word which ſome, on conjecture only, ſuppoſe to have been aſarum, others, alſo on conjecture, chooſe to read differently. Till ſome emendation ſhall be better founded than merely on critical gueſſes, this ſingle ſpecies may be ſafely paſſed over without any prejudice to the medicine. None of the ancient deſcriptions afford any other light in this particular; for they either omit this ingredient, and others alſo, or abound with additions.

Another innovation on both theſe medicines alſo took place. In each of theſe compoſitions were found both cinnamon and caſſia lignea; and it is very evident, from

Preparations and Compositions.

from several parts of Galen's works, that the latter was used by the ancients only on account of the great difficulty of procuring the other; so that to retain the cassia, now that cinnamon is so common, is a blind following of these writers, without any attention to their meaning: the cassia therefore is now rejected, and half the quantity of cinnamom put in its room; which is the proportion that Galen directs to be observed in substituting the one for the other. It is probable that the case is the same with regard to the Celtic and the Indian nard; that the first had a place in these compositions on account of the difficulty of procuring the Indian, for Galen expressly prefers the latter.

There is a material error in regard to the theriaca, which has passed through several editions of our pharmacopœia: this is the substituting the Roman vitriol for the ancient chalcitis, now not certainly known; and, in the catalogue of simples, describing the Roman to be a blue vitriol, whereas the Italian writers are unanimous it is a green vitriol; and were it not, it would not answer to the effects of the chalcitis, which was certainly a chalybeate, and gives the medicine its black colour. What has chiefly occasioned chalcitis to be supposed a cupreous vitriol seems to be its name, derived from χαλκος, *copper*: but it is to be observed that all vitriols were formerly imagined to proceed from copper, and were named accordingly: the green or martial vitriols are still called by the Germans *kupffer-wasser*, and by us *copperas*. It is probable that the ancient chalcitis was no other than a native martial vitriol, calcined by the heat of those warm climates to a degree of yellowish red or coppery colour; and therefore the common green vitriol, thus calcined by art, very properly supplies its place.

The preparation of these medicines has been somewhat facilitated by omitting the *trochisci cypheos* used in the mithridate, and the *hedychroi* and *viperini* for the theriaca; and inserting their ingredients, after Zwelffer's manner, in the compositions they are intended for. This is done in the theriaca very commodiously; the ingredients in these troches uniting with those in the theriaca itself into unbroken numbers. But to render the numbers equally simple in the mithridate, it was necessary to retrench a few odd grains from some of the articles, and make a small addition to some others. The proportions of the ingredients in the *trochisci cypheos* are adjusted from the original description in Galen, the numbers in our former pharmacopœia being very erroneous.

Both the London and Edinburgh colleges ventured at length to discard these venerable relics. The Edinburgh college at first substituted in their room an elegant and simple form, equivalent to them both in efficacy, under the title of *theriaca Edinensis*, Edinburgh theriaca. In later editions, however, they have entirely banished the name of theriaca from their book, and have put in its place the more elegant composition already mentioned, the *thebaic electuary*.

Chap. XXX. *Medicated Waters.*

606 We have already taken notice of many articles which are either dissolved in water, or communicate their virtues to it; and in one sense of the word these may be called *medicated waters*. Sometimes this impregnation is effected by the aid of heat, sometimes without it; and thus are formed decoctions, infusions, and the like. But among those articles referred to in this chapter, there takes place mere watery solution only, and they are used solely with the intention of acting topically in the way of lotion, injection, or at the utmost of gargarism.

Preparations and Compositions.

Compound alum-water. L.

607 Take of alum, vitriolated zinc, each half an ounce; boiling distilled water, two pints. Pour the water on the salts in a glass vessel, and strain.

This water was long known in our shops under the title of *aqua aluminosa Bateana*.

Bates directed the salts to be first powdered and melted over the fire: but this is needless trouble, since the melting only evaporates the aqueous parts, which are restored again on the addition of the water. This liquor is used for cleansing and healing ulcers and wounds; and for removing cutaneous eruptions, the part being bathed with it hot three or four times a-day. It is sometimes likewise employed as a collyrium; and as an injection in the gonorrhœa and fluor albus, when not accompanied with virulence.

Styptic water. E.

608 Take of blue vitriol, alum, each three ounces; water, two pounds. Boil them until the salts be dissolved; then filter the liquor, and add an ounce and an half of vitriolic acid.

This water, though made with the blue in place of the white vitriol, cannot be considered as differing very much from the former. It is formed on the styptic recommended by Sydenham for stopping bleeding at the nose, and other external hemorrhagies; for this purpose cloths or dossils are to be dipt in the liquor, and applied to the part.

Water of ammoniated copper. L.

609 Take of lime-water, one pint; sal ammoniac, one dram. Let them stand together, in a copper vessel, till the ammonia be saturated.

Sapphire-coloured water. E.

Take of lime-water, newly made, eight ounces; sal ammoniac, two scruples; verdegris, powdered, four grains. Mix them, and after 24 hours strain the liquor.

This is a much more elegant and convenient method than the preceding.

This water is at present pretty much in use as a detergent of foul and obstinate ulcers, and for taking away specks or films in the eyes. The copper contributes more to its colour than to its medicinal efficacy; for the quantity of the metal dissolved is extremely small.

Compound water of acetated litharge. L.

610 Take of acetated water of litharge, two drams; distilled water, two pints; proof-spirit, two drams. Mix the spirit with the acetated water of litharge; then add the distilled water.

This

This liquor is of the ſame nature with ſolutions of ſugar of lead, and is analogous to the vegeto-mineral water of Mr Goulard. It is only uſed externally as a coſmetic againſt cutaneous eruptions, redneſs, inflammation, &c. But even here it is alleged that it is not altogether void of danger, and that there are examples of its continued employment having occaſioned ſundry ill conſequences. But at the ſame time the very frequent uſe that is made of it with perfect impunity would lead us to conclude that in theſe obſervations there muſt be ſome miſtake.

Water of vitriolated zinc with camphor. L.

611 Take of vitriolated zinc, half an ounce; camphorated ſpirit, half an ounce; boiling water, two pints. Mix, and filter through paper.

This is an improved method of forming the vitriolic camphorated water of the former editions of the London pharmacopœia. It is uſed externally as a lotion for ſome ulcers, particularly thoſe in which it is neceſſary to reſtrain a great diſcharge. It is alſo not unfrequently employed as a collyrium in ſome caſes of ophthalmia, where a large diſcharge of watery fluid takes place from the eyes, with but little inflammation. But when it is to be applied to this tender organ, it ought, at firſt at leaſt, to be diluted by the addition of more water.

Vitriolic water. E.

612 Take of white vitriol, ſixteen grains; water, eight ounces; weak vitriolic acid, ſixteen drops. Diſſolve the vitriol in the water, and then adding the acid, ſtrain through paper.

Where the eyes are watery or inflamed, this ſolution of white vitriol is a very uſeful application. The ſlighter inflammations will frequently yield to this medicine without any other aſſiſtance; in the more violent ones, veneſection and cathartics are to be premiſed to its uſe.

Chap. XXXI. *Plaſters.*

613 Plasters are compoſed chiefly of oily and unctuous ſubſtances, united with powders into ſuch a conſiſtence that the compound may remain firm in the cold without ſticking to the fingers; that it may be ſoft and pliable in a low degree of heat, and that by the warmth of the human body it be ſo tenacious as readily to adhere both to the part on which it is applied and to the ſubſtance on which it is ſpread.

There is, however, a difference in the conſiſtence of plaſters, according to the purpoſes they are to be applied to: thus, ſuch as was intended for the breaſt and ſtomach ſhould be very ſoft and yielding, while thoſe deſigned for the limbs are made firmer and more adhefive. An ounce of expreſſed oil, an ounce of yellow wax, and half an ounce of any proper powder, will make a plaſter of the firſt conſiſtence: for a hard one, an ounce more of wax, and half an ounce more of powder, may be added. Plaſters may likewiſe be made of reſins, gummy reſins, &c. without wax, eſpecially in extemporaneous preſcription: for officinals theſe compoſitions are leſs proper, as they ſoon grow too ſoft in keeping, and fall flat in a warm air.

It has been ſuppoſed, that plaſters might be impregnated with the ſpecific virtues of different vegetables, by boiling the recent vegetable with the oil employed for the compoſition of the plaſter. The coction was continued till the herb was almoſt criſp, with care to prevent the matter from contracting a black colour: after which the liquid was ſtrained off, and ſet on the fire again, till all the aqueous moiſture had exhaled. We have already obſerved, that this treatment does not communicate to the oils any very valuable qualities, even relative to their uſe in a fluid ſtate: much leſs can plaſters, made with ſuch oils, receive any conſiderable efficacy from the herbs.

Calces of lead, boiled with oils, unite with them into a plaſter of an excellent conſiſtence, and which makes a proper baſis for ſeveral other plaſters.

In the boiling of theſe compoſitions, a quantity of water muſt be added, to prevent the plaſter from burning and growing black. Such water, as it may be neceſſary to add during the boiling, muſt be previouſly made hot; for cold liquor would not only prolong the proceſs, but likewiſe occaſion the matter to explode, and be thrown about with violence, to the great danger of the operator: this accident will equally happen on the addition of hot water, if the plaſter be extremely hot.

Ammoniacum plaſter with quickſilver. L.

614 Take of ſtrained ammoniacum, one pound; purified quickſilver, three ounces; ſulphurated oil, one dram, or what is ſufficient. Rub the quickſilver with the ſulphurated oil until the globules diſappear; then add, by little at a time, the melted ammoniacum, and mix them.

This is a very well contrived mercurial plaſter. The ammoniacum in general affords a good baſis for the application of the mercury. In ſome caſes, however, it is not ſufficiently adhefive. But this inconvenience, when it does occur, may be readily remedied by the addition of a ſmall quantity of turpentine.

Plaſter of Spaniſh flies. L.

615 Take of Spaniſh flies, one pound; wax plaſter, two pounds; prepared hog's lard, half a pound. Having melted the plaſter and lard, a little before they coagulate ſprinkle in the flies, reduced to a very fine powder.

Bliſtering plaſter, or epiſpaſtic plaſter. E.

Take of hog's lard, yellow wax, white reſin, cantharides, each equal weights. Beat the cantharides into a fine powder, and add them to the other ingredients, previouſly melted, and removed from the fire.

Both theſe formulæ are very well ſuited to anſwer the intention in view, that of exciting bliſters; for both are of a proper conſiſtence, and ſufficient degree of tenacity, which are here the only requiſites. Cantharides of good quality, duly applied to the ſkin, never fail of producing bliſters. When, therefore, the deſired effect does not take place, it is to be aſcribed to the flies either being faulty at firſt, or having their activity afterwards deſtroyed by ſome accidental circumſtance; ſuch as too great heat in forming, in ſpreading the plaſter, or the like. And when due attention is paid

Preparations and Compositions.

to these particulars, the simple compositions now introduced answer the purpose better than those compound plasters with mustard-seed, black pepper, vinegar, verdegris, and the like, which had formerly a place in our pharmacopœias. It is not however improbable, that the pain of blistering plasters might be considerably diminished by the addition of a portion of opium, without preventing the good effects otherwise to be derived from them.

Wax-plaster.

616 Take of yellow wax, prepared mutton-suet, each three pounds; yellow resin, one pound. Melt them together, and strain the mixture whilst it is fluid. *L.*

Take of yellow wax, three parts; mutton-suet, white resin, two parts. Melt them together into a plaster; which supplies the place of melilot plaster. *E.*

This plaster had formerly the title of *drawing plaster*, and was chiefly employed as a dressing after blisters, to support some discharge.

It is a very well contrived plaster for that purpose. It is calculated to supply the place of melilot plaster; whose great irritation, when employed for the dressing of blisters, has been continually complained of. This was owing to the large quantity of resin it contained, which is here on that account retrenched. It would seem that, when designed only for dressing blisters, the resin ought to be entirely omitted, unless where a continuance of the pain and irritation, excited by the vesicatory, is required. Indeed plasters of any kind are not very proper for this purpose: their consistence makes them sit uneasy, and their adhesiveness renders the taking them off painful. Cerates, which are softer and less adhesive, appear much more eligible: the cerate of spermaceti will serve for general use; and for some particular purposes, the cerate of yellow resin may be applied.

Cummin-plaster. L.

617 Take of the seeds of cummin, seeds of caraway, bayberries, each three ounces; Burgundy-pitch, three pounds; yellow wax, three ounces. Mix, with the melted pitch and wax, the rest of the ingredients, powdered, and make a plaster.

This plaster stands recommended as a moderately warm discutient; and is directed by some to be applied to the hypogastric region, for strengthening the viscera, and expelling flatulencies: but it is a matter of great doubt, whether it derives any virtue either from the article from which it is named, or from the caraway or bay-berries which enter its composition.

Fetid, commonly called *antihysteric*, *plaster.* E.

618 Take of common plaster, asafœtida, strained, each two parts; yellow wax, strained galbanum, each one part. Mix, and make them into a plaster.

This plaster is applied to the umbilical region, or over the whole abdomen, in hysteric cases; and sometimes with good effect; but probably more from its giving an additional degree of heat to the part, than from any influence derived from the fetid gums. It has indeed been alleged, that from the application of this plaster to the abdomen, the taste of asafœtida can be distinctly perceived in the mouth; and it is not improbable, that some absorption of its active parts may take place by the lymphatic vessels of the surface; while, at the same time, the asafœtida thus applied must constantly, in some degree, act on the nerves of the nose. But, in both these ways, its influence can be inconsiderable only; and much more effect may be obtained from a very small quantity taken internally. And we are on the whole inclined to think, that the addition of the fetid gums to the common plaster is here more disagreeable than useful.

Preparations and Compositions.

Ladanum plaster. L.

619 Take of ladanum, three ounces; frankincense, one ounce; cinnamon powdered, expressed oil, called *oil of mace*, of each half an ounce; essential oil of spearmint, one dram. To the melted frankincense add first the ladanum, softened by heat; then the oil of mace. Mix these afterwards with the cinnamon and oil of mint, and beat them together in a warm mortar into a plaster. Let it be kept in a close vessel.

This has been considered as a very elegant stomach plaster. It is contrived so as to be easily made occasionally (for these kinds of compositions, on account of their volatile ingredients, are not fit for keeping), and to be but moderately adhesive, so as not to offend the skin, and that it may without difficulty be frequently taken off and renewed; which these sorts of applications, in order to their producing any considerable effect, require to be. But after all, it probably acts more from the mere covering which it gives to the stomach, than from any of the articles abounding with essential oil which it contains.

Litharge-plaster. L.

620 Take of litharge, in very fine powder, five pounds; olive-oil, a gallon. Boil them with a slow fire, in about two pints of water, constantly stirring until the oil and litharge unite, and have the consistence of a plaster. But it will be proper to add more boiling water, if the water that was first added be nearly consumed before the end of the process.

Common plaster. E.

Take of litharge, one part: olive-oil, two parts; boil them, adding water, and constantly stirring the mixture till the oil and litharge be formed into a plaster.

The heat in these processes should be gentle, and the matter kept constantly stirring, otherwise it swells up, and is apt to run over the vessel. If the composition proves discoloured, the addition of a little white lead and oil will improve the colour.

These plasters, which have long been known under the name of *Diachylon*, are the common application in excoriations of the skin, slight flesh wounds, and the like. They keep the part soft, and somewhat warm, and defend it from the air, which is all that can be expected in these cases from any plaster. Some

of our induſtrious medicine-makers have thought theſe purpoſes might be anſwered by a cheaper compoſition, and accordingly have added a large quantity of common whitening and hogs lard: this, however, is by no means allowable, not only as it does not ſtick ſo well, but likewiſe as the lard is apt to grow rancid and acrimonious. The counterfeit is diſtinguiſhable by the eye.

Litharge plaſter with gum. L.

621 Take of litharge-plaſter, three pounds; ſtrained gallanum, eight ounces; turpentine, ten drams; frankincenſe, three ounces. The galbanum and turpentine being melted with a ſlow fire, mix with them the powdered frankincenſe, and afterwards the litharge-plaſter melted with a very ſlow fire, and make a plaſter.

Gum-plaſter. E.

Take of common plaſter, eight parts; gum-ammoniacum ſtrained, ſtrained galbanum, yellow wax, each one part. Make them into a plaſter according to art.

Both theſe plaſters are uſed as digeſtives and ſuppuratives; particularly in abſceſſes, after a part of the matter has been maturated and diſcharged, for ſuppurating or diſcuſſing the remaining hard part; but it is very doubtful whether they derive any advantage from the gums entering their compoſition.

Litharge-plaſter with quickſilver. L.

622 Take of litharge-plaſter, one pound; purified quickſilver, three ounces; ſulphurated oil, one dram, or what is ſufficient. Make the plaſter in the ſame manner as the ammoniacum-plaſter with quickſilver.

Mercurial or blue plaſter. E.

Take of olive-oil, white reſin, each one part; quickſilver, three parts; common plaſter, ſix parts. Melt the oil and reſin together, and when this mixture is cold, let the quickſilver be rubbed with it till the globules diſappear; then add by degrees the common plaſter, melted, and let the whole be accurately mixed.

Theſe mercurial plaſters are looked on as powerful reſolvents and diſcutients, acting with much greater certainty for theſe intentions than any compoſition of vegetable ſubſtances alone; the mercury exerting itſelf in a conſiderable degree, and being ſometimes introduced into the habit in ſuch quantity as to affect the mouth. Pains in the joints and limbs from a venereal cauſe, nodes, tophi, and beginning indurations of the glands, are ſaid ſometimes to yield to them.

Litharge plaſter with reſin. L.

623 Take of litharge-plaſter, three pounds; yellow reſin, half a pound. Mix the powdered reſin with litharge plaſter, melted with a very ſlow fire, and make a plaſter.

Sticking-plaſter. E.

Take of common plaſter, five parts; white reſin, one part. Melt them together, ſo as to make a plaſter.

Theſe plaſters are uſed chiefly as adheſives for keeping on other dreſſings, &c.

Plaſter of Burgundy pitch. L.

624 Take of Burgundy pitch, two pounds; ladanum, one pound; yellow reſin, yellow wax, of each four ounces; the expreſſed oil, commonly called the *oil of mace*, one ounce. To the pitch, reſin, and wax, melted together, add firſt the ladanum, and then the oil of mace.

This plaſter was at one time much celebrated under the title of *cephalic plaſter*, the name which it formerly held in our pharmacopœias. It was applied in weakneſs or pains of the head, to the temples, forehead, &c. and ſometimes likewiſe to the feet Schulze relates, that an inveterate rheumatiſm in the temples, which at times extended to the teeth, and occaſioned intolerable pain, was completely cured in two days by a plaſter of this kind (with the addition of a little opium) applied to the part, after many other remedies had been tried in vain. He adds, that a large quantity of liquid matter exuded under the plaſter in drops, which were ſo acrid as to corrode the cuticle: but it is probable, that this was much more the effect of the Burgundy pitch than of any other part of the compoſition; for when applied to very tender ſkin, it often produces even veſication, and in moſt inſtances operates as a rubefacient or hot plaſter: and as far as it has any good effect in headach, it is probable that its influence is to be explained on this ground.

Soap-plaſter. L.

625 Take of ſoap, half a pound; litharge-plaſter, three pounds; mix the ſoap with the melted litharge plaſter, and boil them to the thickneſs of a plaſter.

Saponaceous plaſter. E.

Take of common plaſter, four parts; gum-plaſter, two parts; Caſtile ſoap, ſcraped, one part. To the plaſters, melted together, add the ſoap; then boil for a little, ſo as to form a plaſter.

Theſe plaſters have been ſuppoſed to derive a reſolvent power from the ſoap; and in the laſt, the addition of the gums is ſuppoſed to promote the reſolvent virtue of the ſoap: but it is a matter of great doubt, whether they derive any material advantage from either addition.

Frankincenſe plaſter. L.

626 Take of frankincenſe, half a pound; dragon's blood, three ounces; litharge plaſter, two pounds. To the melted litharge-plaſter add the reſt, powdered.

This plaſter had formerly in the London pharmacopœia the title of *ſtrengthening plaſter*, and is a reformation of the complicated and injudicious compoſition deſcribed in the former pharmacopœias, under the title of *Emplaſtrum ad herniam*. Though far the moſt elegant and ſimple, it is as effectual for that purpoſe as any of the medicines of this kind. If conſtantly worn with a proper bandage, it will, in children, frequently do ſervice; though, perhaps, not ſo much

Preparations and Compositions.

from any ſtrengthening quality of the ingredients, as from its being a ſoft, cloſe, and adheſive covering. It has been ſuppoſed that plaſters compoſed of ſtyptic medicines conſtringe and ſtrengthen the part to which they are applied, but on no very juſt foundation; for plaſters in general relax rather than aſtringe, the unctuous ingredients neceſſary in their compoſition counteracting and deſtroying the effect of the others.

Defenſive or ſtrengthening plaſter. E.

627 Take of common plaſter, twenty-four parts; white reſin, ſix parts; yellow-wax, oil olive, each three parts; colcothar of vitriol, eight parts. Grind the colcothar with the oil, and then add it to the other ingredients previouſly melted.

This plaſter is laid round the lips of wounds and ulcers over the other dreſſings, for defending them from inflammation and a fluxion of humours; which, however, as Mr Sharp very juſtly obſerves, plaſters, on account of their conſiſtence, tend rather to bring on than to prevent. It is alſo uſed in weakneſſes of the large muſcles, as of the loins; and its effects ſeem to proceed from the artificial mechanical ſupport given to the part, which may alſo be done by any other plaſter that adheres with equal firmneſs.

Deadly night-ſhade plaſter. Brun.

628 Take of the juice of the recent herb of belladonna, linſeed oil, each nine ounces; yellow-wax, ſix ounces; Venice turpentine, ſix drams; powder of the herb of belladonna, two ounces. Let them be formed into a plaſter according to art.

There can be no doubt that the belladonna, externally applied, has a very powerful influence, both on the nerves and blood veſſels of the part; and thus it has very conſiderable effect both on the circulation and ſtate of ſenſibility of the part; and when applied under the form of this plaſter, eſpecially in affections of the mammæ and ſcrotum, it has been ſaid to have very powerful influence in alleviating pain, in diſcuſſing tumors, and in promoting a favourable ſuppuration. It has however been but little employed in this country; and we can ſay nothing of it from our own experience.

Corn plaſter. Dan.

629 Take of galbanum, diſſolved in vinegar, and again inſpiſſated, one ounce; pitch, half an ounce; diachylon, or common plaſter, two drams. Let them be melted together; and then mix with them verdegris powdered, ſal ammoniac, each one ſcruple; and make them into a plaſter.

Of this plaſter, as well as the former, we can ſay nothing from our own experience. It has been celebrated for the removal of corns, and for alleviating the pain which they occaſion; and it is not improbable that it may ſometimes have a good effect from the corroſive articles which it contains: but in other caſes, from this very circumſtance, it may tend to aggravate the pain, particularly in the firſt inſtance.

Hemlock plaſter. Suec.

630 Take of yellow wax, half a pound; oil olive, four ounces; gum-ammoniacum, half an ounce: after they are melted together, mix with them powdered herb of hemlock, half a pound.

Preparations and Compositions.

This correſponds very nearly with the Emplaſtrum de cicuta cum ammoniaco, which had formerly a place in our pharmacopœias, and was ſuppoſed to be a powerful cooler and diſcutient, and to be particularly ſerviceable againſt ſwellings of the ſpleen and diſtenſions of the hypochondres. For ſome time paſt, it has been among us entirely neglected; but the high reſolvent power which Dr Stoerk has diſcovered in hemlock, and which he found it to exert in this as well as in other forms, intitle it to further trials. The plaſter appears very well contrived, and the additional ingredients well choſen for aſſiſting the efficacy of the hemlock.

Corroſive plaſter. Gen.

631 Take of corroſive ſublimate mercury, half a dram; hogs lard, half an ounce; yellow wax, two drams. Mix them according to art.

There can be no doubt that the muriated mercury here employed is a very powerful corroſive; and there may be ſome caſes in which it is preferable to other articles of the tribe of cauſtics: but this would ſeem to be a very uneconomical mode of applying it, as but a very ſmall portion of what enters the plaſter can act; and even that portion muſt have its action much reſtrained by the unctuous matters with which it is combined.

Plaſter of fenugreek, or of *mucilages*. Gen.

632 Take of fenugreek-ſeed, two ounces; linſeed-oil, warm, half a pound. Infuſe them according to art, and ſtrain; then take of yellow wax, two pounds and an half; gum-ammoniac, ſtrained, ſix ounces; turpentine, two ounces. Melt the gum-ammoniac with the turpentine, and by degrees add the oil and wax, melted in another veſſel, ſo as to form a plaſter.

This plaſter had formerly a place in our pharmacopœias, but was rejected; and although ſtill held in eſteem by ſome, it is probably of no great value; at leaſt it would ſeem to derive but little either from the fenugreek ſeed, with which it is now made, or from the oil and mucilages which formerly entered its compoſition.

Henbane plaſter. Suec.

633 This is directed to be prepared in the ſame manner as the emplaſtrum e conio, or hemlock-plaſter.

From the well-known ſedative power of this plant, as affecting the nervous energy of the part to which it is applied, we might reaſonably conclude that good effects may be obtained from it when uſed under the form of plaſter; and accordingly it has been with advantage employed in this manner, for allaying pain, and reſolving ſwelling, in caſes of ſcirrhus and cancer.

Pitch plaſter. Roſſ.

634 Take of white reſin, ſix ounces; ſhip-pitch, ſeven ounces; yellow wax, five ounces. Melt them, and form them into a plaſter.

Pitch, applied externally, has been ſuppoſed to act on two principles, by its warmth and by its adheſive quality.

Preparations and Compositions.

quality. In the former way it may have ſome effect; but it has much more influence in the latter: and particularly it has thus been found to produce a cure in caſes of tinea capitis. When a pitch-plaſter is applied to the affected part of the hairy ſcalp, and allowed to remain there for a few days, it becomes ſo attached to the parts, that it cannot be removed without bringing with it the bulbs of the hair in which the diſeaſe is ſeated: and by this means a radical cure is not unfrequently obtained, after every other remedy has been tried in vain. But the cure is a painful one, and not without danger: for in ſome inſtances, inflammations, even of an alarming nature, have been excited by the injury thus done to the parts. Hence this mode of cure is rarely had recourſe to till others have been tried without effect: and when it is employed, if the diſeaſe be extenſive, prudent practitioners direct its application only to a ſmall portion at a time, the ſize of a crown-piece or ſo: and after one part is fully cured, by application to another in ſucceſſion, the affection may be ſoon completely overcome. With this intention it is moſt common to employ the pitch in its pure ſtate: but the plaſter here directed, while it is no leſs adheſive, is more manageable and flexible.

Chap. XXXII. *Ointments and Liniments.*

635 Ointments and liniments differ from plaſters little otherwiſe than in conſiſtence. Any of the officinal plaſters, diluted with ſo much oil as will reduce it to the thickneſs of ſtiff honey, forms an ointment: by farther increaſing the oil, it becomes a liniment.

In making theſe preparations, the Edinburgh college direct, that fat and reſinous ſubſtances are to be melted with a gentle heat; then to be conſtantly ſtirred, ſprinkling in at the ſame time the dry ingredients, if any ſuch are ordered, in the form of a very fine powder, till the mixture on diminiſhing the heat becomes ſtiff.

It is to be underſtood that the above general directions are meant to apply to each particular compoſition contained in the preſent edition of the Edinburgh pharmacopœia. It is alſo to be obſerved, that where any compoſitions are ordered, as baſes or ingredients of others, the college always refer to thoſe made according to their own formula.

Ointment of hog's lard. L.

636 Take of prepared hog's lard, two pounds; roſe-water, three ounces. Beat the lard with the roſe-water until they be mixed; then melt the mixture with a ſlow fire, and ſet it apart that the water may ſubſide; after which, pour off the lard from the water, conſtantly ſtirring until it be cold.

In the laſt edition of the London pharmacopœia, this was ſtyled *Unguentum ſimplex*, the name given by the Edinburgh college to the following.

Simple ointment. E.

Take of olive oil, five parts; white wax, two parts.

Both theſe ointments may be uſed for ſoftening the ſkin and healing chaps. The laſt is, however, preferable, on account of its being of one uniform conſiſtence. For the ſame reaſon it is alſo to be preferred as the baſis of other more compounded ointments. Preparations and Compoſitions.

Ointment of verdegris. E.

Take of baſilicon ointment, fifteen parts; verdegris, one part. 637

This ointment is uſed for cleanſing ſores, and keeping down fungous fleſh. Where ulcers continue to run from a weakneſs in the veſſels of the part, the tonic powers of copper promiſe conſiderable advantage.

It is alſo frequently uſed with advantage in caſes of ophthalmia, depending on ſcroſula, where the palpebræ are principally affected; but when it is to be thus applied, it is in general requiſite that it ſhould be ſomewhat weakened by the addition of a proportion of ſimple ointment or hog's lard. An ointment ſimilar to the above, and celebrated for the cure of ſuch inſtances of ophthalmia, has long been ſold under the name of *Smellon's eye-ſalve.*

Ointment of the white calx of quickſilver. L.

Take of the white calx of quickſilver, one dram; ointment of hog's lard, one ounce and a half. Mix, and make an ointment. 638

This is a very elegant mercurial ointment, and frequently uſed in the cure of obſtinate and cutaneous affections. It is an improvement of the ointment of precipitated mercury of the laſt London pharmacopœia; the precipitated ſulphur being thrown out of the compoſition, and the quantity of mercury increaſed.

Ointment of calx of zinc. E.

Take of ſimple liniment, ſix parts; calx of zinc, one part. 639

This ointment is chiefly uſed in affections of the eye, particularly in thoſe caſes where redneſs ariſes rather from relaxation than from active inflammation.

Ointment of Spaniſh flies. L.

Take of Spaniſh flies, powdered, two ounces; diſtilled water, eight ounces; ointment of yellow reſin eight ounces. Boil the water with the Spaniſh flies to one half, and ſtrain. To the ſtrained liquor add the ointment of yellow reſin. Evaporate this mixture in a water-bath, ſaturated with ſea-ſalt, to the thickneſs of an ointment. 640

Epiſpaſtic ointment from infuſion of cantharides. E.

Take of cantharides, white reſin, yellow wax, each one ounce; hog's lard, Venice turpentine, each two ounces; boiling water, four ounces. Infuſe the cantharides in the water, in a cloſe veſſel, for a night; then ſtrongly preſs out and ſtrain the liquor, and boil it with the lard till the water be conſumed; then add the reſin, wax, and turpentine, and make the whole into an ointment.

Theſe ointments, containing the ſoluble parts of the cantharides, uniformly blended with the other ingredients, are more commodious, in general occaſion leſs pain, and are no leſs effectual in ſome caſes, than the compoſitions with the fly in ſubſtance. This, however,

Preparations and Compositions.

does not uniformly hold; and accordingly the Edinburgh college, with propriety, ſtill retain an ointment containing the flies in ſubſtance.

Epiſpaſtic ointment, from powder of cantharides. E.

641 Take of baſilicon ointment, ſeven parts; powdered cantharides, one part.

This ointment is employed in the dreſſings for bliſters, intended to be made *perpetual*, as they are called, or to be kept running for a conſiderable time, which in many chronic, and ſome acute caſes, is of great ſervice. Particular care ſhould be taken, that the cantharides employed in theſe compoſitions be reduced to a very fine powder, and that the mixture be made as equal and uniform as poſſible. But with theſe precautions, there are ſome particular habits in which this ointment operates with even leſs pain than the former, while at the ſame time it is generally more effectual.

Wax ointment. L.

642 Take of white wax, four ounces; ſpermaceti, three ounces; olive-oil, one pint. Stir them, after being melted with a ſlow fire, conſtantly and briſkly, until cold.

This ointment had formerly the title of *unguentum album* in the London pharmacopœia. It differs very little from the ſimple ointment of the Edinburgh pharmacopœia, and in nothing from the ointment of ſpermaceti of the London pharmacopœia, excepting that in this ointment the proportion of ſpermaceti is ſomewhat leſs. It is an uſeful cooling ointment for excoriations and other frettings of the ſkin.

Ointment of acetated ceruſe. L.

643 Take of acetated ceruſe, two drams; white wax, two ounces; olive-oil, half a pint. Rub the acetated ceruſe, previouſly powdered, with ſome part of the olive-oil; then add it to the wax, melted with the remaining oil. Stir the mixture until it be cold.

Saturnine ointment. E.

Take of ſimple ointment, twenty parts; ſugar of lead, one part.

Both theſe ointments are uſeful coolers and deſiccatives; much ſuperior both in elegance and efficacy to the *nutritum* or *tripharmacum*, at one time very much celebrated.

Ointment of ceruſe, commonly called *white ointment.* E.

644 Take of ſimple ointment, five parts; ceruſe, one part.

This is an uſeful, cooling, emollient ointment, of great ſervice in excoriations and other ſimilar frettings of the ſkin. The ceruſe has been objected to by ſome, on a ſuſpicion that it might produce ſome ill effects, when applied, as theſe unguents frequently are, to the tender bodies of children. Though there does not ſeem to be much danger in this external uſe of ceruſe, the addition of it is the leſs neceſſary here, as we have another ointment containing a more active preparation of the ſame metal, the ſaturnine ointment juſt mentioned; which may be occaſionally mixed with this, or employed by itſelf, in caſes where ſaturnine applications are wanted.

Ointment of elemi. L.

Take of elemi, one pound; turpentine, ten ounces; mutton ſuet, prepared, two pounds; olive-oil, two ounces. Melt the elemi with the ſuet; and having removed it from the fire, mix it immediately with the turpentine and oil, after which ſtrain the mixture. 645

This ointment, perhaps beſt known by the name of *linimentum arcei*, has long been in uſe for digeſting, cleanſing, and incarnating; and for theſe purpoſes is preferred by ſome to all the other compoſitions of this kind.

Theſe, however, are much more proceſſes of nature than of art; and it is much to be doubted whether it has in reality any influence.

Ointment of white hellebore. L.

Take of the root of white hellebore, powdered, one ounce; ointment of hog's lard, four ounces; eſſence of lemons, half a ſcruple. Mix them, and make an ointment. 646

White hellebore externally applied has long been celebrated in the cure of cutaneous affections; and this is perhaps one of the beſt formulæ under which it can be applied, the hog's-lard ointment ſerving as an excellent baſis for it, while the eſſence of lemons communicates to it a very agreeable ſmell.

Stronger ointment of quickſilver. L.

Take of purified quickſilver, two pounds; hog's lard, prepared, twenty-three ounces; mutton-ſuet, prepared, one ounce. Firſt rub the quickſilver with the ſuet and a little of the hog's lard, until the globules diſappear; then add what remains of the lard, and make an ointment. 647

Weaker ointment of quickſilver. L.

Take of the ſtronger ointment of quickſilver, one part; hog's lard, prepared, two parts. Mix them.

Quickſilver, or *blue ointment.* E.

Take of quickſilver, mutton-ſuet, each one part; hog's lard, three parts. Rub them carefully in a mortar till the globules entirely diſappear.

This ointment may alſo be made with double or triple the quantity of quickſilver.

Theſe ointments are principally employed, not with a view to their topical action, but with the intention of introducing mercury in an active ſtate into the circulating ſyſtem. And this may be effected by gentle friction on the ſound ſkin of any part, particularly on the inſide of the thighs or legs. For this purpoſe, theſe ſimple ointments are much better ſuited than the more compounded ones with turpentine and the like, formerly employed. For by any acrid ſubſtance topical inflammation is apt to be excited, preventing farther friction, and giving much uneaſineſs. To avoid this, it is neceſſary, even with the mildeſt and weakeſt ointment, ſomewhat to change the place at which the friction is performed. But by theſe ointments properly managed, mercury may in moſt inſtances be as advantageouſly introduced, either for eradicating ſyphi-

lis,

lis, or combating other obſtinate diſeaſes, as under any form whatever. But to obtain theſe effects, it is requiſite that the ointment ſhould be prepared with very great care: for upon the degree of triture which has been employed, the activity of the mercury muſt entirely depend. The addition of the mutton-ſuet, now adopted by both colleges, is an advantage to the ointment, as it prevents it from running into the ſtate of oil, which the hog's lard alone in warm weather, or in a warm chamber, is ſometimes apt to do, and which is followed by a ſeparation of parts. We are even inclined to think, that the proportion of ſuet directed by the London college is too ſmall for this purpoſe, and indeed ſeems to be principally intended for the more effectual triture of the mercury: But it is much more to be regretted, that, in a medicine of ſuch activity, the two colleges ſhould not have directed the ſame proportion of mercury to the fatty matter. For although both have directed ointments of different ſtrength, neither the weakeſt nor the ſtrongeſt agree in the proportion of mercury which they contain.

Ointment of nitrated quickſilver. L.

648 Take of purified quickſilver, one ounce; nitrous acid, two ounces; hog's lard, prepared, one pound. Diſſolve the quickſilver in the nitrous acid; and, while it is yet hot, mix it with the hog's lard, previouſly melted, and juſt growing cold.

Yellow ointment. E.

Take of quickſilver, one ounce; ſpirit of nitre, two ounces; hog's lard, one pound. Diſſolve the quickſilver in the ſpirit of nitre, by digeſtion in a ſand-heat; and, while the ſolution is very hot, mix with it the lard, previouſly melted by itſelf, and juſt beginning to grow ſtiff. Stir them briſkly together, in a marble mortar, ſo as to form the whole into an ointment.

Theſe ointments differ only in name; and that employed by the London college is certainly the preferable appellation: For here the quickſilver, previous to its union with the lard, is brought to a ſaline ſtate by means of the nitrous acid. And although its activity be very conſiderably moderated by the animal fat with which it is afterwards united, yet it ſtill affords us a very active ointment; and as ſuch it is frequently employed with ſucceſs in cutaneous and other topical affections. In this condition, however, the mercury does not ſo readily enter the ſyſtem as in the preceding form. Hence it may even be employed in ſome caſes with more freedom; but in other inſtances it is apt to excoriate and inflame the parts. On this account a reduction of its ſtrength is ſometimes requiſite; and it is often alſo neceſſary, from the hard conſiſtence which it acquires, in conſequence of the action of acid on the lard.

Tar ointment.

649 Take of tar, mutton ſuet prepared, each half a pound. Melt them together, and ſtrain. L.

Take of tar, five parts; yellow wax, two parts. E.

Theſe compoſitions, though the one be formed into an ointment by means of ſuet, the other by wax, cannot be conſidered as differing eſſentially from each other. As far as they have any peculiar activity, this entirely depends on the tar. And this article, from the empyreumatic oil and ſaline matters which it contains, is undoubtedly, as well as turpentine, of ſome activity. Accordingly, it has been ſucceſsfully employed againſt ſome cutaneous affections, particularly thoſe of domeſtic animals. At one time, as well as the black baſilicon, it was a good deal employed as a dreſſing even for recent wounds. But although it ſtill retains a place in our pharmacopœias, it is at preſent little uſed with any intention.

Ointment of yellow reſin. L.

Take of yellow reſin, yellow wax, each one pound; olive oil, one pint. Melt the reſin and wax with a ſlow fire; then add the oil, and ſtrain the mixture while hot. 650

Baſilicon ointment. E.

Take of hog's lard, eight parts; white reſin, five parts; yellow wax, two parts.

Theſe are commonly employed in dreſſings, for digeſting, cleanſing, and incarnating wounds and ulcers. They differ very little, if at all, in their effects, from the *linimentum arcæi*, or ointment of elemi, as it is now more properly ſtyled. But it is probable that no great effect is to be attributed to either: For there can be no doubt that the ſuppurative and adheſive inflammation are proceſſes of nature, which will occur without the aid of any ointment.

Elder ointment. L.

Take of elder flowers, four pounds; mutton-ſuet, prepared, three pounds; olive-oil, one pint. Boil the flowers in the ſuet and oil, firſt melted together, till they be almoſt criſp; then ſtrain with expreſſion. 651

This ointment does not ſeem ſuperior to ſome others, which are much neater, and leſs expenſive. It can ſcarcely be ſuppoſed to receive any conſiderable virtue from the ingredient from which it takes its name. And accordingly it is not without propriety that it is rejected from the pharmacopœia of the Edinburgh college.

Ointment of ſpermaceti. L.

Take of ſpermaceti, ſix drams; white wax, two drams; olive-oil, three ounces. Melt them together over a ſlow fire, ſtirring them conſtantly and briſkly until they be cold. 652

This had formerly the name of *white liniment*, and it is perhaps only in conſiſtence that it can be conſidered as differing from the ſimple ointment already mentioned, or the ſimple cerate afterwards to be noticed.

Sulphur ointment. L.

Take of ointment of hog's lard, half a pound; flowers of ſulphur, four ounces. Mix them, and make an ointment. 653

Ointment of ſulphur, or *antipſoric ointment.* E.

Take of hog's lard, four parts; ſulphur, beat into a very

Preparations and Compositions.

very fine powder, one part. To each pound of this ointment add eſſence of lemons, or oil of lavender, half a dram.

Sulphur is a certain remedy for the itch, and ſafer than mercury. Sir John Pringle obſerves, that unleſs a mercurial unction was to touch every part of the ſkin, there can be no certainty of ſucceſs: whereas, from a ſulphureous one, a cure may be obtained by only partial unction; the animalcula, which are ſuppoſed to occaſion this diſorder, being, like other inſects, killed by the ſulphureous ſteams which exhale by the heat of the body. As to the internal uſe of mercury, which ſome have accounted a ſpecific, there are ſeveral inſtances of men undergoing a complete ſalivation for the cure of the lues venerea, without being freed from the itch: but there are alſo a multitude of inſtances of men undergoing a long courſe of ſulphur without effect, and who were afterwards readily cured by mercury.

The quantity of ointment, above directed, ſerves for four unctions: the patient is to be rubbed every night; but to prevent any diſorder that might ariſe from ſtopping too many pores at once, a fourth part of the body is to be rubbed at one time. Though the itch may thus be cured by one pot of ointment, it will be proper to renew the application, and to touch the parts moſt affected for a few nights longer, till a ſecond quantity alſo be exhauſted; and in the worſt caſes, to ſubjoin the internal uſe of ſulphur, not with a view to purify the blood, but to diffuſe the ſteams more certainly through the ſkin; there being reaſon to believe, that the animalcula may ſometimes lie too deep to be thoroughly deſtroyed by external applications.

Tutty ointment.

654 Take of prepared tutty, one dram; ointment of ſpermaceti, what is ſufficient. Mix them ſo as to make a ſoft ointment. L.

Take of ſimple liniment, five parts; prepared tutty, one part. *E.*

Theſe ointments have long been celebrated, and are ſtill much employed againſt affections of the eyes. But they cannot, we imagine, be eſteemed elegant.

Both calamine and tutty act only by means of the zinc they contain, and calamine appears to contain the moſt of the two, and likewiſe to be the leaſt variable in its contents. But the pure flowers prepared from zinc itſelf are doubtleſs preferable to either. Hence the ointment of tutty may be conſidered as inferior to both the ointment of calamine and to the ointment of the calx of zinc, which have alſo a place in our pharmacopœia.

Simple liniment. E.

655 Take of olive oil, four parts; white wax, one part.

This conſiſts of the ſame articles which form the ſimple ointment of the Edinburgh pharmacopœia, but merely in a different proportion, ſo as to give a thinner conſiſtence; and where a thin conſiſtence is requiſite, this may be conſidered as a very elegant and uſeful application.

Liniment of ammonia. L.

656 Take of water of ammonia, half an ounce; olive-oil, one ounce and an half. Shake them together in a phial till they are mixed.

Preparations and Compositions.

This has long been known in the ſhops under the title of *volatile liniment*, but is now more properly denominated from the principal active article, which enters its compoſition. It has been much employed in practice, particularly on the recommendation of Sir John Pringle in his Obſervations on the Diſeaſes of the Army. He obſerves, that, in the inflammatory quinſey, or ſtrangulation of the fauces, a piece of flannel, moiſtened with this mixture, applied to the throat, and renewed every four or five hours, is one of the moſt efficacious remedies. By means of this warm ſtimulating application, the neck, and ſometimes the whole body, is put into a ſweat, which after bleeding either carries off or leſſens the inflammation. Where the ſkin cannot bear the acrimony of this mixture, a larger proportion of oil may be uſed.

Stronger liniment of ammonia. L.

Take of water of pure ammonia, one ounce; olive-oil, two ounces. Shake them together in a phial. 657

This article differs from the foregoing in ſtrength only. This ariſes both from its being formed of a more acrid ſpirit, and from its containing that ſpirit in a larger proportion to the oil. It is uſed to ſupply the place of the *epithema et emplaſtrum volatile* of our former pharmacopœias, and is a very acrid ſtimulating compoſition. When largely applied, it often excites inflammation, and even veſication, on tender ſkin. It is often, however, ſucceſsfully employed againſt obſtinate rheumatic and iſchiadic pains.

Camphor liniment. L.

Take of camphor, two ounces; water of ammonia, ſix ounces; ſimple ſpirit of lavender, ſixteen ounces. Mix the water of ammonia with the ſpirit, and diſtil from a glaſs retort, with a ſlow fire, ſixteen ounces. Then diſſolve the camphor in the diſtilled liquor. 658

This formula, which has now for the firſt time a place in the London pharmacopœia, approaches to the volatile eſſence of that celebrated empyric the late Dr Ward: But the above is a more elegant and active formula than either of the receipts publiſhed by Mr Page, from Dr Ward's book of receipts; and there is no reaſon to doubt that it will be equally effectual in removing ſome local pains, ſuch as particular kinds of headach, in conſequence of external application.

Soap-liniment. L.

Take of ſoap, three ounces; camphor, one ounce; ſpirit of roſemary, one pint. Digeſt the ſoap in the ſpirit of roſemary until it be diſſolved, and add to it the camphor. 659

This is the ſoap-liniment of the former edition of the London pharmacopœia, without any alteration; and it differs very little from the ſoap-balſam of the Edinburgh college already mentioned. Though a leſs active and penetrating application than the preceding, it is perhaps no leſs uſeful: and it is often ſucceſsfully employed for external purpoſes againſt rheumatic pains, ſprains, bruiſes, and ſimilar complaints.

Egyp-

Egyptian ointment. Gen.

Take of honey, one pound; ſtrong vinegar, half a pound; verdegris, powdered, five ounces. Let the ingredients be boiled together till the verdegris be diſſolved, ſo that the ointment may have a due degree of thickneſs and a purple colour.

This preparation had formerly a place in our pharmacopœias under the title of *Egyptian honey*: and a ſimilar preparation has now a place under the title of *oxymel of verdegris*. But in that formula the proportion is much leſs than in the above. It may juſtly be conſidered as a very powerful application for cleanſing and deterging foul ulcers, as well as for keeping down fungous fleſh. But theſe purpoſes may in general be anſwered by articles leſs acrid, and exciting leſs pain. Beſides this, the above preparation is alſo liable to conſiderable uncertainty with reſpect to ſtrength; for a large proportion of the verdegris will in a ſhort time ſubſide to the bottom; thus, what is in the top of the pot is much leſs active than that in the bottom.

Anodyne ointment. Gen.

Take of olive-oil, ten drams; yellow wax, half an ounce; crude opium, one dram. Mix them according to art, ſo as to form an ointment.

Opium thus externally applied, will in ſome degree be productive of the ſame effect as when uſed under the form of the anodyne balſam. In that ſtate it produces its effects more immediately; but under the preſent form its effects are more permanent. Beſides this, the preſent ointment furniſhes us with an uſeful dreſſing for ſores attended with ſevere pain; to which opium when diſſolved in ſpirit cannot be applied. Hence the preſent, or ſome analogous formula, is well intitled to a place in our pharmacopœias.

Ointment for an ulcerated cancer. Brun.

Take of the recently expreſſed juice of the ricinus, one pound: let it be expoſed to the rays of the ſun in a leaden veſſel till it acquire the conſiſtence of an oil; then to one pound of this inſpiſſated juice add calcined lead, white precipitate mercury, each one pound. Let them be properly mixed.

This acrid application muſt poſſeſs a conſiderable degree of corroſive power. And in ſome caſes of cancer, by the proper application of corroſives, much benefit may be done: But where the diſeaſe has made any conſiderable progreſs, theſe will in general have the effect rather of haſtening its progreſs than of removing it; particularly if there be a large indolent tumor below the ulcer.

Digeſtive ointment. Roſſ.

Take of Venice turpentine, one pound; the yolks of eight eggs. Mix them together according to art.

This warm ſtimulating application is well ſuited to promote the ſuppurative inflammation, and may be advantageouſly had recourſe to, where it is neceſſary to encourage a large diſcharge of pus.

Hæmorrhoidal ointment.

Take ſaturnine ointment, ſix drams; oil of hyoſcyamus, obtained by boiling, two drams; camphor, powdered, two ſcruples; ſaffron, one ſcruple. Mix them into an ointment. Preparations and Compoſitions.

The name affixed to this ointment expreſſes the purpoſe for which it is applied. From the articles of which it conſiſts, it may be concluded, that it poſſeſſes a gently emollient and anodyne power; and may therefore afford conſiderable relief, where much pain ariſes from external hæmorrhoidal tumors.

Laurel ointment. Suec.

Take of prepared mutton-ſuet, eight ounces. After it is melted and removed from the fire, add to it oil of bays, one pound; ethereal oil of turpentine, one ounce; rectified oil of amber, half an ounce. Let them be mixed and rubbed together till they form an ointment.

This is an improved mode of forming an ointment which had formerly a place in our pharmacopœias under the title of *nervine ointment*. And it furniſhes a warm ſtimulating nervine application, which may in ſome degree reſtore ſenſe and motion to paralytic limbs. And while it at leaſt ſerves to lead to the careful uſe of friction, it may ſomewhat increaſe the benefit which would reſult from it.

Ointment of tobacco. Dan.

Take of the leaves of tobacco, three pounds; juice of tabacco, nine ounces; hog's lard, a pound and a half; reſin, three ounces. Let the cut leaves be macerated for the ſpace of a night, and then boiled over a gentle fire. Having ſtrained the fluid obtained by expreſſion, add to it yellow wax, half an ounce; powder of the root of birthwort, three ounces. Mix them into an ointment.

There can be no doubt that tobacco externally applied has very powerful effects on the human body; and that not merely from its topical action, but ſometimes even as affecting the ſyſtem in general. From this laſt circumſtance it requires to be uſed with great caution. It has, however, been found, under proper management, to afford an effectual cure in obſtinate cutaneous affections. But were it to be uſed with this intention, we would have a more elegant formula, by merely impregnating either hog's lard, or the ſimple ointment, with the active qualities extracted by the aid of heat from the leaves of the prepared tobacco in the ſtate in which it is uſually brought to us from America, than by having recourſe to the recent juice, and to the ariſtolochia and other additions here directed.

Ointment of ſtorax. Suec.

Take of olive oil, a pound and a half; white reſin, gum elemi, yellow wax, each ſeven ounces. After they are melted together and ſtrained, add liquid ſtorax, ſeven ounces. Mix them together, and agitate the mixture till it concretes into an uniform ointment.

An ointment ſuppoſed to derive its activity from the ſtorax, although it have no place in our pharmacopœias, is received into moſt of the foreign ones. And it has been much celebrated not only as a ſtrengthening application to weakly children, but even for the removal of affections of the bones, as in caſes of rachi-

Preparations and Compositions.

tis and the like. It is, however, very doubtful how far theſe properties depend on the ſtorax. If it have really any good effect, it is probable that this is more the conſequence of the friction merely, than of any of the articles which enter the compoſition of the ointment. But there is reaſon to believe that the virtues attributed to this ointment are more imaginary than real.

Onion ointment. Suec.

668 Take of yellow wax, reſin, each half a pound. To theſe melted, add onions roaſted under the aſhes, honey, each two pounds and a half; black ſoap, half a pound. Let them be gently boiled together till all the moiſture be conſumed, then ſtrain the liquor, expreſſing it from the materials, and afterwards agitate it with a wooden peſtle that it may unite into one uniform maſs.

This ointment is applied with the intention of promoting ſuppuration. And it has long been ſuppoſed, that the onion, eſpecially in its roaſted ſtate, has a remarkable influence in this way: but there is reaſon to think, that the powers attributed to it have been greatly over-rated. And there is even ground to preſume that theſe effects totally depend entirely on heat and moiſture. Hence no application is perhaps better ſuited for promoting ſuppuration than a poultice of bread and milk, applied as hot as can be borne with and frequently repeated.

Chap. XXXIII. *Cerates.*

699 Cerates are ſubſtances intended for external application, formed of nearly the ſame materials which conſtitute ointments and plaſters. And they differ principally from theſe in being merely of an intermediate conſiſtence between the two. Accordingly, they are ſeldom the ſubject of a ſeparate chapter by themſelves, but are claſſed either with the one or the other. In the Edinburgh pharmacopœia they are claſſed among the ointments: but as the London college have referred them to a ſeparate head, we ſhall here alſo conſider them by themſelves.

Simple cerate. E.

670 Take of olive oil, ſix parts; white wax, three parts; ſpermaceti, one part. Unite them according to art.

This differs from the ſimple ointment in containing a greater proportion of wax to the oil, and in the addition of the ſpermaceti. But by theſe means it obtains only a more firm conſiſtence, without any eſſential change of properties.

Cerate of cantharides, or *Spaniſh flies.* L.

671 Take of cerate of ſpermaceti, ſoftened with heat, ſix drams; Spaniſh flies, finely powdered, one dram. Mix them.

Under this form cantharides may be made to act to any extent that is requiſite. It may ſupply the place either of the bliſtering plaſter or ointment; and there are caſes in which it is preferable to either. It is particularly more convenient than the plaſter of cantharides, where the ſkin to which the bliſter is to be applied is previouſly much affected, as in caſes of ſmallpox; and in ſupporting a drain under the form of iſſue, it is leſs apt to ſpread than the ſalter ointment.

Preparations and Compositions.

Calamine-cerate. L.

672 Take of calamine prepared, yellow wax, each half a pound; olive oil, one pint. Melt the wax with the oil; and, as ſoon as the mixture begins to thicken, mix with it the calamine, and ſtir the cerate until it be cold.

Cerate of calamine. E.

Take of ſimple cerate, five parts; calamine prepared, one part.

Theſe compoſitions are formed on the cerate which Turner ſtrongly recommends in cutaneous ulcerations and excoriations, and which has been uſually diſtinguiſhed by his name. They appear from experience to be excellent epulotics, and as ſuch are frequently uſed in practice.

Cerate of acetated litharge. L.

673 Take of water of acetated litharge, two ounces and a half; yellow wax, four ounces; olive oil, nine ounces; camphor, half a dram. Rub the camphor with a little of the oil. Melt the wax with the remaining oil; and as ſoon as the mixture begins to thicken, pour in by degrees the water of acetated litharge, and ſtir conſtantly until it be cold; then mix in the camphor before rubbed with oil.

This application has been rendered famous by the recommendations of Mr Goulard. It is unqueſtionably in many caſes very uſeful. It cannot, however, be conſidered as varying eſſentially from the ſaturnine ointment, or ointment of acetated ceruſe, formerly mentioned. It is employed with nearly the ſame intentions, and differs from it chiefly in conſiſtence.

Cerate of yellow reſin. L.

674 Take of ointment of yellow reſin, half a pound; yellow wax, one ounce. Melt them together, and make a cerate.

This had formerly the name of *lemon-ointment.* It is no otherwiſe different from the yellow baſilicum, or ointment of yellow reſin, than being of a ſtiffer conſiſtence, which renders it for ſome purpoſes more commodious.

Soap cerate. L.

675 Take of ſoap, eight ounces; yellow wax, ten ounces; litharge, powdered, one pound; olive oil, one pint; vinegar, one gallon; boil the vinegar with the litharge over a ſlow fire, conſtantly ſtirring until the mixture unites and thickens; then mix in the other articles, and make a cerate.

This, notwithſtanding the name, may rather be conſidered as another ſaturnine application; its activity depending very little on the ſoap; and it may be held as varying in little elſe but conſiſtence from the plaſter of litharge. It can hardly be thought to differ in its properties from the cerate of acetated litharge juſt mentioned; for neither the ſmall proportion of camphor which enters the compoſition of the one, nor the ſoap which gives name to the other, can be conſidered as having much influence.

Preparations and Compositions.

Cerate of ſpermaceti. L.

676 Take of ſpermaceti, half an ounce; white wax, two ounces; olive oil, four ounces. Melt them together, and ſtir until the cerate be cold.

This had formerly the name of *white cerate*, and it differs in nothing from the ointment of ſpermaceti, or white liniment, as it was formerly called, excepting in conſiſtence, both the wax and the ſpermaceti bearing a greater proportion to the oil.

Lip-ſalve. Roſſ.

677 Take of olive oil, eighteen ounces; white wax, one pound; ſpermaceti, an ounce and a half; oil of rhodium, half a dram. Form a cerate, tinging it with alkanet, ſo as to give a red colour.

The name affixed to this cerate points out the uſe for which it is intended. It is chiefly employed againſt thoſe chops and excoriations of the lips, which are often the conſequence of cold weather; and it is very well ſuited for removing affections of that kind. But excepting in the colour and ſmell which it derives from the alkanet and rhodium, it differs in nothing from the cerate of ſpermaceti, and cannot be conſidered as more effectually anſwering the intention in view.

Bougies. Suec.

678 Take of yellow wax, melted, one pound; ſpermaceti, three drams; vinegar of litharge, two drams. Mix them, and upon removal from the fire immerſe into the mixture ſlips of linen, of which bougies are to be formed according to the rules of art. Theſe may alſo be made with double, triple, or quadruple, the quantity of the vinegar.

It is perhaps rather ſurpriſing, that no formula for the preparation of bougies has a place in our pharmacopœias: for there can be no doubt, that although the preparation of them has hitherto been principally truſted to empirics; yet in the hand of the ſkilful practitioner they are of great ſervice in combating obſtinate affections. Although it has been pretended by ſome that their influence is to be aſcribed to certain impregnations; yet it is on better grounds contended, that they act entirely on mechanical principles. The great object is therefore to obtain the union of a proper degree of firmneſs and flexibility. Theſe qualities the above compoſition poſſeſſes; and it does not probably derive any material benefit from being prepared with an additional proportion of the vinegar of litharge.

Chap. XXXIV. *Epithems.*

679 By epithems or cataplaſms are in general underſtood thoſe external applications which are brought to a due conſiſtence or form for being properly applied, not by means of oily or fatty matters, but by water or watery fluids. Of theſe not a few are had recourſe to in actual practice; but they are ſeldom prepared in the ſhops of the apothecaries; and in ſome of the beſt modern pharmacopœias no formulæ of this kind are introduced. The London college, however, although they have abridged the number of epithems, ſtill retain a few. And it is not without ſome advantage that there are fixed forms for the preparation of them.

Cataplaſm of cummin. L.

Take of cummin-ſeed, one pound; bay-berries, dry leaves of water-germander, or ſcordium, Virginian ſnake-root, of each three ounces; cloves, one ounce. Rub them all together; and, with the addition of three times the weight of honey, make a cataplaſm. 680

This is adopted into the preſent edition of the London pharmacopœia with very little alteration from the laſt. It was then intended as a reformation of the *theriaca Londinenſis*, which for ſome time paſt has been ſcarcely otherwiſe uſed than as a warm cataplaſm. In place of the numerous articles which formerly entered that compoſition, only ſuch of its ingredients are retained as contribute moſt to this intention: but even the article from which it now derives its name, as well as ſeveral others which ſtill enter it, probably contribute very little to any medical properties it may poſſeſs.

Muſtard-cataplaſm. L.

Take of muſtard ſeed, powdered, crumb of bread, each half a pound; vinegar, as much as is ſufficient. Mix, and make a cataplaſm. 681

Epithems of this kind are commonly known by the name of *ſinapiſms*. They were formerly not unfrequently prepared in a more complicated ſtate, containing garlic, black-ſoap, and other ſimilar articles; but the above ſimple form will anſwer every purpoſe which they are capable of accompliſhing. They are employed only as ſtimulants: they often inflame the part and raiſe bliſters, but not ſo perfectly as cantharides. They are frequently applied to the ſoles of the feet in the low ſtate of acute diſeaſes, for raiſing the pulſe and relieving the head. The chief advantage they have depends on the ſuddenneſs of their action.

Alum-curd. L.

Take the whites of two eggs; ſhake them with a piece of alum till they be coagulated. 682

This preparation is taken from Riverius. It is an uſeful aſtringent epithem for ſore, moiſt eyes, and excellently cools and repreſſes thin defluxions. Slighter inflammations of the eyes, occaſioned by duſt, expoſure to the ſun, or other ſimilar cauſes, are generally removed by fomenting them with warm milk and water, and waſhing them with ſolutions of white vitriol. Where the complaint is more violent, this preparation, after the inflammation has yielded a little to bleeding, is one of the beſt external remedies. It is to be ſpread on lint, and applied at bed-time.

A Table, ſhowing in what Proportions Mercury *or* Opium *enter different Formulæ.*

Pulvis e creta compoſitus cum opio. L. In about forty-four grains, one grain of opium is contained. 683

Pulvis ipecacuanhæ compoſitus. L. In ten grains, one grain of opium.

Pulvis ſudorificus. E. In eleven grains, one grain of opium.

Pulvis opiatus. L. In ten grains, one grain of opium.

Pulvis e ſcammonio cum calomelane. L. In four grains, one grain of calomel.

Preparations and Compositions

Pilula ex opio. L. In five grains, one grain of opium.
Pilulæ thebaicæ. E. In ten grains, one grain of opium.
Pilulæ ex hydrargyro. L. In two grains and a half, one grain of mercury.
Pilulæ ex hydrargyro. E. In four grains, one grain of mercury.
Pilulæ plummeri. E. In two grains and two-thirds, one grain of calomel.
Confectio opiata. L. In thirty-six grains, one grain of opium.
Electuarium Japonicum. E. In about one hundred and ninety-three grains, one grain of opium.
Electuarium Thebaicum. E. In ninety-seven grains, one grain of opium.
Trochisci bechici cum opio. E. In fifty five grains, one grain of opium.
These trochisci are not unfrequently ordered *cum duplice opio*, and under this form are kept in many shops.
Emplastrum ammoniacum cum hydrargyro. L. In five ounces, one ounce of mercury.
Emplastrum lythargyri cum hydrargyro. L. In five ounces, one ounce of mercury.
Emplastrum e hydrargyro. E. In three ounces and two-thirds, one ounce of mercury.
Unguentum hydrargyri fortius. L. In two drams, one dram of mercury.
Unguentum hydrargyri mitius. L. In five drams, one dram of mercury.
Unguentum ex hydrargyro. E. In five drams, one dram of mercury.
Unguentum hydrargyri nitrati. L. In one dram, four grains of nitrated quicksilver.
Unguentum citrinum. E. In one dram, four grains of nitrated quicksilver.
Unguentum calcis hydrargyri albæ. L. In one dram, four grains and two-thirds of the calx hydrargyri alba.
Tinctura opii (L.) is made with opium, in the proportion of one grain to about thirteen of the menstruum.
Tinctura Thebaica (E.) is made with opium, in the proportion of one grain to twelve of the menstruum.
Tinctura opii camphorata (L.) is made with opium, in the proportion of one grain to two hundred and sixty of the menstruum.
Elixir paregoricum (E.) is made with opium, in the proportion of one grain to sixty-eight of the menstruum.
Balsamum anodynum (E.) is made with opium, in the proportion of one grain to about thirty of the menstruum.

Preparations and Compositions.

INDEX.

Pharos. PHAROS, (Homer, Strabo, &c.), a ſmall oblong iſland, adjoining to the continent of Egypt, over-againſt Alexandria. On this iſland ſtood a cognominal light-tower, of four ſides, each ſide a ſtadium in length; and the tower ſo high as to be ſeen 100 miles off. Some affirm, each of its four corners reſted on a large ſea-crab of glaſs or of hard tranſparent ſtone of Ethiopia or Memphis. Others imagine the crabs were only added externally to the baſe by way of ornament, or as emblematical of its ſituation and uſe. The architect was Soſtrates the Cnidian, as appears by an inſcription on the tower, under Ptolemy Philadelphus, who laid out 800 talents upon it. On account of the port of Alexandria, the entrance to which was difficult and dangerous, the Pharos was called *the key of the Egyptian ſea*, or even of Egypt itſelf (Lucan): and Pharos, from being a proper name, is become an appellative to denote all light-houſes.

Pharos. PHAROS, or *Phare*, a light-houſe; a pile raiſed near a port, where fire is kept burning in the night, to guide and direct veſſels near at hand. The pharos of Alexandria, built in the iſland of Pharos, at the mouth of the Nile, was anciently very famous, inſomuch as to communicate its name to all the reſt. This moſt magnificent tower conſiſted of ſeveral ſtories and galleries, with a lantern at top, in which a light being continually burning, might be ſeen for many leagues at ſea, and along the coaſt. It was accounted one of the ſeven wonders of the world. It was built by the famed architect Soſtrates, a native of Cnidos, or, according to ſome, by Deiphanes, the father of Soſtrates; and coſt Ptolemy Philadelphus 800 talents. The ſeveral ſtories were adorned with columns, balluſtrades, galleries of the fineſt marble and workmanſhip; to which ſome add, that the architect had contrived to faſten ſome looking-glaſſes ſo artificially againſt the higheſt galleries,

Pharpar, Pharfalia. galleries, that one could ſee in them all the ſhips that failed on the ſea for a great way. Inſtead of which noble ſtructure, one ſees now only a kind of irregular caſtle, without ditches or outworks of any ſtrength, the whole being accommodated to the inequality of the ground on which it ſtands, and which it ſeems is no higher than that which it ſhould command. Out of the midſt of this clumſy building riſes a tower, which ſerves for a light-houſe, but which hath nothing of the beauty and grandeur of the old one. The Coloſſus of Rhodes alſo ſerved as a pharos.

PHARPAR, or PHARPHAR, is one of the rivers of Damaſcus, or rather it is an arm of the Barrady or Chryſorrhoas, which waters the city of Damaſcus and the country about it (2 Kings v. 12.) "Are not Abana and Pharpar, rivers of Damaſcus, better than all the waters of Iſrael?" The river of Damaſcus has its fountain in the mountains of Libanus. At its approach to the city it is divided into three arms, one of which paſſes through Damaſcus. The other two water the gardens round about, and then reuniting, they loſe themſelves at four or five leagues from the city, towards the north. See *Maundrell's Travels from Aleppo to Jeruſalem*; ſee alſo the articles ABANA and DAMASCUS.

PHARSALIA, PHARSALIUM, *Pharſalus*, or *Pharſalos*, (anc. geog.), a town of the Phthiotis, a diſtrict of Theſſaly, near Pheræ and Lariſſa, to which laſt place Pompey fled from the plains of Pharſalus; watered by the river Enipeus, which falls into the Apidanus, and both together into the Peneus. Between Pharſalus and Enipeus, Pompey drew up his men at the fatal battle of Pharſalia.

In this battle, the advantage with reſpect to numbers was greatly on the ſide of Pompey. That general himſelf was on the left with the two legions which Cæſar had returned to him at the beginning of the war. Scipio, Pompey's father-in-law, was in the centre, with the legions he had brought from Syria, and the reinforcements ſent by ſeveral kings and ſtates of Aſia. The Cilician legion, and ſome cohorts which had ſerved in Spain, were in the right, under the command of Afranius. As Pompey's right wing was covered by the Enipeus, he ſtrengthened the left with his ſlingers, archers, and the 7000 Roman horſe, on whom chiefly his party founded their hopes of victory. The whole army was drawn up in three lines, with very little ſpaces between them. In conformity to this diſpoſition, Cæſar's army was drawn up in the following order: The tenth legion, which had on all occaſions ſignalized themſelves above all the reſt, was placed in the right wing, and the ninth in the left; but as the latter had been conſiderably weakened in the action at Dyrrhachium, the eighth legion was poſted ſo near it as to be able to ſupport and reinforce it upon occaſion. The reſt of Cæſar's forces filled up the ſpace between the two wings. Marc Antony commanded the left wing, Sylla the right, and Cneius Domitius Calvinus the main body. As for Cæſar, he poſted himſelf in the right over-againſt Pompey, that he might have him always in his ſight.

Thus was the whole plain covered, from Pharſalia to the Enipeus, with two armies, dreſſed and armed after the ſame manner, and bearing the ſame enſigns, the Roman eagles. Pompey obſerving how well the enemy kept their ranks, expecting quietly the ſign of battle, and on the contrary how impatient and unſteady his own men were, running up and down in great diſorder for want of experience, he began to be afraid leſt his ranks ſhould be broken upon the firſt onſet; and therefore commanded the foot in the front to keep their ground, and quietly wait for the enemy. The two armies, though within reach of each other, kept a mournful ſilence; but at length the trumpets ſounded the charge, and Cæſar's army advanced in good order to begin the attack, being encouraged by the example of one Caius Craſtinus, a centurion, who at the head of 120 men threw himſelf upon the enemy's firſt line with incredible fury. This he did to acquit himſelf of a promiſe he had ſolemnly made to Cæſar, who, meeting him as he was going out of his tent in the morning, aſked him, after ſome diſcourſe, *What his opinion was touching the event of the battle?* To which he, ſtretching out his hand, replied aloud, *Thine is the victory, Cæſar; thou ſhalt gloriouſly conquer, and I myſelf this day will be the ſubject of thy praiſe either dead or alive.* In purſuance of this promiſe he broke out of his rank as ſoon as the trumpet ſounded; and, at the head of his company, ran in upon the enemy, and made a great ſlaughter of them. But while he was ſtill preſſing forward, forcing his way through the firſt line, one of Pompey's men ran him in at the mouth with ſuch violence, that the point of his ſword came out at the hind part of his neck. Upon his death Pompey's ſoldiers took courage, and with great bravery ſtood the enemy's onſet. While the foot were thus ſharply engaged in the centre, Pompey's horſe in the left wing marched up confidently; and having firſt widened their ranks, with a deſign to ſurround Cæſar's right wing, charged his cavalry, and forced them to give ground. Hereupon Cæſar ordered his horſe to retreat a little, and give way to the ſix cohorts, which he had poſted in the rear as a body of reſerve. Theſe, upon a ſignal given, coming up, charged the enemy's horſe with that reſolution and good order which is peculiar to men who have ſpent all their lives in camps. They remembered their inſtructions, not ſtriking at the legs or thighs of the enemy, but aiming only at their faces. This unexpected and new manner of fighting had the deſired effect. For the young patricians, whom Cæſar contemptuouſly calls the *pretty young dancers*, not being able to bear the thoughts of having their faces deformed with ſcars, turned their backs, and, covering their faces with their hands, fled in the utmoſt confuſion, leaving the foot at the mercy of the enemy. Cæſar's men did not purſue the fugitives; but charging the foot of that wing, now naked and unguarded, ſurrounded them, and cut moſt of them in pieces. Pharſalia.

Pompey was ſo tranſported with rage, in ſeeing the flower of his forces thus put to flight or cut in pieces, that he left his army, and retired ſlowly towards his camp, looking more like a man diſtracted and beſide himſelf than one who by his exploits had acquired the name of *the Great*. When he had reached the camp, he retired to his tent without ſpeaking a word to any; and continued there, like one diſtracted and out of his ſenſes, till his whole army was defeated: Cæſar no ſooner ſaw himſelf maſter of the field than

Pharſalia. he marched to attack the enemy's entrenchments, that Pompey might not have time to recollect himſelf. When Pompey was informed that his rival was advancing to attack his entrenchments, he then firſt ſeemed to have recovered his ſenſes, and cried out, *What, into my camp too!* He ſaid no more; but immediately laying aſide the marks of his dignity, and putting on ſuch a garment as might beſt favour his flight, he ſtole out at the decuman gate, and took the road to Lariſſa, which city had hitherto ſhown great attachment to him. In the mean time Cæſar began the attack on the enemy's camp, which was vigorouſly defended by the cohorts Pompey had left to guard it; but they were at length forced to yield. Cæſar was not a little ſurpriſed, when, after having forced the entrenchments, he found the enemy's tents and pavilions richly adorned with carpets and hangings, their couches ſtrewed with flowers, their tables ready ſpread, and ſideboards ſet out with abundance of plate, bowls, and glaſſes, and ſome of them even filled with wine. So great was the confidence of Pompey's party, that they made preparations before-hand for pleaſures to be enjoyed after the victory, which they thought certain. In Pompey's tent, Cæſar found the box in which he kept his letters: but, with a moderation and magnanimity worthy of himſelf, he burnt them all, without reading one; ſaying, that he had rather be ignorant of crimes, than obliged to puniſh them.

The next day, when the dead were numbered, it appeared that Cæſar had ſcarce loſt 200 men; among whom was about 30 centurions, whom Cæſar cauſed to be buried with great ſolemnity. He did particular honours to the body of Craſtinus, who had begun the battle; and ordered his aſhes to be depoſited in a tomb, which he erected to his memory. On Pompey's ſide, the number of the dead amounted to 15,000 according to ſome, and to 25,000 according to others. Cæſar took 24,000 priſoners, eight eagles, and 180 enſigns.

PHARSALIA, an epic poem, compoſed by Lucan on the civil war between Pompey and Cæſar, and particularly on the victory of the latter over the former, of which we have given an account in the preceding article. It is a poem univerſally acknowledged to have great beauties and great defects; but we are the leſs capable of eſtimating its merit as a whole, that either time has deprived us of the laſt books, or its author has left it incomplete. "The ſubject of the Pharſalia (ſays an excellent critic) carries undoubtedly all the epic grandeur and dignity: neither does it want unity of object, viz. the triumph of Cæſar over the Roman liberty. In the choice of that ſubject, he thinks, however, that the author was not happy. The civil wars were too recent to admit in the deſcription of them the embelliſhments of fiction and machinery. The fables of the gods mixed with the exploits of Cæſar and Pompey, inſtead of raiſing, would have diminiſhed, the dignity of ſuch well known facts." Another objection to the ſubject, perhaps more forcible than this, ariſes from the ſucceſs of the war and the abilities of the generals. Lucan was a friend to liberty, and wiſhed to raiſe the character of Pompey and Cato; but in ſpite of his utmoſt efforts, they are always eclipſed by the ſuperior talents and conſequent ſucceſs of Cæſar. All his characters, however, are drawn with ſpirit, and with uncommon regard to truth; and ſome of the ſpeeches which he puts into the mouths of his heroes are equal for moral ſublimity to any thing that is to be found in all antiquity. Pharſalia II Ptolemæus.

Blair's Lectures.

"There are in the Pharſalia (continues the critic already quoted) ſeveral very poetical and ſpirited deſcriptions. But the author's chief ſtrength does not lie either in narration or deſcription. His narration is often dry and harſh; his deſcriptions are often overwrought, and employed too upon diſagreeable objects. His principal merit conſiſts in his ſentiments, which are generally noble and ſtriking, and expreſſed in that glowing and ardent manner which peculiarly diſtinguiſhes him. Lucan is the moſt philoſophical and the moſt public-ſpirited poet of all antiquity. He was the nephew of the famous Seneca the philoſopher; was himſelf a Stoic; and the ſpirit of that philoſophy breathes throughout his poem. We muſt obſerve, too, that he is the only ancient epic poet whom the ſubject of his poem really and deeply intereſted. Lucan recounted no fiction. He was a Roman, and had felt all the direful effects of the Roman civil wars, and of that ſevere deſpotiſm which ſucceeded the loſs of liberty. His high and bold ſpirit made him enter deeply into this ſubject, and kindle, on many occaſions, into the moſt real warmth. Hence, he abounds in exclamations and apoſtrophes, which are almoſt always well timed, and ſupported with a vivacity and fire that do him no ſmall honour.

"But it is the fate of this poet, that his beauties can never be mentioned, without their ſuggeſting his blemiſhes alſo. As his principal excellency is a lively and glowing genius, which appears ſometimes in his deſcriptions, and very often in his ſentiments, his great defect in both is want of moderation. He carries every thing to an extreme. He knows not where to ſtop. From an effort to aggrandiſe his objects, he becomes tumid and unnatural: and it frequently happens, that where the ſecond line of one of his deſcriptions is ſublime, the third, in which he meant to riſe ſtill higher, is perfectly bombaſt. Lucan lived in an age when the ſchools of the declaimers had begun to corrupt the eloquence and taſte of Rome. He was not free from the infection; and too often, inſtead of ſhowing the genius of the poet, betrays the ſpirit of the declaimer; but he is, on the whole, an author of lively and original genius."

PHARUS, in botany: A genus of the hexandria order, belonging to the monœcia claſs of plants; and in the natural method ranking under the fourth order, *Gramina*. The male calyx is a bivalved uniflorous glume; the corolla, a bivalved glume; the female calyx the ſame with the male; the corolla an uniflorous, long, and wrapping glume. There is but one ſeed.

PHARYNX, in anatomy. See there, p. 708, 709.

PHASCUM, in botany: A genus of the order of muſci, belonging to the cryptogamia claſs of plants. The anthera is operculated, with a ciliated mouth; the calyptræ are minute.

PHASEOLUS, the KIDNEY-BEAN; a genus of the decandria order, belonging to the diadelphia claſs of plants. There is only one ſpecies; but of this there are many varieties. Thoſe principally cultivated for the table are, 1. The common white, or Dutch kidney-

Phaſeolus. bean. 2. The ſmaller kidney-bean, commonly called the *Batterſea kidney-bean*. And, 3. The upright ſort, called the *tree kidney-bean*.

1. The firſt ſort was ſome time ago propagated in England, and is ſtill in Holland; it grows very tall, and requires long ſtakes and poles to climb on, and its beans are conſiderably broad: this makes them leſs ſaleable in the markets, people ſuppoſing them to be old becauſe they are broad; and they are hence grown into diſuſe, though a much more valuable kind for eating than any other.

2. The ſecond ſort, or Batterſea bean, is what is more univerſally cultivated: it never grows very tall, nor rambles far, and the air can eaſily paſs between the rows, becauſe of its moderate growth; and this makes it bear plentifully, and ripen well for the table. It is the beſt taſted bean, except the laſt.

3. The third, or tree kidney-bean, is alſo a plentiful bearer, and never rambles, but grows up in form of a ſhrub; but its beans are broader than the Batterſea kind, and are not ſo well taſted.

They are all propagated from ſeeds, which are to be put into the ground in the latter end of March or beginning of April for an early crop: but theſe ſhould have a warm ſituation and a dry ſoil; they muſt alſo be planted in a dry ſeaſon. The manner of planting them is, to draw lines with a bough over the bed, at two feet and a half diſtance, into which the ſeeds are to be dropped at about two inches aſunder; and the earth is to be drawn over them with the head of a rake, to cover them about an inch deep. In a week after ſowing, the plants will appear, and the earth ſhould be drawn up about their ſtalks as they riſe up; for a few days after this they will require no further care, except to be kept clear from weeds, and, when the beans appear, to have them gathered twice a-week; for if the beans are ſuffered to hang on too long, they not only become of no value, but they weaken the plant. The firſt crop of kidney-beans will continue a month in good order; and, to ſupply the table afterwards, there ſhould be freſh ſowings in March, April, May, and June; the laſt of which will continue till the froſts come to deſtroy them. Some raiſe their early crops on hot-beds; and this is to be done exactly in the ſame manner as the raiſing the early cucumbers.

A new ſpecies of phaſeolus, apparently a very uſeful one, has been diſcovered by M. Moraney, "an inhabitant of Morne Rouge, dependant on the Cape;" we ſuppoſe Cape François of the iſland of St Domingo. In his ſearch for plants, ſubſervient to his collection of inſects for the king's cabinet, he was overtaken by night, and he paſſed it in a cave, to which he had recourſe for ſhelter. At its extremity he found beds of foſſils, broken pieces of burnt earthen-ware, ſome tools and other things, which ſhowed that this cave had formerly been the habitation of the natives. Near it he ſaw a climbing plant attached to ſome trees, with cluſters of dry pods hanging from it. Theſe he gathered, and on his return ſowed the ſeed. Some months after, the plants grew tall and ſtrong: they appeared to reſemble a phaſeolus known at Perpignan by the name of *caraquèla*, and in the ſuperb portfolios of the king by that of *phaſeolus Indicus, cochleato flore*, which produced many roots, not unlike the manioc. On examining the root after the pods were ripe, he found from three to eight roots of this kind. The force of the vegetation was wonderful; but dreading the deleterious effects of recent manioc, he did not taſte them, but ſubjected them to a chemical analyſis, which proved nothing. After boiling them in water a little ſalted, he ventured to taſte them, and found them moiſt, unctuous, and ſaccharine, not unlike potatoes. He made, after ſome hours trial, very good caſſava with them, without being incommoded by the diſagreeable fibres which are met with in the manioc during this operation. Since that time, biſcuit and bread have been made from theſe roots by M. Lombart counſellor at the Cape. The plant has been found to be very common in the woods. It requires no peculiar management: its roots are in ſeaſon when the pods blacken, and its fibres run in every direction, ſearching for nouriſhment through the clefts of rocks, and receiving the impreſſion of the ſtrata without injury. If the principal root is left, the plant ſhoots again and flouriſhes as before; but it is not yet aſcertained whether it puts forth any new roots. The ſeeds are not alimentary when dreſſed, as if nature deſigned them only for propagating other plants. Every uſe which a farinaceous plant can ſupply, this new phaſeolus has ſucceſsfully anſwered; and the ſeeds in the hands of Meſſrs Heretier and Thouin will probably furniſh a ſufficient quantity for curioſity as well as uſe.

Phaſeolus ‖ Phaſianus.

PHASES, in aſtronomy, from the Greek word φαινω, "to appear;" the ſeveral appearances or quantities of illumination of the moon, Venus, Mercury, and the other planets. See ASTRONOMY.

PHASGA, or PISGAH, (Moſes), a mountain on the other ſide Jordan, joined to Abarim and Nebo, and running ſouth to the mouth of the Arnon: from which Moſes had a view of the promiſed land, and where he died, having before appointed Joſhua his ſucceſſor. Wells takes Piſgah and Nebo to be different names of one and the ſame mountain, a part or branch of the mountains Abarim, (Deut. xxxii. 49. compared with Deut. xxxiv. 1.) Or that the top of Nebo was peculiarly called *Piſgah*; or ſome other part of it, cut out in ſteps, as the primitive word denotes: and thus it is rendered by Aquila, by a Greek word ſignifying *cut out* (Jerome). There was alſo a city of this name, *id.*; and the adjoining country was in like manner called *Piſgah*, id.

PHASIANUS, in ornithology, a genus belonging to the order of gallinæ. The cheeks are covered with a ſmooth naked ſkin.

Gibbons, in his Roman Hiſtory, tells us, that the name *Phaſianus* is derived from the river PHASIS, the banks of which is the native habitation of the pheaſant. See PHASIS.

1. The gallus, or common dunghill cock and hen, with a compreſſed caruncle or fleſhy comb on the top of the head, and a couple of carunoles or wattles under the chin. The ears are naked, and the tail is compreſſed and erected. Of all other birds, perhaps this ſpecies affords the greateſt number of varieties; there being ſcarce two to be found that exactly reſemble each other in plumage and form. The tail, which makes ſuch a beautiful figure in the generality of theſe birds, is yet found entirely wanting in others; and not only Dunghill cock.

Phaſianus. the tail, but the rump alſo. The toes, which are uſually four in all animals of the poultry kind, yet in a ſpecies of the cock are found to amount to five. The feathers, which lie ſo ſleek and in ſuch beautiful order in moſt of thoſe we are acquainted with, are in a peculiar breed all inverted, and ſtand ſtaring the wrong way. Nay, there is a ſpecies that comes from Japan, which inſtead of feathers ſeems to be covered over with hair.

It is not well aſcertained when the cock was firſt made domeſtic in Europe; but it is generally agreed that we firſt had him in our weſtern world from the kingdom of Perſia. Ariſtophanes calls the cock the *Perſian bird;* and tells us he enjoyed that kingdom before ſome of its earlieſt monarchs. This animal was in fact known ſo early even in the moſt ſavage parts of Europe, that we are told the cock was one of the forbidden foods among the ancient Britons. Indeed, the domeſtic fowl ſeems to have baniſhed the wild one. Perſia itſelf, that firſt introduced it to our acquaintance, ſeems no longer to know it in its natural form; and if we did not find it wild in ſome of the woods of India, as well as thoſe of the iſlands in the Indian ocean, we might begin to doubt, as has been done with regard to ſheep, in what form it firſt exiſted in a ſtate of nature. But the cock is ſtill found in the iſlands of Pinian, in many others of the Indian ocean, and in the woods on the coaſt of Malabar, in its ancient ſtate of independence. In his wild condition, his plumage is black and yellow, and his comb and wattles yellow and purple. There is another peculiarity alſo in thoſe of the Indian woods; their bones, which, when boiled, with us are white, as every body knows, in thoſe are as black as ebony.

In their firſt propagation in Europe, there were diſtinctions then that now ſubſiſt no longer. The ancients eſteemed thoſe fowls whoſe plumage was reddiſh as invaluable; but as for the white, it was conſidered as utterly unfit for domeſtic purpoſes. Theſe they regarded as ſubject to become a prey to rapacious birds; and Ariſtotle thinks them leſs fruitful than the former. Indeed, his diviſion of thoſe birds ſeems taken from their culinary uſes: the one ſort he calls *generous and noble*, being remarkable for fecundity; the other ſort, *ignoble and uſeleſs*, from their ſterility. Theſe diſtinctions differ widely from our modern notions of generoſity in this animal: that which we call the *game-cock* being by no means ſo fruitful as the ungenerous dunghill cock, which we treat with contempt. The Athenians had their cock-matches as well as we; but it is probable they did not enter into our refinement of chooſing out the moſt barren of the ſpecies for the purpoſes of combat.

However this be, no animal in the world has greater courage than the cock when oppoſed to one of his own ſpecies; and in every part of the world where refinement and poliſhed manners have not entirely taken place, cock fighting is a principal diverſion. In China, India, the Philippine iſlands, and all over the Eaſt, cock-fighting is the ſport and amuſement even of kings and princes. With us it is declining every day; and it is to be hoped it will in time become only the paſtime of the loweſt vulgar. See the article *Cock pit*.

The cock claps his wings before he ſings or crows. His ſight is very piercing; and he never fails to cry in a peculiar manner, when he diſcovers any bird of prey in the air. His extraordinary courage is thought to proceed from his being the moſt ſalacious of all other birds whatſoever. A ſingle cock ſuffices for ten or a dozen hens; and it is ſaid of him that he is the only animal whoſe ſpirits are not abated by indulgence. But then he ſoon grows old; the radical moiſture is exhauſted; and in three or four years he becomes utterly unfit for the purpoſes of impregnation. "Hens alſo (to uſe the words of Willoughby), as they for the greateſt part of the year daily lay eggs, cannot ſuffice for ſo many births, but for the moſt part after three years become effete and barren: for when they have exhauſted all their ſeed-eggs, of which they had but a certain quantity from the beginning, they muſt neceſſarily ceaſe to lay, there being no new ones generated within." Phaſianus. Domeſtic hen.

The hen ſeldom clutches a brood of chickens above once a ſeaſon, though inſtances have been known in which they produced two. The number of eggs a domeſtic hen will lay in the year are above 200, provided ſhe be well fed and ſupplied with water and liberty. It matters not much whether ſhe be trodden by the cock or no; ſhe will continue to lay, although the eggs of this kind can never by hatching be brought to produce a living animal. Her neſt is made without any care, if left to herſelf; a hole ſcratched into the ground, among a few buſhes, is the only preparation ſhe makes for this ſeaſon of patient expectation. Nature, almoſt exhauſted by its own fecundity, ſeems to inform her of the proper time for hatching, which ſhe herſelf teſtifies by a clucking note, and by diſcontinuing to lay. The good houſewives, who often get more by their hens laying than by their chickens, often artificially protract this clucking ſeaſon, and ſometimes entirely remove it. As ſoon as a hen begins to cluck, they ſtint her in her proviſions; which, if that fails, they plunge her into cold water; this, for the time, effectually puts back her hatching; but then it often kills the poor bird, who takes cold and dies under the operation.

If left entirely to herſelf, the hen would ſeldom lay above 20 eggs in the ſame neſt, without attempting to hatch them: but in proportion as ſhe lays, her eggs are removed; and ſhe continues to lay, vainly hoping to increaſe the number. In the wild ſtate, the hen ſeldom lays above 15 eggs; but then her proviſion is more difficultly obtained, and ſhe is perhaps ſenſible of the difficulty of maintaining too numerous a family.

When the hen begins to ſit, nothing can exceed her perſeverance and patience; ſhe continues for ſome days immoveable; and when forced away by the importunities of hunger, ſhe quickly returns. Sometimes alſo her eggs become too hot for her to bear, eſpecially if ſhe be furniſhed with too warm a neſt within doors, for then ſhe is obliged to leave them to cool a little: thus the warmth of the neſt only retards incubation, and often puts the brood a day or two back in the ſhell. While the hen ſits, ſhe carefully turns her eggs, and even removes them to different ſituations; till a length, in about three weeks, the young brood begin to give ſigns of a deſire to burſt their confinement. When by the repeated efforts of their bill, which ſerves like a pioneer on this occaſion, they have broke themſelves a paſſage through the ſhell, the hen ſtill continues to ſit till

Phaſianus. till all are excluded. The ſtrongeſt and beſt chickens generally are the firſt candidates for liberty; the weakeſt come behind, and ſome even die in the ſhell. When all are produced, ſhe then leads them forth to provide for themſelves. Her affection and her pride ſeem then to alter her very nature, and correct her imperfections. No longer voracious or cowardly, ſhe abſtains from all food that her young can ſwallow, and flies boldly at every creature that ſhe thinks is likely to do them miſchief. Whatever the invading animal be, ſhe boldly attacks him; the horſe, the hog, or the maſtiff. When marching at the head of her little troop, ſhe acts the commander; and has a variety of notes to call her numerous train to their food, or to warn them of approaching danger. Upon one of theſe occaſions, the whole brood have been ſeen to run for ſecurity into the thickeſt part of an hedge, while the hen herſelf ventured boldly forth, and faced a fox that came for plunder.

Ten or twelve chickens are the greateſt number that a good hen can rear and clutch at a time; but as this bears no proportion to the number of her eggs, ſchemes have been imagined to clutch all the eggs of an hen, and thus turn her produce to the greateſt advantage. By theſe contrivances it has been obtained, that a hen that ordinarily produces but 12 chickens in the year, is found to produce as many chickens as eggs, and conſequently often above 200. This contrivance is the artificial method of HATCHING chickens in ſtoves, as is practiſed at Grand Cairo; or in a chemical laboratory properly graduated, as has been effected by Mr Reaumur. At Grand Cairo, they thus produce 6000 or 7000 chickens at a time; where, as they are brought forth in their mild ſpring, which is warmer than our ſummer, the young ones thrive without clutching. But it is otherwiſe in our colder and unequal climate: the little animal may without much difficulty be hatched from the ſhell, but they almoſt all periſh when excluded. To remedy this, Reaumur has made uſe of a woollen hen, as he calls it; which was nothing more than putting the young ones in a warm baſket, and clapping over them a thick woollen canopy.

Capons may very eaſily be caught to clutch a freſh brood of chickens throughout the year; ſo that when one little colony is thus reared, another may be brought to ſucceed it. Nothing is more common than to ſee capons thus employed; and the manner of teaching them is this: Firſt the capon is made very tame, ſo as to feed from one's hand; then, about evening, they pluck the feathers off his breaſt, and rub the bare ſkin with nettles; they then put the chickens to him, which preſently run under his breaſt and belly, and probably rubbing his bare ſkin gently with their heads, allay the ſtinging pain which the nettles had juſt produced. This is repeated for two or three nights, till the animal takes an affection to the chickens that have thus given him relief, and continues to give them the protection they ſeek for: perhaps alſo the querulous voice of the chickens may be pleaſant to him in miſery, and invite him to ſuccour the diſtreſſed. He from that time brings up a brood of chickens like a hen, clutching them, feeding them, clucking, and performing all the functions of the tendereſt parent. A capon once accuſtomed to this ſervice, will not give over; but when one brood is grown up, he may have another nearly hatched put under him, which he will treat with the ſame tenderneſs he did the former. Phaſianus.

The cock, from his ſalaciouſneſs, is allowed to be a ſhort-lived animal; but how long theſe birds live, if left to themſelves, is not yet well aſcertained by any hiſtorian. As they are kept only for profit, and in a few years become unfit for generation, there are few that, from mere motives of curioſity, will make the tedious experiment of maintaining a proper number till they die. Aldrovandus hints their age to be 10 years; and it is probable that this may be its extent. They are ſubject to ſome diſorders; and as for poiſons, beſides nux vomica, which is fatal to moſt animals except man, they are injured, as Linnæus aſſerts, by elderberries; of which they are not a little fond.

Of this ſpecies Mr Latham enumerates no leſs than 13 varieties, beginning with the wild cock, which is a third leſs in the body than the domeſtic cock. This variety he imagines to be the original ſtock from whence all our domeſtic varieties have ſprung. They appear to be natives of the foreſts of India. There are but few places, however, as Mr Latham goes on to obſerve, where the different voyagers have not met with cocks and hens, either wild or tame; and mention has been particularly made of finding them at St Jago, Pulo Condore, Iſle of Timor, Philippine and Moluccа Iſles, Sumatra and Java, New Guinea, Tinian, and moſt of the iſles of the South Seas.—Thoſe of Pulo Condore are very much like our own, but conſiderably leſs, being only of the ſize of a crow. The cocks crow like ours, but their voices are much more ſmall and ſhrill.—*Damp. Voy.* vol. i. p. 392.—Two wild ones were ſhot there by our laſt voyagers.—*Ellis's Narr* ii. p 340. Thoſe of Sumatra and Java are remarkably large, and are called the *St Jago breed*. The cock is ſo tall as to peck off a common dining-table. When fatigued, he ſits down on the firſt joint of the leg; and is then taller than the common fowls. *Hiſt. Sumatr.* p. 98. They are found in New Guinea, but not in great plenty.—*Forr. Voy.* p. 105. The fowls which were met with wild at Tinian "were run down without much trouble, as they could ſcarce fly farther than 100 yards at a flight."—*Anſon's Voy.* p. 416. Forſter obſerves, that they are plenty at Eaſter, Society, and Friendly Iſles: at the two laſt they are of a prodigious ſize. They are not uncommon at the Marqueſas, Hebrides, and New Caledonia; but the Low Iſles are quite deſtitute of them.—See *Obſ.* p. 193.——Ducks and poultry are numerous in the Sandwich Iſles.—*Cook's Journal*, p. 229. In reſpect to Europe, little need be ſaid, as varieties without end are everywhere ſeen, and their manners fully known to every one. It is obſerved, however, that they breed moſt freely in the warmer ſituations. In the very cold regions, though they will live and thrive, they ceaſe to multiply. They are not found to breed in the northern parts of Siberia; and in Groenland are only kept as rarities.—*Faun. Groen.* On the whole, it ſeems quite unneceſſary to enlarge further on a ſubject well known to every body. They are ſo common, that every one who wiſhes to become acquainted with their nature and manners, has the means of ſuch knowledge in his power. Thoſe who wiſh for minuter deſcriptions, we muſt refer to the authors Latham's Synopſis.

Phaſianus. who have profeſſedly written on the ſubject; for the varieties which we have already mentioned, we refer to Mr Latham.

Pheaſants. 2. The motmot, or Guinea pheaſant, is browniſh, ſomewhat red below, with a wedge-like tail, and wants ſpurs. 3. The colchicus is red, with a blue head, a wedge-ſhaped tail, and papillous cheeks. It is a native of Africa and Aſia. 4. The argus is yellowiſh, with black ſpots, a red face, and a blue creſt on the back part of the head. It is found in Chineſe Tartary. 5. The pictus has a yellowiſh creſt, a red breaſt, and a wedge-ſhaped tail. It is a native of China. 6. The necthemerus is white, with a black creſt and belly, and a wedge-ſhaped tail. It is a native of China.

Mr Latham enumerates nine different ſpecies of pheaſants, and of the common pheaſant he reckons ſix varieties. The firſt which he deſcribes is the ſuperb pheaſant. This bird Linnæus deſcribed from the various repreſentations of it painted on paper-hangings and China-ware; and farther confirmed by a figure and deſcription in a Chineſe book which came under his inſpection.

Latham's Syneſis. "We have lately ſeen (ſays Latham) a drawing of the tail feather of a bird of the pheaſant kind, which meaſured above ſix feet in length, and which, it is probable, muſt have belonged to ſome bird not hitherto come to our knowledge. The drawing is in the poſſeſſion of Major Davies, who took it from the original feather; two of which were in the poſſeſſion of a gentleman of his acquaintance, and were brought from China. They are exactly in ſhape of the two middle feathers of the painted pheaſant; the general colour is that of a fine blue grey, margined on the ſides with a rufous cream-colour, and marked on each ſide the ſhaft with numerous bars of black; between 70 and 80 bars in all; thoſe on the oppoſite ſides of the ſhaft ſeldom correſponding with each other.

"The argus, though it be a native of China, is very commonly found in the woods of Sumatra, where it is called *coo-ow*. It is found extremely difficult to be kept alive for any conſiderable time after catching it in the woods; never for more than a month. It ſeems to have an antipathy to the light, being quite inanimate in the open day; but when kept in a dark place, it appears perfectly at eaſe, and ſometimes makes its note or call, from which it takes its name; and which is rather plaintive, and not harſh like that of a peacock. The fleſh reſembles that of the common pheaſant."

Mr Latham obſerves, that the common pheaſant is now found in a ſtate of nature in almoſt the whole of the Old Continent. They ſometimes (he ſays) come into farm yards near woods, and produce croſs breeds with common hens. He then ſays, "M. Salerne remarks, that the hen-pheaſant, when done laying and ſitting, will get the plumage of the male, and after that become ſo little reſpected by him, as to be treated with the ſame incivility as he would ſhow to one of his own ſex. He mentions this as a new obſervation; but it is far more common than may be generally ſuppoſed, and had been long before mentioned by Edwards, who gave for example one kept in the menagery of the duke of Leeds; and remarks, that this change is moſt likely to happen when in a confined ſtate. The circumſtance of the hen acquiring the plumage of the cock after a certain time is not confined to the pheaſant: the inſtance of the pea-hen belonging to Lady Tynte, now in the Leverian Muſeum, evinces the contrary, which, after having many broods, got much of the fine plumage of the cock, with the addition even of the fine train feathers. The female alſo of the rock manakin is ſaid to get the plumage of the oppoſite ſex after a number of years; and perhaps, if obſerved hereafter, this may be found to be the caſe with many other ſpecies. A gentleman of my acquaintance (continues our author), dead long ſince, who uſed to keep theſe birds for his amuſement, obſerved the ſame to me: and the ingenious Mr J. Hunter has a well drawn up paper in the Philoſophical Tranſactions * to the ſame purport; but, in addition to this, I am well informed, that it does not always require mature age to give the hen-pheaſant the appearance of the male, as ſometimes young birds will be adorned with his fine plumage. I will not ſay how this happens, and whether it may be peculiar to this ſpecies to grow barren (if that be the reaſon) ſooner than any other of the gallinaceous tribe; but I am aſſured that ſeveral of theſe ſpurleſs, cock-like hens, have proved on eating to be young birds, from their juicineſs and delicacy of flavour." Phaſianus.

* Vol. lxx. p. 527.

One of the varieties which our author remarks under this ſpecies, he calls the *Hybridal pheaſant*, which is a mixed breed between the pheaſant and cock; one of which is in the Leverian Muſeum. The two laſt ſpecies which our author deſcribes, is the parraka and courier.

The parraka is about the ſize of a ſmall fowl, reſembling it in the bill, legs, and body. Its length is 23 inches. The colour of the bill is dark rufous; the eyes are brown; the general colour of the plumage is a deep brown on the back, and fulvous under the belly: the top of the head is fulvous, and the feathers are ſomewhat long, but not ſo much as to form a real creſt; the wings are ſhort; the webs of ſome of the quills are ſomewhat rufous; the tail conſiſts of 12 feathers, is even at the end, about a foot in length, and is, for the moſt part, carried pendent; the legs are of a dark rufous, inclining to black; the claws are like thoſe of a fowl.

"It is peculiar (ſays Mr Latham) in its internal ſtructure in reſpect to the windpipe; which, inſtead of entering directly the breaſt, as in moſt birds, paſſes over the ſide of the left clavicle, and on the outſide of the fleſhy part of the breaſt, being covered only by the ſkin, then taking a turn upwards, paſſes over the right clavicle into the breaſt, and is diſtributed through the lungs in the uſual way. The female has not this circumvolution of the windpipe. The hannequaw, mentioned by Bancroft, is probably the ſame bird. He ſays that it is black, rooſts in trees, and may be heard early in the morning, diſtinctly, but hoarſely, repeating the word *hannequaw* (eaſily miſtaken for parrequaw) very loud. Theſe are found in the unfrequented woods of the internal parts of Cayenne, Guiana, and many parts of South America. At ſun-riſe they ſet up a very loud cry, which is thought to be the loudeſt of all birds in the new world; at which time the eyes appear red, as does a ſmall ſkin under the breaſt, which is not at all ſeen, except when the bird

Phaſianus. bird makes ſuch exertions, or is angry. This cry is very like the word parraquaw; and is repeated many times together: and often many cry at once, or anſwer one another, but moſt in breeding-time, which is twice in the year; at each time laying from four to ſix eggs; making the neſt in low branches or ſtumps of trees, and behaving with their chickens in the ſame manner as hens. They feed on grain, ſeeds, and herbs; but feed the young in the neſt with worms and ſmall inſects. Theſe, with many other birds, inhabit the woods by day, coming out into the open ſavannas morning and evening to feed; at which times they are chiefly killed by the natives and near inhabitants. They may be brought up tame; and their fleſh is much eſteemed.

"The courier pheaſant is but very imperfectly deſcribed by Fernandez; and is ſaid to be 18 inches long. The general colour of the plumage is white, inclined to fulvous; about the tail they are black, mixed with ſome ſpots of white; the tail itſelf is long, and of a green colour, reflecting in ſome lights like the feathers of a peacock: the wings are ſhort. This ſpecies inhabits the hotter parts of Mexico; flies ſlow; but is recorded to outrun the ſwifteſt horſe*."

* *Hiſt. des Ois.*

Pheaſants were originally brought into Europe from the banks of the Phaſis, a river of Colchis, in Aſia Minor; and from whence they ſtill retain their name. Next to the peacock, they are the moſt beautiful of birds, as well for the vivid colour of their plumes as for their happy mixtures and variety. It is far beyond the power of the pencil to draw any thing ſo gloſſy, ſo bright, or points ſo finely blending into each other. We are told, that when Crœſus, king of Lydia, was ſeated on his throne, adorned with royal magnificence and all the barbarous pomp of eaſtern ſplendor, he aſked Solon if he had ever beheld any thing ſo fine? The Greek philoſopher, no way moved by the objects before him, or taking a pride in his native ſimplicity, replied, That after having ſeen the beautiful plumage of the pheaſant, he could be aſtoniſhed at no other finery.

Theſe birds, tho' ſo beautiful to the eye, are not leſs delicate when ſerved up to the table. Their fleſh is conſidered as the greateſt dainty; and when the old phyſicians ſpoke of the wholeſomeneſs of any viands, they made their compariſon with the fleſh of the pheaſant. However, notwithſtanding all theſe perfections to tempt the curioſity or the palate, the pheaſant has multiplied in its wild ſtate. Phaſianus.

A ſpirit of independence ſeems to attend the pheaſant even in captivity. In the woods, the hen-pheaſant lays from 18 to 20 eggs in a ſeaſon; but in a domeſtic ſtate, ſhe ſeldom lays above 10. In the ſame manner, when wild, ſhe hatches and leads up her brood with patience, vigilance, and courage; but when kept tame, ſhe never ſits well, ſo that a hen is generally her ſubſtitute upon ſuch occaſions: and as for leading her young to their food, ſhe is utterly ignorant of where it is to be found; and the young birds ſtarve, if left ſolely to her protection. The pheaſant, therefore, on every account, ſeems better left at large in the woods than reclaimed to priſtine captivity. Its fecundity when wild is ſufficient to ſtock the foreſt; its beautiful plumage adorns it; and its fleſh retains a higher flavour from its unlimited freedom.

However, it has been the aim of late to take theſe birds once more from the woods, and to keep them in places fitted for their reception. Like all others of the poultry kind, they have no great ſagacity, and ſuffer themſelves eaſily to be taken. At night they rooſt upon the higheſt trees of the wood; and by day they come down into the lower brakes and buſhes, where their food is chiefly found. They generally make a kind of flapping noiſe when they are with the females; and this often appriſes the ſportſman (A) of their retreats. At other times he traces them in the ſnow, and frequently takes them in ſprings. But of all birds they are ſhot moſt eaſily; as they always make a whirring noiſe when they riſe, by which they alarm the gunner, and being a large mark, and flying very ſlow, there is ſcarce any miſſing them.

When theſe birds are taken young into keeping, they become as familiar as chickens: and when they are deſigned for breeding, they are put together in a yard,

(A) Pheaſants may be taken in a variety of ways. One method is, to be well acquainted with their haunts and breeding-places; which are generally young, thick, and well-grown coppices, free from the diſturbances of cattle, and without a path-way through them; for they are timorous birds. When their haunts are diſcovered, it will next be neceſſary to find out where the brood is. And here it is to be remarked, that pheaſants come out of the wood three times a-day to feed in green corn, freſh paſtures, or ſuch like places. The times of coming out are in the morning ſoon after ſunriſe, at noon, and at ſunſet. The ſides of the wood where they may be ſuppoſed to come out ought then to be carefully watched, and the young ones will be ſeen following the female as a flock of chickens follow the hen. The wood ought alſo to be watched in the evenings, when the noiſe of the cock and hen calling the young ones together will ſoon be heard; and the ſportſman muſt then endeavour to get as near as he can to the place; and being very ſtill and ſilent, he may obſerve their numbers and diſpoſition, and learn how to ſpread his nets ſo as moſt eaſily to take the whole brood; but if by the leaſt motion they diſcover him, they will all take to their legs, and run to a great diſtance; for they ſeldom riſe on the wing, except when very cloſe frighted. By practice ſome people have become able to imitate the voice of the old pheaſant, ſo as to be able to call the young ones together to any place that he pleaſes, when the haunts are once found out, and by this means they are eaſily led into the nets.—The beſt time for uſing this call is in the morning or evening; and the note imitated ſhould be that by which they are called out to feed; indeed, by learning to imitate the other notes, they may be brought together at any time of the day. The ſportſman who can make this call, muſt ſhelter himſelf in ſome cloſe place, and begin very ſoftly at firſt; then, if none are near enough to be within hearing, he is gradually to raiſe it louder and louder, and at length he will be anſwered as loud, if any are within hearing, though at a conſiderable diſtance;

Phaſianus. yard, five hens to a cock; for this bird, like all of the poultry kind, is very ſalacious. In her natural ſtate the female makes her neſt of dry graſs and leaves: the ſame muſt be laid for her in the pheaſantry, and ſhe herſelf will ſometimes properly diſpoſe them. If ſhe refuſes to hatch her eggs, then a common hen muſt be got to ſupply her place, which taſk ſhe will perform with perſeverance and ſucceſs. The young ones are very difficult to be reared (B); and they muſt be ſupplied with ants eggs, which is the food the old one leads them to gather when wild in the woods. To make theſe go the further, they are to be chopped up with curds or other meat; and the young ones are to be fed with great exactneſs, both as to the quantity and the time of their ſupply. This food is ſometimes alſo to be varied; and wood lice, earwigs, and other inſects, are to make a variety. The place where they are reared muſt be kept extremely clean; their water muſt be changed twice or thrice a-day; they muſt not be expoſed till the dew is off the ground in the morning, and they ſhould always be taken in before ſunſet. When they become adult, they very well can ſhift for themſelves; but they are particularly fond of oats and barley.

In order to increaſe the breed, and make it ſtill more valuable, Longolius teaches us a method that appears very peculiar. The pheaſant is a very bold bird when firſt brought into the yard among other poultry, not ſparing the peacock, nor even ſuch young cocks and hens as it can maſter; but after a time it will live tamely among them, and will at laſt be brought to couple with a common hen. The breed thus produced take much ſtronger after the pheaſant than the hen; and in a few ſucceſſions, if they be let to breed with the cock-pheaſant (for the mixture is not barren), there will be produced a ſpecies more tame, ſtronger, and more prolific; ſo that he adds, that it is ſtrange why moſt of our pheaſandries are not ſtocked with birds produced in this manner. Phaſianus.

The pheaſant, when full grown, ſeems to feed indifferently upon every thing that offers. It is ſaid by a French writer, that one of the king's ſportſmen ſhooting at a parcel of crows that were gathered round a dead carcaſe, to his great ſurpriſe, upon coming up, found that he had killed as many pheaſants as crows. It is even aſſerted by ſome, that ſuch is the carnivorous diſpoſition of this bird, that when ſeveral of them are put together in the ſame yard, it one of them

---

ſtance; whereas, if he ſhould ſet up the call too loud at firſt, and any of the birds ſhould happen to be very near, they would be frighted away.

When a pheaſant anſwers, the ſportſman is to creep nearer and nearer, ſtill calling, though not ſo loud; and he will ſtill be anſwered, till at length he will be led by the bird's voice within ſight of it. Then he is to ſpread his net, and to begin to call again, keeping in ſome cloſe and well ſheltered place behind the net: in this place he is to call till the bird approaches; and when he has drawn it under the net, he is to appear ſuddenly, and the bird, riſing up, will thus be caught.

There is another method of taking pheaſants much quicker than that we have juſt deſcribed, viz. the having a live cock pheaſant to uſe as a ſtale: this bird is to be fixed under the net, and by his crowing he will ſoon entice others in. The ſportſman muſt lie concealed; and when another pheaſant comes in, he is to draw the net over him. Many people take pheaſants in ſpringes or horſe hair ſnares: to ſucceed in this, it will be neceſſary to be careful in ſearching out their haunts, and the places by which they go out of the woods into the fields. When theſe are diſcovered, a peg muſt be fixed in the ground at each, and at each peg two ſpringes muſt be laid open; the one to take in the legs, the other the head. When the ſpringes are ſet, the ſportſman muſt go into the woods, and get behind the birds in order to fright them with ſome little noiſe, ſuch as ſhall not be enough to raiſe them to the wing, but only to ſet them a-running. They will naturally make their way out of the wood, through their accuſtomed paſſes, and be then caught in the ſpringes.

There is another method of taking theſe birds in winter, provided there be no ſnow. This muſt be done with a net made in the form of a caſting net, but with wider meſhes; they may indeed be five inches wide. Some peas or wheat are to be taken out; and the path of the pheaſants being diſcovered, which may eaſily be done by their dung, a pint or thereabout of corn is to be thrown down in the path in a place marked, ſo that the ſportſman can come to it again. This muſt be done for ſome days, till at length the pheaſants will expect it every day regularly; and all of them that frequent the place are brought together to feed there, and then the net is to be fixed over the place; its top being tied up to ſome bough of a tree, and its bottom fixed down all around, except in one place, where the walk of the pheaſants lies. In this place it muſt be raiſed in the form of an arch, and the entrance muſt be lined with ſeveral rods of hazel; the thick ends of which are to be tied to the net, and the thin ones let into the ſpace covered by it; and thus the pheaſants will eaſily get in by parting the ſmall ends of the ſticks, as fiſh into a wheel, but they will not eaſily get out again. The nets are to be dyed of a ruſſet colour, by laying them in a tan-pit; and they muſt, when planted for this purpoſe, be covered with boughs, ſo that the birds do not diſcover them, and then they will eaſily run into them, and be all taken at once.

(B) The pheaſant is ſo nearly allied to our common poultry that this aſſertion may appear odd: it is nevertheleſs true; and the principal cauſe may be, that their proper food is not known, or not ſufficiently inquired into. They feed voraciouſly on ants and various other inſects; and it is ſaid, that when the mulineſs of corn or want of cleanneſs in their apartments has made them ſick, a repaſt of ants has recovered them. When theſe fail, milipedes and earwigs together anſwer as an excellent medicine, along with their common food (corn), which muſt be very ſweet and clean. Theſe birds are very ſullen, and when coupling time is over, they are ſeldom found more than one in a place.

Phaſis || Phaſſachates.

them happens to fall ſick, or ſeems to be pining, all the reſt will fall upon, kill, and devour it. Such is the language of books; thoſe who have frequent opportunities of examining the manners of the bird itſelf, know what credit ought to be given to ſuch an account.

PHASIS, a river which falls into the Euxine ſea about 700 miles from Conſtantinople. "From the Iberian Caucaſus (ſays Gibbon), the moſt lofty and craggy mountains of Aſia, that river deſcends with ſuch oblique vehemence, that in a ſhort ſpace it is traverſed by 120 bridges. Nor does the ſtream become placid and navigable till it reaches the town of Sarapana, five days journey from the Cyrus, which flows from the ſame hills, but in a contrary direction, to the Caſpian lake. The proximity of theſe rivers has ſuggeſted the practice, or at leaſt the idea, of wafting the precious merchandiſe of India down the Oxus, over the Caſpian, up the Cyrus, and with the current of the Phaſis into the Euxine and Mediterranean ſeas. As it ſucceſſively collects the ſtreams of the plain of Colchos, the Phaſis moves with diminiſhed ſpeed, tho' accumulated weight. At the mouth it is 60 fathoms deep, and half a league broad; but a ſmall woody iſland is interpoſed in the midſt of the channel: the water, ſo ſoon as it has depoſited an earthy or metallic ſediment, floats on the ſurface of the waves, and is no longer ſuſceptible of corruption. In a courſe of 100 miles, 40 of which are navigable for large veſſels, the Phaſis divides the celebrated region of Colchos or Mingrelia, which, on three ſides, is fortified by the Iberian and Armenian mountains, and whoſe maritime coaſt extends about 200 miles, from the neighbourhood of Trebizond to Dioſcurias and the confines of Circaſſia. Both the ſoil and climate are relaxed by exceſſive moiſture: 28 rivers, beſides the Phaſis and his dependent ſtreams, convey their waters to the ſea; and the hollowneſs of the ground appears to indicate the ſubterraneous channels between the Euxine and the Caſpian."

Decline and Fall of the Roman Empire.

PHASMATA, in phyſiology, certain appearances ariſing from the various tinctures of the clouds by the rays of the heavenly bodies, eſpecially the ſun and moon. Theſe are infinitely diverſified by the different figures and ſituations of the clouds, and the appulſes of the rays of light; and, together with the occaſional flaſhings and ſhootings of different meteors, they have, no doubt, occaſioned thoſe prodigies of armies fighting in the air, &c. of which we have ſuch frequent accounts in moſt ſorts of writers. See 2 Maccab. xi. 8. Melanct. Meteor. 2 Shel. de Comet. ann. 1618.

Kircher and Schottus have erroneouſly attempted to explain the phenomenon from the reflection of terreſtrial objects made on opake and congealed clouds in the middle region of the air, which, according to them, have the effect of a mirror. Thus, according to theſe authors, the armies pretended by ſeveral hiſtorians to have been ſeen in the ſkies, were no other than the reflection of the like armies placed on ſome part of the earth. See Hiſt. Acad. Roy. Scienc. ann. 1726, p. 405, & ſeq.

PHASSACHATES, in natural hiſtory, the name of a ſpecies of agate, which the ancients, in its various appearances, ſometimes called *leucachates* and *peribucer*.

PHEASANT, in ornithology. See PHASIANUS. Pheaſant

PHEASANT's-eye, or Bird's-eye. See ADONIS.

PHEBE, a deaconeſs of the port of Corinth, called *Cenchrea*. St Paul had a particular eſteem for this holy woman; and Theodoret thinks the apoſtle lodged at her houſe for ſome time, while he continued in or near Corinth. It is thought ſhe brought to Rome the epiſtle he wrote to the Romans, wherein ſhe is commended and recommended in ſo advantageous a manner. He ſays (Rom. xvi. 1, 2.), "I commend unto you Phebe our ſiſter, which is a ſervant of the church which is at Cenchrea: that ye receive her in the Lord, as becometh ſaints, and that ye aſſiſt her in whatſoever buſineſs ſhe hath need of you; for ſhe hath been a ſuccourer of many, and of myſelf alſo." Some moderns have advanced a notion, that Phebe was wife to St Paul; but none of the ancients have ſaid any thing like it. It is thought, in quality of deaconeſs, ſhe was employed by the church in ſome miniſtrations ſuitable to her ſex and condition; as to viſit and inſtruct the Chriſtian women, to attend them in their ſickneſs, and diſtribute alms to them.

PHEGOR, or PEOR, a deity worſhipped at a very early period by the Midianites and Moabites, and probably by all the other tribes which then inhabited Syria. Much has been ſaid concerning the functions of this god, and the rank which he held among the Pagan divinities (ſee *BAAL-Peor*); and many conjectures have been formed concerning the origin of his name. Moſt of theſe ſeem to have no better foundation than the ſenſeleſs dreams of the Jewiſh rabbies. PHEGOR, or PEOR, is undoubtedly the ſame with the Hebrew word *pechor*, which ſignifies *aperuit*, and probably refers to the prophetic influence always attributed to the ſolar deity, by which he *opened* or *diſcovered* things to come. Accordingly we find PHEGOR or PEOR generally joined to *Baal*, which was the Syrian and Chaldean name of the ſun after he became an object of worſhip; hence *Baal-PHEGOR* muſt have been the ſun worſhipped by ſome particular rites, or under ſome particular character. What theſe were, a reſolution of *Pechor* into its component parts may perhaps inform us. As this word, wherever it occurs in Scripture, has ſome relation to diſtending or opening the mouth wide, it is probably compounded of PHAH the *mouth* or *face*, and EHAR *naked*. In thoſe countries we know that the women wore veils; but it would appear, that in celebrating the rites of this deity they were unveiled. It ſeems even not improbable, that on theſe occaſions the ſexes danced promiſcuouſly without their clothes; a practice which would naturally give birth to the licentious amours mentioned in the 25th chapter of the book of Numbers. If this be admitted, it will follow that *Phegor* was the ſun preſiding over the myſteries of Venus.

PHELLANDRIUM, WATER-HEMLOCK; a genus of the digynia order, belonging to the pentandria claſs of plants. There are two ſpecies, one of which, viz. the aquaticum, is a native of Britain. This grows in ditches and ponds, but is not very common. The ſtalk is remarkably thick and dichotomous, and grows in the water. It is a poiſon to horſes, bringing upon them, as Linnæus informs us, a kind of palſy; which, however, he ſuppoſes to be owing not ſo much to the noxious qualities of the plant itſelf, as to thoſe of an in-

Phellandrium.

Phengites || Pherecrates.

insect which feeds upon it, breeding within the stalks, and which he calls *curculio paraplectus*. The Swedes give swine's dung for the cure. The seeds are sometimes given in intermittent fevers, and the leaves are by some added to discutient cataplasms. In the winter, the roots and stem, dissected by the influence of the weather, afford a very curious skeleton or network. Horses, sheep, and goats, eat the plant; swine are not fond of it; cows refuse it.

PHENGITES, among the ancients, the name of a beautiful species of alabaster. It is a rude irregular mass, very shattery and friable, but of a brightness superior to that of most other marbles, and excelling them all in transparence. The colour is an agreeable pale, yellowish, white, or honey colour; the yellowish is more intense in some places than in others, and sometimes makes an obscure resemblance of veins. It is very weak and brittle in the mass; and when reduced to small pieces, may be easily crumbled between the fingers into loose, but considerably large angular pieces, some perfect, others complex, irregular, or mutilated, and all approaching to a flat shape. The ancients were very fond of this species in public buildings; and the Temple of Fortune, built entirely of it, has long been celebrated. Its great beauty is its transparence, from which alone this temple was perfectly light when the doors were shut, though it was built without a window, and had no other light but what was transmitted through the stone its walls were built with. It was anciently found in Cappadocia, and is still plentiful there: we have it also in Germany and France, and in our own kingdom in Derbyshire, and some other counties. It takes an excellent polish, and is very fit for ornamental works, where there is no great strength required. See Amethyst.

Hill's Hist. of Fossils, p. 490.

PHENICE, a port of the island of Crete, to the west of the island. St Paul having anchored at Phenice, when he was carried to Rome (Acts xxvii. 12.), advised the ship's-crew to spend the winter there, because the season was too far advanced.

PHENICIA. See Phoenicia.

PHEONS, in heraldry, the barbed heads of darts, arrows, or other weapons.

PHEOS, in botany, a name which Theophrastus, Dioscorides, and others, give to a plant used by fullers in dressing their cloths, and of which there were two kinds, a smaller called simply *pheos*, and a larger called *hippopheos*. This plant is sometimes called *phleos*; and is thus confounded with a kind of marsh cudweed, or *gnaphalium*, called also by that name; but it may always be discovered which of the two plants an author means, by observing the sense in which the word is used, and the use to which the plant was put. The *phleos*, properly so called, that is, the cudweed, was used to stuff beds and other such things, and to pack up with earthen vessels to prevent their breaking; but the pheos, improperly called *phleos*, only about cloths: this was, however, also called *flæbe* and *enaphon*.

PHERECRATES, a Greek comic poet, was contemporary with Plato and Aristophanes. After the example of the ancient comedians, who never introduced upon the theatre imaginary but living characters, he acted his contemporaries. But he did not abuse the liberty which at that time prevailed upon the stage; and laid it down as a rule to himself never to destroy the reputation of any person. Twenty-one comedies are attributed to him, of which there now only remain some fragments collected by Hertelius and Grotius. From these fragments, however, it is easy to discern, that Pherecrates wrote the purest Greek, and possessed that ingenious and delicate raillery which is called *attic urbanity*. He was author of a kind of verse called, from his own name, *Pherecratick*. The three last feet were in hexameter verse, and the first of those three feet was always a spondee. This verse of Horace (for example, *Quamvis pontica pinus*) is a Pherecratick verse. We find in Plutarch a fragment of this poet upon the music of the Greeks, which has been critically examined by M. Burette of the academy of inscriptions. See the 15th volume of the collection published by that learned society.

Pherecydes.

PHERECYDES, a native of Scyros, flourished about the year 560 before the Christian era, and was disciple of Pittacus, one of the seven wise men of Greece (see Pittacus). He is said to have been the first of all the philosophers who has written on natural subjects and the essence of the gods. He was also the first, it is said, who held the ridiculous opinion, "that animals are mere machines." He was Pythagoras's master, who loved him as his own father. This grateful scholar having heard that Pherecydes lay dangerously ill in the island of Delos, immediately repaired thither, in order to give every necessary assistance to the old man, and to take care that no means should be left untried for the recovery of his health. His great age, however, and the violence of his disease, having rendered every prescription ineffectual, his next care was to see him decently buried; and when he had paid the last duty to his remains, and erected a monument to his memory, he set out again for Italy. Other causes have been assigned for the death of Pherecydes: some say he was eaten up by lice, and others that he fell headlong from the top of Mount Corycius in his way to Delphos. He lived to the age of 85 years, and was one of the first prose writers among the Greeks.

"Marvellous circumstances have been related of him, which only deserve to be mentioned, in order to show that what has been deemed supernatural by ignorant spectators may be easily conceived to have happened from natural causes. A ship in full sail was at a distance approaching its harbour; Pherecydes predicted that it would never come into the haven, and it happened accordingly; for a storm arose which sunk the vessel. After drinking water from a well, he predicted an earthquake, which happened three days afterwards. It is easy to suppose that these predictions might have been the result of a careful observation of those phenomena which commonly precede storms or earthquakes in a climate where they frequently happen.

Enfield's History of Philosophy.

"It is difficult to give in any degree an accurate account of the doctrines of Pherecydes; both because he delivered them, after the manner of the times, under the concealment of symbols; and because very few memoirs of this philosopher remain. It is most probable that he taught those opinions concerning the gods and the origin of the world which the ancient Grecian theogonists borrowed from Egypt;" and of which the reader will find accounts in different arti-

Pheretima ‖ Phidias.

cles of this work. See EGYPT, METAPHYSICS, MYSTERIES, MYTHOLOGY, and POLYTHEISM.

PHERETIMA, was the wife of Battus king of Cyrene, and the mother of Arceſilaus. After her ſon's death, ſhe recovered the kingdom by means of Amaſis king of Egypt, and to avenge the murder of Arceſilaus, ſhe cauſed all his aſſaſſins to be crucified round the walls of Cyrene, and ſhe cut off the breaſts of their wives, and hung them up near the bodies of their huſbands. It is ſaid that ſhe was devoured alive by worms; a puniſhment which, according to ſome of the ancients, was inflicted by Providence for her unparalleled cruelties.

PHERON, was a king of Egypt, who ſucceeded Seſoſtris. He was blind; and he recovered his ſight by waſhing his eyes, according to the directions of the oracle, in the urine of a woman who had never had any unlawful connections. He tried his wife firſt, but ſhe appeared to have been faithleſs to his bed, and ſhe was burnt with all thoſe whoſe urine could not reſtore ſight to the king. He married the woman whoſe urine proved beneficial.

PHIAL, a well-known veſſel made of glaſs, uſed for various purpoſes.

Leyden PHIAL, is a phial of glaſs coated on both ſides with tin-foil for a conſiderable way up the ſides, of great uſe in electrical experiments. See ELECTRICITY, *paſſim*.

PHIDIAS, the moſt famous ſculptor of antiquity, was an Athenian, and a contemporary of the celebrated Pericles, who flouriſhed in the 83d Olympiad. This wonderful artiſt was not only conſummate in the uſe of his tools, but accompliſhed in thoſe ſciences and branches of knowledge which belong to his profeſſion, as hiſtory, poetry, fable, geometry, optics, &c. He firſt taught the Greeks to imitate nature perfectly in this way; and all his works were received with admiration. They were alſo incredibly numerous; for it was almoſt peculiar to Phidias, that he united the greateſt facility with the greateſt perfection. His Nemeſis was ranked among his firſt pieces: it was carved out of a block of marble, which was found in the camp of the Perſians after they were defeated in the plains of Marathon. He made an excellent ſtatue of Minerva for the Plateans; but the ſtatue of this goddeſs in her magnificent temple at Athens, of which there are ſtill ſome ruined remains, was an aſtoniſhing production of human art. Pericles, who had the care of this pompous edifice, gave orders to Phidias, whoſe prodigious talents he well knew, to make a ſtatue of the goddeſs; and Phidias formed a figure of ivory and gold 39 feet high. Writers never ſpeak of this illuſtrious monument of ſkill without raptures; yet what has rendered the name of the artiſt immortal, proved at that time his ruin. He had carved upon the ſhield of the goddeſs his own portrait and that of Pericles; and this was, by thoſe that envied them, made a crime in Phidias. He was alſo charged with embezzling part of the materials which were deſigned for the ſtatue. Upon this he withdrew to Elis, and revenged himſelf upon the ungrateful Athenians, by making for the Elians the Olympic Jupiter; a prodigy of art, and which was afterwards ranked among the ſeven wonders of the world. It was of ivory and gold; 60 feet high, and every way proportioned. "The majeſty of the work did equal the majeſty of the god (ſays Quintilian), and its beauty ſeems to have added luſtre to the religion of the country." Phidias concluded his labours with this maſterpiece; and the Elians, to do honour to his memory, erected, and appropriated to his deſcendants, an office, which conſiſted in keeping clean this magnificent image.

Phiditia ‖ Philadelphia.

PHIDITIA, in Grecian antiquity, feaſts celebrated with great frugality at Sparta. They were held in the public places and in the open air. Rich and poor aſſiſted at them equally, and on the ſame footing; their deſign being to keep up peace, friendſhip, good underſtanding, and equality among the citizens great and ſmall. It is ſaid that thoſe who attended this feaſt brought each a buſhel of flour, eight meaſures of wine named *chorus*, five mince of cheeſe, and as many figs.

PHILA, in mythology, one of the attributes of Venus, which diſtinguiſhes her as the mother of love, from φιλεω *to love*.

PHILADELPHIA, in antiquity, were games inſtituted at Sardis to celebrate the union of Caracalla and Geta, the ſons of Septimius Severus.

PHILADELPHIA, the capital of the ſtate of Penſylvania in North America, ſituated in W. Long. 75. 8. N. Lat. 39. 57. It is one of the moſt beautiful and regular cities in the world, being of an oblong form, ſituated on the weſt-bank of the river Delaware, on an extenſive plain, about 118 miles (ſome ſay more) from the ſea. The length of the city eaſt and weſt, that is, from the Delaware to the Schuylkill, upon the original plan of Mr Penn, is 10,300 feet, and the breadth, north and ſouth, is 4837 feet. Not two fifths of the plot covered by the city charter is yet built. The inhabitants, however, have not confined themſelves within the original limits of the city, but have built north and ſouth along the Delaware two miles in length. The longeſt ſtreet is Second-ſtreet, about 700 feet from Delaware river, and parallel to it. The circumference of that part of the city which is built, if we include Kenſington on the north and Southwark on the ſouth, may be about five miles. Market-ſtreet is 100 feet wide, and runs the whole length of the city from river to river. Near the middle, it is interſected at right angles by Broad-ſtreet, 113 feet wide, running nearly north and ſouth quite acroſs the city.

Between Delaware river and Broad-ſtreet are 14 ſtreets, nearly equidiſtant, running parallel with Broad-ſtreet acroſs the city; and between Broad-ſtreet and the Schuylkill, there are nine ſtreets equidiſtant from each other. Parallel to Market-ſtreet are eight other ſtreets, running eaſt and weſt from river to river, and interſect the croſs ſtreets at right angles; all theſe ſtreets are 50 feet wide, except Arch-ſtreet, which is 65 feet wide. All the ſtreets which run north and ſouth, except Broad-ſtreet mentioned above, are 50 feet wide. There were four ſquares of eight acres each, one at each corner of the city, originally reſerved for public and common uſes. And in the centre of the city, where Broad-ſtreet and Market-ſtreet interſect each other, is a ſquare of ten acres, reſerved in like manner, to be planted with rows of trees for public walks. This city was founded in 1682 by the celebrated

Philadelphia. lebrated William Penn, who in October 1701 granted a charter incorporating the town with city privileges. In 1749 the dwelling houſes were computed, and found to be 2076; in 1790, they amounted to 5000. They are in general handſomely built of brick; and contain 40,000 inhabitants, compoſed of almoſt all nations and religions. Their places for religious worſhip are as follow: The Friends or Quakers have five, the Preſbyterians ſix, the Epiſcopalians three, the German Lutherans two, the German Calviniſts one, the Catholics three, the Swediſh Lutherans one, the Moravians one, the Baptiſts one, the Univerſal Baptiſts one, the Methodiſts one, the Jews one.

The other public buildings in the city, beſides the univerſity, academies, &c. are the following, viz. a ſtate-houſe and offices, a city court-houſe, a county court-houſe, a carpenter's hall, a philoſophical ſociety's hall, a diſpenſary, an hoſpital and offices, an alms-houſe, a houſe of correction, a public factory of linen, cotton, and woollen, a public obſervatory, three brick market houſes, a fiſh-market, a public gaol.

The univerſity of Philadelphia was founded during the war. Its funds were partly given by the ſtate, and partly taken from the old college of Philadelphia. A medical ſchool, which was founded in 1765, is attached to the univerſity; and has profeſſors in all the branches of medicine, who prepare the ſtudents (whoſe number yearly is 50 or 60) for degrees in that ſcience. Beſides the univerſity and medical ſchool, there is the Proteſtant Epiſcopal academy, a very flouriſhing inſtitution; the academy for young ladies; another for the Friends or Quakers, and one for the Germans; beſides five free ſchools.

In Market-ſtreet, betweeen Front and Fourth ſtreets, is the principal market, built of brick, and is 1500 feet in length. This market, in reſpect to the quantity, the variety, and neatneſs of the proviſions, is not equalled in America, and perhaps not exceeded in the world.

The Philadelphians are not ſo ſocial, nor perhaps ſo hoſpitable, as the people in Boſton, Charleſtown, and New York. Various cauſes have contributed to this difference; among which the moſt operative has been the prevalence of party-ſpirit, which has been and is carried to greater lengths in this city than in any other in America; yet no city can boaſt of ſo many uſeful improvements in manufactures, in the mechanical arts, in the art of healing, and particularly in the ſcience of humanity. In ſhort, whether we conſider the convenient local ſituation, the ſize, the beauty, the variety and utility of the improvements, in mechanics, in agriculture, and manufactures, or the induſtry, the enterpriſe, the humanity, and the abilities, of the inhabitants of the city of Philadelphia, it merits to be viewed as the capital not only of the province, but of the flouriſhing empire of United America.

Several canals are let into the town, which add much to the beauty and convenience of the place. Its quay is 200 feet ſquare, to which ſhips of 400 or 500 tons may come up, and lay their broadſides cloſe to it; with wet and dry docks for building and repairing ſhips, beſides magazines, warehouſes, and all other conveniences for exporting and importing merchandize. Scarce any thing can appear more beautiful than the city and the adjacent country, which for ſome miles may be compared to a fine and flouriſhing garden. Philadelphia.

Though all our readers muſt unqueſtionably have heard of the malignant fever which ſo lately raged in Philadelphia, yet as ſome of them may not be ſo well acquainted with particulars, it will not, we truſt, be thought improper if we give a ſhort account of that dreadful malady in this place. This account we ſhall extract from a pamphlet written by Matthew Carey, which had run through no leſs than three editions before the end of the laſt year.

Of this fever, then, it is obſerved, that, generally ſpeaking, the mortality was not ſo great among women as among men, but that corpulent, high-fed, and drunken men, common proſtitutes, and ſuch of the poor as had been debilitated through the want of ſufficient nouriſhment, and lived in dirty and confined habitations, became an eaſy prey to it; whilſt thoſe who reſided in the ſuburbs, enjoying the benefit of country air, were little affected by it. A ſingular fact is, that the French reſiding in Philadelphia were in a remarkable degree exempt from it; a circumſtance which cannot be accounted for. The report which prevailed here of the Africans having wholly eſcaped the diſeaſe, proves to be not altogether true, ſeveral of them having been ſeized. The fever, however, was found to yield more readily to medicine in them than in white perſons.

We find the following account of the nature and ſymptoms of the diſeaſe, as deſcribed by Dr Currie, in the third edition of the pamphlet already mentioned. "The ſymptoms which characteriſed the firſt ſtage of the fever were, in the greateſt number of caſes, after a chilly fit of ſome duration, a quick tenſe pulſe; hot ſkin; pain in the head, back, and limbs; flushed countenance; inflamed eye, moiſt tongue; oppreſſion and ſenſe of ſoreneſs at the ſtomach, eſpecially upon preſſure; frequent ſick qualms, and retchings to vomit, without diſcharging any thing, except the contents laſt taken into the ſtomach; coſtiveneſs, &c. And when ſtools were procured, the firſt generally ſhowed a defect of bile, or an obſtruction to its entrance into the inteſtines. But briſk purges generally altered this appearance.

"Theſe ſymptoms generally continued with more or leſs violence from one to three, four, or even five days; and then gradually abating, left the patient free from every complaint, except general debility. On the febrile ſymptoms ſuddenly ſubſiding, they were immediately ſucceeded by a yellow tinge in the opaque cornea, or whites of the eyes; an increaſed oppreſſion at the præcordia, a conſtant puking of every thing taken into the ſtomach, with much ſtraining, accompanied with a hoarſe hollow noiſe.

"If theſe ſymptoms were not ſoon relieved, a vomiting of matter reſembling coffee-grounds in colour and conſiſtence, commonly called the *black vomit*, ſometimes accompanied with or ſucceeded by hemorrhagies from the noſe, fauces, gums, and other parts of the body; a yellowiſh purple colour, and putreſcent appearance of the whole body, hiccup, agitations, deep and diſtreſſed ſighing, comatoſe delirium, and finally death, are the conſequence. When the diſeaſe proved fatal, it was generally between the fifth and eighth days.

"This was the moſt uſual progreſs of this formidable

Philadelphia.

midable diſeaſe through its ſeveral ſtages. There were, however, very conſiderable variations in the ſymptoms as well as in the duration of its different ſtages, according to the conſtitution and temperament of the patient, the ſtate of the weather, the manner of treatment, &c.

"In ſome caſes, ſigns of putreſcency appeared at the beginning or before the end of the third day. In theſe, the black vomiting, which was generally a mortal ſymptom, and univerſal yellowneſs, appeared early. In theſe caſes, alſo, a low delirium, and great proſtration of ſtrength, were conſtant ſymptoms, and coma came on very ſpeedily.

"In ſome, the ſymptoms inclined more to the nervous than the inflammatory type. In theſe, the jaundice colour of the eye and ſkin, and the black vomiting, were more rare. But in the majority of caſes, particularly after the nights became ſenſibly cooler, all the ſymptoms indicated violent irritation and inflammatory diatheſis. In theſe caſes, the ſkin was always dry, and the remiſſions very obſcure.

"The febrile ſymptoms, however, as has been already obſerved, either gave way on the third, fourth, or fifth day, and then the patient recovered; or they were ſoon after ſucceeded by a different but much more dangerous train of ſymptoms, by debility, low pulſe, cold ſkin (which aſſumed a tawny colour, mixed with purple), black vomiting, hemorrhagies, hiccup, anxiety, reſtleſſneſs, coma, &c. Many who ſurvived the eighth day, though apparently out of danger, died ſuddenly in conſequence of an hemorrhagy."

Purging the patient with calomel and jalap appears to have proved the moſt ſucceſsful treatment; and the repeated uſe of the lancet, in caſes where no ſymptoms of putridity exiſted. Dr Griffits, who had been ſeized with the diſeaſe, "was bled ſeven times in five days, and aſcribes his recovery principally to that operation." Dr Maeſe alſo, "in five days, loſt 72 ounces of blood, by which he was recovered when at the loweſt ſtage of the diſorder." It was generally remarked that an obſtinate coſtiveneſs took place at the commencement of the diſeaſe; and when this was removed, by purgatives, within the firſt twelve hours, the patient ſeldom failed to do well.

The work concludes with a liſt of the committee for the relief of the ſick, of which our author was a member: alſo the names of a large number of the inhabitants who were cut off, a ſeries of meteorological tables, and a general account of burials during the prevalence of this fatal complaint. From the latter we extract the following account:

"Auguſt - -	325
"September - -	1442
"October - -	1993
"November - -	118
"Jews, returned in groſs -	3
"Baptiſts, do. -	60
"Methodiſts, do. -	32
"Free Quakers, do. -	39
"German part of St Mary's congregation	30
Total	4042"

It is not difficult to conceive the general diſtreſs which ſuch an evil muſt have occaſioned to perſons of every rank and deſcription. Some of the moſt ſtriking inſtances our author has related in very affecting terms; but no picture of human calamity perhaps ever exceeded the following: "A ſervant girl belonging to a family in this city, in which the fever had prevailed, was apprehenſive of danger, and reſolved to remove to a relation's houſe in the country. She was, however, taken ſick on the road, and returned to town, where ſhe could find no perſon to receive her. One of the guardians of the poor provided a cart, and took her to the alms-houſe, into which ſhe was refuſed admittance. She was brought back, and the guardian offered five dollars to procure her a ſingle night's lodgeing, but in vain. And in fine, after every effort made to provide her ſhelter, ſhe abſolutely expired in the cart."

Philadelphia.

We cannot diſmiſs the preſent article, though it has already extended to a ſufficient length, without giving our readers an account of a very extraordinary people who live within 50 miles of Philadelphia; where there is a little town or colony, particularly remarkable on account of its origin and the manners of the people by whom it is inhabited. It was founded by a German, who, weary of the world, returned into the country that he might be more at liberty to give himſelf up to contemplation. Curioſity brought ſeveral of his countrymen to viſit his retreat; and by degrees his pious, ſimple, and peaceable manners, induced them to ſettle near him; when they all formed a little colony, which they called *Euphrates*, in alluſion to the Hebrews, who uſed to ſing pſalms on the borders of that river.

This little town forms a triangle, the outſides of which are bordered with mulberry and apple-trees planted with great regularity; and its inhabitants, we know not for what reaſon, are called *Dumplers*. In the middle of the town is a very large orchard, and between the orchard and thoſe ranges of trees are houſes built of wood, three ſtories high, where every Dumpler is left to enjoy the pleaſures of his meditation without diſturbance. Theſe contemplative men do not amount to above 500; and the extent of their territory is about 250 acres, bounded by a river, a piece of ſtagnated water, and a mountain covered with trees.

The men and women live in ſeparate quarters of the town, and never ſee each other but at places of worſhip; for among the Dumplers there are no aſſemblies of any kind but for public buſineſs. Their lives are ſpent in labour, prayer, and ſleep. Twice every day and night they are called forth from their cells to attend divine ſervice. Like the Methodiſts and Quakers, every individual among them has the right of preaching when he thinks himſelf inſpired. The favourite ſubjects on which they diſcourſe in their aſſemblies, are humility, temperance, chaſtity, and the other Chriſtian virtues. They never violate that day of repoſe which all orders of men, whether idle or luxurious, much delight in. They admit a hell and a paradiſe; but reject the eternity of future puniſhments. They abhor the doctrine of original ſin as an impious blaſphemy; and, in general, every tenet that is ſevere to men appears to them injurious to the Divinity. As they do not allow merit to any but voluntary works, they adminiſter baptiſm only to the adult; at the ſame time, they think baptiſm ſo eſſentially neceſſary to ſalvation, that they imagine the ſouls of Chriſtians

Philadelphia

ſtians in another world are employed in converting thoſe who have not died under the law of the Goſpel. In this ridiculous opinion we have known Chriſtians of other denominations, and who boaſted a higher antiquity, that agreed with them.

Still more diſintereſted than the Quakers, they never enter into any law-ſuit. One may cheat, rob, and abuſe them, without being expoſed to any retaliation, or even to any complaint from them. On them religion has the ſame effect that philoſophy had upon the Stoics: it makes them inſenſible to every kind of inſult

Nothing can be plainer than their dreſs. In winter it is a long white gown, from which there hangs a hood, which ſerves inſtead of a hat, a coarſe ſhirt, thick ſhoes, and very wide breeches. The women are dreſſed very much like the men, except that they have no breeches. Their common food conſiſts wholly of vegetables; not becauſe it is unlawful to eat any other, but becauſe that kind of abſtinence is looked upon as more conformable to the ſpirit of Chriſtianity, which has an averſion from blood.

Each individual follows with cheerfulneſs the branch of buſineſs allotted him; and the produce of all their labours is depoſited in a common ſtock, for the uſe of the whole. This union of induſtry has not only eſtabliſhed agriculture, manufactures, and all the arts neceſſary for the ſupport of this little ſociety, but hath alſo ſupplied, for the purpoſes of exchange, ſuperfluities proportioned to the degree of its population.

Though the two ſexes live ſeparate at Euphrates, the Dumplers do not on that account fooliſhly renounce matrimony; but thoſe who find themſelves diſpoſed to it, leave the town, and form an eſtabliſhment in the country, which is ſupported at the public expence. They repay this by the produce of their labours, which is all thrown into the public treaſury; and their children are ſent to be educated in Euphrates, which they conſider as their mother-country.—Without this wiſe privilege, the Dumplers would be no better than monks; and in proceſs of time they would become either ſavages or libertines. They are at preſent an innocent, though perhaps deluded, race.

PHILADELPHIA, an ancient town of Turkey in Aſia, in Natolia. It is ſeated at the foot of mount Tmolus, by the river Cogamus, from whence there is an exceeding fine view over an extenſive plain. This place was founded by Attalus Philadelphus, brother of Eumenes.

It was very liable to earthquakes, which, perhaps, aroſe from its vicinity to the region called *Catakekanmene*. So ſevere were thoſe earthquakes, that even the city walls were not ſecure; and ſo frequent were they, that theſe experienced daily concuſſions. The inhabitants, therefore, who were not numerous, lived in perpetual apprehenſion, and their conſtant employment was in repairs. In fact, ſo great were their fears, that their chief reſidence was in the country, the ſoil of which was very fertile. Such is Strabo's account of this place. In the year 1097, it was taken by aſſault by John Ducas the Greek general. It was without difficulty reduced alſo in the year 1106, under the ſame emperor. The Turks marched from the Eaſt with a deſign to plunder it and the maritime towns The Emperor Manuel, in 1175, retired for protection from the Turks to this place. In 1300 it fell by lot to Karaman. In 1306 it was beſieged by Aliſaras, and conſiderably haraſſed; but was not taken. In 1391, this place alone refuſed to admit Bajazet; but it was at length forced to capitulate for want of proviſions. It has been matter of ſurpriſe that this town was not totally abandoned; and yet it has ſurvived many cities leſs liable to inconveniences, and is ſtill an extenſive place, tho' in its appearance it is poor and mean. Some remnants of its walls are ſtill ſtanding, but with large gaps. The materials of the wall are ſmall ſtones ſtrongly cemented. It is thick, lofty, and has round towers. Near this place, between the mountains, there is a ſpring of a purgative quality; it is much eſteemed, and many people reſort to it in the hot months. It taſtes like ink, is clear, but tinges the earth with the colour of ochre. The famous wall which credulity has aſſected to be made of human bones, ſtands beyond this and beyond the town. See the next article.

Philadelphia

When Dr Chandler was there, he tells us, "The biſhop of Philadelphia was abſent; but the proto papas or chief-prieſt, his ſubſtitute, whom we went to viſit, received us at his palace, a title given to a very indifferent houſe or rather a cottage of clay. We found him ignorant of the Greek tongue, and were forced to diſcourſe with him by an interpreter in the Turkiſh language. He had no idea that Philadelphia exiſted before Chriſtianity, but told us it had become a city in conſequence of the many religious foundations. The number of churches he reckoned at 24, moſtly in ruins, and mere maſſes of wall decorated with painted ſaints. Only ſix are in a better condition, and have their prieſts. The epiſcopal church is large, and ornamented with gilding, carving, and holy portraits. The Greeks are about 300 families, and live in a friendly intercourſe with the Turks, of whom they ſpeak well. We were aſſured that the clergy and laity in general knew as little of Greek as the proto-papas; and yet the liturgies and offices of the church are read as elſewhere, and have undergone no alteration on that account. *Travels in Greece.*

"The Philadelphians are a civil people. One of the Greeks ſent us a ſmall earthen veſſel full of choice wine. Some families beneath the trees, by a rill of water, invited us to alight, and partake of their refreſhments. They ſaluted us when we met; and the aga or governor, on hearing that we were Franks, bade us welcome by a meſſenger.

"Philadelphia poſſeſſing waters excellent in dying, and being ſituated on one of the moſt capital roads to Smyrna, is much frequented, eſpecially by Armenian merchants. The Greeks ſtill call this place by its ancient name, but the Turks call it *Allahijur*. The number of inhabitants are about 7000 or 8000; of whom 2000 are ſuppoſed to be Chriſtians. It is about 40 miles E. S. E. of Smyrna. E. Long. 28. 15. N. Lat. 38. 28.

PHILADELPHIA-Stones, a name which ſome authors have given to what is otherwiſe called *Chriſtian bones*, found in the walls of that city. It is a vulgar error that theſe walls are built of bones; and the tradition of the country is, that when the Turks took the place, they fortified it for themſelves, and built their walls

of

Philadelphia. Philadelphus.

of the bones of the Chriſtians whom they had killed there. Dr Smyth, in one of his epiſtles, mentions this wall as an inſtance of Turkiſh barbarity. This idle opinion has gained credit merely from a looſe and porous ſtone of the ſparry kind, found in an old aqueduct, which is ſtill in the wall. Sir Paul Rycaut brought home pieces of theſe ſtones, which even he ſuppoſed to have been bones, but they proved on examination to be various bodies, chiefly vegetable, incruſted over and preſerved in a ſpar of the nature of that which forms incruſtations in Knareſborough ſpring, and other places with us. Theſe bodies are often cemented together in conſiderable numbers by this matter, and their true ſhape loſt in the congeries, till a diligent and judicious eye traces them regularly.

Philadelphian ſociety, in eccleſiaſtical hiſtory, an obſcure and inconſiderable ſociety of myſtics. They were formed about the end of the laſt century by an Engliſh female fanatic, whoſe name was *Jane Leadley*. This woman, ſeduced by her viſions, predictions, and doctrines, ſeveral diſciples, among whom were perſons of learning. She believed that all diſſenſions among Chriſtians would ceaſe, and the kingdom of the Redeemer become a ſcene of charity and felicity, if Chriſtians, diſregarding the forms of doctrine or diſcipline of their ſeveral communions, would all join in committing their ſouls to the care of the internal guide, to be inſtructed, governed, and formed, by his divine impulſe and ſuggeſtions. But ſhe went farther than this: ſhe even pretended a divine commiſſion to proclaim the approach of this glorious communion of ſaints; and was convinced that the ſociety eſtabliſhed by herſelf was the true kingdom of Chriſt. One of her leading doctrines was, that of the final reſtoration of all intelligent beings to perfection and happineſs.

PHILADELPHUS, in antiquity, was a title or ſurname borne by ſeveral ancient kings; formed from the Greek φιλος, "friend, lover," and αδελφος, "brother;" *q. d.* one who loves his brother or brethren. See Ptolemy and Egypt.

Philadelphus, the Pipe-tree, or *Mock orange*; a genus of the monogynia order, belonging to the icoſandria claſs of plants.

Species 1. The coronarius, white ſyringe, or mock-orange, has been long cultivated in the gardens of this country as a flowering ſhrub; it is not well known in what country it is to be found native. It riſes ſeven or eight feet high; ſending up a great number of ſlender ſtalks from the root. Theſe have a grey bark, branch out from their ſides, and are garniſhed with oval ſpear-ſhaped leaves. Theſe laſt have deep indentures on their edges; their upper ſurface being of a deep green, but the under ſurface pale, with the taſte of a freſh cucumber. The flowers are white, and come out from the ſides and at the ends of the branches in looſe bunches, each ſtanding on a diſtinct foot-ſtalk: they have four oval petals, which ſpread open, with a great number of ſtamina within, ſurrounding the ſtyle.

Diſt. of Planting and Gardening.

This ſhrub by its flowers makes a fine figure in May and June; for they are produced in cluſters both at the end and from the ſides of the branches. They are of a fine white colour, and exceedingly fragrant. The petals of which each is compoſed are large, and ſpread open like thoſe of the orange; and then forming branches, which ſtand each on its own ſeparate ſhort foot-ſtalk, and being produced in plenty all over the ſhrub, both at once teaſt the eye and the ſmell: The eye, by the pleaſing appearance it will then have; the ſmell, as the air at ſome diſtance will be replete with the odoriferous particles conſtantly emitted from thoſe fragrant flowers. Theſe flowers, however, are very improper for chimneys, water-glaſſes, &c. in rooms; for in thoſe places their ſcent will be too ſtrong; and for the ladies in particular, often too powerful. Philadelphus.

The double-flowering ſyringa, is a low variety of this ſpecies, ſeldom riſing to more than a yard high. The deſcription of the other belongs to this ſort, except that the leaves and branches are proportionally ſmaller and more numerous, and the bark of the ſhoots of a lighter brown. It is called the *Double flowering ſyringa*, becauſe it ſometimes produces a flower or two with three or four rows of petals; whereas, in general, the flowers, which are very few, and ſeldom produced, are ſingle. They are much ſmaller than thoſe of the other; and you will not ſee a flower of any kind on this ſhrub oftener perhaps than once in five years. It is hardly worth propagating on this account; ſo that a few plants only ought to be admitted into a collection, to be ready for obſervation.

The dwarf ſyringa is ſtill of lower growth than the other, ſeldom ariſing to more than two feet in height. The deſcription of the firſt ſort ſtill agrees with this; only that the branches and leaves are ſtill proportionally ſmaller and more numerous, and the bark is ſtill of a lighter brown. It never produces flowers.

2. The nanus, with oval leaves ſomewhat indented, and double flowers, ſeldom riſes above three feet high; the flowers come out ſingly from the ſides of the branches, and have a double or treble row of petals of the ſame ſize and form as well as the ſame ſcent with the former; but this ſort flowers very rarely, ſo is but little eſteemed.

3. The inodorus, with entire leaves, is a native of Carolina, and as yet but little known in Europe. It riſes with a ſhrubby ſtalk of about 16 feet in height, ſending out ſlender branches from the ſides oppoſite, garniſhed with ſmooth leaves ſharped like thoſe of the pear-tree, and ſtanding on pretty long foot-ſtalks. The flowers are produced at the ends of the branches; and are large, white, ſpreading open, with a great number of ſhort ſtamina with yellow ſummits. This is called the *Carolina ſyringa*, is the talleſt grower by far of any ſort of the ſyringa, and makes the grandeſt ſhow when in blow; though the flowers are deſtitute of ſmell.

The propagation of all the ſorts is very eaſy: They are increaſed by layers, cuttings, or ſuckers. 1. The moſt certain method is by layers; for the young twigs being laid in the earth in the winter, will be good-rooted plants by the autumn following. 2. Theſe plants may be increaſed by cuttings, which being planted in October, in a ſhady moiſt border, many of them will grow; though it will be proper to let thoſe of the Carolina ſort remain until ſpring, and then to plant them in pots, and help them by a little heat in the bed. By this aſſiſtance, hardly one cutting will fail. 3. They may be alſo increaſed by ſuckers; for all the ſorts throw out ſuckers, though the Carolina ſyringa the leaſt of any. Theſe will all ſtrike root,

and

Philæni, Philanthropy.

an I be fit for the nurſery ground: nay, the double-flowering and the dwarf ſorts are always increaſed this way; for theſe plants having ſtood five or ſix years, may be taken up and divided into ſeveral ſcores. All the plants, however, whether raiſed from layers, cuttings, or ſuckers, ſhould be planted in the nurſery-ground to get ſtrength, before they are ſet out for good. They ſhould be planted a foot aſunder, and the diſtance in the rows ſhould be two feet. After this, they will require no other care than hoeing the weeds, until they have ſtood about two years, which will be long enough for them to ſtand there.

PHILÆNI, were two brothers, citizens of Carthage, who ſacrificed their lives for the good of their country. At the time when the Carthaginians ruled over the greateſt part of Africa, the Cyrenians were alſo a great and wealthy people. The country in the middle betwixt them was all ſandy, and of an uniform appearance. There was neither river nor mountain to diſtinguiſh their limits; a circumſtance which engaged them in a terrible and tedious war with one another. After their armies and fleets had been often routed and put to flight on both ſides, and they had weakened one another pretty much; and fearing leſt, by and by, ſome third people ſhould fall upon the conquered and conquerors together, equally weakened, upon a ceſſation of arms they made an agreement, "that upon a day appointed deputies ſhould ſet out from their reſpective homes, and the place where they met one another ſhould be accounted the common boundary of both nations." Accordingly, the two brothers called Philæni, ſent from Carthage, made all diſpatch to perform their journey. The Cyrenians proceeded more ſlowly. Theſe laſt, perceiving themſelves a little behind, and turning apprehenſive of puniſhment at home for miſmanaging the affair, charged the Carthaginians with ſetting out before the time; made a mighty buſtle upon it; and, in ſhort, would rather chooſe any thing than go away outdone. But whereas the Carthaginians deſired any other terms, provided only they were fair, the Greeks made this propoſal to the Carthaginians, "either to be buried alive in the place which they claimed as the boundary to their nation, or that they would advance forward to what place they inclined upon the ſame condition." The Philæni accepting the offer, made a ſacrifice of themſelves and their lives to their country, and ſo were buried alive. The Carthaginians dedicated altars in that place to the memory of the two brothers. Theſe altars, called *Aræ Philænorum*, ſerved as a boundary to the empire of the Carthaginians, which extended from this monument to Hercules's Pillars, which is about 2000 miles, or, according to the accurate obſervations of the moderns, only 1420 geographical miles. It is Salluſt who gives this account in his hiſtory of the Jugurthine war.

PHILANTHROPY is compounded of two Greek words which ſignify the love of mankind. It is therefore of nearly the ſame import with *benevolence* (A); and differs from *friendſhip*, as this latter affection ſubſiſts only between a few individuals, whilſt *philanthropy* comprehends the whole ſpecies. Philan-thropy.

Whether man has an inſtinctive propenſity to love his ſpecies, which makes him incapable of happineſs but in the midſt of ſociety, and impels him to do all the good that he can to others, feeling their felicity an addition to his own, is a queſtion that has been warmly debated among philoſophers ever ſince metaphyſics was ſtudied as a ſcience. With the opinions of the ancients we ſhall not, in this detached article, trouble our readers; but it would be unpardonable to paſs without notice the different theories which on ſo intereſting a ſubject have divided the moderns.

Hobbes, who believed, or pretended to believe, that right reſults from power, and that in ſociety there is no other ſtandard of juſtice than the law of the land, or the will of the ſupreme magiſtrate, built his opinions upon a theory of human nature in which philanthropy has no place. According to him, mankind, in the original ſtate of nature, were wholly *ſelfiſh*. Each endeavoured to ſeize, by fraud or force, whatever he thought would contribute to his comfort; and as all had nearly the ſame wants, the inevitable conſequence of this ſelfiſhneſs was univerſal war. We are taught indeed by the ſame philoſopher, that, in a ſeries of ages, mankind diſcovered the miſeries of this ſtate of nature; and therefore, upon the ſame baſis of univerſal ſelfiſhneſs, formed ſocieties, over which they placed ſupreme governors for the purpoſe of protecting the weak againſt the violence of the ſtrong. He does not, however, explain how men, whoſe angry and ſelfiſh paſſions were thus excited to the utmoſt againſt each other, could enter upon this friendly treaty; or, ſuppoſing it formed, how the ignorant multitude were induced to pay obedience to the more enlightened few. Clogged with this and other inſurmountable difficulties, his philoſophy of human nature ſoon fell into merited contempt; but about the *origin* of philanthropy thoſe who united in oppoſition to him ſtill thought very differently from one another.

The elegant *Shaftesbury*, who had imbibed much of the ſpirit of Plato, endeavoured, like his maſter, to deduce all the duties of man, and almoſt all his actions, from a number of internal feelings or inſtincts which he ſuppoſed to be interwoven with his conſtitution by the immediate hand of God. This ſyſtem appeared ſo honourable to human nature, and at the ſame time was ſo eaſily comprehended, that the noble lord had ſoon many followers, and may indeed be conſidered as the founder of a ſchool which has produced philoſophers whoſe works do honour to the age and country in which they flouriſhed. Among theſe we muſt reckon *Biſhop Butler*, *Hutchiſon*, *Lord Kames*, *Dr Beattie*, and perhaps *Dr Reid*.

According to the ſyſtem of theſe writers, the whole duty of man reſults from an intuitive principle, to which they have given the name of the moral ſenſe; and with this ſenſe they conceive philanthropy to be inſeparably

(A) We ſay *nearly* of the ſame import; becauſe *benevolence* extends to every being that has life and ſenſe, and is of courſe ſuſceptible of pain and pleaſure; whereas *philanthropy* cannot comprehend more than the human race.

Philanthropy. inſeparably united, or rather perhaps to make an eſſential part of it. (See MORAL PHILOSOPHY.) If this theory be carried to its utmoſt extent, as it has been by ſome of its patrons, it ſeems to follow, that peace and harmony ſhould reign among ſavages; and that a man who had from his infancy grown up in ſolitude, would be delighted with the firſt ſight of a fellow-creature, and run to him with eagerneſs as to a new ſource of enjoyment. This concluſion, however, is contrary to acknowledged facts. Savages are generally divided into ſmall tribes or hordes; and though the attachment of individuals to their own tribe appears indeed to be abundantly ſtrong, the tribes themſelves are frequently at war, and entertain a conſtant jealouſy of each other. Savages, too, are almoſt univerſally afraid of ſtrangers; and the few ſolitary individuals, who have been caught in parts where they had run wild from their infancy, inſtead of being delighted with the appearance of fellow-men, have either fled from them with their utmoſt ſpeed, or been fixed to the ſpot in terror and aſtoniſhment. Theſe are no indications of that inſtinctive philanthropy for which ſome writers ſo ſtrenuouſly plead. They have indeed induced others to deny, that in human nature there is any inſtinctive principles at all; and to endeavour to account for our ſeveral propenſities by the influence of education producing early and deep-rooted habits.

At the head of this ſchool ſtood Locke and Hartley. The former, employing himſelf almoſt wholly on the intellectual powers of man, and combating the abſurd, though then generally received, belief, that there are in the human mind innate principles of ſpeculative truth, has touched but incidentally on our principles of action. It ſeems, however, to be evident, that he did not conſider any *one* of theſe principles as innate; and his opinion was adopted by Hartley, who ſtudied the ſenſitive part of human nature with greater induſtry and ſucceſs than perhaps any writer who had preceded him in that department of ſcience. This philoſopher refuſes all kinds of inſtinct to man, even the στοργὴ of a mother to her new-born infant, and that which has been generally ſuppoſed innate—the propenſity of the infant to ſuck the breaſt. It is therefore needleſs to ſay that in his theory of human nature innate philanthropy can have no place.

The reader, however, muſt not ſuppoſe that the theory of Hartley is the theory of Hobbes. Though he admits no *innate* principles of action in the human mind, he is far from dreaming that the original ſtate of man was a ſtate of war and ſelfiſhneſs, or that the acquiſition of philanthropic ſentiments is not natural. He conſiders ſuch acquiſitions as even neceſſary and unavoidable, and founds them on the great law of aſſociation, which we have elſewhere endeavoured to explain (See METAPHYSICS, Part I. chap. v.) Hartley was a Chriſtian, and appears to have been a man of great piety. Conceiving with Locke that men are born without any ideas, or any principles either of knowledge or of action, but that they are ſubject to the law of aſſociation as much as to the impreſſions of ſenſe, he ſeems to have thought, that the important purpoſe for which they are ſent into this world is, that they may acquire habits of piety and virtue, which, operating like inſtincts, will fit them for the purer ſociety of a future ſtate. That this theory is unfriendly to morals, no man who underſtands it will preſume to affirm. It appears, indeed, to be more conſiſtent with the neceſſity of a revelation from God than that of Shafteſbury, which has ſo many followers: but notwithſtanding this, we cannot help thinking that the excellent author has carried his antipathy to inſtincts by much too far (ſee INSTINCT), and that the truth lies in the middle between him and his opponents. Philanthropy.

Without ſome inſtincts to influence before the dawn of reaſon, it is not eaſy to be conceived how children could be induced to that exerciſe which is abſolutely neceſſary to life and health; nor does it appear with ſufficient evidence that the human race are deſerted by every inſtinct as ſoon as their rational powers are evolved. It ſeems to be a matter of fact which cannot be controverted, that women have an inſtinctive attachment to their new-born infants; but that theſe, when they become capable of diſtinguiſhing objects, are *inſtinctively* attached to their parents, their brothers, and ſiſters, is a poſition which, though it may be true, ſeems incapable of proof. That they ſoon appear to be ſo attached, is a fact which we believe no man will deny: but the attachment may be accounted for by the aſſociating principle operating upon that deſire of happineſs which is neceſſarily formed as ſoon as happineſs is experienced. (See PASSION.) An infant becomes earlier attached to its nurſe than to any other perſon; becauſe, feeling wants which ſhe ſupplies, the idea of enjoyment becomes ſoon aſſociated in its mind with the perception of the woman. If this woman be its mother, a haſty obſerver immediately attributes this attachment to inſtinct directing the infant to love its parent; but that inſtinct has here no place, is evident from the well-known facts, that a child is as fond of a tender nurſe, though no relation, as of the moſt affectionate mother; and as regardleſs of a mother who ſeldom ſees it, or ſees it with indifference, as of any other perſon. Nay, we have ſeen children of the ſweeteſt diſpoſitions as fond of the maid with whom they ſlept, as of a very affectionate parent by whom they had been tenderly nurſed: and ſure no man will ſay that this could be inſtinct; it was evidently a new aſſociation of the idea of the maid with the greateſt happineſs which they enjoyed after the period of their ſuckling was at an end.

It is much in the ſame way that children acquire an attachment to their brothers and ſiſters. Brothers and ſiſters being conſtantly together, contribute to each other's amuſement: hence ariſes that pleaſure which they have in each other's company, and the uneaſineſs which they feel when ſeparated. This generates mutual love in their minds, which is ſtrengthened by the perpetual injunctions of their parents; for if theſe have any virtue themſelves, they cannot fail to inculcate the duty of loving each other on their tender offſpring. Benevolence, thus generated, ſoon extends to their daily companions; and takes a wider and a wider range as theſe companions are multiplied, and as children advance towards the ſtate of manhood. New objects then preſent themſelves to the mind. A man ſoon diſcovers, that, as he is a member of a community, his happineſs as an individual depends in a great meaſure on the proſperity of the whole. Hence ariſes *patriotiſm*, and that pleaſure which we all take in

Philanthropy, Philemon.

in the eminence of our countrymen. But the principle of benevolence ſtops not here. He whoſe mind is enlarged by a liberal education, conſiders all particular countries as provinces of one great country extended over the whole globe; and all mankind, of courſe, as not only ſharing the ſame nature with himſelf, but as being in reality his fellow-citizens and brethren. The principles of religion, if he be actuated by them, muſt aid theſe reflexions, and make him with the happineſs of all who ſtand in the ſame relation with himſelf to the Great Governor of the world. This is *philanthropy*; and we ſee how it may ſpring, by the great law of aſſociation, from deſires which, in their original ſtate, cannot be conſidered as other than ſelfiſh. It is a calm ſentiment, which we believe hardly ever riſes to the warmth of affection, and certainly not to the heat of paſſion.

Should any of our readers be diſpoſed to controvert this opinion, or to fancy it degrading to human nature, we will not enter into controverſy with them; we only beg leave to aſk, whether they have ever rejoiced in the good fortune of a ſtranger or a foreigner, or regretted his loſs, with any portion of thoſe feelings which they have frequently experienced on hearing of the proſperity or the death of a friend or a neighbour? We anſwer candidly for ourſelves, that we feel no intereſt which can be called *paſſion* or *affection* in the fortunes of a native of China; and yet we ſhould be ſorry to think that our philanthropy is leſs than that of other men. A common clown, we are inclined to believe, ſeldom extends his affection beyond his friends and neighbours; and though, from having often heard his country praiſed, and knowing that he belongs to that country, he would probably be offended at the man who ſhould prefer another to it; yet if no misfortune befal himſelf, or his friends and neighbours, we imagine that his grief for public calamities may be borne with patience. In his mind no ſuch aſſociations have been formed as comprife the good of a country, far leſs of all countries; and therefore his philanthropy muſt be confined to a very limited range. We doubt not, however, but that as opportunity offers, and as circumſtances permit, ſuch a man is ready to feed the hungry and clothe the naked of all countries; not indeed from ſentiments of affection either innate or acquired, but from the obvious reflection that he is not exempted from thoſe calamities which have befallen them, and from a ſtill higher principle—a ſenſe of duty to that God who has made of one blood all nations upon earth, and commanded them to be mutually aiding to each other.

PHILEMON, a Greek comic poet, was ſon to Damon, and cotemporary with Menander. Any advantage he had over this poet, was owing leſs to his own merit than to the intrigues of his friends. Plautus has imitated his comedy *du Marchand*. He is reported to have died laughing on ſeeing his aſs eat figs. He was then about 97 years of age. His ſon, Philemon the younger, was alſo the author of 54 comedies, of which there are ſtill extant ſome conſiderable fragments collected by Grotius. Theſe clearly prove that he was not a poet of the firſt rank. He flouriſhed about the year 274 before our Saviour.

PHILEMON, was a rich citizen of Coloſſæ in Phrygia. He was converted to the Chriſtian faith, with Appia his wife by Epaphras the diſciple of St Paul; for St Paul himſelf did not preach at Coloſſæ, Coloſſ. ii. 1. Perhaps we ſhould have known nothing of St Philemon, had it not been on the account of his ſlave Oneſimus, who having robbed him, and run away from him, came to Rome, where he found St Paul, and was very ſerviceable to him. St Paul converted him, baptized him, and ſent him back to his maſter Philemon; to whom he wrote a letter ſtill extant, and which paſſes for a maſterpiece of that kind of eloquence, natural, lively, ſtrong, and pathetic, that was peculiar to St Paul. Philemon (v. 2) had made a church of his houſe, and all his domeſtics, as well as himſelf, were of the houſehold of faith. His charity, liberality, and compaſſion, were a ſure refuge to all that were in diſtreſs. The Apoſtolical Conſtitutions ſay, that St Paul made him biſhop of Coloſſæ; but the Menæa inſinuate, that he went to Gaza in Paleſtine, of which he was the apoſtle and firſt biſhop. From thence he returned to Coloſſæ, where he ſuffered martyrdom with Appia his wife, in the time of Nero. They relate ſeveral particulars of his martyrdom, and ſay, that his body remained at Coloſſæ, where it performed ſeveral miracles.

Philetas Philibeg

PHILETAS, a Greek poet and grammarian, of the iſland of Cos, flouriſhed under Philip and Alexander the Great, and was preceptor of Ptolemy Philadelphus. He was the author of ſome Elegies, Epigrams, and other works, which have not come down to us. He is celebrated in the poems of Ovid and Propertius, as one of the beſt poets of his age. Elian reports a very improbable ſtory of him, namely, 'that his body was ſo ſlender and feeble, that he was obliged to have ſome lead in his pockets, to prevent him from being carried away by the wind."

PHILETUS. St Paul, writing to Timothy (2 Tim. ii. 16, 17, 18.) in the 65th year of Chriſt, and a little while before his own martyrdom, ſpeaks thus: "But ſhun profane and vain babblings, for they will increaſe unto more ungodlineſs. And their word will eat as doth a canker; of whom is Hymenæus and Philetus; who concerning the truth have erred, ſaying, that the reſurrection is paſt already, and overthrow the faith of ſome." We have nothing very certain concerning Philetus; for we make but ſmall account of what is read in the falſe Abdias, in the life of St James major, even ſuppoſing this author had not put the name of Philetus inſtead of Phygellus. This is the ſubſtance of what is found in Abdias. St James the ſon of Zebedee, paſſing through the ſynagogues of Judea and Samaria, preached everywhere the faith of Jeſus Chriſt. Hermogenes and Philetus ſtrenuouſly oppoſed him, affirming, that Jeſus Chriſt was not the Meſſiah. Hermogenes was a notable magician, and Philetus was his diſciple, who being converted, was deſirous to bring his maſter to St James; but Hermogenes bound him up ſo by his magic art, that he could not come at the apoſtle. Philetus found means to make St James acquainted with what had happened to him; upon which St James unbound him, and Philetus came to him. Hermogenes perceiving how ineffectual his art was againſt the ſaint, became himſelf a convert as well as Philetus.

PHILIBEG, is a little plaid, called alſo *kilt*, and

Philip. is a sort of short petticoat reaching nearly to the knees, worn by the Scotch Highlanders. It is a modern substitute for the lower part of the plaid, being found to be less cumbersome, especially in time of action, when the Highlanders used to tuck their brechdan into their girdle. Almost all of them have a great pouch of badger and other skins, with tassels dangling before, in which they keep their tobacco and money.

PHILIP, foster-brother of Antiochus Epiphanes (1 Macc. vi. 14, & 55. 2 Macc. ix. 29.), was a Phrygian by birth, and very much in Antiochus's favour. This prince made him governor of Jerusalem (2 Macc. viii. S. v. 22.) where he committed many outrages upon the Jews, to force them to forsake their religion. Seeing that Apollonius and Seron were defeated by Judas Maccabæus, he sent for new succours to Ptolemy governor of Cœlo-Syria, who sent him Gorgias and Nicanor with a powerful army. Some time after, Antiochus going beyond the Euphrates, to extort money from the people, Philip went along with him; and Antiochus finding himself near his end (1 Macc. vi. 14.) made him regent of the kingdom, put his diadem into his hands, his royal cloak, and his ring, that he might render them to his son the young Antiochus Eupator. But Lysias having taken possession of the government in the name of young Eupator, who was but a child, Philip not being able to cope with him, durst not return into Syria; but he went into Egypt, carrying the body of Epiphanes along with him, there to implore assistance from Ptolemy Philometor against Lysias the usurper of the government of Syria. The year following, while Lysias was busy in the war carrying on against the Jews, Philip got into Syria, and took possession of Antioch: but Lysias returning into the country, with great diligence, retook Antioch, and put Philip to death, who was taken in the city.

PHILIP the apostle was a native of Bethsaida in Galilee. Jesus Christ having seen him, said to him, "Follow me," John i. 43, 44, &c. Philip followed him; and soon after finding Nathanael, Philip said to him, "We have found the Messiah, of whom Moses and the prophets have spoken, Jesus of Nazareth, the son of Joseph." Nathanael asked him, "Can any thing good come out of Nazareth? To which Philip replied, "Come and see." Then he brought Nathanael to Jesus, and they went with him to the marriage of Cana in Galilee. St Philip was called at the very beginning of our Saviour's mission; and when Jesus Christ was about to feed the 5000 that followed him (Luke vi. 13. Mat. x. 2. John vi. 5—7.), he asked St Philip, only to prove him, whence bread might be bought for such a multitude of people? Philip answered, that 200 penny-worth of bread would not be sufficient for every one to taste a little. Some Gentiles, having a curiosity to see Jesus Christ, a little before his passion, they addressed themselves to St Philip (John xii. 21, 22.), who mentioned it to St Andrew, and these two to Christ. At the last supper, Philip desired our Saviour, that he would be pleased to show them the Father, being all that they desired (John xiv. 8—10.) But Jesus told them, that seeing the Son they saw the Father also. This is all we find concerning Philip in the gospel.

The upper Asia fell to this apostle's lot, where he took great pains in planting the gospel, and by his preaching and miracles made many converts. In the latter part of his life, he came to Hierapolis in Phrygia, a city very much addicted to idolatry, and particularly to the worship of a serpent of a prodigious bigness. St Philip by his prayers procured the death, or at least the disappearing, of this monster, and convinced its worshippers of the absurdity of paying divine honours to such odious creatures. But the magistrates, enraged at Philip's success, imprisoned him, and ordered him to be severely scourged, and then put to death, which some say was by crucifixion; others, by hanging him up against a pillar. St Philip is generally reckoned among the married apostles; and it is said he had three daughters, two whereof preserved their virginity, and died at Hierapolis; the third, having led a very spiritual life, died at Ephesus. He left behind him no writings. The gospel under his name was forged by the Gnostics, to countenance their bad principles and worse practices. The Christian church observes the festival of this saint, together with that of St James, on the first day of May. Euseb. lib. iii. c. 30. Philip.

PHILIP, the second of the seven deacons, was chosen by the apostles after our Saviour's resurrection. (Acts vi. 5.) This deacon, they say, was of Cæsarea in Palestine. It is certain that his daughters lived in this city (Acts xxi. 8, 9.) After the death of St Stephen, all the Christians, excepting the apostles, having left Jerusalem, and being dispersed in several places, St Philip went to preach at Samaria (*id.* viii. 1, 2, &c.), where he performed several miracles, and converted many persons. He baptised them; but being only a deacon, he could not confer on them the Holy Ghost. Wherefore having made known to the apostles at Jerusalem, that Samaria had received the word of God, Peter and John came thither, and the Samaritans that were converted received the Holy Ghost. St Philip was probably at Samaria when the angel of the Lord ordered him to go to the south part of the country, in the road that leads from Jerusalem to old Gaza. Philip obeyed, and there met with an Ethiopian eunuch belonging to Queen Candace, who had the care of her revenues, and had been at Jerusalem to worship God there (*id.* viii. 26, 27, &c.) He was then returning into his own country, and was reading the prophet Isaiah as he went along in his chariot. Philip, hearing the eunuch reading the prophet Isaiah, said to him, Do you understand what you read? The eunuch replied, How should I understand, except somebody explain it to me? He desired Philip therefore to come and sit down by him in the chariot. The passage the eunuch was reading is this, "He was led as a sheep to the slaughter, and like a lamb dumb before his shearer, so he opened not his mouth." The eunuch then says to Philip, Pray, whom does the prophet speak of in this place? Is it of himself, or of some other? Then Philip began to instruct him concerning Jesus Christ. And having gone on together, they came to a fountain; when the eunuch said to Philip, Here is water, what hinders me from being baptized? Philip told him that he might be so, if he believed with all his heart. He replied, I believe that Jesus Christ is the son of God. He then ordered the chariot to stop, and they both alighted and went down into the water,

Philip. ter, where Philip baptized the eunuch. Being come out of the water, the Spirit of the Lord took away Philip, and the eunuch saw no more of him. But Philip was found again at Azotus, and he preached the gospel in all the cities he passed through, till he arrived at Cæsarea in Palestine. After this, the scripture does not inform us of any particulars relating to Philip. The modern Greeks say that he went to Tralles in Asia, where he founded a church, of which he was the apostle and bishop; and where he rested in peace, after performing many miracles. The Latins, on the contrary, say that he died at Cæsarea, and that three of his daughters were there buried with him.

It is thought, that the eunuch converted by St Philip was the first apostle of the Ethiopians; and that the Abyssines boast of having received the Christian faith from him.

Philip II. was the 4th son of Amyntas, king of Macedonia. He was sent to Thebes as an hostage by his father, where he learnt the art of war under Epaminondas, and studied with the greatest care the manners and the pursuits of the Greeks. He discovered, from his earliest years, that quickness of genius and greatness of courage which afterwards procured him so great a name and such powerful enemies. He was recalled to Macedonia; and at the death of his brother Perdiccas he ascended the throne as guardian and protector of the youthful years of his nephew. His ambition, however, soon discovered itself, and he made himself independent about the year 360 before Christ. The valour of a prudent general, and the policy of an experienced statesman, seemed requisite to ensure his power. The neighbouring nations, ridiculing the youth and inexperience of the new king of Macedonia, appeared in arms; but Philip soon convinced them of their error. Unable to meet them as yet in the field of battle, he suspended their fury by presents, and soon turned his arms against Amphipolis, a colony tributary to the Athenians. Amphipolis was conquered, and added to the kingdom of Macedonia; and Philip meditated no less than the destruction of a republic which had rendered itself so formidable to the rest of Greece, and had even claimed submission from the princes of Macedonia. His designs, however, were as yet immature; and before he could make Athens an object of conquest, the Thracians and the Illyrians demanded his attention. He made himself master of a Thracian colony, to which he gave the name of *Philippi*, and from which he received the greatest advantages on account of the golden mines in the neighbourhood. These made it a very important capture. He settled in it a number of workmen, and was the first who caused gold to be coined in his own name. He employed his wealth in procuring spies and partisans in all the great cities of Greece, and in making conquests without the aid of arms. It was at the siege of Methone in Thrace that Philip had the misfortune to receive a wound in his right eye from the stroke of an arrow. In the midst of his political prosperity, Philip did not neglect the honour of his family. He married Olympias the daughter of Neoptolemus, king of the Molossi; and when, some time after, he became father of Alexander, the monarch, conscious of the inestimable advantages which arise from the lessons, the example, and conversation of a learned and virtuous preceptor, wrote a letter with his own hand to the philosopher Aristotle, and begged him to retire from his usual pursuits, and to dedicate his whole time to the instruction of the young prince. Every thing seemed now to conspire to his aggrandizement; and historians have observed that Philip received in one day the intelligence of three things which could gratify the most unbounded ambition, and flatter the hopes of the most aspiring monarch: the birth of a son, an honourable crown at the Olympic games, and a victory over the barbarians of Illyricum. But all these increased rather than satiated his ambition: he declared his inimical sentiments against the power of Athens, and the independence of all Greece, by laying siege to Olynthus, a place which, on account of its situation and consequence, would prove most injurious to the interests of the Athenians, and most advantageous to the intrigues and military operations of every Macedonian prince. The Athenians, roused by the eloquence of Demosthenes, sent 17 vessels and 2000 men to the assistance of Olynthus; but the money of Philip prevailed over all their efforts. The greatest part of the citizens suffered themselves to be bribed by the Macedonian gold, and Olynthus surrendered to the enemy, and was instantly reduced to ruins. Philip soon after defeated the Athenians, and made a great number of them prisoners, whom he dismissed without ransom. Of this victory, the fruit of that excellent discipline which he had established in his army, the Macedonian phalanx had the principal honour. This was a body of infantry heavily armed, consisting commonly of 16,000 men, who had each of them a shield six feet high and a pike 21 feet long. (See Phalanx). The success of his arms, and especially his generosity after victory, made his alliance and a peace a desirable object to the people of Athens; and as both parties were inclined to this measure, it was concluded without delay. His successes were as great in every part of Greece: he was declared head of the Amphictyonic council, and was entrusted with the care of the sacred temple of Apollo at Delphi. If he was recalled to Macedonia, it was only to add fresh laurels to his crown, by victories over his enemies in Illyricum and Thessaly. By assuming the mask of a moderator and peace-maker, he gained confidence; and in attempting to protect the Peloponnesians against the incroaching power of Sparta, he rendered his cause popular; and by ridiculing the insults that were offered to his person as he passed through Corinth, he displayed to the world his moderation and philosophic virtues. In his attempts to make himself master of Eubœa, Philip was unsuccessful; and Phocion, who despised his gold as well as his meanness, obliged him to evacuate an island whose inhabitants were as insensible to the charms of money as they were unmoved at the horrors of war, and the bold efforts of a vigilant enemy. From Eubœa he turned his arms against the Scythians; but the advantages he obtained over this indigent nation were inconsiderable, and he again made Greece an object of plunder and rapine. He advanced far in Bœotia, and a general engagement was fought at Chæronea. The fight was long and bloody, but Philip obtained the victory. His behaviour after the battle reflects great disgrace upon him as a man and as a monarch. In the hour of festivity,

Lempriere's Bibliotheca Class.

Philip.

Philip. ty, and during the entertainment which he had given to celebrate the trophies he had won, Philip ſallied from his camp, and with the inhumanity of a brute, he inſulted the bodies of the ſlain, and exulted over the calamities of the priſoners of war. His inſolence, however, was checked, when Demades, one of the Athenian captives, reminded him of his meanneſs, by exclaiming, "Why do you, O king, act the part of a Therſites, when you can repreſent with ſo much dignity the elevated character of an Agamemnon?" The reproof was felt; Demades received his liberty; and Philip learned how to gain popularity even among his fallen enemies, by relieving their wants and eaſing their diſtreſſes. At the battle of Chæronea the independence of Greece was extinguiſhed; and Philip, unable to find new enemies in Europe, formed new enterprizes, and meditated new conqueſts. He was nominated general of the Greeks againſt the Perſians, and was called upon as well from inclination as duty to revenge thoſe injuries which Greece had ſuffered from the invaſions of Darius and of Xerxes. But he was ſtopped in the midſt of his warlike preparations, being ſtabbed by Pauſanias as he entered the theatre at the celebration of the nuptials of his daughter Cleopatra. This murder has given riſe to many reflections upon the cauſes which produced it; and many who conſider the recent repudiation of Olympias and the reſentment of Alexander, are apt to inveſtigate the cauſes of his death in the boſom of his family. The ridiculous honours which Olympias paid to her huſband's murderer ſtrengthened the ſuſpicion; yet Alexander declared that he invaded the kingdom of Perſia to revenge his father's death upon the Perſian ſatraps and princes, by whoſe immediate intrigues the aſſaſſination had been committed. The character of Philip is that of a ſagacious, artful, prudent, and intriguing monarch: he was brave in the field of battle, eloquent and diſſimulating at home, and he poſſeſſed the wonderful art of changing his conduct according to the diſpoſition and caprice of mankind, without ever altering his purpoſe, or loſing ſight of his ambitious aims. He poſſeſſed much perſeverance, and in the execution of his plans he was always vigorous. He had that eloquence which is inſpired by ſtrong paſſions. The hand of an aſſaſſin prevented him from atchieving the boldeſt and the moſt extenſive of his undertakings; and he might have acquired as many laurels, and conquered as many nations, as his ſon Alexander did in the ſucceeding reign; and the kingdom of Perſia might have been added to the Macedonian empire, perhaps with greater moderation, with more glory, and with more laſting advantages. The private character of Philip lies open to cenſure, and raiſes indignation. The admirer of his virtues is diſguſted to find him among the moſt abandoned proſtitutes, and diſgracing himſelf by the moſt unnatural crimes and laſcivious indulgencies which can make even the moſt debauched and the moſt profligate to bluſh. He was murdered in the 47th year of his age, and the 24th of his reign, about 336 years before the Chriſtian era. His reign is become uncommonly intereſting, and his adminiſtration a matter of inſtruction. He is the firſt monarch whoſe life and actions are deſcribed with peculiar accuracy and hiſtorical faithfulneſs. Philip was the father of Alexander the Great and of Cleopatra, by Olympias; he had alſo by Audata an Illyrian, Cyna, who married Amyntas the ſon of Perdiccas, Philip's elder brother; by Nicaſipolis a Theſſalian, Nicæa, who married Caſſander; by Philena a Lariſſæan dancer, Aridæus, who reigned ſome time after Alexander's death: by Cleopatra, the niece of Attalus, Caranus and Europa, who were both murdered by Olympias; and Ptolemy, the firſt king of Egypt, by Arſinoe, who in the firſt month of her pregnancy was married to Lagus. Of the many memorable actions and ſayings reported by Plutarch of this prince, the following are the moſt remarkable. Being preſent at the ſale of ſome captives, in an indecent poſture, one of them informed him of it; "Set this man at liberty (ſays Philip), I did not know that he was my friend." Being ſolicited to favour a lord of his court, who was like to loſe his character by a juſt but ſevere ſentence, Philip refuſed to hearken to the ſolicitation, and added, "I had rather that he be diſgraced than myſelf." A poor woman was importuning him to do her juſtice; and as he ſent her away from day to day, under the pretence that he had no time to attend to her petition, ſhe ſaid to him with ſome warmth, "Ceaſe then to be a king." Philip felt all the force of this reproof, and immediately gave her ſatisfaction.—Another woman came to aſk juſtice of him as he was going out from a great entertainment, and was condemned. "I appeal (exclaimed ſhe)!" "And to whom do you appeal (ſaid the king to her)?" "To Philip faſting." This anſwer opened the eyes of the monarch, who retracted his ſentence. If he poſſeſſed any virtue, it was principally that of ſuffering injuries with patience. Demochares, to whom the Greeks gave the ſurname of *Parrheſiaſtes*, on account of his exceſſive petulance of tongue, was one of the deputies whom the Athenians ſent to this monarch. Philip, at the concluſion of the audience, begged the ambaſſadors to tell him, "if he could be of any ſervice to the Athenians;" to which Demochares gave an inſolent return, which he forgave. Having learned that ſome Athenian ambaſſadors charged him, in full aſſembly, with atrocious calumnies: "I am under great obligations (ſaid he) to thoſe gentlemen, for I ſhall henceforwards be ſo circumſpect in my words and actions, that I ſhall convict them of falſehood." One ſaying of Philip, which does him leſs honour than thoſe we have before-mentioned, was, "Let us amuſe children with playthings, and men with oaths." This abominable maxim, which was the ſoul and ſpring of his politics, gave riſe to the obſervation, "That he was in full length, what Louis XI afterwards was in miniature." It is well known that Philip had a perſon about him, who called out at times, "Philip, remember that thou art mortal;" but whether we ſhould place this to the account of his pride or his humility, it is difficult to ſay.

Philip. Philip V was king of Macedonia, and ſon of Demetrius. His infancy, at the death of his father, was protected by Antigonus, one of his friends, who aſcended the throne, and reigned for 12 years, with the title of *Independent monarch*. When Antigonus died, Philip recovered his father's throne, though only 15 years of age, and he early diſtinguiſhed himſelf by his boldneſs and his ambitious views. He came to the throne in the year 220 before our Saviour, and the beginning of his reign was rendered glorious by the conqueſts of Aratus; a general who was as eminent for his love of juſtice as his ſkill in war. But ſo virtuous

Philip. a character could hardly fail to be diſagreeable to a prince who wanted to indulge himſelf in every ſpecies of diſſipation and vice: and indeed his cruelty to him ſoon diſplayed his character in its true light; for to the gratification of every vice, and every extravagant propenſity, he had the meanneſs to ſacrifice this faithful and virtuous Athenian. Not ſatisfied with the kingdom of Macedonia, Philip aſpired to become the friend of Annibal, and wiſhed to ſhare with him the ſpoils which the diſtreſſes and continual loſs of the Romans ſeemed ſoon to promiſe. But his expectations were fruſtrated; the Romans diſcovered his intrigues; and though weakened by the valour and artifice of the Carthaginian, yet they were ſoon enabled to meet him in the field of battle. The conſul Lævinus entered without delay his territories of Macedonia; and after he had obtained a victory over him near Apollonia, and reduced his fleet to aſhes, he compelled him to ſue for peace. This peaceful diſpoſition was not permanent; and when the Romans diſcovered that he had aſſiſted their formidable enemy Annibal with men and money, they appointed T. Q. Flaminius to puniſh his perfidy, and the violation of the treaty. The Roman conſul, with his uſual expedition, invaded Macedonia; and in a general engagement, which was fought near Cynocephalæ, the hoſtile army was totally defeated, and the monarch ſaved his life with difficulty by flying from the field of battle. Deſtitute of reſources, without friends either at home or abroad, Philip was obliged to ſubmit to the mercy of the conqueror, and to demand peace by his ambaſſadors. It was granted with difficulty: the terms were humiliating; but the poverty of Philip obliged him to accept the conditions, however diſavantageous and degrading to his dignity. In the midſt of theſe public calamaties, the peace of his family was diſturbed; and Perſes, the eldeſt of his ſons by a concubine, raiſed ſeditions againſt his brother Demetrius, whoſe condeſcenſion and humanity had gained popularity among the Macedonians, and who from his reſidence at Rome, as an hoſtage, had gained the good graces of the ſenate, and by the modeſty and innocence of his manners had obtained forgiveneſs from that venerable body for the hoſtilities of his father. Philip liſtened with too much avidity to the falſe accuſations of Perſes; and when he heard it aſſerted that Demetrius wiſhed to rob him of his crown, he no longer heſitated to puniſh with death ſo unworthy and ſo ungrateful a ſon. No ſooner was Demetrius ſacrificed to credulity, than Philip became convinced of his cruelty and raſhneſs; and to puniſh the perfidy of Perſes, he attempted to make Antigonus, another ſon, his ſucceſſor on the Macedonian throne. But he was prevented from executing his purpoſe by death, in the 42d year of his reign, 178 years before the Chriſtian era. The aſſaſſin of Demetrius ſucceeded his father, and with the ſame ambition, with the ſame raſhneſs and oppreſſion, renewed the war againſt the Romans, till his empire was deſtroyed, and Macedonia became a Roman province. Philip has been compared with his great anceſtor of the ſame name; but though they poſſeſſed the ſame virtues, the ſame ambition, and were tainted with the ſame vices, yet the father of Alexander was more ſagacious and more intriguing, and the ſon of Demetrius was more ſuſpicious, more cruel, and more implacable; and, according to the pretended prophecy of one of the Sybils, Macedonia was indebted to one Philip for her riſe and conſequence among nations, and under another Philip ſhe lamented the loſs of her power, her empire, and her dignity. Philip.

Philip (M. Julius), a Roman emperor, of an obſcure family in Arabia, from whence he was ſurnamed *Arabian*. From the loweſt rank in the army he gradually roſe to the higheſt offices; and when he was made general of the pretorian guards, he aſſaſſinated Gordian, to make himſelf emperor. To ſecure himſelf on the imperial throne, he left Meſopotamia a prey to the continual invaſions of the Perſians, and hurried to Rome, where his election was univerſally approved by the ſenate and the Roman people. Philip rendered his cauſe popular by his liberality and profuſion; and it added much to his ſplendor and dignity, that the Romans during his reign commemorated the foundation of their city; a ſolemnity which was obſerved but once every 100 years, and which was celebrated with more pomp and more magnificence than under the preceding reigns. The people were entertained with games and ſpectacles; the theatre of Pompey was ſucceſſively crowded during three days and three nights; and 2000 gladiators bled in the circus at once, for the amuſement and pleaſure of a gazing populace. His uſurpation, however, was ſhort. Philip was defeated by Decius, who had proclaimed himſelf emperor in Pannonia; and he was aſſaſſinated by his own ſoldiers near Verona, in the 45th year of his age, and the 5th of his reign. His ſon, who bore the ſame name, and who had ſhared with him the imperial dignity, was alſo maſſacred in the arms of his mother. Young Philip was then in the 12th year of his age, and the Romans lamented in him the loſs of riſing talents, of natural humanity, and endearing virtues. *Hiſt.*

Philip, a native of Acarnania, phyſician to Alexander the Great. When that monarch had been ſuddenly taken ill, after bathing in the Cydnus, Philip undertook to remove the complaint, when the reſt of the phyſicians believed that all medical aſſiſtance would be ineffectual. But as he was preparing his medicine, Alexander received a letter from Parmenio, in which he was adviſed to beware of his phyſician Philip, as he had conſpired againſt his life. The monarch was alarmed; and when Philip preſented him the medicine, he gave him Parmenio's letter to peruſe, and began to drink the potion. The ſerenity and compoſure of Philip's countenance, as he read the letter, removed every ſuſpicion from Alexander's breaſt, and he purſued the directions of his phyſician, and in a few days recovered. *Hiſt.*

There were, beſides, a vaſt number of perſons of this name in antiquity, and many of them were very eminent.

Philip I. king of France, ſucceeded his father Henry I. in 1060, when but eight years of age, under the regency and guardianſhip of Baudouin V. count of Flanders, who diſcharged his truſt with zeal and fidelity. He defeated the Gaſcons who were inclined to revolt, and died, leaving his pupil 15 years of age. This young prince made war in Flanders againſt Robert, Baudouin's younger ſon, who had invaded Flanders, which belonged to the children of his elder

Philip. der brother. Philip marched againſt him with a numerous army, which was cut to pieces near Mount Caſſel. Peace was the conſequence of the victory, and the conqueror quietly enjoyed his uſurpation. Philip, after the fatigues of the war, by way of relaxation gave himſelf up entirely to pleaſure and diſſipation. Tired of his wife Bertha, and fond of Bertrade, ſpouſe of Foulques count of Anjou, he carried her off from her huſband. Having, in 1093, legally annulled his own marriage, under the pretext of barrenneſs, and Bertrade's marriage with the count of Anjou having been ſet aſide under the ſame pretext, Philip and ſhe were afterwards ſolemnly married by the biſhop of Beauvais. This union was declared void by Pope Urban II. a Frenchman by birth, who pronounced the ſentence in the king's own dominions, to which he had come for an aſylum. Philip, fearing that the anathemas of the Roman pontiff might be the means of exciting his ſubjects to rebellion, ſent deputies to the pope, who obtained a delay, during which time he was permitted to uſe the crown. To know what is meant by this permiſſion, it is neceſſary to recollect, that at that period kings appeared on public ſolemnities in royal habit, with the crown on their heads, which they received from the hand of a biſhop. This delay was not of long duration. Philip was excommunicated anew in a council held at Poitiers in 1100; but in the year 1104, Lambert biſhop of Arras, legate of Pope Paſchal II. at laſt brought him his abſolution to Paris, after having made him promiſe never to ſee Bertrade more; a promiſe which he did not keep. It would appear that the pope afterwards approved their marriage; for Suger informs us, that their ſons were declared capable of ſucceeding to the crown. Philip died at Melun the 29th of July 1108, aged 57 years, after having witneſſed the firſt cruſade, in which he declined taking any part. His reign, which comprehends a period of 48 years, was the longeſt of any of his predeceſſors, excepting that of Clotarius, and of all who came after him except thoſe of Louis XIV. and Louis XV. It was diſtinguiſhed by ſeveral great events: but Philip, though brave in battle, and wiſe in counſels, was no very excellent character. He appeared ſo much the more contemptible to his ſubjects, as that age abounded with heroes. Philip is not the firſt of the French monarchs (as is commonly reported), who, in order to give the greater authority to his charters, cauſed them to be ſubſcribed by the officers of the crown; for Henry I. had ſometimes done the ſame before him.

Philip II. ſurnamed *Auguſtus*, the *conqueror* and *given of God*, ſon of Louis VII. (called the *younger*). King of France, and of Alix, his third wife, daughter of Thibault, count of Champagne, was born the 22d of Auguſt 1165. He came to the crown, after his father's death in 1180, at the age of 15 years. His youth was not ſpent like that of the generality of other princes; for, by avoiding the rock of pleaſure on which ſo many are apt to ſplit, his courage thereby became the more lively and intrepid. The king of England ſeemed willing to take advantage of his minority, and to ſeize upon a part of his dominions. But Philip marched againſt him, and compelled him, ſword in hand, to confirm the ancient treaties between the two kingdoms. As ſoon as the war was ended, he made his people enjoy the bleſſings of peace. He gave a check to the oppreſſions of the great lords, baniſhed the comedians, puniſhed blaſphemies, cauſed the ſtreets and public places of Paris to be paved, and annexed to that capital a part of the adjacent villages. It was incloſed by walls with towers; and the inhabitants of other cities were equally proud to fortify and embelliſh theirs. The Jews having for a long time practiſed the moſt ſhameful frauds in France, Philip expelled them from his kingdom, and declared his ſubjects quit with them; an action unjuſt, contrary to the laws of nature, and conſequently to religion. The tranquillity of France was ſomewhat diſturbed by a difference with the count of Flanders, which was however happily terminated in 1184. Some time after he declared war againſt Henry II. king of England, and took from him the towns of Iſſoudun, Tours, Mans and other places. The epidemical madneſs of the cruſades then agitated all Europe; and Philip, as well as other princes, caught the infection. He embarked in the year 1190, with Richard I. king of England, for the relief of the Chriſtians in Paleſtine who were oppreſſed by Saladin. Thoſe two monarchs ſat down before Acre, which is the ancient Ptolemais; as did almoſt all the Chriſtians of the eaſt, while Saladin was engaged in a civil war on the banks of the Euphrates. When the two European monarchs had joined their forces to thoſe of the Aſiatic Chriſtians, they counted above 300,000 fighting men. Acre ſurrendered the 13th of July 1191; but the unhappy diſagreement which took place between Philip and Richard, rivals of glory and of intereſt, did more miſchief than could be compenſated by the ſucceſsful exertions of thoſe 300,000 men. Philip, tired of theſe diviſions, and diſpleaſed with the behaviour of Richard his vaſſal, returned to his own country, which, perhaps, he ſhould never have left, or at leaſt have ſeen again with more glory. "Beſides, he was attacked (ſay hiſtorians) with a languiſhing diſorder, the effects of which were attributed to poiſon; but which might have been occaſioned merely by the ſcorching heat of a climate ſo different from that of France. He loſt his hair, his beard, and his nails; nay, his very fleſh came off. The phyſicians urged him to return home; and he ſoon determined to follow their advice. The year after, he obliged Baudouin VIII. count of Flanders to leave him the county of Artois. He next turned his arms againſt Richard king of England, from whom he took Evreux and Vexin; though he had promiſed upon the holy goſpels never to take any advantage of his rival during his abſence; ſo that the conſequences of this war were very unfortunate. The French monarch, repulſed from Rouen with loſs, made a truce for ſix months; during which time he married Ingelburge, princeſs of Denmark, whoſe beauty could only be equalled by her virtue. The divorcing of this lady, whom he quitted in order to marry Agnes daughter of the duke of Merania, embroiled him with the court of Rome. The pope iſſued a ſentence of excommunication againſt him; but it was taken off upon his promiſing to take back his former wife. John Sansterre, ſucceeded to the crown of England in 1190, to the prejudice of his nephew Arthur, to whom of right it belonged. The nephew, ſupported by Philip,

Philip. lip, took arms againſt the uncle, but was defeated in Poitou, where he was taken priſoner, and afterwards murdered. The murderer being ſummoned before the court of the peers of France, not having appeared, was declared guilty of his nephew's death, and condemned to loſe his life in 1203. His lands, ſituated in France, were forfeited to the crown. Philip ſoon ſet about gathering the fruit of his vaſſal's crime. He ſeized upon Normandy, then carried his victorious arms into Maine, Anjou, Touraine, Poitou, and brought thoſe provinces, as they anciently were, under the immediate authority of his crown. The Engliſh had no other part left them in France but the province of Guienne. To crown his good fortune, John his enemy was embroiled with the court of Rome, which had lately excommunicated him. This eccleſiaſtical thunder was very favourable for Philip. Innocent II. put into his hands, and transferred to him, a perpetual right to the kingdom of England. The king of France, when formerly excommunicated by the pope, had declared his cenſures void and abuſive; he thought very differently, however, when he found himſelf the executor of a bull inveſting him with the Engliſh crown. To give the greater force to the ſentence pronounced by his holineſs, he employed a whole year in building 1700 ſhips, and in preparing the fineſt army that was ever ſeen in France. Europe was in expectation of a deciſive battle between the two kings, when the pope laughed at both, and artfully took to himſelf what he had beſtowed upon Philip. A legate of the holy ſee perſuaded John Sans terre to give his crown to the court of Rome, which received it with enthuſiaſm. Then Philip was expreſsly forbid by the pope to make any attempt upon England, now become a fee of the Roman church, or againſt John who was under her protection. Meanwhile, the great preparations which Philip had made alarmed all Europe; Germany, England, and the Low-Countries were united againſt him in the ſame manner as we have ſeen them united againſt Louis XIV. Ferrand, count of Flanders, joined the emperor Othon IV. He was Philip's vaſſal; which was the ſtrongeſt reaſon for declaring againſt him. The French king was nowiſe diſconcerted; his fortune and his courage diſſipated all his enemies. His valour was particularly conſpicuous at the battle of Bouvines, which was fought on the 27th of July 1214, and laſted from noon till night. Before the engagement, he knew well that ſome of his nobles followed him with reluctance. He aſſembled them together; and placing himſelf in the midſt of them, he took a large golden cup, which he filled with wine, and into which he put ſeveral ſlices of bread. He eat one of them himſelf, and offering the cup to the reſt, he ſaid, "My companions, let thoſe who would live and die with me follow my example." The cup was emptied in a moment, and thoſe who were the leaſt attached to him fought with all the bravery that could be expected from his warmeſt friends. It is alſo reported, that after ſhowing the army the crown that was worn by ſovereigns upon theſe occaſions, he ſaid, "If any one thought himſelf more worthy than he was to wear it, he had only to explain himſelf; that he ſhould be content it were the prize of that man who ſhould diſplay the greateſt valour in battle." The enemy had an army of 150,000 fighting men; that of Philip was not half ſo numerous; but it was compoſed of the flower of his nobility. The king run great hazard of his life; for he was thrown down under the horſes feet, and wounded in the neck. It is ſaid 30,000 Germans were killed; but the number is probably much exaggerated. The counts of Flanders and Boulogne were led to Paris with irons upon their feet and hands; a barbarous cuſtom which prevailed at that time. The French king made no conqueſt on the ſide of Germany after this ever memorable action; but it gained him an additional power over his vaſſals. Philip, conqueror of Germany, and poſſeſſor of almoſt all the Engliſh dominions in France, was invited to the crown of England by the ſubjects of King John, who were grown weary of his tyranny. The king of France, upon this occaſion, conducted himſelf like an able politician. He perſuaded the Engliſh to aſk his ſon Louis for their king; but as he wiſhed at the ſame time to manage the pope, and not loſe the crown of England, he choſe to aſſiſt the prince his ſon, without appearing to act himſelf. Louis made a deſcent upon England, was crowned at London, and excommunicated at Rome in 1216; but that excommunication made no change upon John's ſituation, who died of grief. His death extinguiſhed the reſentment of the Engliſh, who having declared themſelves for his ſon Henry III. forced Louis to leave England. Philip-Auguſtus died a little time after, at Mantes, the 14th of July 1223, aged 59, after a reign of 43 years. Of all the kings of the 3d race, he made the greateſt acceſſion to the crown lands, and tranſmitted the greateſt power to his ſucceſſors. He reunited to his dominions Normandy, Anjou, Maine, Touraine, Poitou, &c. After having ſubdued John Sans-terre, he humbled the great lords, and by the overthrow of foreign and domeſtic enemies, took away the counterpoiſe which balanced his authority in the kingdom. He was more than a conqueror; he was a great king and an excellent politician; fond of ſplendor on public occaſions, but frugal in private life; exact in the adminiſtration of juſtice; ſkilful in employing alternately flattery and threatenings rewards and puniſhments; he was zealous in the defence of religion, and always diſpoſed to defend the church; but he knew well how to procure from her ſuccours for ſupplying the exigencies of the ſtate. The lords of Coucy, Rhetel, Roſey, and ſeveral others, ſeized upon the property of the clergy. A great many of the prelates applied for protection to the king, who promiſed them his good offices with the depredators. But, notwithſtanding his recommendations, the pillages continued. The biſhops redoubled their complaints, and intreated Philip to march againſt their enemies. "With all my heart (ſaid he), but in order to fight them, it is neceſſary to have troops, and troops cannot be raiſed without money." The clergy underſtood his meaning; they furniſhed ſubſidies, and the pillages ceaſed. The enterprizes of Philip Auguſtus were almoſt always ſucceſsful; becauſe he formed his projects with deliberation, and executed them without delay. He began by rendering the French happy, and in the end rendered them formidable; though he was more inclined to anger than to gentleneſs, to puniſh than to pardon, he was regretted by his ſubjects as a powerful genius and

Philip. as the father of his country. It was in his reign that the marſhal of France was ſeen, for the firſt time, at the head of the army. It was then, alſo, that families began to have fixed and hereditary ſurnames; the lords took them from the lands which they poſſeſſed; men of letters from the place of their birth; the converted Jews and rich merchants from that of their reſidence. Two very cruel evils, *viz.* leproſy and uſury, were prevalent at that time; the one infected the body, the other proved the ruin of the fortunes of families. The number of lepers was ſo great, that the ſmalleſt villages were obliged to have an hoſpital for the cure of that diſtemper. It is remarkable, that when Philip was on the point of engaging Richard, the Engliſh, who were lying in ambuſh near the Loire, run away with his equipages, in which he cauſed to be carried all the deeds or writings reſpecting the rights of the crown; a cuſtom which is uſed at this day by the grand ſeignior. Philip cauſed copies of his charters to be collected wherever they could be found; but after all his endeavours, ſome of them were never recovered. The ſurname of *Auguſtus* was given to Philip by his cotemporaries. Mezerai is miſtaken, when he aſſerts that Paulus Emilius was the firſt who rendered the name of *conqueror* by that of Auguſtus; a learned critic has proved the contrary by undoubted authorities.

Philip of *Valois*, firſt king of France of the collateral branch of the Valois, was ſon to Charles count of Valois, brother of Philip *the Fair*. He mounted the throne in 1328, on the death of his couſin Charles the Fair, after having held for ſome time the regency of the kingdom. France was much divided in the beginning of his reign, by diſputes about the ſucceſſion to the crown. Edward III. king of England laid claim to it as grandſon of Philip the Fair, by his mother; but Philip of Valois took poſſeſſion of it as firſt prince of the blood. The people gave him, upon his acceſſion to the throne, the title of *fortunate*; to which might have been added, for ſome time, thoſe of *victorious* and *juſt*. He marched to the relief of his vaſſal the count of Flanders, whoſe ſubjects, on account of bad uſage, had taken up arms againſt him. He engaged the rebels at Caſſel, performed prodigies of valour, and gained a ſignal victory, the 24th of Auguſt 1328. Having made all quiet, he went home, after ſaying to the count of Flanders, "Be more prudent and more humane, and you will have fewer diſloyal ſubjects." The victorious Philip devoted the time of peace to the internal regulations of his kingdom. The financiers were called to an account, and ſome of them condemned to death; among others Peter Remi, general of the finances, who left behind him near 20 millions. He afterwards enacted the law reſpecting freeholds, impoſing a tax upon churches, and commoners who had acquired the lands of the nobility. Then, alſo, began to be introduced the form of *appeal comme d'abus*, the principles of which are more ancient than the name. The year 1329 was diſtinguiſhed by a ſolemn homage paid to Philip, by Edward king of England, for the duchy of Guienne, upon his knees, and with his head uncovered. The interior peace of the kingdom was diſturbed by diſputes about the diſtinction of the church and ſtate. An aſſembly was ſummoned for hearing the two parties, in the preſence of the king: and in this aſſembly Peter de Cugnieres, his majeſty's advocate, defended the ſecular juriſdiction Philip. with great ability as a man well-informed, and an enlightened philoſopher. Bertrand biſhop of Autun, and Roger archbiſhop of Sens, pled the cauſe of the clergy with leſs ingenuity and judgment. This did not, however, prevent the king from ſhowing them favours, though the controverſy itſelf laid the foundation of all the diſputes which were afterwards agitated about the authority of the two powers; diſputes which contributed not a little to confine the eccleſiaſtical juriſdiction within narrower limits. While Philip was employing himſelf in ſome uſeful regulations, he was unhappily interrupted by Edward III. declaring war againſt France. This prince immediately recovered thoſe parts of Guienne of which Philip was in poſſeſſion. The Flemiſh having again revolted from France in ſpite of oaths and treaties, joined the ſtandard of Edward; and required that he would aſſume the title of *king of France*, in conſequence of his pretenſions to the crown; becauſe then, agreeably to the letter of their treaty, they only followed the king of France. From this period is dated the union of the flower-de-luce and leopards in the arms of England. Edward, in order to juſtify the change of his arms, cauſed the following manifeſto to be publiſhed in the verſe of the times.

Rex ſum regnorum, bina ratione, duorum:
Anglorum in regno ſum rex ego jure paterno;
Matris jure quidem Francorum nunzupor idem:
Hinc eſt armorum variatio facta meorum.

In the way of a parody to theſe lines, Philip made the following reply:

Prædo regnorum qui diceris eſſe duorum,
Francorum regno privaberis, atque paterno.
Succedunt mares huic regno, non mulieres:
Hinc eſt armorum variatio ſtulta tuorum.

In the mean time Philip put himſelf in a poſture of defence. His arms were at firſt attended with ſome ſucceſs; but thoſe advantages were far from compenſating the loſs of the battle of Ecluſe, in which the French fleet, conſiſting of 120 large ſhips, and manned by 40,000 ſeamen, was beat by that of England in the year 1340. This defeat is to be attributed, in part, to the little attention which had been paid to the navy of France, notwithſtanding her favourable ſituation, by being waſhed by two ſeas. She was obliged to make uſe of foreign ſhips, which obeyed but ſlowly, and even with ſome reluctance. This war, which had been alternately diſcontinued and renewed, begun again with more heat than ever in 1345. The two armies having come to an engagement the 26th of Auguſt 1346, near Creey, a village in the county of Ponthieu, the Engliſh there gained a ſignal victory. Edward had only 40,000 men, while Philip had nearly twice that number; but the army of the former was inured to war, and that of the latter was ill-diſciplined and overcome with fatiguing marches. France loſt from 25,000 to 30,000 men; of which numbers were John king of Bohemia (who, though blind, fought gallantly), and about 1500 gentlemen, the flower of the French nobility. The loſs of Calais, and ſeveral other places, was the ſad fruit of this defeat. Some time before Edward had challenged Philip of Valois

to

Philip. to a ſingle combat; which he refuſed, not on the ſcore of cowardice, but from the idea that it was improper for a ſovereign prince to accept a challenge from a king who was his vaſſal. At length, in 1347, a truce for ſix months was concluded between France and England, and afterwards prolonged at different times. Philip died a ſhort time after, the 23d of Auguſt 1350, aged 57 years, and far from bearing on his monument the title of *Fortunate*. He had, however, reunited Dauphiny to France. Humbert, the laſt prince of that country, having loſt all his children, and wearied with the wars which he had held out againſt Savoy, turned a Dominican, and gave his province to Philip, in 1349, on condition that the eldeſt ſon of the kings of France ſhould bear the title of Dauphin. Philip likewiſe added to his domain Rouſſillon and a part of Cerdagne, by lending ſome money to the king of Majorca, who gave him thoſe provinces as a ſecurity; provinces which Charles VIII. afterwards reſtored without any reimburſement. It is ſurpriſing that in ſo unfortunate a reign he ſhould have been able to purchaſe thoſe provinces after having paid a great deal for Dauphiny; but the duty on ſalt, the riſe on the other taxes, and eſpecially the frauds committed in the coinage of money, are ſuppoſed to have enabled him to make thoſe acquiſitions. The fictitious and ideal value of the coin was not only raiſed, but a great deal of bad money was iſſued from the mint. The officers of the mint were ſworn upon the goſpels to keep the ſecret: but how could Philip flatter himſelf that ſo groſs a fraud would not be diſcovered?

Philip II. ſon of Charles V. and of Iſabella of Portugal, who was born at Valladolid on the 21ſt of May 1527, became king of Naples and Sicily by his father's abdication in 1554. He aſcended the throne of Spain on the 17th of January 1556 by the ſame means. Charles had made a truce with the French, but his ſon broke it; and having formed an alliance with England, poured into Picardy an army of 40,000 men. The French were cut to pieces at the battle of St Quintin, which was fought on the 20th of Auguſt 1557. That town was taken by aſſault, and the day on which the breach was mounted Philip appeared armed cap-a-pee in order to animate the ſoldiers. It was the firſt and laſt time that he was obſerved to wear this military dreſs. It is well known, indeed, that his terror was ſo great during the action that he made two vows; one, that he ſhould never again be preſent in a battle; and the other, to build a magnificent monaſtery dedicated to St Lawrence, to whom he attributed the ſucceſs of his arms, which he executed at Eſcurial, a village about ſeven leagues from Madrid. After the engagement, his general, the Duke of Savoy, wanted to kiſs his hand; but Philip prevented him, ſaying, "It is rather my duty to kiſs your's, who have the merit of ſo glorious a victory;" and immediately preſented him with the colours taken during the action. The taking of Catelet, Ham, and Noyon, were the only advantages which were derived from a battle which might have proved the ruin of France. When Charles V. was informed of this victory, it is ſaid he aſked the perſon who brought him the intelligence, "if his ſon was at Paris?" and being anſwered in the negative, he went away without uttering a ſingle word. The Duke of Guiſe having had time to aſſemble an army, repaired the diſgrace of his country by the taking of Calais and Thionville. While he was animating the French, Philip gained a pretty conſiderable battle againſt Marſhall de Thermes near Gravelines. His army was, on this occaſion, commanded by Count Egmont, whom he afterwards cauſed to be beheaded. The conqueror made no better uſe of the victory of Gravelines than he had done of that of St Quintin; but he reaped conſiderable advantage from the glorious peace of Cateau-Cambreſis, the maſter-piece of his politics. By that treaty, concluded the 13th of April 1559, he gained poſſeſſion of the ſtrong places of Thionville, Marienbourg, Montmedi, Heſdin, and the county of Charollois. This war, ſo terrible, and attended with ſo much cruelty, was terminated, like many others, by a marriage. Philip took for his third wife Elizabeth, daughter of Henry II. who had been promiſed to Don Carlos. Philip

After theſe glorious atchievements, Philip returned in triumph to Spain, without having drawn a ſword. His firſt care, upon his arrival at Valladolid, was to demand of the grand inquiſitor the ſpectacle of an *auto-da-fé*. This was immediately granted him; 40 wretches, ſome of whom were prieſts or monks, were ſtrangled and burnt, and one of them was burnt alive. Don Carlos de Seza, one of thoſe unfortunate victims, ventured to draw near to the king, and ſaid to him, "How, Sir, can you ſuffer ſo many wretches to be committed to the flames? Can you be witneſs of ſuch barbarity without weeping?" To this Philip coolly replied, "If my own ſon were ſuſpected of herety, I would myſelf give him up to the ſeverity of the inquiſition. Such is the horror which I feel when I think of you and your companions, that if an executioner were wanting, I would ſupply his place myſelf." On other occaſions he conducted himſelf agreeably to the ſpirit which had dictated this anſwer. In a valley of Piedmont, bordering on the country of the Milaneſe, there were ſome heretics; and the governor of Milan had orders to put them all to death by the gibbet. The new opinions having found their way into ſome of the diſtricts of Calabria, he gave orders that the innovators ſhould be put to the ſword, with the reſervation of 60 of them, of whom 30 were afterwards ſtrangled, and the reſt committed to the flames. Philip

This ſpirit of cruelty, and ſhameful abuſe of his power, had the effect to weaken that power itſelf. The Flemiſh, no longer able to bear ſo hard a yoke, revolted. The revolution began with the fine and large provinces of the continent; but the maritime provinces only obtained their liberty. In 1579 they formed themſelves into a republic, under the title of the United Provinces. Philip ſent the Duke of Alba to reduce them; but the cruelty of that general only ſerved to exaſperate the ſpirit of the rebels. Never did either party fight with more courage, or with more fury. The Spaniards, at the ſiege of Haerlem, having thrown into the town the head of a Dutch officer who had been killed in a ſkirmiſh, the inhabitants threw to them the heads of eleven Spaniards, with this inſcription: "Ten heads for the payment of the tenth penny, and the eleventh for intereſt." Haerlem having ſurrendered at diſcretion, the conquerors cauſed all the magiſtrates, all the paſtors, and above 1500 citizens, to be hanged.

Philip. The Duke of Alba, being at length recalled, the grand commander of the Requeſnes was ſent in his place, and after his death Don John of Auſtria; but neither of thoſe generals could reſtore tranquillity in the Low Countries. To this ſon of Charles V. ſucceeded a grandſon no leſs illuſtrious, namely, Alexander Farneſe duke of Parma, the greateſt man of his time; but he could neither prevent the independence of the United Provinces, nor the progreſs of that republic which aroſe under his own eye. It was then that Philip, always at his eaſe in Spain, inſtead of coming to reduce the rebels in Flanders, proſcribed the Prince of Orange, and ſet 25,000 crowns upon his head. William, ſuperior to Philip, diſdained to make uſe of that kind of vengeance, and truſted to his ſword for his preſervation.

In the mean time the king of Spain ſucceeded to the crown of Portugal, to which he had a right by his mother Iſabella. This kingdom was ſubjected to him by the Duke of Alba, in the ſpace of three weeks, in the year 1580. Antony, prior of Crato, being proclaimed king by the populace of Liſbon, had the reſolution to come to an engagement; but he was vanquiſhed, purſued, and obliged to fly for his life.

A cowardly aſſaſſin, Balthazar Gerard, by a piſtol-ſhot killed the Prince of Orange, and thereby delivered Philip from his moſt implacable enemy. Philip was charged with this crime, it is believed without reaſon; though, when the news was communicated to him, he was imprudent enough to exclaim, "If this blow had been given two years ago, the Catholic religion and I would have gained a great deal by it."

This murder had not the effect to reſtore to Philip the Seven United Provinces. That republic, already powerful by ſea, aſſiſted England againſt him. Philip having reſolved to diſtreſs Elizabeth, fitted out, in 1588, a fleet called the *Invincible*. It conſiſted of 150 large ſhips, on which were counted 2650 pieces of cannon, 8000 ſeamen, 20,000 ſoldiers, and all the flower of the Spaniſh nobility. This fleet, commanded by the Duke of Medina Sidonia, ſailed from Liſbon when the ſeaſon was too far advanced; and being overtaken by a violent ſtorm, a great part of it was diſperſed. Twelve ſhips, driven upon the coaſt of England, were captured by the Engliſh fleet, which conſiſted of 100 ſhips; 50 were wrecked on the coaſts of France, Scotland, Ireland, Holland, and Denmark. Such was the ſucceſs of the Invincible. See ARMADA.

This enterpriſe, which coſt Spain 40 millions of ducats, 20,000 men, and 100 ſhips, was productive only of diſgrace. Philip ſupported this misfortune with an heroic reſolution. When one of his courtiers told him, with an air of conſternation, what had happened, he coolly replied, "I ſent to fight the Engliſh, and not the winds. God's will be done." The day after Philip ordered the biſhops to return thanks to God for having preſerved ſome remains of his fleet; and he wrote thus to the pope: "Holy father, as long as I remain maſter of the fountain head, I ſhall not much regard the loſs of a rivulet. I will thank the Supreme Diſpoſer of empires, who has given me the power of eaſily repairing a diſaſter which my enemies muſt attribute ſolely to the elements which have fought for them."

At the ſame time that Philip attacked England, he was encouraging in France the Holy League; the object of which was to overturn the throne and divide the ſtate. The leaguers conferred upon him the title of *Protector* of their aſſociation; which he eagerly accepted, from a perſuaſion that their exertions would ſoon conduct him, or one of his family, to the throne of France. He thought himſelf ſo ſure of his prey, that when ſpeaking of the principal cities in France, he uſed to ſay, "My fine city of Paris, my fine city of Orleans," in the ſame manner as he would have ſpoken of Madrid and Seville. What was the reſult of all thoſe intrigues? Henry IV. embraced the Catholic religion, and by his abjuration of Proteſtantiſm made his rival loſe France in a quarter of an hour. Philip.

Philip, at length, worn out by the debaucheries of his youth, and by the toils of government, drew near his laſt hour. A ſlow fever, the moſt painful gout, and a complication of other diſorders, could not diſengage him from buſineſs, nor draw from him the leaſt complaint. "What!" ſaid he to the phyſicians who heſitated about letting blood of him; "What! are you afraid of drawing a few drops of blood from the veins of a king who has made whole rivers of it flow from heretics?" At laſt, exhauſted by a complication of diſtempers, which he bore with an heroic patience, and being eaten up of lice, he expired the 13th of September 1598, aged 72 years, after a reign of 43 years and eight months. During the laſt 50 days of his illneſs he ſhowed a great ſenſe of religion, and had his eyes almoſt always fixed towards heaven.

No character was ever drawn by different hiſtorians in more oppoſite colours than that of Philip; and yet, conſidering the length and activity of his reign, there is none which it ſhould ſeem would be more eaſy to aſcertain. From the facts recorded in hiſtory, we cannot doubt that he poſſeſſed, in an eminent degree, penetration, vigilance, and a capacity for government. His eyes were continually open upon every part of his extenſive dominions. He entered into every branch of adminiſtration; watched over the conduct of his miniſters with unwearied attention; and in his choice both of them and of his generals diſcovered a conſiderable ſhare of ſagacity. He had at all times a compoſed and ſettled countenance, and never appeared to be either elated or depreſſed. His temper was the moſt imperious, and his looks and demeanor were haughty and ſevere; yet among his Spaniſh ſubjects he was of eaſy acceſs; liſtened patiently to their repreſentations and complaints; and where his ambition and bigotry did not interfere, was generally willing to redreſs their grievances. When we have ſaid thus much in his praiſe, we have ſaid all that truth requires or truth permits. It is indeed impoſſible to ſuppoſe that he was ſincere in his zeal for religion. But as his religion was of the moſt corrupt kind, it ſerved to increaſe the natural depravity of his diſpoſition; and not only allowed, but even prompted, him to commit the moſt odious and ſhocking crimes. Although a prince in the bigotted age of Philip might be perſuaded that the intereſt of religion would be advanced by falſehood and perſecution; yet it might be expected, that, in a virtuous prince, the ſentiments of honour and humanity would on ſome occaſions triumph over the dictates of ſuperſtition: but of this triumph there occurs not a ſingle inſtance in the reign of Philip; who without heſitation violated his moſt ſacred obli- *Philip II.*

Philip. gations as often as religion afforded him a pretence, and under that pretence exerciſed for many years the moſt unrelenting cruelty without reluctance or remorſe. His ambition, which was exorbitant; his reſentment, which was implacable; his arbitrary temper, which would ſubmit to no controul—concurred with his bigotted zeal for the Catholic religion, and carried the ſanguinary ſpirit, which that religion was calculated to inſpire, to a greater height in Philip than it ever attained in any other prince of that or of any former or ſucceeding age.

Though of a ſmall ſize, he had an agreeable perſon. His countenance was grave, his air tranquil, and one could not diſcover from his looks either joy in proſperity or chagrin in adverſity. The wars againſt Holland, France, and England, coſt Philip 564 millions of ducats; but America furniſhed him with more than the half of that ſum. His revenues, after the junction of Portugal, are ſaid to have amounted to 25 millions of ducats, of which he only laid out 100,000 for the ſupport of his own houſehold. Philip was very jealous of outward reſpect; he was unwilling that any ſhould ſpeak to him but upon their knees. The duke of Alba having one day entered this prince's cabinet without being introduced, he received the following harſh ſalutation, accompanied with a ſtormy countenance: "An impudence like this of your's would deſerve the hatchet." If he thought only how to make himſelf be feared, he ſucceeded in doing ſo; for few princes have been more dreaded, more abhorred, or have cauſed more blood to flow, than Philip II. of Spain. He had ſucceſſively, if not all at once, war to maintain againſt Turkey, France, England, Holland, and almoſt all the Proteſtants of the empire, without having a ſingle ally, not even the branch of his own houſe in Germany. Notwithſtanding ſo many millions employed againſt the enemies of Spain, Philip found in his œconomy and his reſources wherewith to build 30 citadels, 64 fortified places, 9 ſea-ports, 25 arſenals, and as many palaces, without including the eſcurial. His debts amounted to 140 millions of ducats, of which, after having paid ſeven millions of intereſt, the greateſt part was due to the Genoeſe. Moreover, he had ſold or alienated a capital ſtock of 100 millions of ducats in Italy. He made a law, fixing the majority of the kings of Spain at 14 years of age. He affected to be more than commonly devout; he eat often at the refectory with the monks; he never entered their churches without kiſſing all the relics; he cauſed knead his bread with the water of a fountain which was thought to poſſeſs a miraculous virtue; he boaſted of never having danced, and of never wearing breeches after the Grecian faſhion. Grave and ſolemn in all his actions, he drove from his preſence a woman who had ſmiled while he was blowing his noſe. One great event of his domeſtic life is the death of his ſon Don Carlos. The manner of this prince's death is not certainly known. His body, which lies in the monument of the eſcurial, is there ſeparated from his head; but it is pretended that the head is ſeparated only becauſe the leaden coffin which contains the body is too ſmall. The particulars of his crime are as little known as the manner in which it was committed. There is no evidence, nor is there any probability, that Philip would have cauſed him to be condemned by the inquiſition. All that we know of the matter is, that in 1568 his father, having diſcovered that he had ſome correſpondence with the Hollanders his enemies, arreſted him himſelf in his own room. He wrote at the ſame time to Pope Pius V. in order to give him an account of his ſon's impriſonment; and in his letter to this pontiff, the 20th of January 1568, he ſays, "that from his earlieſt years the ſtrength of a wicked nature has ſtifled in Don Carlos every paternal inſtruction." It was Philip II. who cauſed to be printed at Anvers, between 1569 and 1572, in 8 vols folio, the fine Polyglot Bible, which bears his name; and it was he who ſubjected the iſlands afterwards called the *Philippines*. He married ſucceſſively, 1ſt, Mary daughter of John III. king of Portugal; 2dly, Mary daughter of Henry VIII. and queen of England; 3dly, Elizabeth of France, daughter of Henry II.; 4thly, Anne, daughter of the Emperor Maximilian II. Don Carlos was the ſon of his firſt wife, and Philip III. of the laſt. Philippi.

PHILIPPI (anc. geog.), a town of Macedonia, in the territory of the Edones, on the confines of Thrace (Pliny, Ptolemy), ſituated on the ſide of a ſteep eminence; anciently called *Datum* and *Drenides* (Appian), though Strabo ſeems to diſtinguiſh them. This town was famous on ſeveral accounts; not only as taking its name from the celebrated Philip of Macedon, father to Alexander the Great, who conſidered it as a fit place for carrying on the war againſt the Thracians; but alſo on account of two battles fought in its neighbourhood between Auguſtus and the republican party. In the firſt of theſe battles, Brutus and Caſſius had the command of the republican army; while Octavianus, afterwards Auguſtus, and Mark Antony, had the command of their adverſaries. The army of Brutus and Caſſius conſiſted of 19 legions and 20,000 horſe; the imperial forces of an equal number of legions, but more complete, and 13,000 horſe; ſo that the numbers on both ſides were pretty equal. The troops of Brutus were very richly dreſſed, moſt of them having their armour adorned with gold and ſilver; for Brutus, though very frugal in other reſpects, was thus extravagant with reſpect to his men, thinking that the riches that they had about them would make them exert themſelves the more, to prevent theſe from falling into the enemy's hands. Both the republican generals appear to have been inferior in ſkill to Mark Antony; for as to Octavianus, he is allowed never to have conquered but by the valour of others. A little before the firſt engagement, Octavianus, who had been indiſpoſed, was carried out of the camp, at the perſuaſion of Artorius his phyſician, who had dreamed that he ſaw a viſion directing him to be removed. Brutus's men, who oppoſed the wing commanded by Octavianus, charged without orders, which cauſed great confuſion. However, they were ſucceſsful; for part of them, taking a compaſs about, fell upon the enemy's rear: after which they took and plundered the camp, making a great ſlaughter of ſuch as were in it; and among the reſt putting 2000 Lacedemonians to the ſword who were newly come to the aſſiſtance of Octavianus. The emperor himſelf was ſought for, but in vain, having been conveyed away for the reaſon abovementioned; and as the ſoldiers pierced the litter in which he was uſually carried, it was thence reported

Philippi, Philippics.

that he had been killed. This threw that whole part of the army into such consternation, that when Brutus attacked them in front, they were most completely routed; three whole legions being cut in pieces, and a prodigious slaughter made among the fugitives. But by the imprudence of the general in pursuing too far, the wing of the republican army commanded by Cassius was left naked and separated from the rest of the army; on which they were attacked at once in front and in flank, and thus they were defeated and their camp taken, while Brutus imagined that he had gained a complete victory. Cassius himself retired to an eminence at a small distance from Philippi; whence he sent one of his greatest intimates to procure intelligence concerning the fate of Brutus. That general was on his way, and already in view, when the messenger set out. He soon met his friends; but they surrounding him to inquire the news, Cassius, who beheld what passed, imagined that he was taken prisoner by the enemy, retired to his tent, and in despair caused one of his freedmen cut off his head. Thus far at least is certain, that he went into the tent with that freedman, and that his head was found separated from his body when Brutus entered. However, the freedman was never afterwards seen.

The second engagement was pretty similar to the first. Brutus again opposed Octavianus, and met with the same success; but in the mean time Antony, to whom he ought undoubtedly to have opposed himself, having to do only with the lieutenants of Cassius, gained a complete victory over them. What was worst, the fugitives, instead of leaving the field of battle altogether, fled for protection to Brutus's army; where, crowding in among the ranks, they carried despair and confusion wherever they went, so that a total defeat ensued, and the republican army was almost entirely cut in pieces. After the battle, Brutus put an end to his own life, as is related more fully under the article Rome.

The city of Philippi is likewise remarkable on account of an epistle written by St Paul to the church in that place. It was a Roman colony (Luke, Pliny, Coin, Inscription). It is also remarkable for being the birth-place of Adrastus, the Peripatetic philosopher, and disciple of Aristotle.—The town is still in being, and is an archbishop's see; but greatly decayed and badly peopled.. However, there is an old amphitheatre, and several other monuments of its ancient grandeur. E. Long. 44. 55. N. Lat. 41. 0.

PHILIPPICS, Φιλιππικοι λογοι, in literature, is a name which is given to the orations of Demosthenes against Philip king of Macedon. The Philippics are reckoned the master-pieces of that great orator: Longinus quotes many instances of the sublime from them; and points out a thousand latent beauties. Indeed that pathetic in which Demosthenes excelled, the frequent interrogations and apostrophes wherewith he attacked the indolence of the Athenians, where could they be better employed? Whatever delicacy there be in the oration against Leptines, the Philippics have the advantage over it, were it only on account of the subject, which gives Demosthenes so fair a field to display his chief talent, we mean, with Longinus, that of moving and astonishing.

Dionysius Halicarnasseus ranks the oration on the Halonese among the Philippics, and places it the eighth in order: but though his authority be great, yet that force and majesty wherein Cicero characterises the Philippics of Demosthenes, seem to exclude the oration on the Halonese out of the number; and authorise the almost universal opinion of the learned, who reject it as spurious. Libanius, Photius, and others, but above all the languidness of the style, and the lowness of the expressions, which reign throughout the whole, father it on Hegesippus. Philippic, Philippine Islands.

Philippic is likewise applied to the fourteen orations of Cicero against Mark Antony. Cicero himself gave them this title in his epistles to Brutus; and posterity have found it so just, that it has been continued to our times. Juvenal, Sat. x. calls the second the *divine Philippic*, and witnesses it to be of great fame, *conspicuæ divina Philippica famæ*. That orator's intitling his last and most valued orations after the Philippics of Demosthenes shows the high opinion he had of them. Cicero's Philippics cost him his life; Mark Antony having been so irritated with them, that when he arrived at the triumvirate, he procured Cicero's murder, cut off his head, and stuck it up in the very place whence the orator had delivered the Philippics.

PHILIPPINE islands, are certain islands of Asia, which lie between 114 and 126 degrees of east longitude, and between 6 and 20 degrees of north latitude; about 300 miles south-east of China. They are said to be about 1200 in number, of which there are 400 very considerable. They form a principal division of that immense Indian Archipelago, which consists of so many thousand islands, some of which are the largest, and many of them the richest, in the world. The Philippines form the northernmost cluster of these islands, and were discovered in the year 1521 by the famous navigator Ferdinand Magellan, a Portuguese gentleman, who had served his native country both in the wars of Africa and in the East Indies; particularly under Albuquerque, the famous Portuguese general, who reduced Goa and Malacca to the obedience of that crown. Magellan having had a considerable share in those actions, and finding himself neglected by the government of Portugal, and even denied, as it is said, the small advance of a ducat a month in his pay, left the court of Portugal in disgust, and offered his services to Charles V. then emperor of Germany and king of Spain, whom he convinced of the probability of discovering a way to the Spice Islands, in the East Indies, by the west; whereupon the command of five small ships being given him, he set sail from Seville, on the 10th of August 1510, and standing over to the coast of South America, proceeded southward to 52°, where he fortunately hit upon a strait, since called the *Strait of Magellan*, which carried him into the Pacific Ocean or South Sea; and then steering northward, repassed the equator: after which, he stretched away to the west, across that vast ocean, till he arrived at Guam, one of the Ladrones, on the 10th of March 1521; and soon after sailed to the westward, and discovered the Philippines, which he did on St Lazarus's day; and, in honour of that saint, he called them the *Archipelago of St Lazarus*. He took possession of them in the name of the king of Spain, but happened to be killed in a skirmish he had with the natives of one of them. His people, *Benson's Mil. Mem.*

Philippine Islands.

however, arrived afterwards at the Molucces, or Clove Islands, where they left a colony, and returned to Spain by the way of the Cape of Good Hope; being the firſt perſons that ever ſailed round the globe.—But there was no attempt made by the Spaniards to ſubdue or plant the Philippine Iſlands until the year 1564, in the reign of Philip II. ſon of Charles V. when Don Louis de Velaſco, viceroy of Mexico, ſent Michael Lopez Delagaſpes thither with a fleet, and a force ſufficient to make a conqueſt of theſe iſlands, which he named the *Philippines*, in honour of Philip II. then upon the throne of Spain; and they have remained under the dominion of that crown till taken by Sir William Draper. The Philippines are ſcarce inferior to any other iſlands of Aſia in all the natural productions of that happy climate; and they are by far the beſt ſituated for an extenſive and advantageous commerce. By their poſition, they form the centre of intercourſe with China, Japan, and the Spice Iſlands; and whilſt they are under the dominion of Spain, they connect the Aſiatic and American commerce, and become a general magazine for the rich manufactures of the one and for the treaſures of the other. Beſides, they are well ſituated for a ſupply of European goods, both from the ſide of Acapulco and by the way of the Cape of Good Hope. In fact, they formerly enjoyed a traffic in ſome degree proportioned to the peculiar felicity of their ſituation; but the Spaniſh dominion is too vaſt and unconnected to be improved to the beſt advantage.—The ſpirit of commerce is not powerful in that people. The trade of the Philippines is thought to have declined; its great branch is now reduced to two ſhips, which annually paſs between theſe iſlands and Acapulco in America, and to a ſingle port of Manila in the iſland of Luconia.

Indeed the Spaniards appear by no means to be actuated by the ſpirit of induſtry: for, ſo far from improving the fine ſituation of theſe iſlands to the utmoſt, it happens, on the contrary, that the trade is hurtful to the mother-country; for (to confine ourſelves to Manila, with which they have moſt to do), inſtead of taking Spaniſh manufactures, they trade with the Chineſe for ſpices, ſilks, ſtockings, Indian ſtuffs, callicoes, chintz, and many other articles; and with the Japaneſe for cabinets, and all ſorts of lacquered ware; for all which they pay in gold or ſilver. All theſe commodities, together with what the iſlands produce, and great quantities of wrought plate by the Chineſe artiſans, are collected at Manila, and tranſported annually in two ſhips to Acapulco in Mexico. Each of theſe ſhips is eſteemed worth L.600,000 Sterling; and in the war which began in 1739, and which was not diſtinguiſhed by ſuch a ſeries of wonderful ſucceſſes as that which ended in 1763, the taking of one of the galleons which carry on the trade between Manila and America, was conſidered as one of the moſt brilliant advantages which we gained. This trade is not laid open to all the inhabitants of Manila, but is confined by very particular regulations, ſomewhat analogous to thoſe by which the trade of the regiſter ſhips from Cadiz to the Weſt Indies is reſtrained. The ſhips employed are all king's ſhips, commiſſioned and paid by him; and the tonage is divided into a certain number of bales, all of the ſame ſize. Theſe are divided among the convents at Manila, but principally the Jeſuits (A), as a donation to ſupport their miſſions, for the propagation of the Roman Catholic faith. Moſt of the religious are concerned in this trade, and ſell to the merchants at a great price what room in the ſhip they are not to occupy. This trade is by a royal edict limited to a certain value, but it always exceeds it, each ſhip being generally worth 3,000,000 of dollars. The returns made from America are in ſilver, cochineal, ſweetmeats, together with ſome European millinery ware for the women, and ſome ſtrong Spaniſh wine. It is obvious, that the greateſt part of the treaſure remitted does not remain at Manila, but is diſperſed over India for goods. Many ſtrong remonſtrances againſt this Indian trade to Mexico have been made to the court of Spain, wherein they urge, that the ſilk manufactories of Valentia and other parts of Spain, the linens from Cadiz, and their other manufactories, are hurt in their ſale in Mexico and Peru, by the Chineſe being able to afford them goods of the ſame ſort cheaper than they are able; that were this trade laid open, the whole treaſure of the New World would centre in Spain, or with European merchants; but now it enriches only the Jeſuits and a few private perſons. Wiſe as theſe arguments are, the Jeſuits and prieſts, verſant in intrigue, and the moſt ſelfiſh ſet of men on earth, had intereſt enough at court to ſtop the effect.

At Cavite in this bay are a fort, a town, and a fine dock-yard, where theſe large galleons are built and repaired, and where they load and unload, together with all the other large ſhips that trade to this bay.

The principal of the Philippine iſlands are Luconia or Manila, Tandago or Samul, Maſbate, Mindora, Luban, Paragoa, Panay, Leyte, Bohel, Sibu, Sogbu, Negros, St John, Xolo, and Mindanao. In moſt of theſe, the Spaniſh power prevails, and all are under the governor of Luconia; but there are ſome in which that nation has little authority, or even influence, ſuch as Mindanao.

The inhabitants of theſe iſlands conſiſt of Chineſe, Ethiopians, Malays, Spaniards, Portugueſe, Pintados or Painted People, and Meſtees, a mixture of all theſe. Their perſons and habits reſemble thoſe of the ſeveral nations whence they derive their original; only, it is obſervable, that the features of the blacks of theſe iſlands are as agreeable as thoſe of the white people. There is not a ſoil in the world that produces greater plenty of all things for life; as appears by the multitude of inhabitants to be found in the woods and mountains, who ſubſiſt almoſt entirely by the fruits of the earth, and the veniſon they take. Nor can any country appear more beautiful; for there is a perpetual verdure, and buds, bloſſoms, and fruit, are found upon the trees all the year round, as well on the mountains as in the cultivated gardens. (A) We do not know who has the Jeſuits ſhare ſince they were expelled the Spaniſh dominions.

Philippine Islands.

ties of gold are washed down from the hills by the rains, and found mixed with the sand of their rivers. There are also mines of other metals, and excellent load-stones found here; and such numbers of wild buffaloes, that a good huntsman on horseback, armed with a spear, will kill 10 or 20 in a day. The Spaniards take them for their hides, which they sell to the Chinese; and their carcases serve the mountaineers for food. Their woods also abound with deer, wild hogs, and goats. Of the last, there is such plenty in one of these islands, that the Spaniards gave it the name of *Cabras*. Horses and cows have been likewise imported into these islands, from New Spain, China, and Japan, which have multiplied considerably; but the sheep that were brought over came to nothing. The trees produce a great variety of gums; one kind, which is the commonest, by the Spaniards called *brea*, is used instead of pitch; of the others some are medicinal, others odoriferous.

In those islands are monkeys and baboons of a monstrous bigness, that will defend themselves if attacked by men. When they can find no fruit in the mountains, they go down to the sea to catch crabs and oysters; and that the oysters may not close and catch their paws, they first put in a stone to prevent their shutting close: they take crabs by putting their tail in the holes where they lie, and when the crab lays hold of it, they draw him out. There are also great numbers of civet-cats in some of the islands. The bird called *tavan*, is a black sea-fowl, something less than a hen, and has a long neck; it lays its eggs in the sand by the sea-side, 40 or 50 in a trench, and then covers them, and they are hatched by the heat of the sun. They have likewise the bird *saligan*, which builds her nest on the sides of rocks, as the swallows do against a wall; and these are the delicious *Birds-Nests* so much esteemed, being a kind of jelly that dissolves in warm water.

The Spaniards have introduced several of the American fruits, which thrive here as well as in America; the cocoa or chocolate-nut particularly, which increases so that they have no occasion now to import it from Mexico. Here is also the *Fountain-Tree*, from which the natives draw water; and there is likewise a kind of cane, by the Spaniards called *vaxuco*, which, if cut, yields fair water enough for a draught, of which there are plenty in the mountains, where water is most wanted.

These islands being hot and moist, produce abundance of venomous creatures, as the soil does poisonous herbs and flowers, which do not kill those who touch or taste them, but so infect the air, that many people die in the time of their blossoming.

The orange, lemon, and several other trees, bear twice a year. A sprig, when planted, becomes a tree and bears fruit in a year's time; so that without any hyperbole it may be affirmed, that a more luxuriant verdant soil can scarcely be conceived. The woods are filled with old, large, and lofty trees, and such as yield more sustenance to man than is to be found in almost any other part of the world. These islands, however, besides their other inconveniences, of which they have many, are very subject to earthquakes, which often prove very fatal. See Manila.

Philippines

Philippines, a religious society of young women at Rome, so called from their taking St Philip de Neri for their protector. The society consists of 100 poor girls, who are brought up till they are of age to be married, or become nuns, under the direction of some religious women, who teach them to read, write, and work, and instruct them in the duties of Christianity. They wear a white veil, and a black cross on their breasts. See Macedonia.

Philips

PHILIPPISTS, a sect or party among the Lutherans; the followers of Philip Melancthon. He had strenuously opposed the Ubiquists, who arose in his time; and the dispute growing still hotter after his death, the university of Wittemberg, who espoused Melancthon's opinion, were called by the Flacians, who attacked it, *Philippists*.

PHILIPS (Fabian), was author of several books relating to ancient customs and privileges in England. He was born at Prestbury in Gloucestershire, September 28th 1601. When very young, he spent some time in one of the Inns of Chancery; and went from thence to the Middle Temple, where he became learned in the law. In the civil wars, he was a bold assertor of the king's prerogative; and was so passionate a lover of Charles I. that, two days before that illustrious monarch was beheaded, he wrote a protestation against the intended murder, and caused it to be printed, and affixed to posts in all public places. He likewise published, in 1649, 4to, a pamphlet intituled, "*Veritas Inconcussa*; or King Charles I. no Man of Blood, but a Martyr for his People:" which was reprinted in 1660, 8vo. In 1663, when the courts of justice at Westminster, especially the Chancery, were voted down by Oliver's parliament, he published, "Considerations against the dissolving and taking them away:" for which he received the thanks of William Lenthal, Esq; speaker of the late parliament, and of the keepers of the liberties of England. He was for some time filazer for London, Middlesex, Cambridgeshire, and Huntingdonshire; and spent much money in searching records, and writing in favour of the royal prerogative. The only advantage he received for this attachment to the royal cause was, the place of one of the commissioners for regulating the law, worth L. 200 *per annum*, which only lasted two years. After the Restoration of Charles II. when the bill for taking away the tenures was depending in parliament, he wrote and published a book to show the necessity of preserving them, intitled, "*Tenenda non tollenda*; or, the Necessity of preserving Tenures *in capite*, and by Knight's-service, which, according to their first institution, were, and are yet, a great part of the *salus populi*, &c. 1660," 4to. In 1663 he published, "The Antiquity, Legality, Reason, Duty, and Necessity of Pre-emption and Pourveyance for the King," 4to; and afterwards many other pieces upon subjects of a similar kind. He assisted Dr Bates in his "*Elenchus Motuum*; especially in searching the records and offices for that work. He died, November 17th, 1690, in his 89th year; and was buried near his wife in the church of Twyford in Middlesex. He was a man well acquainted with records and antiquities; but his manner of writing is neither close nor well digested. He published a political pamphlet in 1681, intitled,

Philips. intitled, "*Urſa Major et Minor*; ſhowing that there is no ſuch Fear, as is factitiouſly pretended, of Popery and arbitrary Power."

Philips (Ambroſe), an Engliſh poet, was deſcended from a very ancient and conſiderable family of that name in Leiceſterſhire. He received his education at St John's college, Cambridge; during his ſtay at which univerſity, he wrote his paſtorals, which acquired him at the time ſo high a reputation. His next performance was, *The Life of Archbiſhop Williams*, written, according to Mr Cibber, to make known his political principles, which in the courſe of it he had a free opportunity of doing, as the archbiſhop, who is the hero of his work, was a ſtrong opponent to the high-church meaſures.

When he quitted the univerſity, and came to London, he became a conſtant attendant at, and one of the wits of, Button's coffee-houſe, where he obtained the friendſhip and intimacy of many of the celebrated geniuſes of that age, more particularly of Sir Richard Steele, who, in the firſt volume of his *Tatler*, has inſerted a little poem of Mr Philips's, which he calls a *Winter Piece*, dated from Copenhagen, and addreſſed to the earl of Dorſet, on which he beſtows the higheſt encomiums; and, indeed, ſo much juſtice is there in theſe his commendations, that even Mr Pope himſelf, who had a fixed averſion for the author, while he affected to deſpiſe his other works, uſed always to except this from the number.

The firſt diſlike Mr Pope conceived againſt Mr Philips, proceeded from that jealouſy of fame which was ſo conſpicuous in the character of that great poet; for Sir Richard Steele had taken ſo ſtrong a liking to the paſtorals of the latter, as to have formed a deſign for a critical compariſon of them with thoſe of Pope, in the concluſion of which the preference was to have been given to Philips. This deſign, however, coming to Mr Pope's knowledge, that gentleman, who could not bear a rival near the throne, determined to ward off this ſtroke by a ſtratagem of the moſt artful kind; which was no other than taking the ſame taſk on himſelf; and, in a paper in the Guardian, by drawing the like compariſon, and giving a like preference, but on principles of criticiſm apparently fallacious, to point out the abſurdity of ſuch a judgment. However, notwithſtanding the ridicule that was drawn on him in conſequence of his ſtanding as it were in competition with ſo powerful an antagoniſt, it is allowed, that there are, in ſome parts of Philips's paſtorals, certain ſtrokes of nature, and a degree of ſimplicity, that are much better ſuited to the purpoſes of paſtoral, than the more correctly turned periods of Mr Pope's verſification. Mr Philips and Mr Pope being of different political principles, was another cauſe of enmity between them; which roſe at length to ſo great a height, that the former, finding his antagoniſt too hard for him at the weapon of wit, had even determined on making uſe of a rougher kind of argument; for which purpoſe he even went ſo far as to hang up a rod at Button's for the chaſtiſement of his adverſary whenever he ſhould come thither; which, however, Mr Pope declining to do, avoided the *argumentum baculinum*, in which he would, no doubt, have found himſelf on the weakeſt ſide of the queſtion. Our author alſo wrote ſeveral dramatical pieces; The Briton, Diſtreſſed Mo- Phillps. ther, and Humphrey Duke of Glouceſter; all of which met with ſucceſs, and one of them is at this time a ſtandard of entertainment at the theatres, being generally repeated ſeveral times in every ſeaſon. Mr Philips's circumſtances were in general, through his life, not only eaſy, but rather affluent, in conſequence of his being connected, by his political principles, with perſons of great rank and conſequence. He was concerned with Dr Hugh Boulter, afterwards archbiſhop of Armagh, the right honourable Richard Weſt, Eſq; lord chancellor of Ireland, the reverend Mr Gilbert Burnet, and the reverend Mr Henry Stevens, in writing a ſeries of papers called the *Free Thinker*, which were all publiſhed together by Mr Philips, in three volumes in 12mo.

In the latter part of Queen Anne's reign, he was ſecretary to the Hanover club, who were a ſet of noblemen and gentlemen who had formed an aſſociation in honour of that ſucceſſion, and for the ſupport of its intereſts, and who uſed particularly to diſtinguiſh in their toaſts ſuch of the fair ſex as were moſt zealouſly attached to the illuſtrious Houſe of Brunſwic. Mr Philips's ſtation in this club, together with the zeal ſhown in his writings, recommended him to the notice and favour of the new government. He was, ſoon after the acceſſion of king George I. put into the commiſſion of the peace, and appointed one of the commiſſioners of the lottery. And, on his friend Dr Boulter's being made primate of Ireland, he accompanied that prelate acroſs St George's Channel, where he had conſiderable preferments beſtowed on him, and was elected a member of the Houſe of Commons there, as repreſentative for the county of Armagh. At length, having purchaſed an annuity for life of 400 l. *per annum*, he came over to England ſome time in the year 1748; but having a very bad ſtate of health, and being moreover of an advanced age, he died ſoon after, at his lodgings near Vauxhall, in Surry.

"Of his perſonal character (ſays Dr Johnſon) all I have heard is, that he was eminent for bravery, and ſkill in the ſword, and that in converſation he was ſolemn and pompous." He is ſomewhere called *Quaker Philips*, but, however, appears to have been a man of integrity; for the late Paul Whitehead relates, that when Mr Addiſon was ſecretary of ſtate, Philips applied to him for ſome preferment, but was coolly anſwered, "that it was thought that he was already provided for, by being made a juſtice for Weſtminſter." To this obſervation our author, with ſome indignation, replied, "Though poetry was a trade he could not live by, yet he ſcorned to owe ſubſiſtence to another which he ought not to live by."

The following anecdote is told of our author by Dr Johnſon: "At a coffee-houſe, he (Philips) was diſcourſing upon pictures, and pitying the painters, who, in their hiſtorical pieces, always draw the ſame ſort of *ſky*. "They ſhould travel (ſaid he), and then they would ſee that there is a different *ſky* in every country, in England, France, Italy, and ſo forth." "Your remark is juſt (ſaid a grave gentleman who ſat by), I have been a traveller, and can teſtify what you obſerve is true; but the greateſt variety of *ſkies* that I found was in Poland." "In Poland, Sir? (ſays Philips)."

Philips. lips)." "Yes, in Poland; for there is Sobie*ſky*, and Sabrun*ſky*, and Jablon*ſky*, and Podebra*ſky*, and many more *ſkies*."

PHILIPS (Catharine), a very ingenious lady, the daughter of Mr John Fowler merchant, was born at London in January 1631, and educated at a ſchool at Hackney. She married James Philips of the priory of Cardigan, Eſq; and went with the viſcounteſs of Dungannon into Ireland, where ſhe tranſlated Corneille's tragedy of Pompey into Engliſh, which was ſeveral times acted there with great applauſe.

She tranſlated alſo the four firſt acts of Horace, another tragedy of Corneille, the fifth being done by Sir John Denham. This excellent and amiable lady, for ſuch it ſeems ſhe was, died of the ſmallpox in London, the 22d of June 1664, much and juſtly regretted; "having not left (ſays Langbaine) any of her ſex her equal in poetry.—She not only equalled (adds he) all that is reported of the poeteſſes of antiquity, the Leſbian Sappho and the Roman Sulpitia, but juſtly found her admirers among the greateſt poets of our age." Cowley wrote an ode upon her death. Dr Jeremy Taylor had addreſſed to her his "Meaſures and Offices of Friendſhip:" the ſecond edition of which was printed in 1657, 12mo. She aſſumed the name of *Orinda*. In 1667, were printed, in folio, "Poems by the moſt deſervedly admired Mrs Catharine Philips, the matchleſs Orinda. To which is added, Monſieur Corneille's Pompey and Horace, tragedies. With ſeveral other tranſlations from the French;" and her picture before them, engraven by Faithorne. There was likewiſe another edition in 1678, folio; in the preface of which we are told, that "ſhe wrote her familiar letters with great facility, in a very fair hand, and perfect orthography; and if they were collected with thoſe excellent diſcourſes ſhe wrote on ſeveral ſubjects, they would make a volume much larger than that of her poems." In 1705, a ſmall volume of her letters to Sir Charles Cotrel were printed under the title of "Letters from Orinda to Poliarchus. The editor of theſe letters tells us, that "they were the effect of an happy intimacy between herſelf and the late famous Poliarchus, and are an admirable pattern for the pleaſing correſpondence of a virtuous friendſhip. They will ſufficiently inſtruct us, how an intercourſe of writing between perſons of different ſexes ought to be managed with delight and innocence; and teach the world not to load ſuch a commerce with cenſure and detraction, when it is removed at ſuch a diſtance from even the appearance of guilt."

PHILIPS (John), an eminent Engliſh poet, was born in 1676. He was educated at Winchester and Oxford, where he became acquainted with Milton, whom he ſtudied with great application, and traced in all his ſucceſsful tranſlations from the ancients. The firſt poem which diſtinguiſhed our author, was his *Splendid Shilling*, which is in the *Tatler* ſtyled the *fineſt burleſque poem in the Engliſh language*. His next was intitled *Blenheim*, which he wrote at the requeſt of the earl of Oxford, and Mr Henry St John, afterwards Lord Bolingbroke, on the victory obtained there by the duke of Marlborough in 1704. It was publiſhed in 1705; and the year after he finiſhed another poem upon cyder, the firſt book of which had been written at Oxford. It is on the model of Virgil's Georgics, and is a very excellent piece. We have no more of Mr Philips but a Latin ode to Henry St John, Eſq; which is eſteemed a maſterpiece. He was contriving greater things; but illneſs coming on, he was obliged to drop every thing but the care of his health. This care, however, did not ſave him: for, after lingering a long time, he died at Hereford, Feb. 15. 1708, of a conſumption and aſthma, before he had reached his 33d year. He was interred in the cathedral of that city with an inſcription over his grave; and had a monument erected to his memory in Weſtminſter-abbey by Sir Simon Harcourt, afterwards lord-chancellor, with an epitaph upon it written by Dr Atterbury, though commonly aſcribed to Dr Freind. He was one of thoſe few poets whoſe muſe and manners were equally excellent and amiable; and both were ſo in a very eminent degree. Philips.

Dr Johnſon obſerves, that "Philips has been always praiſed, without contradiction, as a man modeſt, blameleſs, and pious; who bore a narrow fortune without diſcontent, and tedious and painful maladies without impatience; beloved by thoſe that knew him, but not ambitious to be known. He was probably not formed for a wide circle. His converſation is commended for its innocent gaiety, which ſeems to have flowed only among his intimates; for I have been told, that he was in company ſilent and barren, and employed only upon the pleaſures of his pipe. His addiction to tobacco is mentioned by one of his biographers, who remarks, that in all his writings except Blenheim he has found an opportunity of celebrating the fragrant fume. In common life, he was probably one of thoſe who pleaſe by not offending, and whoſe perſon was loved, becauſe his writings were admired. He died honoured and lamented, before any part of his reputation had withered, and before his patron St John had diſgraced him. His works are few. The Splendid Shilling has the uncommon merit of an original deſign, unleſs it may be thought precluded by the ancient *Centos*. To degrade the ſounding words and ſtately conſtruction of Milton, by an application to the loweſt and moſt trivial things, gratifies the mind with a momentary triumph over that grandeur which hitherto held its captives in admiration; the words and things are preſented with a new appearance, and novelty is always grateful where it gives no pain. But the merit of ſuch performances begins and ends with the firſt author. He that ſhould again adapt Milton's phraſe to the groſs incidents of common life, and even adapt it with more art, which would not be difficult, muſt yet expect but a ſmall part of the praiſe which Philips has obtained; he can only hope to be conſidered as the repeater of a jeſt.

"There is a Latin ode written to his patron St John, in return for a preſent of wine and tobacco, which cannot be paſſed without notice. It is gay and elegant, and exhibits ſeveral artful accommodations of claſſic expreſſions to new purpoſes. It ſeems better turned than the odes of Haunes. To the poem on cyder, written in imitation of the Georgics, may be given this peculiar praiſe, that it is grounded in truth; that the precepts which it contains are exact and juſt; and that it is therefore at once a book of entertainment and of ſcience. This I was told by Miller, the great

Philips || Philiſtines.

great gardener and botaniſt, whoſe expreſſion was, that 'there were many books written on the ſame ſubject in proſe, which do not contain ſo much truth as that poem.' In the diſpoſition of his matter, ſo as to interſperſe precept, relating to the culture of trees, with ſentiments more generally pleaſing, and in eaſy and graceful tranſitions from one ſubject to another, he has very diligently imitated his maſter; but he unhappily pleaſed himſelf with blank verſe, and ſuppoſed that the numbers of Milton, which impreſs the mind with veneration, combined as they are with ſubjects of inconceivable grandeur, could be ſuſtained by images which at moſt can riſe only to elegance. Contending angels may ſhake the regions of heaven in blank verſe; but the flow of equal meaſures, and the embelliſhment of rhime, muſt recommend to our attention the art of engrafting, and decide the merit of the redſtreak and pearmain. What ſtudy could confer, Philips had obtained; but natural deficiency cannot be ſupplied. He ſeems not born to greatneſs and elevation. He is never lofty, nor does he often ſurpriſe with unexpected excellence: but perhaps to his laſt poem may be applied what Tully ſaid of the work of Lucretius, that 'it is written with much art, though with few blazes of genius.'

It deſerves to be remarked, that there were two poets of both the names of our author, and who flouriſhed in his time. One of them was Milton's nephew, and wrote ſeveral things, particularly ſome memoirs of his uncle, and part of Virgil Traveſtied. The other was the author of two political farces, which were both printed in 1716; 1. The Earl of Marr married, with the Humours of Jocky the Highlander. 2. The Pretender's Flight; or a Mock Coronation, with the Humours of the facetious Harry St John.

PHILIPSBURG, is an imperial town of Germany, in the circle of the Upper Rhine. It is very ſtrong, and looked upon as one of the bulwarks of the empire. It is ſeated in a moraſs, and fortified with ſeven baſtions, and ſeveral advanced works. The town belongs to the biſhop of Spire, but all the works and the fortifications to the empire. It has been ſeveral times taken and retaken, particularly by the French in 1734, when the duke of Berwick was killed at the ſiege; but it was rendered back the year following, in conſequence of the treaty of Vienna. It is ſeated on the river Rhine, over which there is a bridge ſeven miles ſouth of Spire, 22 ſouth-eaſt of Worms, and 40 north-eaſt of Straſburg. E. Long. 8. 33. N. Lat. 49. 12.

PHILISTÆA (anc. geog.), the country of the Philiſtines (Bible); which lay along the Mediterranean, from Joppa to the boundary of Egypt, and extending to inland places not far from the coaſt. *Paleſtini*, the people; *Paleſtina*, the country (Joſephus): Afterwards applied to the whole of the Holy Land and its inhabitants. *Philiſtai*, the people (Septuagint); *Philiſtini* (Vulgate); the *Caphtorim* and *Philiſtim*, originally from Egypt, and deſcendants of Cham (Moſes). Expelled and deſtroyed the Hivites the ancient inhabitants, and occupied their country; that is, the region which retained the name of *Philiſtim*, in which that of *Caphtorim* was ſwallowed up.

PHILISTINES, were the ancient inhabitants of Paleſtine, well known in ſacred hiſtory. Theſe people are ſometimes called in Scripture *Cherethites* and *Caphtorims*. The earlier part of their hiſtory is, like that of moſt other nations, very obſcure and uncertain. The authors of the Univerſal Hiſtory tell us, that they were deſcended from the Caſluhim partly, and partly from the Caphtorim, both from the loins of Mizraim the ſon of Ham, the ſon of Noah. Moſes tells us (Deut. xi. 23.), that they drove out the Avim or Avites even to Azzah or Gazah, where they ſettled; but when this happened cannot be determined. On the whole, however, our learned authors are clearly of opinion, that the Caſluhim and Caphtorim, from whom the Philiſtines are deſcended, came originally from Egypt, and called the country which they had conquered by their own name (See PALESTINE). Many interpreters, however, think, that Caphtor was but another name for Cappadocia, which they imagine to have been the original country of the Philiſtines. But Father Calmet, in a particular diſſertation prefixed to the firſt book of Samuel, endeavours to ſhow that they were originally of the iſle of Crete. The reaſons which led him to think that Caphtor is the iſle of Crete are as follow: The Philiſtines were ſtrangers in Paleſtine, as appears in various parts of Scripture; ſuch as Gen. x. 14. Deut. ii. 23. Jer. xlvii. 4. and Amos ix. 7. whence the Septuagint always tranſlate this name *Strangers*. Their proper name was Cherethims, for Ezekiel (xxv. 16.), ſpeaking againſt the Philiſtines, has theſe words, "I will ſtretch out mine hand upon the Philiſtines, and I will cut off the Cherethims, and deſtroy the remnant of the ſea-coaſt." Zephaniah (ii. 5.), inveighing againſt the ſame people, ſays, "Wo unto the inhabitants of the ſea-coaſts, the nation of the Cherethites." And Samuel (Book I. xxx. 14.) ſays, that the Amalekites made an irruption into the country of the Cherethites, that is to ſay, of the Philiſtines, as the ſequel of the diſcourſe proves. And afterwards the kings of Judah had foreign guards called the *Cherethites* and *Pelethites*, who were of the number of the Philiſtines (2 Sam. xv. 18.) The Septuagint, under the name *Cherethites*, underſtood the *Cretans*; and by *Cherith* they underſtood *Crete*. Beſides the Scripture ſays, that the Philiſtines came from the iſle of Caphtor. Now we ſee no iſland in the Mediterranean wherein the marks whereby the Scripture deſcribes Caphtor and Cherethim agree better than in the iſle of Crete. The name *Cretim* or *Cherethim* is the ſame with that of *Cretenſes*. The Cretans are one of the moſt ancient and celebrated people which inhabited the iſlands of the Mediterranean. They pretended to have been produced originally out of their own ſoil. This iſland was well peopled in the time of the Trojan war. Homer calls it the iſland with a hundred cities. The city of Gaza in Paleſtine went by the name of *Minoa* (*Steph. Byzant. in Gaza*), becauſe Minos king of Crete coming into that country, called this ancient city by his own name.

Philiſtines.

Herodotus acknowledges that the Cretans were originally all barbarians, and did not come from Greece. Homer ſays, that a different language was ſpoken in the iſle of Crete; that there were Greeks there, true or ancient Cretans, Pelaſgians, &c. The ancient Cretans are the ſame as the Cherethites, the Pelaſgians as the Philiſtines or Pelethites of the Scripture: their language was the ſame with that of the Canaanites or Phœnicians, that is, Hebrew: they were deſcended, as well

Philiſtines. well as Canaan, from Ham, by Mizraim (Gen. x. 6, 13, 14.) The manners, arms, religion, and gods of the Cretans and Philiſtines were the ſame. The arms of the one and the other were bows and arrows. Dagon the god of the Philiſtines was the ſame as the Dictynna of the Cretans.

Whether theſe arguments are convincing, it is not for us to determine; but Wells does not think they are, as he is of the ſame opinion with the authors of the Univerſal Hiſtory, who ſay, that *Coptus*, the name of an old city of Egypt, is a corruption of the ancient *Caphtor*. It is not, however, of great importance to determine whether they came from Crete, from Cappadocia, or from Egypt: they had certainly been a conſiderable time in the land of Canaan, when Abraham arrived there in the year of the world 2083. They were then a very powerful people, were governed by kings, and in poſſeſſion of ſeveral conſiderable cities. The race of kings then in power were honoured with the title of *Abimelech*. This race, however, was but of ſhort duration; for their monarchy became an ariſtocracy of five lords, who were, as far as we can diſcover, partly independent of each other, though they acted in concert for the common cauſe. This form of government was again ſucceeded by another race of kings, diſtinguiſhed by the title of *Achiſh*, though they alſo bore that of *Abimelech*. The kings were always under great limitations. The Philiſtines appear to have been a very warlike people, induſtrious, and lovers of freedom; they did not circumciſe, and in the early periods of their hiſtory held adultery in the greateſt abhorrence. "Their character (ſay the authors of the Univerſal Hiſtory) muſt be conſidered at different periods; for we may ſay they were not always the ſame people. In the days of Abraham and Iſaac, they were without all doubt a righteous and hoſpitable nation: but afterwards a revolution in government, religion, and morals, may have enſued. From thenceforward they became like other idolatrous nations; the ſame enormities crept in and prevailed among them. They are conſtantly mentioned in Scripture as ſtrangers; and, though poſſeſſed of a moſt conſiderable part of the Land of Promiſe, yet God would never ſuffer them to be driven out, they being Egyptians by deſcent, and not original natives, whoſe land only was promiſed to Abraham and his ſeed. Their arrogance and ambition were great; and ſo irreconcileable was their enmity (A) to the Iſraelites, that one would be almoſt tempted to think they were created on purpoſe to be a thorn in their ſides; for though the hand of God was evidently againſt them ſeveral times, and particularly when they detained the ark, yet they hardened their hearts, and cloſed their eyes againſt conviction. They ſeem to have entertained a very fond veneration for their deities, in which they perſiſted, tho' they were eye-witneſſes of the ſhame and ignominy which befel them in the preſence of the captive ark; nay, they were ſo biaſſed in their favour, as to imagine that their gods might prevail againſt Him who had in ſo glaring a manner put them to ſhame and diſgrace. They were much addicted to trade; which, conſidering their ſituation, they may have exerciſed from the beginning; but, by the acceſſion of the fugitive Edomites in David's time, they roſe to ſo great a reputation as merchants, that the Greeks, it ſeems, preferred them to all other nations in that reſpect, and from them called all the country bordering on theirs *Paleſtine*. Their language was not ſo different from that ſpoken by the Hebrews as to cauſe any difficulty for them to converſe together, as will be perceived by their intercourſe with Abraham and Iſaac; ſo that, in all this region, the ſeveral nations ſpoke one and the ſame tongue, perhaps with ſome variation of dialect. They had doubtleſs the arts and ſciences in common with the moſt learned and ingenious among their contemporaries, and perhaps ſome of them in greater perfection. They had giants among them; but whether they were originally of the breed of the Anakims, who retired hither when they were expelled from Hebron, or were ſprung from accidental births, is not eaſily determined. We muſt not forget, that the invention of the bow and arrow is aſcribed to this people.

Philiſtines

Anc. part, vol. i. p. 408. &c

"Their religion was different at different times; under their firſt race of kings, they uſed the ſame rites with the Hebrews. Abimelech, in the ſin he had like to have committed with Sarah, through Abraham's timidity, was favoured with a divine admonition from God; and, by his ſpeech and behaviour at that time, it ſeems as if he had been uſed to converſe with the Deity. In after-times, they erred into endleſs ſuperſtitions, and different kinds of idolatry; each of the principal or five cities ſeemed to have had an idol of its own. Marna, Marnas, or Marnaſh, was worſhipped at Gaza, and is ſaid to have migrated into Crete, and to have become the Cretan Jupiter. Dagon was worſhipped at Azotus; he ſeems to have been the greateſt, the moſt ancient, and moſt favourite god they had; to which may be added, that he perhaps ſubſiſted the longeſt of any that did not ſtraggle out of the country. To him they aſcribed the invention of bread-corn, or of agriculture, as his name imports. We cannot enter into the common notion of his being repreſented as a monſter, half man half fiſh; nor conſequently into another almoſt as common, that he is the ſame with the Syrian goddeſs Derceto, who, we are told, was repreſented under ſome ſuch mixed form. Our opinion is, that this idol was in ſhape wholly like a man; for we read of his head, his hands, and his feet. He ſtood in a temple at Azotus, and had prieſts of his own who paid him a very conſtant attendance.

(A) "From a paſſage in Chronicles, it is gueſſed to have been of very ancient date; where it is ſaid, that 'the men of Gath ſlew the children of Ephraim, who would have taken their cattle from them.' This incident is nowhere elſe to be found; and there are various notions concerning the ſenſe in which we muſt take this paſſage. As to the time of the tranſaction, moſt people allow it to have been while the children of Iſrael were ſojourners in Egypt. It plainly appears, by the next verſe, that Ephraim himſelf was living at that period. The Targum ſuppoſes his children miſcomputed the time they were to ſerve in Egypt, and began too early an attempt upon their Promiſed Land."

Philiſtines

Next to Dagon was Baalzebub the God of Ekron. In the text of the New Teſtament he is called *Beelzebub*, and the *prince of devils*. His name is rendered *lord of flies*; which by ſome is held to be a mock appellation beſtowed on him by the Jews; but others think him ſo ſtyled by his worſhippers, as Hercules Apomyios, and others, were, from his driving thoſe inſects away; and urge, that Ahaziah, in his ſickneſs, would ſcarcely have applied to him, if his name had carried in it any reproach. But it muſt be remembered, it is the ſacred hiſtorian that makes uſe of that contemptuous term in deriſion; whereas the idolatrous monarch, who was one of his votaries, might call him by his common name, ſuppoſed to have been *Baal-zebaoth*, 'the lord of armies,' or *Baal-ſhamim*, 'lord of heaven,' or ſome other bordering on Baal-zebub. How, or under what form he was repreſented, is uncertain: ſome place him on a throne, and attire him like a king; others paint him as a fly. Not to dwell on this obſcurity, it appears that he became an oracle of the higheſt repute for omniſcience and veracity; that he had prieſts of his own; and that he, in the middle times at leaſt, was much ſought after by thoſe who were anxious about futurity. Derceto we take certainly to have been the goddeſs of Aſcalon; but we are ſupported by profane authority, without the leaſt countenance from Scripture. Gath is ſeemingly the only city of all the five unprovided with a deity; wherefore, as the Scripture declares, that Aſhtaroth, or Aſtarte, was worſhipped by this people, we are ready to place her at Gath, and the rather, as this of all their cities may have had moſt communication with Sidon. To ſpeak in general concerning their religious rites and ceremonies, which is all we can do, they ſeem to have erected very large and ſpacious temples, or very wide halls, for the celebration of their ſolemn ſeaſons and feſtivals (for ſuch they ſurely had); their religious offices were attended with much pomp, and a great concourſe from all parts; and they preſented their gods with the chief part of their ſpoil, and carried them about with them when they went to war. We do not find in Scripture that they ſacrificed their children; and yet the Curetes(B) are ſaid to be their deſcendants."

With reſpect to the hiſtory of this extraordinary people, we find from the above extract, that they were not comprehended in the number of nations devoted to extermination, and whoſe territory the Lord had abandoned to the Hebrews; nor were they of the curſed ſeed of Canaan. However, Joſhua did not forbear to give their lands to the Hebrews, and to ſet upon them by command from the Lord, becauſe they poſſeſſed a country which was promiſed to the people of God (Joſh. xv. 45—47. and xiii. 2, 3.) But theſe conqueſts of Joſhua muſt have been ill maintained, ſince under the Judges, under Saul, and at the beginning of the reign of David, the Philiſtines oppreſſed the Iſraelites. True it is, Shamgar, Samſon, Samuel, and Saul, made head againſt them, but did not reduce their power; and they continued independent down to the reign of David, who ſubjected them to his government. Philiſtines, Phillyrea.

They continued in ſubjection to the kings of Judah down to the reign of Jehoram, ſon of Jehoſhaphat; that is, for about 246 years. However, Jehoram made war againſt them, and probably reduced them to his obedience again; becauſe it is obſerved in Scripture, that they revolted again from Uzziah; and that this prince kept them to their duty during the time of his reign (2 Chr. xxi. 16. and xxvi. 6 7.) During the unfortunate reign of Ahaz, the Philiſtines made great havoc in the territories of Judah; but his ſon and ſucceſſor Hezekiah ſubdued them (2 Chr. xxviii. 18 and 2 Kings xviii. 8.) Laſtly, they regained their full liberty under the latter kings of Judah; and we may ſee by the menaces denounced againſt them by the prophets Iſaiah, Amos. Zephaniah, Jeremiah, and Ezekiel, that they brought a thouſand hardſhips and calamities upon the children of Iſrael: for which cruelties God threatened to puniſh them. Eſarhaddon beſieged Aſhdod or Azoth, and took it (Iſa. xx. 1.) And according to Herodotus, Pſammeticus king of Egypt took the ſame city, after a ſiege of 29 years. There is great probability, that Nebuchadnezzar, when he ſubdued the Ammonites, Moabites, Egyptians, and other nations, bordering upon the Jews, reduced alſo the Philiſtines. After this, they fell under the dominion of the Perſians; then under that of Alexander the Great, who deſtroyed the city of Gaza, the only city of Phœnicia that durſt oppoſe him. After the perſecution of Antiochus Epiphanes, the Aſmonæans ſubjected under their obedience ſeveral cities of the Philiſtines; and Tryphon gave to Jonathan Maccabæus the government of the whole coaſt of the Mediterranean, from Tyre as far as Egypt, which included all the country of the Philiſtines.

PHILLYREA, MOCK-PRIVET; a genus of the monogynia order, belonging to the diandria claſs of plants. Each flower contains two males and one female. Some ſay there are ſeven ſpecies, all of them ſhrubby plants, and natives of France or Italy. Others reckon only three ſpecies, which are as follow:

1. *Phillyrea media*; the oval leaved phillyrea or mock privet, or the medial leaved phillyrea, a tall evergreen ſhrub, native of the ſouth of Europe. 2. *Phillyrea latifolia*; the broad-leaved phillyrea or mock-privet, a tall evergreen ſhrub, native of the ſouth of Europe. 3. *Phillyrea anguſtifolia*; the narrow-leaved phillyrea or mock-privet, a deciduous ſhrub, native of Spain and Italy. *Dict. Planting and Gardening.*

1. The firſt has three varieties, *viz.* The firſt is the common ſmooth-leaved phillyrea. This plant grows to be 12 or 14 feet high, and the branches are very numerous. The older branches are covered with a dark brown bark, but the bark on the young ſhoots is of a fine green colour. They are oval, ſpear-ſhaped, and grow oppoſite, by pairs, on ſtrong ſhort footſtalks. The

(B) "The Curetes ſacrificed their children to Saturn; and from the ſimilitude this name bears to Chezethites or Philiſtines, it has been advanced that they are the ſame people; but as we have no warrant for ſaying the Philiſtines practiſed ſo barbarous and unnatural a cuſtom, we may venture to pronounce, that they learned it not from them, but borrowed it elſewhere."

Phillyrea. The flowers are produced in clusters from the wings of the young branches. They are small, and of a kind of greenish-white colour; they appear in March, and are succeeded by berries, which are first green, then red, and black in the autumn when ripe. The second variety is the privet-leaved phillyrea, which grows to be 10 or 12 feet high, and the branches of which are covered with a brown bark. The leaves a little resemble the privet; they are of a fine green colour, and grow by pairs on the branches. They are of a lanceolate figure, and their edges are entire, or nearly so; for some signs of serratures sometimes appear. The flowers grow like others in clusters in March. They are whitish, and are succeeded by small black berries. The third variety, or the olive-leaved phillyrea, is the most beautiful of all the sorts. It will grow to be about 10 or 12 feet high; and the branches, which are not numerous, spread abroad in a free easy manner, which may not improperly be said to give the tree a fine air. They are long and slender, and are covered with a light brown bark; and on these the leaves stand opposite by pairs at proper intervals on short footstalks. They resemble those of the olive-tree, and are of so delightful a green as to force esteem. Their surface is exceeding smooth, their edges are entire, and the membrane of a thickish consistence. The flowers are small and white, and like the other sorts make no show. They are succeeded by single roundish berries.

2. The broad-leaved phillyrea will grow to be about 12 feet high. The branches seem to be produced stronger and more upright than those of the former species. The bark is of a grey colour, spotted with white, which has a pretty effect; and the leaves grow opposite by pairs. They are of a heart-shaped oval figure, of a thick consistence, and a strong dark-green colour. Their edges are sharply serrated, and they stand on short strong footstalks. The flowers grow from the wings of the leaves in clusters in March. They are of a kind of greenish-white colour, make no show, and are succeeded by small round black berries. There are also three varieties of this species, *viz.* the ilex-leaved phillyrea, the prickly phillyrea, and the olive phillyrea with slightly serrated edges.

3. The narrow-leaved phillyrea is of lower growth, seldom rising higher than 8 or 10 feet. The branches are few and slender, and they also are beautifully spotted with grey spots. The leaves, like the others, stand opposite by pairs. They are long and narrow, spear-shaped, and undivided, of a deep green colour, and of a thick consistence. Their edges are entire, and they also stand on short footstalks. The flowers, like the others, make no show. They are whitish, and grow in clusters from the wings of the branches, in March; and are succeeded by small round black berries. The varieties of this species are, the rosemary phillyrea, lavender phillyrea, striped phillyrea, &c.

This vegetable is to be propagated by seeds or layers. 1. By seeds. These ripen in the autumn, and should be sown soon after. The mould must be made fine; and if it is not naturally sandy, if some drift sand be added, it will be so much the better. The seeds for the most part remain until the second spring before they come up; and if they are not sown soon after they are ripe, some will come up even the third spring after. They must be sown about an inch deep; and during the following summer should be kept clean from weeds. After they are come up, the same care must be observed, and also watering in dry weather; and if the beds are hooped, and the plants shaded in the hottest season, they will be so much the better for it. However, at the approach of winter they must be hooped, and the beds covered with mats in the hardest frosts, otherwise there will be danger of losing the whole crop; for these trees, though they are very hardy when grown tolerably large, are rather tender whilst seedlings. It will be proper to let them remain in the seed-beds with this management for two summers; and then waiting for the first autumnal rains, whether in September or October (and having prepared a spot of ground), they should at that juncture be planted out, and this will occasion them immediately to strike root. The distance they should be planted from each other need not be more than a foot, if they are not designed to remain long in the nursery. If there is a probability of their not being wanted for some years, they should be allowed near double that distance; and every winter the ground in the rows should be well dug, to break their roots, and cause them to put out fresh fibres, otherwise they will be in danger of being lost when brought into the shrubbery quarters. 2. By layers they will easily grow. The autumn is the best time for this operation, and the young shoots are fit for the purpose. The best way of layering them is by making a slit at the joint; though they will often grow well by a twist being only made. When the gardener chooses the method of twisting a young branch for the layers, he must be careful to twist it about a joint so as only to break the bark; for if it is too much twisted, it will die from that time, and his expectations wholly vanish. But if it be gently twisted with art and care, it will at the twisted parts be preparing to strike root, and by the autumn following, as well as those layers that had been slit, will have good roots; the strongest of which will be fit for planting where they are wanted to remain, whilst the weaker and worst-rooted layers may be planted in the nursery-ground like the seedlings, and treated accordingly.

Phillyrea, Philo.

PHILO, an ancient Greek writer, was of a noble family among the Jews, and flourished at Alexandria during the reign of Caligula. He was the chief of an embassy sent to Rome about the year 42, to plead the cause of the Jews against Apion, who was sent by the Alexandrians to charge them with neglecting the honours due to Cæsar. Caligula, however, would not allow him to speak, and behaved to him in such a manner that Philo was in considerable danger of losing his life. Others again tell us that he was heard; but that his demands were refused. He afterwards went to Rome in the reign of Claudius; and then, Eusebius and Jerome inform us, he became acquainted with St Peter, with whom he was on terms of friendship. Photius adds, that he became a Christian, and afterwards, from some motive of resentment, renounced it. Great part of this, however, is uncertain, for few believe that St Peter was at Rome so early as the reign of Claudius, if he ever was there at all.

Philo was educated at Alexandria, and made very great progress in eloquence and philosophy. After the fashion of the time, he cultivated, like many of his nation and faith, the philosophy of Plato, whose prin-

Philo. Philocles.

ciples he so thoroughly imbibed, and whose manner he so well imitated, that it became a common saying, "Aut Plato philonizat, aut Philo platonizat." Josephus says, he was a man "eminent on all accounts:" and Eusebius describes him, "copious in speech, rich in sentiments, and sublime in the knowledge of holy writ." He was, however, so much immersed in philosophy, particularly the Platonic, that he neglected the Hebrew language, and the rites and customs of his own people. Scaliger says, that Philo "knew no more of Hebrew and Syriac than a Gaul or a Scythian." Grotius is of opinion, that "he is not fully to be depended on, in what relates to the manners of the Hebrews:" and Cudworth goes further; for "though a Jew by nation (says he), he was yet very ignorant of Jewish customs." Fabricius thinks differently; for though he allows some inadvertencies and errors of Philo with regard to these matters, yet he does not see a sufficient foundation on which to charge so illustrious a doctor of the law with ignorance. He allows, however, that Philo's passion for philosophy had made him more than half a Pagan; for it led him to interpret the whole law and the prophets upon Platonic ideas; and to admit nothing as truly interpreted which was not agreeable to the principles of the academy. Besides, this led him farther; he turned every thing into allegory, and deduced the darkest meanings from the plainest words. This most pernicious practice ORIGEN, it is known, imitated, and exposed himself by it to the scoffs of Celsus and of Porphyry. Philo's writings abound with high and mystical, new and subtile, far-fetched and abstracted, notions; and indeed the doctrines of Plato and Moses are so promiscuously blended, that it is not an easy matter to assign to each his principles. There are certainly, however, in his works many excellent things. Though he is continually Platonising and allegorising the Scriptures, he abounds with fine sentiments and lessons of morality; and his morals are rather the morals of a Christian than of a Jew. History, together with his own writings, give us every reason to believe that he was a man of great prudence, constancy, and virtue.

His works were first published in Greek by Turnebus at Paris 1552. A Latin translation made by Gelenius was afterwards added, and printed several times with it. The Paris edition of 1640 in folio was the best for a whole century; which made Cotelerius say, that "Philo was an author that deserved to have a better text and a better version." In 1742, a handsome edition of his work was published at London by Dr Mangey in two volumes folio; which is certainly preferable if it were only for the paper and print, but it is not so good a one as Philo deserves.

Many of our readers may be desirous of further details respecting this celebrated man; we refer such therefore to *Josephus's Antiquities*, *Eusebius's Ecclesiastical History*, St Jerome's work *De Scriptoribus Ecclesiasticis*, *Fabricius Bibl. Grac.* *Cave Hist. Liter.* and Vol. II. of *Monuments of the Greek Church*.

PHILOCLES, an admiral of the Athenian fleet during the Peloponnesian war. He recommended to his countrymen to cut off the right hand of such of the enemies as were taken, that they might be rendered unfit for service. His plan was adopted by all the ten admirals except one; but their expectations were frustrated, and instead of being conquerors they were totally defeated at Ægospotamos by Lysander, and Philocles was put to death with the rest of his colleagues.

Philoctetes, Philolaus.

PHILOCTETES, in fabulous history, the son of Paean, was the faithful companion of Hercules; who at his death obliged him to swear not to discover the place where his ashes were interred, and presented him with his arrows dipped in the Hydra's blood. The Greeks at the siege of Troy being informed by an oracle that they could never take that city without those fatal arrows, went to Philoctetes, and insisted upon his discovering where he had left his friend: when Philoctetes, to evade the guilt of perjury, let them know where Hercules was interred, by stamping upon the place: but he was punished for the violation of his oath, by dropping an arrow upon that foot; which, after giving him great agony, was at length cured by Machaon. He was afterwards taken by Ulysses to the siege of Troy, where he killed Paris with one of his arrows.

PHILOLAUS, of Crotona, was a celebrated philosopher of antiquity, of the school of Pythagoras, to whom that philosopher's *Golden Verses* have been ascribed. He made the heavens his principal object of contemplation; and has been idly (A) supposed to have been the author of that true system of the world which Copernicus afterwards revived. This made Bullialdus place the name of Philolaus at the head of two works, written to illustrate and confirm that system.

Hist of Philosophy.

"He was (says Dr Enfield) a disciple of Archytas, and flourished in the time of Plato. It was from him that Plato purchased the written records of the Pythagorean system, contrary to an express oath taken by the society of Pythagoreans, pledging themselves to keep secret the mysteries of their sect. It is probable, that among these books were the writings of Timæus, upon which Plato formed the dialogue which bore his name. Plutarch relates, that Philolaus was one of the persons who escaped from the house which was burned by Cylon, during the life of Pythagoras; but this account cannot be correct. Philolaus was contemporary with Plato, and therefore certainly not with Pythagoras. Interfering in affairs of state, he fell a sacrifice to political jealousy.

"Philolaus treated the doctrine of nature with great subtlety, but at the same time with great obscurity; referring every thing that exists to mathematical principles. He taught, that reason, improved by mathematical learning, is alone capable of judging concerning the nature of things; that the whole world consists of infinite and finite; that number subsists by itself, and is the chain which by its power sustains the eternal frame of things; that the Monad is not the sole principle of all things, but that the Binary is necessary to furnish materials from which all subsequent numbers may be produced; that the world is one whole, which has a fiery centre, about which the ten celestial spheres revolve, heaven, the sun, the planets, the

(A) We say idly, because there is undoubted evidence that Pythagoras learned that system in Egypt. See PHILOSOPHY.

Philolaus

the earth, and the moon; that the ſun has a vitreous ſurface, whence the fire diffuſed through the world is reflected, rendering the mirror from which it is reflected viſible; that all things are preſerved in harmony by the law of neceſſity; and that the world is liable to deſtruction both by fire and by water. From this ſummary of the doctrine of Philolaus it appears probable, that, following Timæus, whoſe writings he poſſeſſed, he ſo far departed from the Pythagorean ſyſtem as to conceive two independent principles in nature, God and Matter, and that it was from the ſame ſource that Plato derived his doctrine upon this ſubject." Philolaus.

PHILOLOGY.

1 Definition.

PHILOLOGY is compounded of the two Greek words φιλος and λογος, and imports "the deſire of inveſtigating the properties and affections of *words*." The ſages of Greece were, in the moſt ancient times, denominated Σοφοι, that is, *wiſe men*. Pythagoras renounced this pompous appellation, and aſſumed the more humble title of φιλοσοφος, that is, *a lover of wiſe men*. The learned Greeks were afterwards called *philoſophers*; and in proceſs of time, in imitation of this epithet, the word *philologer* was adopted, to import "a man deeply verſed in languages, etymology, antiquities, &c." Hence the term *philology*, which denotes the ſcience that we propoſe briefly to diſcuſs in the following article.

Though philology, in its original import, denoted only the ſtudy of words and language, it gradually acquired a much more extenſive, and at the ſame time a much more uſeful, as well as more exalted, ſignification. It comprehended the ſtudy of grammar, criticiſm, etymology, the interpretation of ancient authors, antiquities; and, in a word, every thing relating to ancient manners, laws, religion, government, language, &c. In this enlarged ſenſe of the word, philology becomes a ſcience of the greateſt utility; opens a wide field of intellectual inveſtigation; and indeed calls for a more intenſe exertion of induſtry, and multifarious erudition, than moſt of thoſe departments of literature which cuſtom hath dignified with more high-ſounding names. It is indeed apparent, that, without the aid of philological ſtudies, it is impoſſible, upon many occaſions, to develope the origin of nations; to trace their primary frame and conſtitution; to diſcover their manners, cuſtoms, laws, religion, government, language, progreſs in arts and arms; or to learn by what men and what meaſures the moſt celebrated ſtates of antiquity roſe into grandeur and conſideration. The ſtudy of hiſtory, ſo eminently uſeful to the legiſlator, the divine, the military man, the lawyer, the philoſopher, and the private gentleman who wiſhes to employ his learned leiſure in a manner honourable and improving to himſelf, and uſeful to his country, will contribute very little towards enlightening the mind without the aid of philological reſearches. For theſe reaſons we ſhall endeavour to explain the various branches of that uſeful ſcience as fully and as intelligibly as the nature of the preſent undertaking will permit.

2 Objects and uſes of Philology.

Moſt of the branches of philology have been already canvaſſed under the various heads of CRITICISM, ETYMOLOGY, GRAMMAR, LANGUAGE, &c. There ſtill remains one part, which has been either ſlightly touched upon, or totally omitted, under the foregoing topics: we mean, the nature and complexion of moſt of the oriental tongues; as alſo ſome of the radical dialects of the languages of the weſt. As we would willingly gratify our readers of every deſcription to the utmoſt of our power, we ſhall endeavour in this place to communicate to them as much information upon that ſubject as the extent of our reading, and the limits preſcribed one ſingle article, will permit. 3 Object of this article.

Before we enter upon this ſubject, we muſt obſerve, that it is not our intention to fill our pages with a tedious, unintereſting, catalogue of barbarous languages, ſpoken by ſavage and inconſiderable tribes, of which little, or perhaps nothing, more is known than barely their names. Such an enumeration would ſwell the article without communicating one ſingle new idea to the reader's antecedent ſtock. We ſhall therefore confine our inquiries to ſuch languages as have been uſed by conſiderable ſtates and ſocieties, and which of conſequence have acquired a high degree of celebrity in the regions of the eaſt.

What was the antediluvian language, or whether it was divided into a variety of dialects as at this day, can only be determined by the rules of analogy; and theſe will lead us to believe, that whatever might have been the primitive language of mankind, if human nature was then conſtituted as it is at preſent, a great variety of dialects muſt of neceſſity have ſprung up in the ſpace of near 2000 years. If we adopt the Moſaic account of the antediluvian events, we muſt admit that the deſcendants of Cain for ſome ages lived ſeparated from thoſe of Seth. Their manner of life, their religious ceremonies, their laws, their form of government, were probably different, and theſe circumſtances would of courſe produce a variety in their language. The poſterity of Cain were an inventive race. They found out the art of metallurgy, muſic, and ſome think of weaving; and in all probability many other articles conducive to the eaſe and accommodation of life were the produce of their ingenuity. A people of this character muſt have paid no ſmall regard to their words and modes of expreſſion. Wherever muſic is cultivated, language will naturally be improved and refined. When new inventions are introduced, a new race of words and phraſes of neceſſity ſpring up, correſponding to the recent ſtock of ideas to be intimated. Beſides, among an inventive race of people, new vocables would be continually fabricated, in order to ſupply the deficiencies of the primitive language, which was probably ſcanty in words, and its phraſeology unpoliſhed. The Cainites, then, among their other improvements, cannot well be ſuppoſed to have neglected the cultivation of language. 4 Variety of dialects before the deluge, 5 Eſpecially among the children of Cain.

Many conjectures have been hazarded both by ancient and modern authors with reſpect to the origin of writing; an art nearly connected with that of ſpeaking. According to Pliny*, "the Aſſyrian letters had always exiſted; ſome imagined that letters had been invented

* Nat. Hiſt. lib. vii. cap. 56.

History of Language.

vented by the Egyptian Mercury; others aſcribed the honour of the invention to the Syrians." The truth ſeems to be, that letters were an antediluvian invention, preſerved among the Chaldeans or Aſſyrians, who were the immediate deſcendants of Noah, and inhabited thoſe very regions in the neighbourhood of which the ark reſted, and where that patriarch afterwards fixed his reſidence. This circumſtance, we think, affords a ſtrong preſumption that the uſe of letters was known before the deluge, and tranſmitted to the Aſſyrians and Chaldeans by Noah their progenitor, or at leaſt by their immediate anceſtors of his family. If, then, the art of writing was an antediluvian invention, we think that in all probability it originated among the poſterity of Cain.

6 Origin of writing.

The deſcendants of Seth, according to the oriental tradition, were chiefly addicted to agriculture and tending of cattle. They devoted a great part of their time to the exerciſes of piety and devotion. From this circumſtance they came to be diſtinguiſhed by the title of the (A) *ſons of God*. According to this deſcription, the Sethites were a ſimple (B), unimproved race of people till they mingled with the race of Cain; after which period they at once adopted the improvements and the vices of that wicked family.

It is not, however, probable, that all the deſcendants of Seth, without exception, mingled with the Cainites. That family of which Noah was deſcended had not incorporated with the race of Cain: it was, according to the ſacred hiſtorian, lineally deſcended from Seth, and had preſerved the worſhip of the true God, when, it is probable, the greateſt part of mankind had apoſtatiſed and become idolaters (C). Along with the true religion, the progenitors of Noah had preſerved that ſimplicity of manners and equability of character which had diſtinguiſhed their remote anceſtors. Agriculture and rearing cattle had been their favourite occupations. Accordingly we find, that the patriarch Noah, immediately "after the deluge," became a huſbandman, and "planted a vineyard." The choſen patriarchs, who doubtleſs imitated their pious anceſtors, were ſhepherds, and employed in rearing and tending cattle. Indeed there are ſtrong preſumptions that the Chaldeans, Aſſyrians, Syrians, Canaanites, and Arabians, in the earlieſt ages followed the ſame profeſſion.

From this deduction, we imagine it is at leaſt probable, that the anceſtors of Noah perſiſted in the obſervance of the ſame ſimplicity of manners which had been handed down from Adam to Seth, and from him to Enoch, Methuſelah, Lamech, and from this laſt to Noah. According both to ſcripture and tradition, innovations were the province of the Cainites, while the deſcendants of Seth adhered to the primitive and truly patriarchal inſtitutions

Language.

If theſe premiſes are allowed the merit of probability, we may juſtly infer that the language of Noah, whatever it was, differed very little from that of Adam (D); and that if it is poſſible to aſcertain the language of the former, that of the latter will of courſe be diſcovered. We ſhall then proceed to throw together a few obſervations relating to the language of Noah, and leave our readers to judge for themſelves. We believe it will be ſuperfluous to ſuggeſt, that our intention in the courſe of this deduction, is, if poſſible, to trace the origin and antiquity of the Hebrew tongue; and to try to diſcover whether that language, or any of its ſiſter dialects, may claim the honour of being the original language of mankind.

7 The original language preſerved in the family from which Noah ſprung.

Whatever may have been the dialect of Noah and his family, that ſame dialect, according to the Moſaic account, muſt have obtained, without any alteration, till the era of the building of the tower of Babel.—Upon this occaſion a dreadful convulſion took place: the language of mankind was confounded, and men were *ſcattered abroad upon the face of all the earth.*

8 Confuſion at the tower of Babel.

How far this cataſtrophe (E) extended, is not the buſineſs of the preſent inquiry to determine. One thing is certain beyond all controverſy, namely, that the languages of all the nations which ſettled near the centre of population were but ſlightly affected by its influence. A very judicious writer has obſerved *, that 3000 years after, the inhabitants of thoſe countries exhibited a very ſtrong reſemblance of cognation, "in their *language*, manner of living, and the lineaments of their bodies. At the ſame time he obſerves, that the reſemblance in all thoſe particulars was moſt remarkable among the inhabitants of Meſopotamia." This obſervation, with reſpect to language, will, we doubt not, be vouched by every one of our readers who has acquired even a ſuperficial knowledge of the languages current in thoſe quarters, at a very early period.

* *Strabo.*

It appears, then, that the languages of the Armenians, Syrians, Aſſyrians, Arabians, and probably of the Chanaanim, did not ſuffer materially by the confuſion of tongues. This obſervation may, we imagine, be extended to many of the dialects (F) ſpoken by the people who ſettled in thoſe countries not far diſtant

---

(A) From this paſſage (Gen. ch. vi. ver. 2.) miſunderſtood, originated the abſurd idea of the connection between angels and mortal women. See *Joſeph. Antiq. Jud.* l. 1. cap. 4. See *Euſeb. Chron.* lib. 1. All the fathers of the church, almoſt without exception, adopted this fooliſh notion. See alſo *Philo. Jud.* p. 198. ed. Turn, Paris 1552.

(B) The orientals, however, affirm that Seth, whom they call *Edris*, was the inventor of aſtronomy.

(C) We think it highly probable that idolatry was eſtabliſhed before the flood; becauſe it prevailed almoſt immediately after that cataſtrophe. See POLYTHEISM.

(D) For the firſt language communicated to Adam, ſee the article on LANGUAGE; alſo *Shenckford's Connect.* Vol. I. l. ii. p. 111. *et ſeq.*

(E) Joſephus and the fathers of the church tell us, that the number of languages produced by the confuſion of tongues was 72; but this is a mere rabbinical legend.

(F) The languages of the Medes, Perſians, Phœnicians, and Egyptians, very much reſembled each other in their original complexion; and all had a ſtrong affinity to the Hebrew, Chaldean, Syriac, &c. See Walton's *Proleg.*;

History of Language.

stant from the region where the sacred historian has fixed the original seat of mankind after the deluge. The inference then is, that if Noah and his family spoke the original language of Adam, as they most probably did, the judgment which affected the confusion of tongues did not produce any considerable alteration in the language of such of the descendants of Noah as settled near the region where that patriarch had fixed his residence after he quitted the ark.

9 Only a part of mankind engaged in building the tower,

But supposing the changes of language produced by the catastrophe at the building of the tower as considerable as has ever been imagined, it does not, after all, appear certain that all mankind without exception were engaged in this impious project. If this assertion should be well founded, the consequence will be, that there was a chosen race who did not engage in that enterprise. If there was such a family, society, or body of men, it will follow, that this family, society, &c. retained the language of its great ancestor without change or variation. That such a family did actually exist, is highly probable, for the following reasons:

1. We think there is reason to believe, that Ham, upon the heavy curse denounced upon him by his father ‡, retired from his brethren, and fixed his residence elsewhere. Accordingly, we find his descendants scattered far and wide, at a very great distance from the Gordyœan mountains, where the ark is generally supposed to have rested immediately after the flood. Some of them we find in Chaldea, others in Arabia Felix, others in Ethiopia (G), others in Canaan, and others in Egypt; and, finally, multitudes scattered over all the coast of Africa. Between those countries were planted many colonies of Shemites, in Elam, Assyria, Syria, Arabia, &c. We find, at the same time, the descendants of Shem and Japheth settled, in a great degree, contiguous to each other. This dispersion of the Hamites, irregular as it is, can scarce, we think, have been accidental; it must have been owing to some uncommon cause, and none seems more probable than that assigned above. If, then, the descendants of Ham separated early, and took different routs, as from their posterior situations it appears they did, they could not all be present at the building of the tower.

Gen. x. 25.

10 And those not the descendants of Shem. Chap x. verse 22.

2. It is not probable that the descendants of Shem were engaged in this undertaking, since we find that they were not *scattered abroad upon the face of all the earth*. The children of Shem were || Elam, Ashur, Arphaxad, Lud, and Aram. Elam settled near the mouth of the river Tigris, in the country which, by Gentile writers, was called *Elymais*. Above him, on the same river, lay the demesne of Ashur on the western side. In like manner, upon the same river, above him was situated Aram, who possessed the country of Aramea; and opposite to him was Arphaxad, or Arbaces or Arbaches, and his country was denominated *Arphachitis*. Lud, as some think, settled in Lydia, among the sons of Japhet; but this opinion seems to be without foundation (H). Here, then, there is dispersion, but such as must have originated from the nature of the thing. The four, or rather the five, brothers, all settled contiguous, without being *scattered abroad upon the face of the whole earth*. Besides, there was no confusion of language among these tribes: they continued to use one and the same *lip* through many succeeding generations.

11 The language of Adam preserved in the family of Shem,

From these circumstances, it appears that the posterity of Shem were not involved in the guilt of the builders of the tower, and of consequence did not undergo their punishment. If, then, the language of the Shemites was not confounded upon the erection of the tower, the presumption is, that they retained the language of Noah, which, in all probability, was that of Adam. Some dialectical differences would in process of time creep in, but the radical fabric of the language would remain unaltered.

3. The posterity of Shem appear in general to have cultivated the pastoral life. They imitated the style of living adopted by the antediluvian posterity of *Seth*. No sooner had Noah descended from the ark, than he became *Ish ha Adamah*, a man of the earth; that is, a husbandman, and planted a vineyard. We find that some ages after, Laban the Syrian had flocks and herds; and that the chief wealth of the patriarch Abraham and his children consisted in their flocks and herds. Even his Gentile descendants, the Ishmaelites and Midianites, seem to have followed the same occupation. But people of this profession are seldom given to changes: their wants are few, and of consequence they are under few or no temptations to deviate from the beaten track. This circumstance renders it probable, that the language of Noah, the same with that of Adam, was preserved with little variation among the descendants of Arphaxad down to Abraham.

12 down to Abraham.

We have observed above, that Ham upon the curse denounced against him by his father, very probably left the society of his other brothers, and emigrated elsewhere, as Cain had done in the antediluvian world. There is a tradition still current in the East, and which was adopted by many of the Christian fathers (I), that Noah, in the 930th year of his life, by divine appoint-

4 ment,

Proleg.; Gale's *Court of the Gent.* vol. i. l. i. ch. 11. page 70. *et seq.*; Boch. *Phalec* and *Chanaan passim*. To these we may add the Greek language, as will appear more fully below.

(G) Josephus informs us, that all the nations of Asia called the Ethiopians *Cushim*, l. i. cap. 7.

(H) The ancient name of Lydia was *Mæonia*. See Strabo *Casaub.* l. 13. page 586. chap. 7. *Rhod.* 577. The Lydians were celebrated for inventing games; on which account they were nicknamed by the Æolian Greeks Λυδοι, *Lydi* or *Ludi*, from the Hebrew words *lutz*, *ludere*, *illudere*, *deridere*. We find (Ezek. chap. xxvii. ver. 10.) the men of Elam and the men of Lud joined in the defence of Tyre; which seems to intimate, that the Elamites and Ludim were neighbours. If this was actually the case, then Lud settled in the same quarter with his brothers.

History of

ment, did, in the moſt formal manner, divide the whole terraqueous globe among his three ſons, obliging them to take an oath that they would ſtand by the deciſion. Upon this happened a migration at the birth of Peleg, that is, about three centuries after the flood. It is aſſumed, that Nimrod the arch-rebel diſregarded this partition, and encroached upon the territory of Aſhur, which occaſioned the firſt war after the flood.

The Greeks had acquired ſome idea of this partition, which they ſuppoſed to have been between Jupiter †, Neptune, and Pluto. Plato ſeems to have heard of it (K): For (ſays he) the gods of old obtained the dominion of the whole earth, according to their different allotments. This was effected without any contention, for they took poſſeſſion of their ſeveral provinces in a fair and amicable way, by lot."

† *Calymach. Hym. Hom. Iliad*, lib. xv.

Joſephus §, in his account of the diſperſion of mankind, plainly inſinuates a divine deſtination; and Philo Judeus (L) was of the ſame opinion before him.

§ *Ant. Jud.* lib. i. c. 5.

In conſequence of this arrangement, the ſons of Shem poſſeſſed themſelves of the countries mentioned in the preceding pages: the poſterity of Japhet had ſpread themſelves towards the north and weſt; but the Hamites, who had ſeparated from their brethren in conſequence of the curſe, not chooſing to retire to their quarters, which were indeed very diſtant from the place where the ark reſted, ſeized upon the land of Canaan (M). Perhaps, too, it might be ſuggeſted by ſome malicious ſpirits, that the aged patriarch was dealing partially, when he aſſigned Ham and his poſterity a quarter of the world to inhabit not only remote from the centre of population, but likewiſe ſequeſtered from the reſt of mankind (N).

Be that as it may, the children of Ham removed eaſtward, and at length deſcending from the Carduchean or Gordyæan mountains, directed their courſe weſtward, and arrived at the plains of Shinar, which had been poſſeſſed by the Aſhurim ever ſince the era of the firſt migration at the birth of Peleg. The ſacred hiſtorian informs us, that the whole *earth* "was of one language and of one ſpeech;" that in journeying from the eaſt, they lighted upon the plain of Shinar, and dwelt there. In this paſſage we find no particular people ſpecified; but as we find Nimrod, one of the deſcendants of Ham, ſettled in that country, we are ſure that they were the offſpring of that patriarch. It would not, we think, be eaſy to aſſign a reaſon how one branch of the family of Ham came to plant itſelf in the midſt of the ſons of Shem by any other means but by violence. Language.

It is indeed generally ſuppoſed, that Nimrod, at the head of a body of the children of Ham, made war upon Aſhur, and drove him out of the country of Shinar; and there laid the foundation of that kingdom, the beginning of which was Babel: that this chief, ſupported by all the Cuſhites, and a great number of apoſtates from the family of Shem and Japhet who had joined him, refuſed to ſubmit to the divine ordinance by the mouth of Noah, with reſpect to the partition of the earth; and that he and his adherents were the people who erected the celebrated tower, in conſequence of a reſolution which they had formed to keep together, without repairing to the quarters aſſigned them by the determination of Heaven. This was the crime which brought down the judgment of the Almighty upon them, by which they were *ſcattered abroad upon the face of all the earth.* The main body of the children of Shem and Japhet were not engaged in this impious undertaking; their language, therefore, was not confounded, nor were they themſelves ſcattered abroad. Their habitations were contiguous; thoſe of the Shemites towards the centre of Aſia; the dwellings of Japhet were extended towards the north and north-weſt; and the languages of both theſe families continued for many ages without the leaſt variation, except what time, climate, laws, religion, new inventions, arts, ſciences, and commerce, &c. will produce in every tongue in a ſucceſſion of years. 13 The tower of Babel built by the children of Ham.

The general opinion then was, that none but the progeny of Ham and their aſſociates were preſent at the building of the tower, and that they only ſuffered by the judgment (O) conſequent upon that attempt. There are even among the Pagans ſome alluſions to the diviſion of the world among the three ſons of Noah. Many of the learned have imagined that this patriarch was *Saturn*; and that his three ſons were *Jupiter*, *Neptune*, and *Pluto*, as has been obſerved above.

Bero-

(K) Critias, vol. 3. pag. 109. *Serr.* Apollodorus mentions a time when the gods reſpectively ſelected particular cities and regions, which they were to take under their peculiar protection.

(L) L. 10. p. 236. Turn. Paris 1552. We have a plain alluſion to this diſtribution (Deut. ch. xxxii. ver. 7.) "When the moſt High divided to the nations their inheritance, when he ſeparated the ſons of Adam, he ſets the bounds of the people, according to the number of the children of Iſrael; for the Lord's portion is his people; Jacob is the lot of his inheritance." From this paſſage it appears, that the whole was arranged by the appointment of God, and that the land of Canaan was expreſsly reſerved for the children of Iſrael. St Paul, Acts ch. xvii. ver. 26. ſpeaks of this divine arrangement, "God made of one blood all nations of men, for to dwell on all the face of the earth; and determined the bounds of their habitation."

(M) The ark, according to the moſt probable accounts, reſted upon mount Ararat in Armenia.

(N) We think it is by no means improbable that Noah, well knowing the wickedneſs of the family of Ham, and eſpecially their inclination to the idolatry of the antediluvians, might actually intend to ſeparate them from the reſt of mankind.

(O) Some learned men have imagined that this confuſion of language, which the Hebrew calls of *Lip*, was only a temporary failure of pronunciation, which was afterwards removed. This they are led to conclude, from the agreement of the languages of theſe people in after times.

History of Language.

Berosus *, in his history of the Babylonians, informs us, that Noah, at the foot of Mount Baris or Luban, where the ark rested, gave his children their last instructions, and then vanished out of sight. It is now generally believed that the Xithrusus of Berosus was Noah. Eupolemus †, another Heathen writer, tells us, "that the city Babel was first founded, and afterwards the celebrated tower; both which were built by some of those people who escaped the deluge. They were the same with those who in after times were exhibited under the name of *giants*. The tower was at length ruined by the hand of the Almighty, and those giants were scattered over the whole earth." This quotation plainly intimates, that according to the opinion of the author, only the rascally mob of the Hamites, and their apostate associates, were engaged in this daring enterprize.

* *Euseb. Chron.*

† *Euseb. Præp. Ev. lib. 9.*

Indeed it can never be supposed that Shem, if he was alive at that period, as he certainly was, would co-operate in such an absurd and impious undertaking. That devout patriarch, we think, would rather employ his influence and authority to divert his descendants from an attempt which he knew was undertaken in contradiction to an express ordinance of Heaven: and it is surely very little probable that Elam, Ashur, Arphaxad, and Aram, would join that impious confederacy, in opposition to the remonstrances of their father.

The building of the tower, according to the most probable chronology, was undertaken at a period so late, that *all mankind* could not possibly have concurred in the enterprize.

Many of the fathers were of opinion, that Noah settled in Armenia, the country where the ark rested; and that his descendants did not leave that region for five generations ‡, during the space of 659 years. By this period the human race must have been so amazingly multiplied, that the plains of Shinar could not have contained them. According to the Samaritan Pentateuch, and the Septuagint version, Peleg was born in the 134th year of his father Eber. Even admitting the vulgar opinion, that the tower was begun to be built, and the dispersion consequent upon that event to have taken place at this era, the human race would have been by much too numerous to have universally concurred in one design.

‡ *Epiph. Hæres. lib. 1.*

From these circumstances, we hope it appears that the whole mass of mankind was not engaged in building the tower; that the language of all the human race was not confounded upon that occasion; and that the dispersion reached only to a combination of Hamites, and of the most profligate part of the two other families, who had joined their wicked confederacy.

We have pursued this argument to considerable length, because some have inferred, from the difference in languages existing at this day, that mankind cannot have sprung from two individuals; because, from the connection still existing among languages, some have been bold enough to question the fact, though plainly recorded in sacred history; and lastly, because we imagine that some of our readers, who do not pretend to peruse the writings of the learned, may be gratified by seeing the various opinions respecting the confusion of tongues, and the dispersion of mankind, collected into one mass, equally brief, we hope, and intelligible: and this view of these opinions, with the foundations on which they respectively rest, we think may suffice to prove, that the language of Noah was for some ages preserved unmixed among the descendants of both Shem and Japhet.

14 Therefore the original language preserved in the other two families.

To gratify still farther such of our curious readers as may not have access to more ample information, we shall in this place exhibit a brief detail of the circumstances which attended this fatal attempt. The people engaged in it have been held up as a profligate race. The Almighty himself denominates them "*the children of men*," which is the very appellation by which the antediluvian sinners were characterized; *the sons of God saw the daughters of men*, &c. Their design in raising this edifice was "*to make them a name, and to prevent their being scattered abroad upon the face of the whole earth* *."

* Gen. chap. xi.

Whatever resolution the rest of mankind might take, they had determined to maintain themselves on that spot. The tower was intended as a centre of union, and perhaps as a fortress of defence. Such a stupendous fabric, they imagined, would immortalize their memory, and transmit the name of their confederacy with eclat (P) to future ages. This design plainly intimates, that there was only a party concerned in the undertaking, since, had all mankind been engaged in it, the purpose would have been foolish and futile. Again, they intended, by making themselves *a name*, to prevent their being scattered abroad upon the face of the earth. This was an act of rebellion in direct contradiction to the divine appointment, which constituted their crime, and brought down the judgment of Heaven upon their guilty heads. The consequence of the confusion of languages was, that the projectors left off to build (Q), and were actually scattered abroad, contrary to their intention.

15 Pagan tradition concerning the tower of Babel.

Abydenus, in his Assyrian annals, records, that the (R) "tower was carried up to heaven; but that the gods ruined it by storms and whirlwinds, and overthrew it upon the heads of those who were employed in the work, and that the ruins of it were called *Babylon*.

(P) Many foolish and absurd notions have been entertained concerning this structure. Some have imagined that they meant to take shelter there in case of a second deluge; others, that it was intended for idolatrous purposes; others, that it was to be employed as an observatory. Its dimensions have likewise been most extravagantly magnified. Indeed Strabo, l. 16. mentions a tower of immense size remaining at Babylon in his time, the dimensions of which were a stadium every way. This, however, seems to have been the remains of the temple of Bel or Belus.

(Q) For a description of the tower, see the article BABEL.

(R) See the Greek original of this quotation, Euseb. Chron. lib. 1. page 19.

bylon. Before this there was but one language subsisting among men: but now there arose πολυθρουν, *a manifold speech*; and he adds, that a war soon after broke out between (s) Titan and Cronus." (T) The Sybilline oracles give much the same account of this early and important transaction.

"Justin * informs us, that the Phœnicians who built Tyre were driven from Assyria by an earthquake. These Phœnicians were the descendants of Mizraim the youngest son of Ham; and were, we think, confederates in building the tower, and were driven away by the catastrophe that ensued. Many other allusions to the dispersion of this branch of the family occur in Pagan authors, which the limits to be observed in an inquiry of this nature oblige us to omit. Upon the whole, we think it probable that the country of Shinar lay desolate for some time after this revolution; for the dread of the judgment inflicted upon the original inhabitants would deter men from settling in that inauspicious region. At last, however, a new colony arrived, and Babel, or Babylon, became the capital of a flourishing kingdom.

* Philip. lib 13. cap. 3.

Our readers, we believe, will expect that we should say something of Nimrod the mighty hunter, who is generally thought to have been deeply concerned in the transactions of this period. According to most authors, both ancient and modern, this patriarch was the leader of the confederates who erected the tower, and the chief instigator to that enterprize. But if the tower was built at the birth of Pheleg, according to the Hebrew computation, that chief was † either a child, or rather not born at that period (U). The Seventy have pronounced him a giant, as well as a huntsman. They have translated the Hebrew word *gebur*, which generally signifies *strong*, *mighty*, by the word γιγας *giant*; an idea which we imagine those translators borrowed from the Greeks. The antediluvian giants are called *Nephelim* and *Rephaim*, but never *Geburim*. The Rabbinical writers, who justly hated the Babylonians, readily adopted this idea (X); and the fathers of the church, and the Byzantine historians, have universally followed them. He has been called *Nimrod*, *Nebrod*, *Nymbroth*, *Nebroth*, and *Nebris*. Not a few have made him the first *Bacchus*, and compounded his name of *Bar*, a son, and *Cush*, that is, the son of *Cush*. Some have imagined that he was the Orion of the Pagans, whose shade is so nobly described by Homer ‡. But the etymology of this last name implies something (Y) honourable, and very unsuitable to the idea of the *tyrant Nimrod*. It must be observed, however, that we find nothing in Scripture to warrant the supposition of his having been a tyrant; so far from it, that (Z) some have deemed him a benefactor to mankind. See NIMROD.

† Pectar. Phaleg. lib 1. cap 10.

‡ Odyss. l. 11. vers. 571.

The beginning of this prince's kingdom was Babel. Eusebius gives us first * a catalogue of six kings of the Chaldæans, and then another of five kings of Arabian extraction, who reigned in Chaldæa after them. This might naturally enough happen, since it appears that the inhabitants of those parts of Arabia which are adjacent to Chaldea were actually Cushites, of the † same family with the Babylonians.

* Chron. lib. 1. pag. 14.

† Gen x. Ezek. xxvii.

The Cushites, however, were at last subdued, perhaps partly expelled Chaldea by the *Chasidim*, who probably claimed that territory as the patrimony of their progenitors. That the Chasidim were neither *Cushites*, nor indeed *Hamites*, is obvious from the name. The Hebrews, and indeed all the Orientals ‡, denominated both the people who inhabited the eastern coast of Arabia *Cushim*, and also the Ethiopians who sprung from the last mentioned people. Had the later inhabitants of Chaldea been the descendants of Cush, the Jewish writers would have called them *Cushim*. We find they called the Phœnicians *Chanaanim*, the Syrians *Aramim*, the Egyptians *Mizraim*, the Greeks *Jonim*, &c. The Chasidim, therefore, or modern inhabitants of Chaldea, were positively descended of one Chesed or Chased; but who this family-chief was, it is not easy to determine. The only person of that name whom we meet with in early times is the fourth son of Nahor §, the brother of Abraham; and some have been of opinion that the Chaldeans were the progeny of this same Chesed. This appears to us highly probable, because both Abram and Nahor were || natives of *Ur* of the Chasidim. The former, we know, in consequence of the divine command, removed to *Haran*, afterwards *Charræ*; but the latter remained in *Ur*, where his family multiplied, and, in process of time, became masters of the country which they called the land of the Chasidim, from *Chesed* or *Chased*, the name of their ancestor. This account is the more probable, as we find the other branches of Nahor's family settled in the same neighbourhood (A).

16 Origin of the name Chaldæi.

How the Greeks came to denominate these people χαλδαιοι *Chaldæi*, is a question rather difficult to be resolved; but we know that they always affected to distinguish people and places by names derived from their own language. They knew a rugged, erratic nation (B) on the banks of the river Thermodon, in the territory of Pontus, bordering on Armenia the Less

History of Language.

Leſs. Theſe, in ancient times, were called *Alybes*, or *Chalybes*, becauſe they were much employed in forging and poliſhing iron. Their neighbours, at length, gave them the name of *Chald* or *Caled*, which imports, in the Armenian dialect, *fierce, hardy, robuſt*. This title the Greeks adopted, and out of it formed the word χαλδαιοι "Chaldeans."

The Moſaic hiſtory informs us (c), that Aſhur went out of *that land* (Shinar) and built Nineveh and ſeveral other conſiderable cities. One of the ſucceſſors of Aſhur was the celebrated Ninus, who firſt broke the peace of the world *, made war upon his neighbours, and obliged them by force of arms to become his ſubjects, and pay tribute. Some authors make him the immediate ſucceſſor of Aſhur, and the builder of Nineveh. This we think is not probable; Euſebius, as we have obſerved above, gives a liſt of ſix Arabian princes who reigned in Babylon. Theſe we take to have been the immediate ſucceſſors of Nimrod, called *Arabians*; becauſe theſe people were Cuſhites. Ninus might be reputed the firſt king of the Aſſyrians, becauſe he figured beyond his predeceſſors; and he might paſs for the builder of Nineveh, becauſe he greatly enlarged and beautified that city. We therefore imagine, that Ninus was the fifth or ſixth in ſucceſſion after Aſhur.

Juſtin. 1. cap. 1.

Ninus, according to Diodorus Siculus †, made an alliance with Ariæus king of the Arabians, and conquered the Babylonians. This event, in our opinion, put an end to the empire of the Hamites or Cuſhim in Shinar or Babylonia. The author obſerves, that the Babylon which figured afterwards did not then exiſt. This fact is confirmed by the prophet Iſaiah ‡: "Behold the land of the Chaſidim; this people was not till Aſhur founded it for them that dwell in the wilderneſs. They ſet up the towers thereof, &c." After Babylonia was ſubdued by the Aſſyrians under Ninus, the capital was either deſtroyed by that conqueror or deſerted by the inhabitants. At length it was re-edified by ſome one or other of the Aſſyrian monarchs, who collected the roving Chaſidim, and obliged them to ſettle in the new city. Theſe were ſubject to the Aſſyrian empire till the reign of Sardanapalus, when both the Medes and Babylonians rebelled againſt that effeminate prince.

Lib. 2.

Ch. xxiii. verſ. 13.

The Chaſidim were celebrated by all antiquity for their proficiency in aſtronomy, aſtrology, magic, and curious ſciences. Ur or Orchoe (d) was a kind of univerſity for thoſe branches of learning. Such was their reputation in thoſe ſtudies, that over a great part of Aſia and Europe a Chaldean and an aſtrologer were ſynonymous terms. Theſe ſciences, according to the tradition of the Orientals, had been invented by Seth, whom they call *Edris*; and had been cultivated by his deſcendants downward to Noah, by whom they were tranſmitted to Shem, who conveyed them to Arphaxad and his poſterity.

To us it appears probable, that the religious ſentiments tranſmitted from Noah through the line of Shem, were kept alive in the family of Arphaxad, and ſo handed down to the families of Serug, Nahor, Terah, Abram, Nahor II. and Haran, &c. The Jewiſh rabbis, and all the Perſian and Mahomedan writers, make Abraham contemporary with Nimrod; who, ſay they, perſecuted him moſt cruelly for adhering to the true religion. That theſe two patriarchs were contemporary, is very improbable, ſince Nimrod was the third generation after Noah, and Abram the tenth. Abram has been inveſted by the rabbinical writers with every department of learning. According to them, he tranſported from Charræ into Chanaan and Egypt, aſtronomy, aſtrology, mathematics, geography, magic, alphabetical writing, &c. &c.

17 Legendary tales concerning Abraham.

After the Babyloniſh captivity, when the Jews were diſperſed over all the eaſt, and began to make *proſelytes of the gate* among the Pagans, wonderful things were reported of Abram with reſpect to his acquirements in human erudition, as well as his ſupereminence in virtue and piety. Theſe legendary tales were believed by the proſelytes, and by them retailed to their connections and acquaintances. But certainly the holy man either was not deeply verſed in human ſciences, or did not deem them of importance enough to be communicated to his poſterity; ſince the Jews are, on all hands, acknowledged to have made little progreſs in theſe improvements. To think of raiſing the fame of Abraham, by claſſing him with the philoſophers, betrays an extreme defect in judgment. He is intitled to praiſe of a higher kind; for he excelled in piety, was the father of the faithful, the root of the Meſ-

manufacturing iron, ſo were they celebrated for making the choiceſt pieces of armour. They excelled in making χαλιβανοι, or coats of mail, or brigantines uſed by the braveſt of the Perſian horſemen. Bochart Phaleg, l. 3. cap. 12 and 13, has proved that the word *Cheliba* ſignifies "ſcales of braſs or ſteel." From the word *Cheliba*, the Greeks formed their χαλυβες, *Chalybes*. Xenoph. Cyrop. l. 3. page 43. Steph. repreſents the Chaldeans, who inhabited a mountainous country bordering upon Armenia, as a very fierce warlike people. Ib. page 107. we have an example of their rapacious character. Id. ib. l. 4. page 192. Hen. Steph. we have an account of their bravery and of their arms. Another inſtance of their rapacity occurs in their plundering the cattle of Job.

(c) A diſpute has ariſen about the ſenſe of verſe 10. chap. 10. Out of that land went forth Aſhur, and builded Nineveh. Some approve our tranſlation, which we think is juſt; others, conſidering that the inſpired writer had been juſt ſpeaking of Nimrod and the beginning of his kingdom, are of opinion that it ſhould be tranſlated, And out of this land *He* (that is Nimrod) went into Aſhur and builded Nineveh. Thia they make a military expedition, and a violent irruption into the territory of Aſhur.

(d) Ur or Orchoe was ſituated between Niſibis and Corduena. See Ammianus Marcel. Expeditio Juliana, l. 15. It lay not far from the river Tigris. Strabo, l. 16. page 739, tells us that the Chaldean philoſophers were divided into different ſects, the Orcheni, the Borſippeni, and ſeveral others. Diod. Sicul. likewiſe, lib. ii. page 82. Steph. gives an exact detail of the functions, profeſſion, and eſtabliſhment of the Chaldeans, to which we muſt refer our curious readers.

History of

fiah, and the friend of God. Before these, all other titles vanish away. Such of our readers, however, as have leisure enough, and at the same time learning enough to enable them to consult the rabbinical legends, will be furnished with a full and ample detail of his imaginary exploits and adventures. Others, who are either not willing or not qualified to peruse the writings of the rabbins, may consult Dr Hyde * de Relig. vet. Pers. and the authors of the Universal History †, where they will find materials sufficient to gratify their curiosity. We shall only observe, in addition to what we have already said, that the Persians, Chaldeans, and Arabians, pretended that their religion was that of Abraham; that honourable mention is made of him in the Koran; and that the name of Abraham or Ibrahim was celebrated over all the east. See ABRAHAM.

* Chap. ii
† Vol. I.

In the progress of this disquisition, we have seen that the language of Noah was, in all probability, the same or nearly the same with that of Adam. Additions and improvements might be introduced, but still the radical stamina of the language remained unchanged. It has likewise, we hope, appeared, that the confusion of language at the building of the tower of Babel was only partial, and affected none but the rebellious crew of the race of Ham and the apostate part of the families of Shem and Japhet. We have concluded, that the main body of the race of Shem, at least, were neither dispersed nor their language confounded; and that consequently the descendants of that patriarch continued to speak their paternal dialect or the uncorrupted language of Noah. To these arguments we may take the liberty to add another, which is, that in all probability the worship of the true God was preserved in the line of Arphaxad, after the generality of the other sects had lapsed into idolatry. Out of this family Abraham was taken, in whose line the true religion was to be preserved. Whether Abraham was an idolator when he dwelt in Chaldea, the scripture does not inform us, though it seems to be evident that his father was. One thing, however, is certain, namely, that Jehovah (E) appeared to him, and pronounced a blessing upon him before he left Ur of the Chaldees. This circumstance no doubt indicates, that this patriarch had made uncommon advances in piety and virtue, even prior to his emigration. The progenitors of his family had been distinguished by adhering to the true religion. About this time, however, they began to degenerate, and to adopt the sabiism of their apostate neighbours. It was then that Abraham was commanded by Heaven to "leave his kindred and his father's house, and to travel into a land which was to be shown him." The Almighty intended that the true religion should be preserved in his line, and therefore removed him from a country and kindred, by the influence of whose bad example his religious principles might be endangered. His family had only of late apostatized; till that period they had preserved both the language and religion of their venerable ancestors.

But however much Abraham might differ from the other branches of his family in his religious sentiments, his language was certainly in unison with theirs. The consequence of this unquestionable position is, that the language which he carried with him into Canaan was exactly the same with that of his family which he relinquished when he began his peregrinations. But if this be true, it will follow, that the language afterwards denominated Hebrew, and that of the Chasidim or Chaldeans were originally one and the same. This position, we think, will not be controverted. There is then an end of the dispute concerning the original language of mankind. We have advanced some presumptive proofs in the preceding pages, that the language of Adam was transmitted to Noah, and that the dialect of the latter was preserved in the line of Arphaxad downwards to the family of Abraham: and it now appears that the Hebrew and Chaldean were originally spoken by the same family, and of course were the same between themselves, and were actually the first language upon earth, according to the Mosaic history. Numberless additions, alterations, improvements, we acknowledge, were introduced in the course of 2000 years; but still the original stamina of the language were unchanged. Our readers will please to observe, that the Orientals are not a people *given to change*; and that this character, in the earliest ages, was still more prevalent than at present. This assertion, we presume, needs no proof.

Language.

18 The Hebrew and Chaldean originally the same, and the first language spoken on earth.

In confirmation of these presumptive arguments, we may add the popular one which is commonly urged upon this occasion, viz. that the names of antediluvian persons and places mentioned by the sacred historian, are generally of Hebrew original, and significant in that language. Some of them, we acknowledge, are not so; but in this case it ought to be remembered, that a very small part of that language now exists, and that probably the radicals from which these words are descended are among the number of those which have long been lost.

SECT. I. *The Hebrew Language.*

19 Characteristics of the Hebrew language.

HAVING thus proved the priority of the Hebrew to every other language that has been spoken by men, we shall now proceed to consider its nature and genius; from which it will appear still more evidently to be an original language, neither improved nor debased by foreign idioms. The words of which it is composed are short, and admit of very little flexion. The names of places are descriptive of their nature, situation, accidental circumstances, &c. Its compounds are few, and inartificially joined together. In it we find few of those artificial affixes which distinguish the other cognate dialects; such as the Chaldean, Syrian, Arabian, Phœnician, &c. We find in it no traces of improvement from the age of Mosea to the era of the Babylonish captivity. The age of David and Solomon was the golden period of the Hebrew tongue; and yet, in our opinion, it would puzzle a critic of the nicest acumen to discover much improvement even during that happy era. In fact, the Jews were by no means an inventive people. We hear nothing of their progress in literary pursuits; nor do they seem to have been

(E) Compare Gen. chap. 12. ver. 2. with Acts chap. 7. verse 4.

Hebrew Language.

been induſtrious in borrowing from their neighbours. The laws and ſtatutes communicated by Moſes were the principal objects of their ſtudies. Theſe they were commanded to contemplate day and night; and in them they were to place their chief delight. The conſequence of this command was, that little or no regard could be paid to taſte, or any other ſubject of philoſophical inveſtigation. Every unimproved language abounds in figurative expreſſions borrowed from ſenſible objects. This is in a peculiar manner the characteriſtic of the language in queſtion; of which it would be ſuperfluous to produce inſtances, as the fact muſt be obvious even to the attentive reader of the Engliſh Bible.

In the courſe of this argument, we think it ought to be obſerved, and we deem it an obſervation of the greateſt importance, that if we compare the other languages which have claimed the prize of originality from the Hebrew with that dialect, we ſhall quickly be convinced that the latter has a juſt title to the preference. The writers who have treated this ſubject, generally bring into competition the Hebrew, Chaldean, Syrian, and Arabian. Some one or other of theſe has commonly been thought the original language of mankind. The arguments for the Syrian and Arabian are altogether futile. The numerous improvements ſuperinduced upon theſe languages, evidently prove that they could not have been the original language. In all cognate dialects, etymologiſts hold it as a maxim, that the leaſt improved is likely to be the moſt ancient.

We have obſerved above, that the language of Abraham and that of the Cheſedim or Chaldeans were originally the ſame; and we are perſuaded, that if an able critic ſhould take the pains to examine ſtrictly theſe two languages, and to take from each what may reaſonably be ſuppoſed to have been improvements or additions ſince the age of Abraham, he will find intrinſic evidence ſufficient to convince him of the truth of this poſition. There appear ſtill in the Chaldean tongue great numbers of (F) words the ſame with the Hebrew, perhaps as many as mankind had occaſion for in the moſt early ages; and much greater numbers would probably be found if both languages had come down to us entire. The conſtruction of the two languages is indeed ſomewhat different; but this difference ariſes chiefly from the ſuperior improvement of the Chaldean. While the Hebrew language was in a manner ſtationary, the Chaldean underwent progreſſive improvements; was mellowed by antitheſes, rendered ſonorous by the diſpoſition of vocal ſounds, acquired a copiouſneſs by compounds, and a majeſty by affixes and prefixes, &c. In proceſs of time, however, the difference became ſo great, that the Iſraelites did not underſtand the Chaldean language at the era of the Babyloniſh captivity. This much the prophet * intimates, when he promiſes the pious Jews protection "from a fierce people; a people of a deeper ſpeech than they could perceive; of a ſtammering tongue, that they could not underſtand."

20 How it was changed into what is called the Chaldean.

Hebrew Language.

* Iſaiah, ch. xxxiii. verſ. 19.

The priority of the Chaldean tongue is indeed contended for by very learned writers. Cambden † calls it the mother of all languages; and moſt of the fathers were of the ſame opinion. Amira ‡ has made a collection of arguments, not inconſiderable, in favour of it; and Myriceus §, after him, did the ſame. Erpenius ||, in his Oration for the Hebrew tongue, thought the argument for it and the Chaldean ſo equal, that he did not chooſe to take upon him to determine the queſtion.

† *Brit.*

‡ *Præf. ad Gram. Syr.*

§ *Præf. ad Gram. Chald.*

|| *Oratio de lingua Hebr.* xii.

Many circumſtances, however, concur to make us aſſign the priority to the Hebrew, or rather to make us believe that it has ſuffered feweſt of thoſe changes to which every living tongue is more or leſs liable. If we ſtrip this language of every thing obviouſly adventitious, we ſhall find it extremely ſimple and primitive. 1. Every thing maſoretical, ſuppoſing the vowels and points (G) eſſential, was certainly unknown in its original character. 2. All the prefixed and affixed letters were added time after time, to give more compaſs and preciſion to the language. 3. The various voices, moods, tenſes, numbers, and perſons of verbs, were poſterior improvements; for in that tongue, nothing at firſt appeared but the indeclinable radix. 4. In the ſame manner, the few adjectives that occur in the language, and the numbers and regimen of nouns, were not from the beginning. 5. Moſt of the Hebrew nouns are derived from verbs; indeed many of them are written with the very ſame letters. This rule, however, is not general; for often verbs are derived from nouns, and even ſome from prepoſitions. 6. All the verbs of that language, at leaſt all that originally belonged to it, uniformly conſiſt of three letters, and ſeem to have been at firſt pronounced as monoſyllables. If we anatomize the Hebrew language in this manner, we ſhall reduce it to very great ſimplicity; we ſhall confine it to a few names of things, perſons, and actions; we ſhall make all its words monoſyllables, and give it the true characters of an original language. If at the ſame time we reflect on the ſmall number of (H) radical words in that dialect, we ſhall be more and more convinced of its originality.

21 Reaſons for maintaining the priority of the Hebrew.

It will not be expected that we ſhould enter into a minute diſcuſſion of the grammatical peculiarities of this ancient language. For theſe we muſt refer our readers to the numerous and elaborate grammars of that tongue, which are everywhere eaſily to be found. We ſhall only make a few ſtrictures, which naturally preſent themſelves, before we diſmiſs the ſubject.

The generality of writers who have maintained the ſuperior

5

(F) Moſt of the Chaldean names mentioned in Scripture are pure Hebrew words compounded; ſuch as *Nebuchadnezzar*, *Nebuzaradan*, *Rabſhakeh*, *Rabmag*, *Belſhazzar*, *Rabſaris*, *Nahar*, *Malahtha*, *Phrat* or *Pharad*, *Baroſus*, *Carchemiſh*, *Ur*, *Cutha*, Heb. *Cuſh*, &c. All theſe words, and a multitude of others which we could mention, approach ſo near the Hebrew dialect, that their original is diſcernible at firſt ſight. Moſt of theſe are compounds, which the limits preſcribed us will not allow us to decompound and explain.

(G) The futility of theſe points will be proved in the following part of this ſection.

(H) The radical words in the Hebrew language, as it now ſtands, are about 500.

Hebrew Language.

22 All languages in the east originally the same

superior antiquity of the Hebrew language, have at the same time contended that all other languages of Asia, and most of those of Europe, have been derived from that tongue as their source and matrix. We, for our part, are of opinion, that perhaps all the languages in the eastern part of the globe are coeval with it, and were originally one and the same; and that the differences which afterwards distinguished them sprung from climate, caprice, inventions, religions, commerce, conquests, and other accidental causes, which will occur to our intelligent readers. We have endeavoured to prove, in the preceding pages, that all mankind were not concerned in the building of the fatal tower, nor affected by the punishment consequent upon that attempt: and we now add, that even that punishment was only temporary; since we find, that those very Hamites or Cushim, who are allowed to have been affected by it, did certainly afterwards recover the former organization of their *lip*, and differed not more from the original standard than the descendants of Japhet and Shem.

The Jewish rabbis have pretended to ascertain the number of languages generated by the vengeance of Heaven at the building of Babel. They tell us that mankind was divided into 70 nations and 70 languages, and that each of these nations had its tutelar or guardian angel. This fabulous legend is founded on the number of the progeny of Jacob at the time when that patriarch and his family went down into Egypt. Others attribute its origin to the number of the sons and grandsons of Noah, who are enumerated Gen. chap. x.

* *Clem. Alex. Strom. Euseb. Chron.* lib. 1. *Epiphan. Haref. August.* &c.

The fathers * of the church make the languages at the confusion to amount to 72; which number they complete by adding Cainan and Elishah, according to the Septuagint, who are not mentioned in the Hebrew text. This opinion, they think, is supported by the words of Moses, when he saith, that † "when the Most High divided to the nations their inheritance, when he separated the sons of Adam, he set the bounds of the people according to the number of the tribes of Israel." That is, say they, he divided them into 72 nations, which was the number of the children of Israel when they came into Egypt. The Targum of Ben-Uzziel plainly favours this interpretation; but the Jerusalem Targum intimates that the number of nations were only 12, according to the number of the tribes of Israel. This passage, however, seems to refer to the tribes of the Chanaanim; and imports, that the Almighty assigned to the different septs of that family such a tract of land as he knew would make a sufficient inheritance for the children of Israel ‡. Others have increased the different languages of the dispersion to 120; but the general opinion has fixed them to 70 or 72. Our readers need scarce be put in mind that these opinions are futile and absurd; neither founded in Scripture, profane history, or common sense. At the same time, it must not be omitted, that, according to Horapello §, the Egyptians held, that the world was divided into 72 habitable regions; and that, in consequence of this tradition, they made the cynocephalus the emblem of the world, because that in the space of 72 days that animal pines away and dies.

† Deut. ch. xxxii. verse 8.

‡ *Pacanini Episcop. Berun. apud Hieron. in Catalogo Epist.* 22.

§ 14 page 25. *Hoesch.*

Origin of the name *Hebrew.*

23 It has been made a question, whether the Hebrew language was denominated from Heber the progenitor of Abraham, or from a word which in that tongue imports *over*, *beyond*. Most of the Christian fathers, prior to St Origen, believed that both the Gentile name *Hebrew*, and the name of the language, were derived from the name of the patriarch; but that learned man imagined, that Abraham was called the *Hebrew*, not because he was a descendant of Heber, but because he was a transfluvianus, or from beyond the river Euphrates. The learned Bochart * has strained hard to prove the former position; but to us his arguments do not appear decisive. We are rather inclined to believe, that Abraham was called *Chibri*, (Hebrew), from the situation of the country from which he emigrated when he came to the country of Chanaan; and that in process of time that word became a Gentile appellation, and was afterwards applied to his posterity (1) often by way of reproach, much in the same manner as we say a *Northlander*, a *Norman*, a *Tramontane*, &c.

* *Phaleg*, lib. 1. c. 15.

Here we may be indulged an observation, namely, that Abraham, a Hebrew, lived among the Chaldeans, travelled among the Chanaanites, sojourned among the Philistines, lived some time in Egypt; and in all appearance conversed with all those nations without any apparent difficulty. This circumstance plainly proves, that all these nations at that time spoke nearly the same language. The nations had not yet begun to improve their respective dialects, nor to deviate in any great measure from the monosyllabic tongue of the Hebrews. With respect to the language of Chanaan, afterwards the Phœnician, its similarity to the Hebrew is obvious from the names of gods, men, cities, mountains, rivers, &c. which are the very same in both tongues, as might be shown in numberless cases, were this a proper place for etymological researches.

Before we dismiss this part of our subject, we would wish to gratify our unlearned readers with a brief account of the Hebrew letters, and of the Masoretical points which have been in a manner ingrafted on these letters. In the course of this deduction, we shall endeavour to follow such authors as are allowed to have handled that matter with the greatest acuteness, learning, and perspicuity. If, upon any occasion, we should be tempted to hazard a conjecture of our own, it is cheerfully submitted to the candour of the public.

Much has been written, and numberless hypotheses proposed, with a view to investigate the origin of *alphabetical writing*. To give even an abridged account of all these, would fill many volumes. The most plausible, in our opinion, is that which supposes that the primary characters employed by men were the figures of material objects analogous to those of the Mexicans, so often mentioned by the authors who have

(1) The Egyptians might not eat bread with the Hebrews, for that is an abomination to the Egyptians. The Philistines (Samuel I. *pass.*) always call the Israelites *Hebrews* by way of reproach.

Hebrew Language.

have written the history of that people at the era of the Spanish invasion of their country. As this plan was too much circumscribed to be generally useful, hieroglyphical figures were in process of time invented as subsidiaries to this contracted orthography. In this scheme, we imagine, the process was somewhat more extensive. A *lion* might be sketched, to import fierceness or valour; an *ox*, to denote strength; a *stag*, to signify swiftness; a *hare*, to intimate timorousness, &c.

24 Origin of alphabetic writing.

The next step in this process would naturally extend to the inventing and appropriating of a few arbitrary characters, for representing abstract ideas, and other relations, which could not be well ascertained by the methods above-mentioned. These arbitrary signs might readily acquire a currency by compact, as money and medals do over a great part of the world.—Upon this plan we imagine the ancient Chinese formed their language.

But neither the picture nor the hieroglyphic, nor the method of denoting *ideas* by arbitrary characters appropriated by compact, could ever have arrived at such perfection as to answer all the purposes of ideal communication. The grand desideratum then would be to fabricate characters to represent simple sounds, and to reduce these characters to so small a number as to be easily learned and preserved in the memory. In this attempt the Chinese have notoriously failed; their letters, or rather their characters, are so numerous, that few, if any, of their most learned and industrious authors, have been able to learn and retain the whole catalogue. Indeed those people are not able to conceive how any combinations of 20 or 30 characters should be competent to answer all the purposes of written language.

Many different nations have claimed the honour of this invention. The Greeks ascribed it to the Phœnicians; and consequently used the word φοινίσσειν *, *to act the Phœnician*, in the same sense with ἀναγινώσκειν, *to read*; and consequently the poet † ascribes the invention to the same ingenious people. The Greeks borrowed their letters from the Phœnicians, and of course looked up to them as the inventors.

* *Hesych.*

† *Lucan.*

Others have attributed the invention to the Egyptians. That people ascribed every useful and ingenious invention to their Thyoth, or Mercury Trismegistus. Plato seems to have believed this tradition (K), and pretends to record a dispute between the king of Egypt that then reigned and this personage, with respect to the influence that the art of alphabetic writing might possibly have upon the improvements of mankind in science and liberal arts. Diodorus the Sicilian ‡ gives a similar history of the same invention, but carries it back to the reign of Osiris.

Bibl. l. 1. ng 10. Steph.

Pliny informs us ||, that Gellius attributed letters to the same Egyptian Mercury, and others to the Syrians; but that for "his part, he thought that the Assyrian letters were eternal." That learned Roman then imagined, that the Assyrian letters had existed at a period prior to all the records of history; which was in fact the case. By the Assyrian letters, he must mean the Chaldaic, and by the Syrian probably the Hebrew. The earliest Greek historians generally confound the Jews with the Syrians. Herodotus, enumerating the people who had * learned circumcision from the Egyptians, mentions the Syrians of Palestine; and elsewhere he tells us, that Necho † beat the Syrians, and took Cadytis, a large and populous city belonging to that people. Hence it is evident that the Syrian alphabet, or the Syrian letters, were the same with the Hebrew. That the Assyrian or Chaldaic and Hebrew languages were the same, has, we hope, been fully proved already: that their letters were the same in their original structure, can scarce be controverted. These letters, we think, were antediluvian; whether, to use the expression of Plato, they were dictated by some god, or fabricated by some man divinely inspired. As this opinion may admit some dispute, we shall take the liberty to subjoin our reasons.

Hebrew Language.

* Lib. 2. c. 104.

† Ibid. c. 159.

25 Antediluvian.

1. It appears that the era of this invention is buried in impenetrable obscurity. Had an invention of such capital importance to mankind been made in the postdiluvian ages, we imagine the author would have been commemorated in the historical annals of the country where he lived (L).

2. The art of writing in alphabetical characters, according to the sacred records, was practised at so early a period, that there was not a long enough interval between that and the deluge to give birth to that noble invention. If we consider the state of the world during some ages after that disastrous event, we shall quickly be convinced that little respite could be found from the labour and industry indispensably requisite to provide the necessaries, and only a few of the conveniencies, of life. Such a state of things was certainly most unfavourable to the invention of those arts and improvements which contribute nothing towards procuring the accommodations of life. The consequence is obvious.

Moses has recorded the history of the creation, of a few of the capital transactions of the antediluvian world, the birth, the age, the death, of the lineal descendants of Seth. He has preserved the dimensions of the ark, the duration of the universal deluge, its effects upon man and all terrestrial animals, the population of the world by the posterity of Noah, the age, &c. of the patriarchs of the line of Shem, from which his own ancestors had sprung. To this he has subjoined the petty occurrences which diversified the lives of Abraham, Isaac, and Jacob, and their descendants. Whence did the historian derive his information? We believe few of our readers will be so enthusiastic as to imagine that the author received it from divine inspiration. Tradition is a fallible guide; and in many cases the accounts are so minutely precise, as to defy the power of that species of conveyance. The inspired author must certainly have extracted

(L) It is true, the Egyptians attribute the invention to their Thoth, and the Phœnicians to their Hercules, or Melicerta or Baal; but these were only imaginary personages.

Hebrew Language.

tracted his abridgment from written memoirs, or hiſtories of the tranſactions of his anceſtors regularly tranſmitted from the moſt early periods. Theſe annals he probably abridged, as Ezra did afterwards the hiſtory of the Kings of Iſrael. If this was the caſe, as it moſt certainly was, the art of writing in alphabetical letters muſt have been known and practiſed many ages before Moſes. It has indeed been pretended, that the Jewiſh decalogue, inſcribed upon two tables of ſtone, was the very firſt ſpecimen of alphabetical writing. The arguments adduced in proof of this fact are lame and inconcluſive (M). Had that been the

Hebrew Language.

(M) The moſt ingenious and plauſible of thoſe arguments which have fallen under our obſervation, is given by Mr Johnſon vicar of Cranbrook, a writer of great learning and piety, who flouriſhed in the beginning of the preſent century, and whoſe works deſerve to be more generally known than we have reaſon to think they are at preſent. After endeavouring to prove that alphabetical writing was not practiſed before the era of Moſes, and expatiating upon the difficulty of the invention, this excellent ſcholar attempts to ſhow, that the original Hebrew alphabet was actually communicated to the Jewiſh legiſlator at the ſame time with the two tables of the law. "I know not (ſays he) any juſt cauſe why the law ſhould be *written by God*, or by an *angel* at his command, except it were for want of a man that could well perform this part. This could give no addition of authority to the law, eſpecially after it had been publiſhed in that aſtoniſhing and miraculous manner at Mount Sinai. The true writing of the original was indeed perfectly adjuſted, and preciſely aſcertained to all future ages, by God's giving a copy of it under his own hand: but this, I conceive, had been done altogether as effectually by God's dictating every word to Moſes, had he been capable of performing the office of an amanuenſis." The learned writer goes on to ſuppoſe, that it was for the purpoſe of *teaching Moſes the alphabet*, that God detained him forty days in the mount; and thence he concludes, that the Decalogue was the firſt writing in alphabetical characters, and that thoſe characters were a divine, and not a human invention.

It is always raſh, if not ſomething worſe, to conceive reaſons not aſſigned by God himſelf, for any particular tranſaction of his with thoſe men whom he from time to time inſpired with heavenly wiſdom. That it was *not* for the purpoſe of teaching Moſes the alphabet that God detained him forty days in the mount, when he gave him the two tables of the law, ſeems evident from his detaining him juſt as many days when he gave him the ſecond tables after the firſt were broken. If the legiſlator of the Jews had not been ſufficiently inſtructed in the art of reading during his firſt ſtay in the mount, he would have been detained longer; and it is not conceivable, that though in a fit of pious paſſion he was ſo far thrown off his guard as to break the two tables, his mind was ſo totally unhinged by the idolatry of his countrymen, as to forget completely an art which, by the ſuppoſition, the Supreme Being had ſpent *forty days* in teaching him! "But if Moſes could, at his firſt aſcent into the mount, perform the office of an amanuenſis, why are the original tables ſaid to have been written by the finger of God, and not by him who wrote the ſecond?" We pretend not to ſay why they were written by God rather than man; but we think there is ſufficient evidence, that by whomſoever they were written, the characters employed were of human invention. The Hebrew alphabet, without the Maſoretic points, is confeſſedly defective; and every man who is in any degree acquainted with the language, and is not under the influence of inveterate prejudice, will readily admit that thoſe points are no improvement. But we cannot, without impiety, ſuppoſe an art invented by infinite wiſdom, to fall ſhort of the utmoſt perfection of which it is capable: an alphabet communicated to man by God, would undoubtedly have been free both from defects and from redundancies; it would have had a diſtinct character for every ſimple ſound, and been at leaſt as perfect as the Greek or the Roman.

But we need not fill our pages with reaſonings of this kind againſt the hypotheſis maintained by Mr Johnſon. We know that "Moſes wrote all the words of the Lord," *i. e.* the ſubſtance of all that had been delivered in *Exod.* xx, xxi, xxii, xxiii. before he was called up into the mount to receive the tables of ſtone; nay, that he had long before been commanded by God himſelf to "write in a book" an account of the victory obtained over Amalek (*Exod.* xvii. 14). All this, indeed, the learned writer was aware of; and to reconcile it with his hypotheſis, he frames another, more improbable than even that which it is meant to ſupport. "It is not unreaſonable (ſays he) to believe that God had written theſe tables of ſtone, and put them in mount Horeb, from the time that by his angel he had there firſt appeared to Moſes; and that, therefore, all the time after, while he kept Jethro's ſheep thereabouts, he had free acceſs to thoſe tables, and peruſed them at diſcretion." But if belief ſhould reſt upon evidence, we beg leave to reply, that to believe all this would be in the higheſt degree unreaſonable; for there is not a ſingle hint in Scripture of the tables having been written at ſo early a period, or upon ſuch an occaſion, as God's firſt appearance to Moſes in the burning buſh. We know how reluctant Moſes was to go upon the embaſſy to which he was then appointed; and it is ſtrange, we think paſſing ſtrange, that when he records ſo faithfully his own backwardneſs, and the means made uſe of by God to reconcile him to the arduous undertaking, he ſhould make no mention of theſe important tables, if at that period he had known any thing of their exiſtence. Beſides all this, is it not wonderful, if Moſes had been practiſing the art of writing, as our author ſuppoſes, from the time of the burning buſh to the giving of the law, he ſhould then have ſtood in need of *forty days* teaching from God, to enable him to *read* with eaſe the firſt tables; and of other forty, to enable him to *write* the ſecond? This gives ſuch a mean view of the natural capacity of the Hebrew legiſlator, as renders the hypotheſis which implies it wholly incredible. *See a Collection of Diſcourſes*, &c. *in two volumes, by the reverend John Johnſon, A. M. vicar of Cranbrook in Kent.*

Hebrew Language.

the caſe, ſome notice muſt have been taken of ſo palpable a circumſtance. Moſes wrote out his hiſtory, his laws, and his memoirs; and it appears plainly from the text, that all the learned among his countrymen could read them. Writing was then no novel invention in the age of the Jewiſh legiſlator, but current and generally known at that era.

The patriarch Job lived at an earlier period (N). In that book we find many alluſions to the art of writing, and ſome paſſages which plainly prove its exiſtence. This ſhows that alphabetical characters were not confined to the choſen ſeed, ſince Job was in all probability a deſcendant of Huz, the eldeſt ſon of Nahor * the brother of Abraham. From this circumſtance, we think we may fairly conclude, that this art was known and practiſed in the family of Terah the father of Abraham.

* Gen. xxii. 20, &c.

3. There was certainly a tradition among the Jews in the age of Joſephus, that writing was an antediluvian invention ‡. That hiſtorian pretends, that the deſcendants of Seth erected two pillars, the one of ſtone and the other of brick, and inſcribed upon them their aſtronomical obſervations and other improvements.—This legend ſhows that there did exiſt ſuch an opinion of the antiquity of the art of writing.

‡ *Antiq.* lib. i. cap. 3.

26 Traditions to this purpoſe.

4. There muſt have been a tradition to the ſame purpoſe among the Chaldeans, ſince the writers who have copied from Beroſus, the celebrated Chaldean hiſtorian (O), ſpeak of alphabetical writing as an art well known among the antediluvians. According to them, Oannes the Chaldean legiſlator gave his diſciples "an inſight into *letters* and ſcience. This perſon alſo *wrote* concerning the generation of mankind, of their different purſuits, of civil polity, &c. Immediately before the deluge (ſay they) the god Cronus appeared to Siſuthrus or Xiſuthrus, and commanded him to commit to *writing* the beginning, improvement, and concluſion of all things down to the preſent term, and to bury theſe accounts ſecurely in the temple of the Sun at Seppara." All theſe traditions may be deemed fabulous in the main; but ſtill they evince that ſuch an opinion was current, and that though the uſe of letters was not indeed eternal (P), it was, however, prior to all the records of hiſtory; and of courſe, we think, an antediluvian diſcovery.

27 The original alphabet preſerved in the family of Noah.

This original alphabet, whatever it was, and however conſtructed, was, we think, preſerved in the family of Noah, and from it conveyed down to ſucceeding generations. If we can then diſcover the original Hebrew alphabet, we ſhall be able to inveſtigate the primary ſpecies of letters expreſſive of thoſe articulate ſounds by which man is in a great meaſure diſtinguiſhed from the brute creation. Whatever might be the nature of that alphabet, we may be convinced that the ancient Jews deemed it ſacred, and therefore preſerved it pure and unmixed till the Babyloniſh captivity. If, then, any monuments are ſtill extant inſcribed with letters prior to that event, we may reſt aſſured that theſe are the remains of the original alphabet.

Hebrew Language.

There have, from time to time, been dug up at Jeruſalem, and other parts of Judea, coins and medals, and medallions, inſcribed with letters of a form very different from thoſe ſquare letters in which the Hebrew Scriptures are now written.

28 The ſame with the Samaritan;

When the Samaritan Pentateuch was diſcovered (Q), it evidently appeared that the inſcriptions on thoſe medals and coins were drawn in genuine Samaritan characters. The learned Abbé Barthelemi, in his * diſſertation "on the two medals of Antigonus king of Judea, one of the later Aſmonean princes, proves that all the inſcriptions on the coins and medals of Jonathan and Simon Macabeus, and alſo on his, were invariably in the Samaritan character, down to the 40th year before the Chriſtian era."

* *Mem de l'Academ. de l'Inſcrip.* &c.

It were eaſy to prove, from the Miſhna and Jeruſalem talmud, that the Scriptures publicly read in the ſynagogues to the end of the ſecond century were written in the Samaritan character, we mean in the ſame character with the Pentateuch in queſtion. As the ancient Hebrew, however, ceaſed to be the vulgar language of the Jews after their return from the Babyloniſh captivity, the copies of the Bible, eſpecially in private hands, were accompanied with a Chaldaic paraphraſe; and at length the original Hebrew character fell into diſuſe, and the Chaldaic was univerſally adopted.

29 Which afterwards gave place to the Chaldaic,

It now appears that the letters inſcribed on the ancient coins and medals of the Jews were written in the Samaritan form, and that the Scriptures were written in the very ſame characters: we ſhall therefore leave it to our readers to judge whether (conſidering the implacable hatred which ſubſiſted between theſe two nations) it be likely that the one copied from the other; or at leaſt that the Jews preferred to the beautiful letters uſed by their anceſtors, the rude and inelegant characters of their moſt deteſted rivals. If, then, the inſcriptions on the coins and medals were actually in the characters of the Samaritan Pentateuch (and it is abſurd to ſuppoſe that the Jews borrowed them from the Samaritans), the conſequence plainly is, that the letters of the inſcriptions were thoſe of the original Hebrew alphabet, coeval with that language, which we dare to maintain was the firſt upon earth.

It may, perhaps, be thought rather ſuperfluous to men-

(N) We have ſeen a manuſcript, which may one day ſee the light, in which it is ſhown, with great probability, that Job was nearly cotemporary with the patriarch Jacob.

(O) Apollodorus, Alexander Polyhiſtor, Abydenus. See *Syncellus*, cap. 39. *et ſeq. Euſeb. Chron.* l. 1. page 3.

(P) Plin. Nat. Hiſt. l. 7. page 413.—*Ex quo apparet æternus literarum uſus.*

(Q) The celebrated Archbiſhop Uſher was the firſt who brought the Samaritan Pentateuch into Europe. In a letter to Ludovicus Capellus "he acknowledges, that the frequent mention he had ſeen made of it by ſome authors, would not ſuffer him to be at reſt till he had procured five or ſix copies of it from Paleſtine and Syria."

Hebrew Language.

mention, that the Samaritan coloniſts, whom the kings of Aſſyria planted in the cities of Samaria (R), were natives of countries where Chaldaic letters were current, and who were probably ignorant of the Hebrew language and characters. When thoſe coloniſts embraced the Jewiſh religion, they procured a copy of the Hebrew Pentateuch written in its native character, which, from ſuperſtition, they preſerved inviolate as they received it; and from it were copied ſucceſſively the others which were current in Syria and Paleſtine when Archbiſhop Uſher procured his.

From the reaſons above exhibited, we hope it will appear, that if the Hebrew alphabet, as it appears in the Samaritan Pentateuch, was not the primitive one, it was at leaſt that in which the Holy Scriptures were firſt committed to writing.

† *Chron. in anno* 4740. ‡ *Præf. in Reg.*

Scaliger has inferred, from a paſſage in Euſebius†, and another in St Jerom‡, that Ezra, when he reformed the Jewiſh church, tranſcribed the Scriptures from the ancient characters of the Hebrews into the ſquare letters of the Chaldeans. This, he thinks, was done for the uſe of thoſe Jews who, being born during the captivity, knew no other alphabet than that of the people among whom they were educated.—This account of the matter, though probable in itſelf, and ſupported by paſſages from both Talmuds, has been attacked by Buxtorf with great learning and no leſs acrimony. Scaliger, however, has been followed by a crowd of learned men (S), whoſe opinion is now pretty generally eſpouſed by the ſacred critics.

30 Which was introduced by Ezra.

Having ſaid ſo much concerning the Hebrew alphabet in the preceding pages, we find ourſelves laid under a kind of neceſſity of hazarding a few ſtrictures on the vowels and Maſoretic points; the *firſt* eſſential, and the *laſt* an appendage, of that ancient language. The number of the one, and the nature, antiquity, and neceſſity of the other, in order to read the language with propriety and with diſcrimination, have been the ſubject of much and often illiberal controverſy among philological writers. To enter into a minute detail of the arguments on either ſide, would require a complete volume: we ſhall, therefore, briefly exhibit the ſtate of the controverſy, and then adduce a few obſervations, which, in our opinion, ought to determine the queſtion.

31 The Hebrew vowels.

The controverſy then is, Whether the Hebrews uſed any vowels; or whether the points, which are now called by that name, were ſubſtituted inſtead of them? or if they were, whether they be as old as Moſes, or were invented by Ezra, or by the Maſſorites(T)? This controverſy has exerciſed the wits of the moſt learned critics of the two laſt centuries, and is ſtill far enough from being determined in the preſent. The Jews maintain, that theſe vowel points (U) were delivered to Moſes along with the tables of the law; and conſequently hold them as ſacred as they do the letters themſelves. Many Chriſtian authors who have handled this ſubject, though they do not affirm their divine original, nor their extravagant antiquity, pretend, however, that they are the only proper vowels in the language, and regulate and aſcertain its true pronunciation. Though they differ from the Jews with reſpect to the origin of theſe points, they yet allow them a pretty high antiquity, aſcribing them to Ezra and the members of the great ſynagogue.

Hebrew Language.

32 The Maſoretic points a modern invention.

At length, however, about the middle of the 16th century, Elias Levita, a learned German Jew who then flouriſhed at Rome, diſcovered the deluſion, and made it appear that theſe appendages had never been in uſe till after the writing of the talmuds, about 500 years after Chriſt. This innovation raiſed Elias a multitude of adverſaries, both of his own countrymen and Chriſtians. Among the latter appeared the two Buxtorfs, the father and the ſon, who produced ſome cabbaliſtical books of great antiquity(X), at leaſt in the opinion of the Jews, in which there was expreſs mention of the points. The Buxtorfs were anſwered by Capellus and other critics *, till Father Morinus §, having examined all that had been urged on both ſides, produced his learned diſſertation on that ſubject; againſt which there has been nothing replied of any conſequence, whilſt his work has been univerſally admired, and his opinion confirmed by thoſe that have beaten the ſame field after him.

* Walton, Dupin, and Voſſius. § *Diſſert. Bibl.*

According to this learned father, it plainly appears that neither Origen, nor St Jerome, nor even the compilers of the talmuds, knew any thing of what has been called the vowel points; and yet theſe books, according to the ſame author, were not finiſhed till the ſeventh century. Even the Jewiſh rabbis who wrote during the eighth and ninth centuries, according to him, were not in the leaſt acquainted with theſe points. He adds, that the firſt veſtiges he could trace of them were in the writings of *rabbi Ben Aber* chief of the weſtern, and of *rabbi Ben Naphtali* chief of the eaſtern, ſchool, that is, about the middle of the tenth century; ſo that they can hardly be ſaid to be older than the beginning of that period.

Some

(R) II. Kings, chap. xvii. ver. 24. "And the king of Aſſyria brought men from Babylon, and from Cuthah, and from Avah, and from Hamath, and from Sepharvaim, and placed them in the cities of Samaria." Babylon, and Cuthah, and Avah, were neighbouring cities, and undoubtedly both ſpoke and wrote in the Chaldaic ſtyle. The natives of Hamath ſpoke the Syriac, which at that time differed very little from the Chaldaic.

(S) Caſaubon, Grotius, Voſſius, Bochart, Morin, Brerewood, Walton, Prideaux, Huet, and Lewis Capel, always a ſworn enemy to Buxtorf. All, then, have maintained the ſame ground with Scaliger: how truly, appears above.

(T) The term *maſorah* or *maſſoreth* ſignifies "tradition;" and imports the unwritten canon by which the reading and writing of the ſacred books was fixed.

(U) Theſe points are 14 in number, whoſe figures, names, and effects, may be ſeen in moſt Hebrew grammars.

(X) Theſe books are the *Babir*, *Zahar*, and the *Kizri*. As for the Kizri, the Jews make it about 1900 years old; and the other about a century later. But the fidelity of the Jews in ſuch matters cannot be relied upon.

Hebrew Language. Some learned men (y) have ascribed the invention of the vowel points in question to the rabbis of the school of Tiberias; which, according to them, flourished about the middle of the second century. This opinion is by no means probable, because it appears plain from history, that before that period all the Jewish seminaries in that province were destroyed, and their heads forced into exile. Some of these retired into Babylonia, and settled at Sora, Neherda, and Pombeditha, where they established famous universities. After this era there remained no more any rabbinical schools in Judæa, headed by professors capable of undertaking this difficult operation, nor indeed of sufficient authority to recommend it to general practice, had they been ever so thoroughly qualified for executing it.

Capellus and father Morin, who contend for the late introduction of the vowel-points, acknowledge that there can certainly be no language without vocal sounds, which are indeed the soul and essence of speech; but they affirm that the Hebrew alphabet actually contains vowel characters, as well as the Greek and Latin and the alphabets of modern Europe.

53 The *matres lectionis*. These are *aleph, he, vau, jod*. These they call the *matres lectionis*, or, if you please, the parents of reading. To these some, we think very properly, add *ain* or *oin*, *ojin*. These, they conclude, perform exactly the same office in Hebrew that their descendants do in Greek. It is indeed agreed upon all hands, that the Greek alphabet is derived from the Phœnician, which is known to be the same with the Samaritan or Hebrew. This position we shall prove more fully when we come to trace the origin of the Greek tongue. Hitherto the analogy is not only plausible, but the resemblance precise. The Hebrews and Samaritans employed these vowels exactly in the same manner with the Greeks; and so all was easy and natural.

34 Objections answered. But the asserters of the Masoretic system maintain, that the letters mentioned above are not vowels but consonants or aspirations, or any thing you please but vocal letters. This they endeavour to prove from their use among the Arabians, Persians, and other oriental nations: But to us it appears abundantly strange to suppose that the Greeks pronounced *beta*, *gamma*, *delta*, &c. exactly as the Hebrews and the Phœnicians did, and yet at the same time did not adopt their mode of pronunciation with respect to the five letters under consideration. To this argument we think every objection must undoubtedly yield. The Greeks borrowed their letters from the Phœnicians; these letters were the Hebrew or Samaritan. The Greeks wrote and (z) pronounced all the other letters of their alphabet, except the five in question, in the same manner with their originals of the east: if they did so, it obviously follows that the Greek and oriental office of these letters was the same.

Another objection to reading the Hebrew without the aid of the Masoretic vowel points, arises from the consideration, that without these there will be a great number of radical Hebrew words, both nouns and verbs, without any vowel intervening amongst the consonants, which is certainly absurd. Nothwithstanding this supposed absurdity, it is a well known fact, that all the copies of the Hebrew scriptures, used in the Jewish synagogues throughout the world, are written or printed without points. These copies are deemed sacred, and kept in a coffer with the greatest care, in allusion to the ark of the testimony in the tabernacle and temple. The prefect, however, reads the portions of the law and hagiographa without any difficulty. The same is done by the remains of the Samaritans at this day. Every oriental scholar knows that the people of these countries look upon consonants as the stamina of words. Accordingly, in writing letters, in dispatches upon business, and all affairs of small moment, the vowels are generally omitted. It is obvious, that in every original language the sound of the vowels is variable and of little importance. Such was the case with the Hebrew tongue: Nor do we think that the natives of the country would find it a matter of much difficulty to learn to read without the help of the vowels. They knew the words beforehand, and so might readily enough learn by practice what vowels were to be inserted.

When the Hebrew became a dead language, as it certainly was in a great measure to the vulgar after the return from the Babylonish captivity; such subsidiaries might, we think, have been useful, and of course might possibly have been adopted for the use of the vulgar: but the scribe, the lawyer, and the learned rabbi, probably disdained such beggarly elements. We shall in this place hazard a conjecture, which, to us at least, is altogether new. We imagine that the Phœnicians, who were an inventive, ingenious people, had, prior to the age of Cadmus, who first brought their letters into Greece, adopted the more commodious method of inserting the vowels in their proper places; whereas the Jews, zealously attached to the customs of their ancestors, continued to write and read without them. In this manner the Gephuræi ‡, who were the followers of Cadmus, communicated them to the Jones their neighbours. We are convinced that the materials of the Greek tongue are to be gleaned up in the east; and upon that ground have often endeavoured to trace the origin of Greek words in the Hebrew, Phœnician, Chaldean, and Arabian languages. Reading without the vowel points we have seldom failed in our search; but when we followed the method of reading by the Masoretic points, we seldom succeeded; and this, we believe, every man of tolerable erudition who will make a trial will find by experience to be true. This argument appears to us superior to every objection. Upon this basis, the most learned Bochart has erected his etymological fabric, which will be admired by the learned and ingenious as long as philology shall be cultivated by men.

‡ *Herod.* lib. i cap. 56.

35 Proof that the Masoretic points are modern.

3 R 2 It

(y) See Buxtorf the father, in Tiber. cap. 5, 6, 7. Buxtorf the son de Antiq. Punct. P. II. 11.

(z) This is so true, that, according to Hesychius and Suidas, φοινικιζειν, to act the Phœnician, signified "to read."

Hebrew Language.

It has been urged by the zealots for the Maſoretic ſyſtem, that the Arabians and Perſians employ the vowel points. That they do ſo at preſent is readily granted; but whether they did ſo from the beginning ſeems to be the queſtion. That Arabia was overſpread with Jewiſh exiles at a very early period, is abundantly certain. It was natural for them to retire to a land where they would not hear of war nor the ſound of the trumpet. Accordingly we find that, prior to the age of the Arabian impoſtor, Arabia ſwarmed with Jewiſh ſettlements. From theſe Jews, it is highly probable that their neighbours learned the uſe of the points in queſtion; which in the courſe of their conqueſts the Saracens communicated to the Perſians.

It has been alleged with great ſhow of reaſon, that without the vowel points, it is often impoſſible to develope the genuine ſignification of many words which occur frequently in the language; many words of different and ſometimes oppoſite ſignifications are written with exactly the ſame conſonants. Without the points then, how are we to know the diſtinction? In anſwer to this objection, we beg leave to obſerve, that, during the firſt period of a language, it is impoſſible that there ſhould not occur a number of ſimilar ſounds of different ſignifications. This is ſurely to be attributed to the poverty of the language. When a few terms have been once fabricated, men will rather annex new ſignifications to old terms, than be at the expence of time or thought to invent new ones. This muſt have been the caſe with the Hebrew in particular; and indeed no language on earth is without inſtances of this inconveniency, which, however, in a living tongue, is eaſily overcome by a difference of accent, tone, geſture, pronunciation; all which, we think, might obviate the difficulty.

From the preceding arguments, we think ourſelves authorized to infer that the Maſora is a novel ſyſtem, utterly unknown to the moſt ancient Jews, and never admitted into thoſe copies of the Scriptures which were deemed moſt ſacred and moſt authentic by that people.

According to ORIGEN.

Brêſith bara Elôeim eth aſamaim oueth aarcs.

Ouaares aietha Thôau ouboou ouôſekh al phne Theôm ouroué elôeim maraepheth al phne amaim.

Ouiômer elôeim iei ôr ouiei ôr.

Ouiar elôeim eth aôr khi tôb ouiabdêl elôeim bên aôr oubên aôſekh.

With reſpect to the original introduction of the points, we agree with the learned and judicious * Dr Prideaux, who imagines that they were gradually introduced after the Hebrew became a dead language, with a view to facilitate the learning to read that language, more eſpecially among the vulgar. By whom they were introduced, we think, cannot eaſily be determined; nor is it probable that they were all introduced at once, or by one and the ſame perſon. They have been aſcribed to Ezra by many, for no other reaſon that we can diſcover but to enhance their authenticity, and becauſe the ſentiment is analogous to the other articles of reformation eſtabliſhed by that holy prieſt. If our curious reader ſhould not be ſatisfied with the preceding detail, we muſt remit him to Capellus and Morinus on the one ſide, and the two Buxtorfs, Schultens, and Dr James Robertſon profeſſor of oriental languages in the univerſity of Edinburgh, on the other. This learned orientaliſt, in his diſſertation prefixed to his *Clavis Pentateuchi*, has collected and arranged, with a true ſpirit of criticiſm, every thing that has been advanced in favour of the Maſoretical ſyſtem.—*Si Pergama dextra defendi poſſent, etiam hac defenſa fuiſſent.*

Hebrew Language.

* *Con.* Part I. Book i.

36 From Origen's Hexapla.

St Origen, who flouriſhed about the beginning of the 3d century, was a profound Hebrew ſcholar. He publiſhed a moſt laborious and learned work, which is generally called the *Hexapla*, becauſe it conſiſted of ſix columns; the firſt of which contained the Hebrew text; the ſecond, the ſame text, but written in Greek characters; the third column exhibited the verſion of Aquila; the fourth, that of Symmachus; the fifth, the Septuagint; and the ſixth, the verſion of Theodotan. In ſome fragments of that vaſt work which are ſtill extant, we have a ſpecimen of the manner in which the Hebrew was pronounced in the third century, by which it appears that it was very different from that which reſults from obſerving the Maſoretical points. The following is an inſtance copied from the beginning of Geneſis.

According to the MASORITES.

Bereſhith bara Elohim eth aſhamajim veeth aaretz.

Vajare elohim eth aor ki tob vajabedel elohim bein aor oubein hakhoſhek.

37 And the practice of the ancient Greeks.

Upon the whole, we preſume to give it as our opinion, that in the moſt early periods, the vowels *aleph*, *he*, *jod* or *yod*, *vaw* or *waw*, and perhaps *oin* or *ajin*, were regularly written wherever they were ſounded. This to us appears plain from the practice of the ancient Greeks. It is agreed on all hands that the Samaritan and Phœnician alphabets were the ſame; and that the former was that of the Jews originally. The Phœnicians certainly wrote the vowels exactly, for ſo did the Greeks who copied their alphabet: If the Phœnicians wrote their vowels, ſo then did the Jews of the age of Cadmus; but Cadmus was contemporary with ſome of the earlieſt judges of Iſrael; the conſequence is evident, namely, that the Jews wrote their vowels as late as the arrival of that Coloney-chief in Greece. We ought naturally to judge of the Hebrew by the Chaldaic, Syriac, and Arabian, its ſiſter dialects. All theſe languages in ancient times had their vowels regularly inſerted; and why not the Hebrew in the ſame manner with the reſt?

As theſe firſt vowels, which were coeval with the other letters, often varied in their ſound and application, the points, in all appearance, were firſt invented and employed to aſcertain their different ſounds in different connections. Other marks might be invented to point out the various tones of voice, like the τονοι, or accents, with which the vowels were to be pronounced, as was done among the later Greeks. In proceſs

Hebrew Language.

process of time, in order to promote celerity of writing, the vowels were omitted, and the points substituted in their place.

Before we conclude our observations on the Hebrew language, we ought, perhaps, to make an apology for omitting to interlard our details with quotations from the two Talmuds, the Mishna, the Gemara, the Cabbalas, and a multitude of rabbinical writers who are commonly cited upon such an occasion. We believe we could have quoted almost numberless passages from the two Buxtorfs, Father Morin, Capellus, and other Hebrew critics, with no great trouble to ourselves, and little emolument to the far greater part of our readers. But our opinion is, that such a pedantic display of philological erudition would probably have excited the mirth of our learned, and roused the indignation of our unlearned, readers. Our wish is to gratify readers of both descriptions, by contributing to the edification of one class without disgusting the other.

We cannot, we imagine, handsomely take leave of the sacred language without giving a brief detail of those excellencies which, in our opinion, give it a just claim to the superiority over those other tongues which have sometimes contended with it for the prize of antiquity: and of these the following in our apprehension deserve particular notice.

38 Excellencies of the Hebrew language.

If this language may claim any advantage over its antagonists, with respect to its being rather a mother than a daughter to any of them, it is undoubtedly in consequence of its simplicity, its purity, its energy, its fecundity of expressions and significations. In all these, notwithstanding its paucity of words, it excels the vast variety of other languages which are its cognate dialects. To these we may add the significancy of the names, both of men and brutes; the nature and properties of the latter of which are more clearly and more fully exhibited by their names in this than in any other tongue hitherto known. Besides, its well authenticated antiquity and the venerable tone of its writings surpass any thing left upon record in any other dialect now extant in the world. These extraordinary qualities excite our admiration at present under every disadvantage; and from this circumstance we may infer its incomparable beauty in the age of the Jewish legislator, and what effects it would naturally produce, could we know it now as it was spoken and written in the days of David and Solomon.

As far, however, as we understand it in its present mutilated condition, and are able to judge of its character from those few books that have come down to our time, we plainly perceive that its genius is simple, primitive, natural, and exactly conformable to the character of those uncultivated patriarchs who used it themselves, and transmitted it to their descendants in its native purity and simplicity. Its words are comparatively few, yet concise and expressive; derived from a very small number of radicals, without the artificial composition of modern languages. No tongue, ancient or modern, can rival it in the happy and rich fecundity of its verbs, resulting from the variety and significancy of its conjugations; which are so admirably arranged and diversified, that by changing a letter or two of the primitive, they express the various modes of acting, suffering, motion, rest, &c. in such a precise and significant manner, that frequently in one word they convey an idea which, in any other language, would require a tedious paraphrase. These positions might easily be illustrated by numerous examples; but to the Hebrew scholar these would be superfluous, and to the illiterate class neither interesting nor entertaining.

Hebrew Language.

To these we may add the monosyllabic tone of the language, which, by a few prefixes and affixes without affecting the radix, varies the signification almost at pleasure, while the method of affixing the person to the verb exhibits the gender of the object introduced. In the nouns of this language there is no flexion except what is necessary to point out the difference of gender and number. Its cases are distinguished by articles, which are only single letters at the beginning of the word: the pronouns are only single letters affixed; and the prepositions are of the same character prefixed to words. Its words follow one another in an easy and natural arrangement, without intricacy or transposition, without suspending the attention or involving the sense by intricate and artificial periods. All these striking and peculiar excellencies combined, plainly demonstrate the beauty, the stability, and antiquity of the language under consideration.

We would not, however, be thought to insinuate that this tongue continued altogether without changes and imperfections. We admit that many radical words of it were lost in a course of ages, and that foreign ones were substituted in their place. The long sojourning of the Israelites in Egypt, and their close connection with that people, even *quoad sacra*, must have introduced a multitude of Egyptian vocables and phrases into the vulgar dialect at least, which must have gradually incorporated with the written language, and in process of time have become parts of its essence. In Egypt, the Israelites imbibed those principles of idolatry which nothing less than the final extirpation of their polity could eradicate. If that people were so obstinately attached to the Egyptian idolatry, it is not very probable that they would be averse from the Egyptian language. Besides, the Scripture informs us, that there came up out of Egypt *a mixed multitude*; a circumstance which must have infected the Hebrew tongue with the dialect of Egypt. As none of the genuine Hebrew radicals exceed three letters, whatever words exceed that number in their radical state may be justly deemed of foreign extraction.

Some Hebrew critics have thought that verbs constitute the radicals of the whole language; but this opinion appears to us ill founded: for though many Hebrew nouns are undoubtedly derived from verbs, we find at the same time numbers of the latter deduced from the former.

39 Hutchinsonianism.

Before we conclude our detail of the Hebrew tongue, a few of our readers may possibly imagine that we ought to give some account of the Hutchinsonian system; a system so highly in vogue not many years ago. But as this allegorical scheme of interpretation is now in a manner exploded, we shall beg leave to remit our curious Hebraist to Mr Holloway's Originals a small book in 2 vols 8vo, but replete with multifarious erudition, especially in the Hutchinsonian style and character.—*Fides sit penes autorem.*

Sect. II.

Sect. II. *The Arabic Language.*

40
Arabic language originally Hebrew.

We now proceed to give some account of the Arabian language, which is evidently one of the sister dialects of the Hebrew. Both, we imagine, were originally the same; the former highly improved and enlarged; the latter, in appearance, retaining its original simplicity and rude aspect, spoken by a people of a genius by no means inventive. In this inquiry, too, as in the former, we shall spare ourselves the trouble of descending to the grammatical minutiæ of the tongue; a method which, we are persuaded, would neither gratify our learned nor edify our unlearned readers. To those who are inclined to acquire the first elements of that various, copious, and highly improved tongue, we beg to recommend *Erpenii Rudimenta Ling. Arab. Golii Gram. Arab.* the Dissertations of Hariri, translated by the elder Schultens; Mr Richardson's Persic and Arabic Gram. &c.

We have pronounced the Hebrew and Arabian sister dialects; a relation which, as far as we know, has been seldom controverted: but we think there is authentic historical evidence that they were positively one and the same, at a period when the one as well as the other appeared in its infant unadorned simplicity. The following detail will, we hope, fully authenticate the truth of our position.

* Gen. x. 25.

"Unto Eber (says the Scripture *) were born two sons. The name of one was Peleg, because in his days the earth was divided; and his brother's name was Joktan," or rather Yoktan. This last, says the sacred historian, "had thirteen sons; and their dwelling reached from Mesha (Mocha) to Sephar (A)," a mount of the east. According to this account, the descendants of Yoktan possessed all the maritime coast of Arabia from Mesha (Mocha) to mount Sephar towards the east of that peninsula. Moses, describing the rivers of paradise, tells us, that one of the branches of that river † "encompassed the whole land of Havilah, where there was great store of gold." Havilah was the twelfth son of Yoktan, whom the Arabians call Kobtan; and consequently his territory was situated towards the eastern limit of the possessions of the posterity of the youngest son of Eber. Yoktan or Kobtan was too young to be concerned in the building of the tower; and consequently retained the language of his family, which was undoubtedly the Hebrew. His descendants must have carried the same language into their respective settlements, where it must have been transmitted to succeeding generations. The original language of all the tribes of the Arabians who inhabit a vast tract of country along the southern shore, according to this deduction, was that of their father Kobtan, that is, the Hebrew. Indeed, the most learned Arabians of modern times unanimously acknowledge this patriarch as the founder of their language as well as of their nation.

† Gen. ii. 11.

The other districts of Arabia were peopled by the offspring of Abraham. The Ishmaelites, the posterity of that patriarch by Hagar, penetrated into the very centre of the peninsula; incorporated, and in process of time became one people with the Kobtanites. Another region was possessed by the children of the same holy man by Cheturah his second wife. The Moabites, Ammonites, Edomites, Amalekites, &c. who settled in the various regions of Arabia Petræa, were all branches of Abraham's family, and used the same language with their great progenitor. The Scripture indeed speaks of people who inhabited the country last mentioned prior to the branches of Abraham's family; but these, according to the same history, were extirpated by the former. The conclusion then is, if we credit the Mosaic account, that all the inhabitants of the three divisions of Arabia did, in the earliest periods, universally use the Hebrew tongue.

There was, we are sensible, a region of Arabia inhabited by the Cushim, or descendants of Cush. This district was situated on the confines of Babylonia. Our translators have confounded this country with the modern Ethiopia; and have consequently ascribed the exploits of the Arabian Cushim to the Ethiopians. The Arabian kings of Babylon were of those Cushim. These were conquered and expelled Babylonia by the Chasdim. These spoke the Chaldean dialect, as will appear when we come to speak of that of the Abyssinians. Here the candid reader is desired to reflect that the Hebrew and Chaldaic are cognate dialects.

The foregoing proofs, deduced from the Mosaic history, will be corroborated by a mass of internal evidence in the succeeding parts of our inquiry.

The Arabic tongue, originally pure Hebrew, was in process of time greatly transformed and altered from its simple unsophisticated state. The Arabians were divided into many different tribes; a circumstance which naturally produced many different dialects. These, however, were not of foreign growth. No foreign enemy ever conquered those independent hords. The Persians, Greeks, and Romans, sometimes attempted to invade their territories; but the roughness of the ground, the scarcity of forage, the penury of water, and their natural bravery, always protected them. They were indeed once invaded by the Abyssinians or Ethiopians with some show of success; but these invaders were in a short time expelled the country. Their language, of consequence, was never adulterated with foreign words or exotic phrases and idioms. Whatever augmentations or improvements it received were derived from the genius and industry of the natives, and not from adventitious or imported acquisitions. From this circumstance we may justly infer, that the Arabian tongue was a long time stationary, and of course differed in no considerable degree from its Hebrew archetype. The learned Schultens, in his Commentary on Job, hath shown, to the conviction of every candid inquirer, that it is impossible to understand that sublime composition without having recourse to the Arabic idioms. That patriarch was a Chuzite. His country might be reckoned a part of Arabia. His three friends were actually Arabians,

41
Gradually deviated from that simplicity.

(A) Sephar, in the Septuagint Σωφηρα, and in some editions Σαφηρα: hence probably Σωφιρ. *Orig. in Job.* cap. xxii. ver. 14. φασὶ δέ τινες τῶν Ἑρμηνέων Σωφὶρ τὴν Ἀραβίαν εἶναι.

Arabic Language.

Arabians, being the deſcendants of Iſhmael and Eſau. His country bordered upon that of the predatory Chaldeans, who were an Arabian banditti. When we conſider all theſe circumſtances *in cumulo*, we are ſtrongly inclined to believe that the book of Job was actually written in Arabic, as the language ſtood at that period; which, according to the moſt probable opinion, could not have been later than the age of Moſes. The learned are generally agreed that this whole book, the three firſt chapters excepted, is a poetical compoſition, replete with the moſt brilliant and moſt magnificent imagery, the boldeſt, the juſteſt, and moſt gorgeous tropes and alluſions, and a grandeur of ſentiment wholely divine. Whoever has read the poetical compoſitions of the modern Arabians, on divine ſubjects, with any degree of taſte, will, we flatter ourſelves, diſcover a ſtriking ſimilarity both of diction and ſentiment. Be this as it may, we think there is no reaſon to conclude that the Arabic dialect deviated much from the Hebrew ſtandard prior to the Chriſtian era.

42 The two principal dialects of Arabia.

Of thoſe different dialects which prevailed among the various tribes among which the peninſula of Arabia was divided, the principal were the Hemyaret and the Koreiſh. Though ſome of theſe were tributary to the Tobbas, or Hemyaret ſovereign of Arabia Felix, yet they took no great pains to cultivate the language of that province, and of courſe theſe people did not thoroughly underſtand it. As for the independent tribes, they had no temptation to cultivate any other language than their own.

The Koreiſh tribe was the nobleſt and the moſt learned of all the weſtern Arabs; and the kaaba, or ſquare temple of Mecca, was before the era of Mohammed ſolely under their protection. This temple drew annually a great concourſe of pilgrims from every Arabian tribe, and indeed from every other country where the Sabian religion prevailed. The language of the Koreiſh was ſtudied with emulation by the neighbouring tribes. Numbers of the pilgrims were people of the firſt rank, and poſſeſſed all the ſcience peculiar to their country or their age. Great fairs were held during their reſidence at Mecca, and a variety of gay amuſements filled up the intervals of their religious duties. In theſe entertainments literary compoſitions bore the higheſt and moſt diſtinguiſhed rank; every man of genius conſidering not his own reputation alone, but even that of his nation or his tribe, as intereſted in his ſucceſs. Poetry and rhetoric were chiefly eſteemed and admired; the firſt being looked upon as highly ornamental, and the other as a neceſſary accompliſhment in the education of every leading man. An aſſembly at a place called *Ocadh*, had been in conſequence eſtabliſhed about the end of the ſixth century, where all were admitted to a rivalſhip of genius.

43 The dialect of the Koreiſh became the politeſt, and why.

The merits of their reſpective productions were impartially determined by the aſſembly at large; and the moſt approved of their poems, written on ſilk, in characters of gold, were with much ſolemnity ſuſpended in the temple as the higheſt mark of honour which could be conferred on literary merit. Theſe poems were called the *Moallabat*, "ſuſpended," or *Modhabebat*, "golden." Seven of theſe are ſtill preſerved in many European libraries.

From this uncommon attention to promote emulation, and refine their language, the dialect of the Koreiſh became the pureſt, the richeſt, and the moſt polite of all the Arabian idioms. It was ſtudied with a kind of predilection; and about the beginning of the ſeventh century it was the general language of Arabia, the other dialects being either incorporated with it, or ſliding gradually into diſuſe. By this ſingular idiomatic union the Arabic has acquired a prodigious fecundity; whilſt the luxuriance of ſynonymes, and the equivocal or oppoſite ſenſes of the ſame or ſimilar words, hath furniſhed their writers with a wonderful power of indulging, in the fulleſt range, their favourite paſſion for antitheſis and quaint alluſion. One inſtance of this we have in the word *veli*; which ſignifies a *prince*, a *friend*, and alſo a *ſlave*. This ſame word, with the change of one letter only, becomes *vali*; which, without equivocation, imports a *ſovereign*. Examples of this kind occur in almoſt every page of every Arabic dictionary.

Arabic Language.

44 This ſuperiority modern.

But all thoſe advantages of this incomparable language are merely modern, and do not reach higher than the beginning of the ſixth century. Prior to that era, as we have obſerved above, a variety of dialects obtained; and as the Arabs were by their ſituation in a manner ſequeſtered from all the reſt of mankind, it may not perhaps be ſuperfluous to inquire briefly into the cauſe and origin of this inſtantaneous and univerſal change.

For a courſe of more than 20 centuries the Arabians had been ſhut up within the narrow limits of their own peninſula, and in a great meaſure ſecluded from the reſt of the world. Their commerce with India was purely mercantile, and little calculated to excite or promote intellectual improvements. They traded with the Egyptians from time immemorial; but ſince the invaſion and uſurpation of the paſtor kings, every ſhepherd, that is, every Arabian, was an abomination to the Egyptians. From that quarter, therefore, they could not derive much intellectual improvement. Beſides, when an extenſive territory is parcelled out among a number of petty ſepts or clans, the feuds and conteſts which originate from interfering intereſts and territorial diſputes, leave but little time, and leſs inclination, for the culture of the mind. In theſe circumſtances, the military art alone will be cultivated, and the profeſſion of arms alone will be deemed honourable. Of conſequence, we find that, in the general opinion, poetry, rhetoric, and the profeſſion of arms, were the only ſciences cultivated by the people in queſtion. As for the ſcience of arms, we are convinced that it was both ſtudied and practiſed at a very early period; but as to the two former, we imagine they were very late acquiſitions, and ſprung from ſome circumſtance external and adventitious.

The tribe of the Koreiſh were much engaged in commerce. They exported frankincenſe, myrrh, caſſia, galbanum, and other drugs and ſpices, to Damaſcus, Tripoli, Palmyra, and other commercial cities of Syria and its neighbourhood. Upon theſe occaſions the Arabian traders muſt have become acquainted with the Greek language, and perhaps with the more amuſing and affecting parts of the Grecian literature. They might hear of the high renown of Homer and Demoſthenes; and it is not impoſſible that ſome of them might be able to read their compoſitions. Every body

Arabic Language.

body knows with what unremitting ardour the learned Arabs, under the firſt khaliffs, peruſed and tranſlated the philoſophical works of the Grecian ſages. The very ſame ſpirit might animate their predeceſſors, though they wanted learning, and perhaps public encouragement, to arouſe their exertions. From this quarter, we think, the Arabs may have learned to admire, and then to imitate, the Grecian worthies.

The Ptolemies of Egypt were the profeſſed patrons of commerce as well as of learning. Under theſe princes all nations were invited to trade with that happy country. The Arabs, now no longer fettered by Egyptian jealouſy, carried their precious commodities to Alexandria: where the Grecian literature, though no longer in its meridian ſplendor, ſhone however with a clear unfaded luſtre. The court of the firſt Ptolemies was the retreat of all the moſt celebrated geniuſes of Greece and of the age; in a word, Alexandria was the native land of learning and ingenuity. Here the ingenious Arab muſt have heard the praiſes of learning inceſſantly proclaimed; muſt have been often preſent at the public exhibitions of the poets and orators; and even though he did not underſtand them exactly, might be charmed with the melody of the diction, and ſtruck with ſurpriſe at their effects on the audience. The reader will pleaſe to reflect, that the Arabian traders were the firſt men of the nation, both with reſpect to birth, learning, and fortune. Theſe wiſe men, to uſe the language of Scripture, inſpired with the natural curioſity of their race, might hear of the celebrated Olympic games, the public recitations before that aſſembly, and the glorious prize beſtowed upon the conquerors. Such information might animate them to inſtitute ſomething parallel at Mecca, with a view to improve their language, and at the ſame time to derive honour and emolument to themſelves. The Koreiſhim might promiſe themſelves the like advantages from the eſtabliſhment of the fair and aſſembly at Ocadh, as the natives of Elis drew from the inſtitution of the Olympic games. For theſe reaſons, we conjecture, the literary competitions at the place juſt mentioned were inſtituted at ſo late a period, though the nation had exiſted more than 2000 years before the eſtabliſhment of this anniverſary. Upon the whole, we are inclined to believe, that the Arabs, notwithſtanding all the fine things recorded of them by their own poetical hiſtorians, and believed perhaps too eaſily by thoſe of other countries, were in the days of ignorance like the earlieſt Romans, *latrones et ſemibarbari*. For our part, we think it by no means probable, that a people of that character ſhould, after ſo long a courſe of years, have ſtumbled upon ſo laudable and ſo beneficial an inſtitution, without taking the hint from ſome foreign one of a ſimilar complexion. This we acknowledge is only a conjecture, and as ſuch it is ſubmitted to the judgment of the reader.

45 Inſtitution at Mecca ſimilar to the Olympic games.

There were, as has been obſerved above, two principal dialects of the original Arabic: The Hamyarite ſpoken by the genuine Arabs, and the Koreiſhite or pure Arabic, which at laſt became the general language of that people. The former of theſe inclined towards the Syriac or Chaldean; the latter being, according to them, the language of Iſhmael, was deeply tinctured with the Hebrew idiom. The oriental writers tell us that Terah, the grandfather of Hamyar, was the firſt whoſe language deviated from the Syriac to the Arabic. Hence, ſay they, the Hamyaritic dialect muſt have approached nearer to the purity of the Syriac, and of conſequence muſt have been more remote from the true genius of the Arabic than that of any of the other tribes. The fact ſeems to ſtand thus: The Hamyarites were neighbours to the Chaldeans and Syrians, and conſequently were connected with thoſe people by commerce, wars, alliances, &c. This circumſtance introduced into their language many phraſes and idioms from both theſe nations. That Terah was concerned in adulterating the dialect of the Hamyarites, is a mere oriental legend, fabricated by the Arabs after they began to peruſe the Hebrew Scriptures. The Koreiſh being ſituated in the centre of Arabia, were leſs expoſed to intercourſe with foreigners, and therefore preſerved their language more pure and untainted.

Arabic Language.

46 The Koran written in the Koreiſh dialect.

The learned well know, that the Koran was written in the dialect of the Koreiſh; a circumſtance which communicated additional ſplendor to that branch of the Arabian tongue. It has been proved, that the language of the original inhabitants of Arabia was genuine Hebrew; but upon this ſuppoſition a queſtion will ariſe, namely, whether the Arabians actually preſerved their original tongue pure and unſophiſticated during a ſpace of 3000 years, which elapſed between the deluge and the birth of Mohammed? or, whether, during that period, according to the ordinary courſe of human affairs, it underwent many changes and deviations from the original ſtandard?

The admirers of that language ſtrenuouſly maintain the former poſition; others, who are more moderate in their attachment, are diſpoſed to admit the latter. Chardin obſerves of the oriental languages in general, that they do not vary and fluctuate with time like the European tongues*. "Ce qu'il y a de plus admirable, dit il, et de plus remarquable, dans ces langues, c'eſt, qu'elles ne changent point, et n'ont point changé du tout, ſoit à l'égard de termes, ſoit à l'égard du tour: rien n'y eſt, ni nouveau ni vieux, nulle bonne façon de parler, n'a ceſſé *d'etre* en credit. L'Alcoran, par exemple, eſt aujourdhui, comme il y a mille années, le modele de plus pure, plus courte, et plus eloquente diction." It is not to our purpoſe to tranſcribe the remaining part of the author's reflection upon this ſubject: From the above it plainly appears that he concludes, that the Arabian tongue has ſuffered no change ſince the publication of the Koran; and at the ſame time inſinuates, that it had continued invariable in its original purity through all ages, from the days of Kobtan to the appearance of that book. Whether both or either of theſe ſentiments is properly authenticated will appear in the ſequel.

* *Voyage*, vol. 3. p. 43.

47 Means adopted by the Arabs to preſerve the purity of their language.

The learned Dr Robertſon, profeſſor of oriental languages in the univerſity of Edinburgh, informs us, that the Arabians, in order to preſerve the purity of their language, ſtrictly prohibited their merchants, who were obliged to go abroad for the ſake of commerce, all commerce with ſtrange women. We know not where this injunction is recorded, but certainly it was a moſt terrible interdict to an amorous ſon of the deſart. If ſuch a prohibition actually exiſted, we ſuſpect it originated from ſome other ſource than the fear of corrupting their language. Be that as it may, the Doc-

Arabic Language.

tor, as well as the great Schultens, is clearly of opinion, that the language in queſtion, though divided into a great number of ſtreams and canals, ſtill flowed pure and limpid in its courſe.

Our readers who are acquainted with the hiſtory of the orientals are already apprized of the ſteady attachment of thoſe people to ancient cuſtoms and inſtitutions. We readily allow, that in the article of Language this ſame predilection is abundantly obvious; but every oriental ſcholar muſt confeſs, that the ſtyle of the Koran is at this day in a manner obſolete, and become almoſt a dead language. This fact, we believe, will not be queſtioned. If the Arabian has deviated ſo very conſiderably from the ſtandard of the Koran in little more than 1000 years, and that too after an archetype is aſcertained; by a parity of reaſon we may infer, that much greater deviations muſt have affected the language in the ſpace of 3000 years.

48 The ſtyle of the Koran now obſolete,

It is univerſally allowed by ſuch as maintain the unſullied purity of the Arabian tongue, that it was originally the ſame with the Hebrew, or with the ancient Syriac and Chaldaic. Let any one now compare the words, idioms, and phraſeology of the Koran with the remains of thoſe three languages, and we think we may venture to affirm that the difference will be palpable. This circumſtance, one would think, indicates in the ſtrongeſt terms a remarkable alteration.

The Arabs themſelves are agreed, that, notwithſtanding the amazing fecundity of their language, vaſt numbers of its radical terms have been irrecoverably loſt. But this loſs could not be ſupplied without either fabricating new words or borrowing them from foreign languages. To the latter method we have ſeen their averſion; and muſt therefore conclude that they adopted the former.

The Chaldeans, Syrians, and Phœnicians, had made innovations on their language at a very early period, even before conqueſts were undertaken: We ſee no reaſon to ſuppoſe that the Arabs did not innovate as well as their neareſt neighbours: the Hamyarites did actually innovate.

There are, we think, very ſtrong reaſons to believe, that Job was an Arabian, and flouriſhed prior to Moſes, perhaps as early as Jacob. The ſtyle, the genius, the figurative tone of the compoſition; the amazing ſublimity of the ſentiments, the alluſions, the pathos, the boldneſs, the variety, and irregularity; the poetical enthuſiaſm which pervade the whole poem, ſtrongly breath the Arabian ſpirit: indeed the very diction is peculiar to that ſingle book, and differs widely from that of the Pſalms and every poetical part of the ſacred canon. If we compare this book with Mohammed's Koran, we ſhall ſcarce find any reſemblance of words or phraſeology; but a wonderful ſimilarity of figures, enthuſiaſm, and elevation of ſentiments.

49 nd reembling ie Hebrew in its hraſeology.

We are then led to conclude, that the Arabic did actually loſe and gain a multitude of vocables between the era of its firſt eſtabliſhment among the deſcendants of Joktan and Iſmael and the birth of the impoſtor.

The art of writing was introduced among the Arabs at a very late period: Without the aſſiſtance of this art, one would think it altogether impoſſible to preſerve any language in its primæval purity and ſimplicity. Our curious readers may here expect ſome account of the Arabic characters: the following detail is the moſt probable one we have been able to collect on that ſubject. Arabic Language.

It is generally agreed*, that the art of writing was known among the Hamyarites or Homerites at a very early period. Theſe people were ſovereigns of Arabia during a courſe of many ages. Their character was ſomewhat perplexed and confuſed. It was called *alting Moſnad*, from the mutual connection of the letters. The alphabet of theſe people reſembled that of the Hebrews both in the number and order of the letters, and is called *abgad heviz* †, from the firſt ten letters of the Hebrew alphabet, artificially thrown together. "And this word (ſays the learned Chardin‡) *a, b, g, d*, is formed of the four letters which were heretofore the firſt in the Arabian language, as they are ſtill in that of the Hebrews." The ſame traveller is poſitive that theſe were the ancient characters of the Arabs; that they differed from Cuphite letters, which were afterwards introduced; and that they were furniſhed with vowel points. Theſe, we imagine, were the firſt rude ſketches of the Chaldean character, which probably the Hamyarites retained in their priſtine unpoliſhed form, after they had been poliſhed and reduced to a more elegant ſize by the original inventors.

* *Pococke's Specim. Hiſt. Arab.*

50 Art of writing among the Hamyarites

† *Id. Ibid.*

‡ Vol iii. p. 153.

Monuments bearing inſcriptions in theſe characters are, they tell us, ſtill to be ſeen in ſome places of Arabia. Some were engraved on rocks; and to theſe we think it probable that the patriarch Job alludes in thoſe paſſages where he ſeems to intimate an inclination to have his ſufferings recorded in a book and graven in the rock for ever. All the Arabians agree, that the dialect of the Hamyarites inclined towards the Syriac or Chaldean. This we have imputed to the connection of that people with the Chaldeans, who lived in their neighbourhood. If the Hamyaritic dialect was infected with the Syriac or Chaldaic, there can be no doubt that they derived their letters from the ſame quarter.

51 In Chaldaic characters.

We conclude then, that the Hamyarites knew the art of writing from the earlieſt antiquity, and that the letters they employed were the rude Chaldaic in their unimproved ſtate ‖. Some of the Arabians do indeed hold, that Iſhmael was the firſt author of letters; but that his characters were rude and indiſtinct, without any interval between letters or words, and that theſe were adopted by Kedar and his other children: but this tradition hath met with little credit.

‖ *Pococke Orat. de Ling. Arab.*

With reſpect to the highly poliſhed Koreiſhites, it is agreed on all hands, that they were unacquainted with the uſe of letters till a few years before the birth of Mohammed. Two difficulties here preſent themſelves. The firſt is, how the Koreiſhite dialect, without the art of writing, happened to excel all the other dialects of the Arabic tongue, aſſiſted by that art, apparently ſo neceſſary for preſerving a language in its original purity. The ſecond is ſtill, we think, rather greater, namely, how the Koreiſh learned that moſt uſeful art at ſo late a period as the ſixth century. It is a well known fact, that ever after the Babyloniſh captivity Arabia ſwarmed with Jewiſh villages, in which the art of writing was generally known; and almoſt at the beginning of the Chriſtian era, multitudes of Chriſtians retired to the ſame country, in order to avoid the perſecutions which they ſuffered in the Roman empire. In theſe circumſtances, we think it rather

52 Art of writing among the Koreiſhites.

Arabic Language.

ther ſtrange, that the Koreiſhites, highly poliſhed and acute as they were, never thought of laying hold on the opportunity of learning an art ſo very uſeful. Theſe two problems we leave to be ſolved by our more learned readers.

But however they be ſolved, it is univerſally acknowledged, that the Koreiſh were ignorant of letters till a few years before the birth of their prophet. Ebn Chalican(B), one of their moſt celebrated hiſtorians, informs us, that Moramer the ſon of Morra, an Anbarian, a native of Anbaris, a city of Irak (C), firſt invented alphabetical characters, and taught his countrymen to uſe them, from whom this noble invention was derived to the Koreiſhites. Theſe letters, though neither beautiful nor convenient, were long uſed by the Arabs. They were denominated *Cuphite*, from *Cupha* a city of Irak. In this character the original copy of the Koran was written. Theſe we think were the original clumſy characters which were retained by the vulgar after the beautiful ſquare Chaldaic letters were invented; and probably uſed by prieſts, philoſophers, and the learned in general. Theſe letters are often at this day uſed by the Arabs for the titles of books and public inſcriptions.

* *Robert Clav. Pent.* P. 35, 36.

53 Improved about 300 years after Mohammed.

Abauli the ſon of Mocla *, about 300 years after the death of Mohammed, found out a more elegant and more expeditious character. This invention of Abauli was afterwards carried to perfection by Ebn Bowla, who died in the year of the hegira 413, when Kader was caliph of Bagdad. This character, with little variation, obtains at this day. As we think this article of ſome importance, we ſhall, for the ſake of our unlearned readers, tranſcribe an excellent account of this whole matter from the very learned Schultens.

"The Cuphic characters, ſays he, which had been brought from the region of the Chaldeans to the province of Hejaz, and to Mecca its capital, in the age of Mohammed, was employed by the Koreiſhites, and in it the koran was firſt written. But as this character was rude and clumſy, in conſequence of its ſize, and ill calculated for expedition, Abauli Ebn Mocla deviſed a more elegant and expeditious one. This perſon was viſir to Arradius the 41ſt caliph, who began to reign in the year of the hegira 322. Accordingly, in the 10th century, under this emperor of the Saracens, the form of the Arabian alphabet underwent a change; and the former clumſy embarraſſed character was made to give way to the poliſhed, eaſy, and expeditious type. Regarding this expedition alone, the author of the invention left very few vowel characters; and as the Hebrew manner of writing admits five long ones and five ſhort in different ſhapes, he taught how to expreſs all the vowels, both long and ſhort, ſuitably to the genius of the language, by three, or rather by two, ſmall points, without any danger of a miſtake: an abbreviation truly deſerving applauſe and admiration; for by placing a very ſmall line above ـَ he expreſſed *a* and *e*; and by placing the ſame below ـِ he meant to intimate *i* only. To the other ſhort ones, *o* and *u*, he aſſigned a ſmall *waw* above. In order to repreſent the long ones, he called in the *matres lectionis*, the "quieſcent letters א, ו, י;" ſo that *phata* with *elif* intimated *a* and *o* long, *i. e. kametz* and *cholem*; *jod* placed after *kefram* became *tzeri* and *chirek* long. *Waw* annexed to *damma* made *ſchurek*."

Arabic Language.

In this paſſage, this great orientaliſt acknowledges that the viſir above-mentioned, who carried the Arabian alphabet to the pinnacle of perfection, invented and annexed the vowel points for the ſake of eaſe and expedition in writing; from which we may infer, that prior to the tenth century the Arabians had no vowel points; and conſequently either read without vowels, or contented themſelves with the *matres lectionis* above-mentioned.

The deſign of the author of the invention in fabricating theſe points, was confeſſedly eaſe and expedition in writing; a circumſtance which furniſhes a violent preſumption that the Hebrew vowel-points were deviſed and annexed at ſome late period for the very ſame purpoſes.

Some, indeed, have gone ſo far as to affirm that the Arabians were the original fabricators of the vowel-points. "The Arabians§ (ſays the learned Dr Gregory Sharp) were the original authors of the vowel points. They invented three, called *fatha*, and *damma*, and *kefra*: but theſe were not in uſe till ſeveral years after Mohammed; for it is certain that the firſt copies of the koran were without them. The rabbis ſtole them from the Arabs." This, however, is carrying the matter too far, ſince it is certain that the Jews were acquainted with the points in queſtion long before the period above-mentioned.

§ *Diſſ. on the Origin and Conſt. of Lang. &c.*

Though it is none of our intention to enter into a minute detail of the pecularities of this noble language, we cannot omit obſerving one thing, which indeed belongs to grammar, but is not generally taken notice of by the Arabic grammarians. The roots of verbs in this dialect are univerſally trilateral; ſo that the compoſition of the 28 Arabian letters would give near 22,000 elements of the language. This circumſtance demonſtrates the ſupriſing extent of it: for although great numbers of its roots are irrecoverably loſt, and ſome perhaps were never in uſe; yet if we ſuppoſe 10,000 of them, without reckoning quadriliterals to exiſt, and each of them to admit only five variations, one with another, in forming derivative nouns, the whole language would then conſiſt of 50,000 words, each of which may receive a multitude of changes by the rules of grammar.

54 Surpriſing extent of the Arabic language.

Again, the Arabic ſeems to abhor the compoſition of words, and invariably expreſſes very complex ideas by circumlocution; ſo that if a compound word be found in any dialect of that language, we may at once pronounce it of foreign extraction. This is indeed a diſtinguiſhing feature in the ſtructure of this tongue, as well as of ſome of its ſiſter dialects. This circumſtance has, in our opinion, contributed not a little to the amazing fecundity of that language: for as every ingredient in the compoſition of a complex idea requires a

(B) See this whole detail in Dr Pocock's *Specim. Hiſt. Arab.* p. 250. *et ſeq.*

(C) *Irak*, "Babylonia," from *Erech*, one of the cities built by Nimrod. The Arabians have generally reſtored the ancient names of places. Thus with them Tyre is *Tzur*, Sidon *Seyd*, Egypt *Mezri*, &c.

Arabic Language.

a word to express it, as many words became necessary to complete the language as there were simple ideas to be intimated by discourse. Were all the compounds of the Greek language to be dissolved, as probably once they were, the vocables of that tongue would infinitely exceed their present number.

The Arabic authors boast most unconscionably of the richness and variety of their language. No human understanding, say they, is capacious enough to comprehend all its treasures. Inspiration alone can qualify one for exhausting its sources *. Ebn Chalawalb, a most renowned grammarian of theirs, has spent a whole volume upon the various names of the lion, which amount to 500; another on the names of the serpent, which make up 200. Mohammed al Firancabudius affirms that he wrote a book on the usefulness and different denominations of honey, in which he enumerates 80 of them; and after all, he assures us that he was still far from having exhausted his subject. To excel in a language so amazingly copious, was certainly a proof of uncommon capacity, and considered as no mean talent even among the Koreishites. Hence Mohammed, when some people were expressing their admiration of the eloquence of the koran, told them that he had been taught by the angel Gabriel the language of Ishmael, which had fallen into desuetude.

* *Pococke's Specimen.*

55 Oratory and poetry of the Arabs.

In a language so richly replenished with the choicest and most energetic terms, both oratory and poetry were cultivated with ease. All the difficulty consisted in making a choice among words and phrases equally elegant. We may compare one of those poets or orators to a young gentleman, of a taste highly refined, walking into a repository where a profusion of the richest and most elegant dresses are piled up in wild confusion. Our beau is here distressed with variety; but to be able to choose the most handsome and most becoming, he must have received from nature a superior good taste; which he must likewise have cultivated by assiduous industry, and by associating with the most genteel company.

The orations of the Arabs were of two kinds, metrical and prosaic. The former they compared to pearls set in gold, and the latter to loose ones. They were ambitious of excelling in both; and whoever did so, was highly distinguished. His success in either of those departments was thought to confer honour, not only on his family, but even on his tribe. In their poems were preserved the genealogies of their families, the privileges of their tribes, the memory of their heroes, the exploits of their ancestors, the propriety of their language, the magnificence of banquets, the generosity of their wealthy chiefs and great men, &c. After all, we cannot avoid being of the unpopular opinion, that this mighty parade of eloquence and poetry did not reach backward above two centuries before the birth of Mohammed, as it certainly vanished at the era of the propagation of his religious institutions. The two succeeding centuries were the reigns of superstition and bloodshed. The voice of the muses is seldom heard amidst the din of arms.

The ancient Arabs, at whatever time poetry began to be in request among them, did not at first write poems of considerable length. They only expressed themselves in metre occasionally, in acute rather than harmonious strains. The Proverbs of Solomon, and the book of Ecclesiastes seem to be composed in this species of versification. The prosody of the Arabs was never digested into rules till some time after the death of Mohammed; and this is said to have been done by Al Khalti al Farabidi, who lived in the reign of the caliph Karan of Rashid.

Arabic Language.

After so many encomiums on the copiousness of the Arabic tongue, one class of our readers may possibly expect that we should subjoin a brief detail of its genius and character; and this we shall do with all possible brevity.

56 Genius and character of the language.

All the primary or radical words of the language are composed of different combinations of consonants by *triads*; so that the various combinations and conjunctions of radicals make more than 10,000, even without including those which may arise from the meeting of guttural letters. From this quality of the language has flowed that stability of the dialect which has preserved it pure and entire for so many thousand years, and secured it from those changes and that fluctuation to which most other tongues are subject.

Perhaps, notwithstanding its copiousness and variety, no other language can vie with the one in question in point of perspicuity and precision. It is possessed of a brevity and rotundity which, amidst the greatest variety, enables it to express with clearness and energy what could not be expressed in any other tongue without tedious circumlocutions. To this purpose we shall beg leave to transcribe a passage from Bishop Pocock's oration on the Arabic language. As we imagine few of our readers who will have the curiosity to peruse this article can be unacquainted with the Latin tongue, we shall give it as it stands in the original, without a translation:

"Neque in nulla certe laudis parte, mira illa qua, non solum verborum in significando, perspicuitate, sed in prolatione, elegantiæ et dulcedini caverunt, sedulitas; quoque, non solum accurata, inter literas ex significata proportione, sensûs vel intensioni, vel remissioni, prout res postulaverit, literarum appositione, subductione, vel juxta organorum, rationem prospexerunt; sed et ne quid delicatulis auribus ingratum, ne quid horridum, aut ασυμφωνον, reperiatur, effecerunt. Hoc in genere est, quod nusquam in verbo aliquo, genuinæ apud Arabes originis, concurrunt, non intercedente vocalis alicujus motione consonantes, cum vel tres, vel plures, aliis in linguis frequenter collidantur. Immo neque, si adsint, quæ asperitati remedio sint, vocales, quas libet temerè tamen committunt consonantes; sed ita rei natura postulat, ut concurrere debeant illæ, quæ se invicem, sine asperitatis inductione consequi, et inter se connecti non possint; illi vel situs, vel literarum mutatione, eas abjiciendo, inferendo, emolliendo, aliisve quibus possent modis, remedia quærunt; adeo ab omni, quod vel absonum, vel dissonum est, abhorrent. Quod si nobis secus videntur, et asperius sonare ab Arabibus prolata, illud auribus nostris, et usui, non linguæ imputandum, nec mollius illis sonare nostra, quam eorum nobis censendum. Quin et gutturalium, quæ nobis maxima asperitatis causa videntur, absentiam, et magnum in lingua Græca defectum, arguunt Arabes."

The learned Dr Hunt, late professor of the Hebrew and Arabic languages at Oxford, is of the same opinion with the very learned prelate, part of whose ora-

Arabic Language.

tion we have tranſcribed above, with reſpect to the delicacy and elegance of the Arabian language:— "Nuſquam, mihi credite, (inquit ille) auribus magis parcitur quam in Arabia; nulla lingua a κακοφωνία, alienior quam Arabica. Quamquam enim nonnullæ ejus literæ minus fortaſſe ſuaviter, immo durius etiam ſonuerint, ita tamen Arabes eas temperarunt cum lenibus, duras cum mollibus, graves cum acutis miſcendo, voces inde non minus auribus jucundæ, quam pronunciatu faciles conſeverint, totique ſermoni mirani ſonorum tam dulcedinem quam varietatem addiderint. Quod quidem orationis modulandæ ſtudium in Corano adeo manifeſtum eſt, ut primi Iſlamiſmi oppugnatores eum librum magica ideo arte ſcriptum dixerint. Non auribus tantum gratus eſt Arabiſmus, ſed et animi conceptibus exprimendis aptus, ſonos ſuos ſententiis ſemper accommodans, et felici verborum junctura eorum naturam depingens."

To theſe we might add quotations from Erpenius's oration on the ſame ſubject, from Golius, Schultens, Hottinger, Bochart, and Sir William Jones; beſides a whole cloud of oriental witneſſes, whoſe extravagant encomiums would rather aſtoniſh than edify the far greater part of our readers. Theſe panegyrics may perhaps be in ſome meaſure hyperbolical; but in general we believe them pretty well founded. At the ſame time we are convinced that the Arabic, however melodious in the ears of a native, ſounds harſh and unharmonious in that of a European.

57 Difficulty of acquiring a thorough knowledge of it.

When we conſider the richneſs and variety of the Arabic tongue, we are led to conclude, that to acquire a tolerable degree of ſkill in its idioms, is a more difficult taſk than is generally imagined; at leaſt ſome people who have acquired the knowledge of the Greek and Latin, and likewiſe of the more faſhionable modern languages, with facility enough, have found it ſo. Be that as it may, there are two claſſes of men who, in our opinion, cannot handſomely diſpenſe with the knowledge of that almoſt univerſal tongue: the gentleman, who is to be employed in the political tranſactions of the moſt reſpectable mercantile company upon earth, in the eaſtern parts of the world; and the divine, who applies himſelf to inveſtigate the true purport of the ſacred oracles: without this, the former will often find himſelf embarraſſed in both his civil and mercantile negociations; and the latter will often grope in the dark, when a moderate acquaintance with that tongue would make all ſunſhine around him.

Bochart, Hottinger, Schultens, Pocock, Hunt, and Robertſon, &c. have taken wonderful pains, and laviſhed a profuſion of learning, in proving the affinity and dialectical cognation between the Hebrew and Arabic. Much of this labour, we think, might have been ſpared. We preſume to affirm, that no perſon tolerably verſed in both languages can read a ſingle paragraph of the Arabic verſion of the New Teſtament, or indeed of the Koran itſelf, without being convinced of the truth of this poſition: it is but ſtripping the latter of its adventitious frippery, and the kindred features will immediately appear.

The learned profeſſors of the univerſity of Leyden were the firſt who entered upon the career of Arabian learning. To them the European ſtudents are principally indebted for what knowledge of that language they have hitherto been able to attain. Though ſeveral Italians have contributed their endeavours, yet the fruit of their labours has been rendered almoſt uſeleſs by more commodious and more accurate works printed in Holland.

Chaldean Language, &c.

The palm of glory, in this branch of literature, is due to Golius, whoſe works are equally profound and elegant; ſo perſpicuous in method, that they may always be conſulted without fatigue, and read without languor. Erpenius's excellent grammar, and his memorable dictionary, will enable the ſtudent to explain the hiſtory of *Taimur* by *Ibni Arabſhah*. If he has once maſtered that ſublime work, he will underſtand the learned *Arabic* better than moſt of the Khatabs of Conſtantinople or of Mecca.

The Arabian language, however, notwithſtanding all its boaſted perfections, has undoubtedly ſhared the fate of other living languages; it has gradually undergone ſuch conſiderable alterations, that the Arabic ſpoke and written in the age of Mohammed may be now regarded as a dead language: it is indeed ſo widely different from the modern language of Arabia, that it is taught and ſtudied in the college of Mecca juſt as the Latin is at Rome.

The dialect of the Highlands of Yemen is ſaid to have the neareſt analogy to the language of the Koran, becauſe theſe Highlanders have little intercourſe with ſtrangers. The old Arabic is through all the Eaſt, like the Latin in Europe, a learned tongue, taught in colleges, and only to be acquired by the peruſal of the beſt authors.

"*Ut folia in ſylvis pronos mutantur in annos*, &c."

Sect. III. *Of the Chaldean, Phœnician, Ethiopian or Abyſſinian, and Egyptian Languages.*

58 Connection of the Chaldean, Phœnician, Ethiopic, and Egyptian languages

As there is a very ſtrict connection and dialectical analogy among theſe languages, we have arranged them all under one ſection; eſpecially ſince what is obſerved relating to one of them may, without the leaſt ſtraining, be extended to them all. We ſhall begin with the Chaldaic.

The Chaldeans, or Chaſidim, as they are always called in Scripture, were the deſcendants of Cheſed the ſon of Nahor, the brother of Abraham. The deſcendants of this patriarch drove the Cuſhim or Arabians out of Babylonia, and poſſeſſed themſelves of that country at a very early period. As theſe Chaſidim or Chaldeans were the poſterity of Nahor, the deſcendant of Heber, they undoubtedly ſpoke the original Hebrew tongue as well as the other branches of that family. But being an ingenious inventive people, they ſeem to have poliſhed their language with much care and delicacy of taſte.

The only genuine remains of the ancient Chaldaic language are to be found in the Hebrew Scriptures; and thoſe are contained in 268 verſes, of which we have 200 in Daniel, reaching from verſe 4th chapter 2d to chapter 8th excluſive; in Ezra 67, in chapter 4th, 17 verſes; chapter 5th, the ſame number; chapter 6th, 18 verſes; and in chapter 7th, 15: in Jeremiah, chapter 10th, there is extant only one verſe. From theſe fragments, compared with the Hebrew

Chaldean Language, &c.

brew, it plainly appears, that the difference between that language and the Chaldaic is ſcarce equal to that between the Doric and Ionic dialects of the Greek.

Whatever might have been the form of the moſt ancient Chaldaic letters, it is generally known that the beautiful ſquare characters, in which the Hebrew Scriptures began to be written after the age of Ezra, were current among them at an era prior to the Babyloniſh captivity. Thoſe elegant characters were probably the invention of the Chaldean academies, which were eſtabliſhed in various parts of that extenſive and fertile country.

59 Chaldean differs little from the Hebrew.

The Chaldean declenſions and conjugations differ ſo little from the Hebrew modifications, that it would be almoſt ſuperfluous to dwell upon them in this ſection. The moſt effectual way to acquire an idea of the ancient Chaldaic, is to decompound the names confeſſedly of that dialect, which occur in many places of Scripture. By this method of proceeding, its beautiful ſtructure and expreſſive energy will be readily comprehended even by the moſt illiterate claſſes of our readers. At the ſame time, we muſt obſerve, that the Chaldaic and ancient Syriac bore ſo near a reſemblance to each other, that they have generally been claſſed under one head.

The firſt Chaldaic word that occurs in the Old Teſtament is *bara* "*creavit*". This word has all along been aſſigned to the language under conſideration; for what reaſon, we confeſs we are not able to diſcover. The greateſt part of the Hebrew tongue is now loſt. The words *bar*, "a ſon," and *bara* "*creavit*," (rather *filiavit*), may probably be of that number. Another Scripture word which is often quoted, and always aſcribed either to the Syriac or Chaldaic, is *igar* or *jegar ſahadutha*, which ſignifies "a monument of witneſſes." Every body knows, that when Jacob and Laban made their compact, the latter denominated the heap of ſtones reared upon that occaſion in this manner; while the former called it *Galeed*, as we now write and pronounce it. This pronunciation, however, does not appear to us altogether genuine. The word is probably compounded of גל *gal*, *cumulus*, "a heap," and ע *chad*, *æternitas*, *ſeculum*, "eternity, an age:" ſo that גלעד *galchad*, or *galuad* as it came to be written afterwards, ſignified an "everlaſting heap." Laban then had reſpect to the end for which the monument was erected; but Jacob alluded to its duration. It appears, however, upon this and every other occaſion, when Chaldaic words are mentioned, that א, *a*, was a favourite letter both with the Syrians and Chaldeans. We may likewiſe obſerve, that the ſame people always changed the Hebrew ש *ſhin* into ת *thau*, in order to avoid the ſerpentine ſound of that conſonant.

60 Its proper names pure Hebrew.

The Chaldaic names of gods, men, places, &c. which occur in Scripture, appear to be no other than Hebrew poliſhed and improved. *Bel*, *Belus* in Latin, is evidently בעל *Baal*, or we think rather ב-על *Bechel*. The Phœnicians, and ſometimes the Hebrews, uſed it to ſignify *the moſt high*. The Chaldeans uſed their word *Bel* for the ſame purpoſe; and becauſe this word originally imported the *High One*, they dignified their firſt monarch with that name. They denominated their capital city *Ba-Bel*, which imports the *temple of Bel*, and afterwards *Babylon*, which intimates *the abode or dwelling of our lord the ſun*. *Nebo* was a name of the moon among the Babylonians, derived from the Hebrew נבא, *nabah*, *vaticinari*, "to prophecy." *Azer* was the planet Mars, from אזר, *Azer* or *Ezur*, *accinxit*, "to gird," alluding to the girding on of arms. *Ahad* was an Aſſyrian name of the ſun*, a word deduced from the Hebrew אחד *ahad*, *unus*, "one." *Netzar* was the name of an Arabian idol§, which often occurs in the compoſition of Babylonian names. In Arabic it ſignifies an *eagle*: we think, however, that the word is the Hebrew נצר *natzar*, *cuſtodivit*, *ſervavit*, "to keep, to preſerve." To theſe names of deities many more might be added, which the nature of our deſign will not allow us to mention.

Chaldean Language, &c.

* *Merod.* lib. 1. c. 23.
§ *Pocock Specim. Hiſt. Arab.*

Almoſt all the Chaldean proper names which occur either in ſacred or prophane hiſtory are evidently of Hebrew original, or cognate with that language. We ſhall ſubjoin a few examples: *Nabonaſſar* is evidently compounded of *Nabo* and *nazur*, both Hebrew words. *Nabopoliazar* is made up of *Nabo-Pul*, the ſame with *Bel*, and *Azer* or *Azor*, above explained. *Beleſis* is made up of *Bel* and אש *Eſha*, "fire." Nebuchadnezzar, Belſhazzar, Beltiſhazzar, Nerigliſſar, Nebuzaradan, Rabmag, Rabſaris, Nergal Sharezer, Rabſhakeh, Ezarhaddon, Merodach, Evil Merodach, and numberleſs others, are ſo manifeſtly reducible to Hebrew vocables, when decompounded, that the oriental ſcholar will readily diſtinguiſh them.

Names of places in the Chaldaic are likewiſe ſo nearly Hebrew, that nothing but the dialectical tone ſeparates them. Thus *Ur* of the Chaldeans is actually אור *light*, that city being ſacred to the ſun; *Sippora* is plainly the Hebrew word *Zipporah*; *Carchemiſh*, a city on the Euphrates, is evidently compounded of *Kir* or *Kar* "a city," and *Chemoſh*, a name of the ſun. In ſhort, every Chaldean or old Syrian word now extant, without any difficulty, bewray their Hebrew original. As for their dialectical differences, theſe we remit to the Chaldaic and Syriac grammars and lexicons.

61 Phœnician language derived from the Hebrew.

We now proceed to the conſideration of the Phœnician language, which is known to have been that of the ancient Canaanites. That this was one of the original dialects, and conſequently a cognate of the Hebrew, is univerſally acknowledged. Inſtead therefore of endeavouring to prove this poſition, we may refer our readers to the works of the learned Mr Bochart, where that author has in a manner demonſtrated this point, by deriving almoſt all the names of the Phœnician colonies from the Hebrew, upon the ſuppoſition that the dialect of thoſe people was cloſely connected with that tongue. St Auguſtine, *de Civitate Dei*, has obſerved, that even in his time many of the vulgar in the neighbourhood of Carthage and Hippo ſpoke a dialect of the old Punic which nearly reſembled the Hebrew. Procopius, *de bello Goth.* informs us, that there exiſted even in his days in Africa a pillar with this inſcription in Hebrew, "We flee from the face of Joſhua the robber, the ſon of Nun." The names of all the ancient cities built by the Carthaginians on the coaſt of Africa are eaſily reducible to a Hebrew original. The Carthaginian names of perſons mentioned in the Greek and Latin hiſtory, ſuch as Himilco, Hamilcar, Aſdrubal, Hannibal, Hanno, Dido, Anna or Hannah, Sophoniſba, Giſgo, Maharbal, Adherbal, &c. all breathe a Hebrew extraction.

The

Chaldean Language, &c.

The Greeks borrowed a great part of their religious worſhip from the people of whoſe language we are treating; of conſequence, the names of moſt of their gods are Phœnician. Almoſt every one of theſe is actually Hebrew, as might eaſily be ſhown. The names of perſons and places mentioned in the fragments of Sanchoniathon, preſerved by Euſebius, are all of Hebrew complexion. The names mentioned in the Hebrew ſcriptures of places which belonged to the Canaanites prior to the invaſion of the Iſraelites under Joſhua, are as much Hebrew as thoſe which were afterwards ſubſtituted in their ſtead. The Punic ſcene in Plautus has been analyſed by Bochart and ſeveral other learned men, by whom the language has been clearly proved to be deduced from the Hebrew, with ſome dialectical variations.

The iſland of Malta (Melita now) was inhabited by a colony of Phœnicians many ages before the Moors took poſſeſſion of it. Among the vulgar of that iſland many Punic vocables are current to this day, all which may be readily traced up to the Hebrew fountain. To theſe we may add many inſcriptions on ſtones, coins, medals, &c. which are certainly Phœnician, and as certainly of Hebrew extraction. We have thrown together theſe few hints without purſuing them to any great length, as we deemed it unneceſſary to dwell long on a point ſo hackneyed and ſo generally acknowledged.

62 Origin of the Ethiopians.

Before we proceed to treat of the ancient language of the Ethiopians, we find ourſelves obliged to hazard a few ſtrictures on the origin of that ancient nation. If we can once ſettle that ſingle point, the diſcovery will open an avenue to their primitive dialect, the article about which we are chiefly concerned in the preſent diſcuſſion.

In our Section concerning the Hebrew language, we were led often to mention the patriarch Cuſh the eldeſt ſon of Ham. The poſterity of this family-chief, under his ſon Nimrod, poſſeſſed themſelves of Shinar, afterwards denominated *Chaldea*. Theſe were probably the Arabians whoſe kings (according to Euſebius, Africanus, and other ancient chronologers) reigned in Babylon during ſeveral ſucceſſive generations. Thoſe were the Cuſhim or Cuſhites, whom the learned Mr Bryant has conducted over a great part of the world, and to whoſe induſtry and ingenuity he has aſcribed almoſt all the inventions, arts, ſciences, laws, policy, religions, &c. which diſtinguiſhed mankind in the earlieſt ages.

In proceſs of time, the poſterity of Chaſid or Cheſed, called *Chaſdim* or *Chaſidim* in the eaſt, and *Chaldeans* in the weſt, drove out the Cuſhim, and ſeized upon their country. The Cuſhim retired weſtward, and ſpread themſelves over that part of Arabia ſituated towards the ſouth-eaſt. They probably extended themſelves over all the eaſtern part of that peninſula from the ſea to the wilderneſs between Arabia and Syria. Thoſe were the Ethiopians mentioned in Scripture by a very unpardonable inadvertency of our tranſlators. Theſe, then, we think, were the primitive Cuſhim.

Chaldean Language, &c.

Joſephus informs us*, that all the Aſiatics called the Ethiopians of Africa by the name of *Cuſhim*. This denomination was not given them without good reaſon: it imports at leaſt, that they deemed them the deſcendants of Cuſh; it being the conſtant practice of the orientals in the early ages to denominate nations and tribes from the name of their great patriarch or founder. The name *Cuſhim* muſt then have been given to the Ethiopians, from a perſuaſion that they were the progeny of the ſon of Ham who bore that name. By what route ſoever the Cuſhim penetrated into that region of Africa which was called by their name, it may be taken for granted that they were the deſcendants of Cuſh above mentioned.

* *Antiq. Jud.* lib. 1. c. 7.

It has been obſerved above, that the poſterity of Cuſh poſſeſſed the country of Shinar or Chaldea at a very early period, but were expelled by the Chaſidim or Chaldeans. Upon this cataſtrophe, or perhaps ſomewhat later, a colony from the fugitive Cuſhim tranſported themſelves from the ſouth and ſouth-eaſt coaſt of Arabia over the ſea, which lies between that country and Ethiopia. However imperfect the art of navigation might be in that age, the diſtance was ſo ſmall that they might eaſily enough make a voyage croſs that narrow ſea in open boats, or perhaps in canoes. However that may have been, it cannot be doubted that the tribes on both ſides of that branch of the ſea were kindred nations.

If, then, both the northern and ſouthern Cuſhim ſprung from the ſame ſtock, there can be no doubt that both ſpoke the ſame language. The language of the Babylonian Cuſhim was Chaldaic, and of conſequence that of the Ethiopian Cuſhim was the ſame. We may therefore reſt aſſured, that whatever changes the Ethiopian dialect may have undergone in the courſe of 3000 years, it was originally either Chaldaic, or at leaſt a branch of that language. Scaliger informs us, that the Ethiopians call themſelves Chaldeans; and that, ſays he, not without reaſon, becauſe of thoſe many ſacred and profane books which are extant among them, the moſt elegant and moſt beautiful are written in a ſtyle near that of the Chaldean or Aſſyrian. Marianus Victorius, who was the firſt that reduced the Ethiopic tongue to the rules of grammar, tells us in his *Proœmium*, "that the Ethiopians call their tongue Chaldaic; that it ſprings from the Babylonian; and is very like the Hebrew, Syriac, and Arabic: At the ſame time (he concludes), that this language may be eaſily learned by thoſe who are maſters of the Hebrew." The learned Bochart, and Biſhop Walton in his *Proleg.* are clearly of the ſame opinion.

63 Their language originally Chaldean.

The vulgar letters of the Ethiopians, according to Diodorus Siculus, were the ſame with the ſacred characters of the Egyptians (D). From this account, if the Sicilian may be truſted, the ſacred letters of theſe people, concerning which ſo many wiſe conjec-

§ *Lib.* 3. *p.* 101. *Steph.*

2 tures

(D) We find the ſame obſervation confirmed by Heliodorus (*Ethiop.* lib. x. p. 476.) "The royal letters of the Ethiopians (ſays he) were the ſacred characters of the Egyptians." Caſſiodorus likewiſe aſſures us, "That the letters inſcribed upon the Egyptian obeliſks were Chaldeans." See Sect. *Shanſcrit.*

Chaldean Language, &c.

tures have been formed, were actually Chaldaic. To carry on this inveſtigation a little farther, we may obſerve, that Sir William Jones ſeems to have proved, by very plauſible arguments, that the Shanſcrit characters were deduced from the Chaldaic. This circumſtance affords a preſumption that the Ethiopian Cuſhim were likewiſe concerned with the Egyptians; who, as is remarked in the Section concerning the *Shanſcrit*, probably introduced the religion of the Brahmans into Hindoſtan. This is advanced as a conjecture only; and yet when we conſider the affinity between the Egyptian and Gentoo religions, we are ſtrongly inclined to hope that this ſurmiſe may one day be verified by undeniable facts.

The original Ethiopians were a people highly civilized; their laws, their inſtitutions, and eſpecially their religion, were celebrated far and wide. Homer talks in raptures of the piety of the Ethiopians, and ſends his gods every now and then to revel 12 days with that devout people. The Sicilian adduces a number of very ſpecious arguments to prove that theſe two nations had ſprung from the ſame ſtock. He mentions a ſimilarity of features, of manners, of cuſtoms, of laws, of letters, of the fabrication of ſtatues, of religion, as evidences of the relation between thoſe two neighbouring nations. There was, every body knows, a communion, as to ſacred rites, between the two countries. The Egyptians ſent annually a deputation of their prieſts, furniſhed with the portable ſtatues of their gods, to viſit the fanes of the devout Ethiopians. Upon this occaſion, a ſolemn religious banquet was prepared, which laſted 12 days, and of which the prieſts of both nations were partakers. It was, we imagine, a kind of ſacramental inſtitution, by which both parties publicly avouched their agreement in the ceremonies of their religion reſpectively. Theſe obſervations plainly ſhow, that the moſt ancient Ethiopians were a people highly civilized; indeed ſo much, that the Egyptians were at one time contented to be their ſcholars. The tone of their language was certainly the ſame with that of the Chaldeans or Arabian Cuſhim, from whom they were deſcended. We know not whether there are any books in the ancient Ethiopic now extant; ſo that it is not eaſy to produce inſtances of its coincidence with the Chaldaic. Diogenes Laertius* informs us that Thraſyllus, in his catalogue of the books compoſed by Democritus, mentions one, περι των εν Μεροη ιερων γραμματων, *concerning the ſacred letters in the iſland of Meroe* (E); and another concerning the ſacred letters in Babylon. Had theſe books ſurvived the ravages of time, they would in this age of reſearch and curioſity have determined not only the point under our conſideration, but the affinity of ſacred rites among the Chaldeans, Ethiopians, and Egyptians.

64 Antient intercourſe between the Ethiopians and Egyptians.

* *Lib. 9. p. 461. Caſaub.*

We have now ſhown that the Ethiopians were a colony of Cuſhites; that the Cuſhites were originally ſovereigns of Shinar or Chaldea, and conſequently ſpoke either Chaldaic or a dialect of that tongue; that their coloniſts muſt have uſed the ſame language; that the ancient Ethiopians were a people highly poliſhed, and celebrated in the moſt early ages on account of their virtue and piety. It has likewiſe appeared, that the common letters of that people were the ſacred characters of the Egyptians. Theſe letters, we imagine, were the Cuphite; for which ſee the Sect. on the *Arabic*. When they were diſcarded, and the modern ſubſtituted in their room, cannot be determined; nor is it, we apprehend, a matter of much importance. We ſhall therefore drop that part of the ſubject, and refer our curious and inquiſitive readers to the very learned Job Ludolf's (F) excellent grammar and Dictionary of the Abyſſinian or Geez tongue, where they will find every thing worth knowing on that ſubject. We ſhall endeavour to gratify our readers with a very brief account of the modern Ethiopic or Abyſſinian tongue; for which both they and we will be obliged to James Bruce, Eſq; that learned, indefatigable, and adventurous traveller; who, by his obſervations on that country, which he made in perſon, often at the hazard of his life, has diſcovered, as it were, a new world both to Europe and Aſia.

Chaldean Language, &c.

65 Modern Ethiopic tongues.

The moſt ancient language of Ethiopia, which we ſhall now call *Abyſſinia* (its modern name), according to that gentleman, was the *Geez*, which was ſpoken by the ancient Cuſhite ſhepherds. This, we ſhould think, approaches neareſt to the old Chaldaic. Upon a revolution in that country, the court reſided many years in the province of Amhara, where the people ſpoke a different language, or at leaſt a very different dialect of the ſame language. During this interval, the *Geez*, or language of the ſhepherds, was dropt, and retained only in writing, and as a dead language: the ſacred Scriptures being in that tongue only ſaved it from going into diſuſe. This tongue is exceedingly harſh and unharmonious. It is full of theſe two letters D and T, in which an accent is put that nearly reſembles ſtammering. Conſidering the ſmall extent of ſea that divides this country from Arabia, we need not wonder that it has great affinity with the Arabic. It is not difficult to be acquired by thoſe who underſtand any other of the oriental languages; and as the roots of many Hebrew words are only to be found here, it ſeems to be abſolutely neceſſary to all thoſe who wiſh to obtain a critical ſkill in that language.

66 Ethiopic alphabet.

The Ethiopic alphabet conſiſts of 26 letters, each of which, by a *virgula* or point annexed, varies its ſound in ſuch a manner as that thoſe 26 form as it were 62 diſtinct letters. At firſt they had but 25 of theſe original letters, the Latin P being wanting; ſo that they were obliged to ſubſtitute another letter in its place. *Paulus*, for example, they call *Taulus*, *Aulus*, or *Caulus*: *Petros*, they pronounced *Ketros*. At laſt they ſubſtituted T, and added this to the end of their alphabet; giving it the force of P, though it was really a repetition of a character rather than the invention of a new one. Beſides theſe, there are 20 others of the nature of diphthongs; but ſome of them are

(E) Where the capital of Ethiopia was ſituated.

(F) A very learned German, who publiſhed a grammar and dictionary of the Geez in folio.

Chaldean Language, &c.

are probably not of the same antiquity with the letters of the alphabet, but have been invented in later times by the scribes for convenience.

The Amharic, during the long banishment of the royal family in Shoa, became the language of the court, and seven new characters were of necessity added to answer the pronunciation of this new language; but no book was ever yet written in any other language than *Geez*. There is an old law in the country, handed down by tradition, that whoever shall attempt to translate the Holy Scripture into Amharic or any other language, his throat shall be cut after the manner in which they kill sheep, his family sold to slavery, and their houses razed to the ground.

Before we leave this subject, we may observe, that all the ancients, both poets and historians, talk of a double race of Ethiopians; one in India, and another in Africa. What may have given rise to this opinion it is not easy to discover. Perhaps the swarthy complexion of both people may have led them to this sentiment. Eusebius indeed informs us*, that "a numerous colony of people emigrated from the banks of the Indus, and crossing the ocean, fixed their residence in the country now called Ethiopia." For our part, we are rather inclined to believe that the original Ethiopians transported themselves into India, and there perhaps co-operated with the Egyptians in digging the excavations and framing the statues, some of which are still to be seen in that country, and which we have mentioned in another Section. The Greeks called those people Αἰθίοπες, *Æthiopes* we believe, from their sun-burnt countenance; but indeed they were very little acquainted either with the country or its inhabitants.

* *Chron.* p. 12.

67 Antient language of Egypt a sister dialect of Hebrew.

The most ancient name of Egypt was *Mizraim*, of consequence the Arabians still call it *Mesri*. It was likewise distinguished by other names, such as *Oceana*, *Aeria*, &c. It appears from the sacred historian, that it was inhabited by the descendants of Mizraim the second son of Ham. Mizraim had several sons, who, according to the Scripture account, settled respectively in that country. If we trust to the sacred records, there will be little difficulty in ascertaining the language of the Mizraim. It will appear to be one of the sister dialects of the Hebrew, Phœnician, Arabic, Chaldaic, &c.; and this, to us, appears to be the fact. But the origin of that people, their language, religion, laws, and institutions, have been so warped and confounded, both by their own historians and those of other countries, that one is scarce able to determine what to believe or what to reject. Herodotus, Diodorus Siculus, Strabo, Ptolemy, and most other ancient geographers and historians, are universally agreed, that Egypt, at least that part of it called *Delta*, was overflown by the sea, and consequently uninhabitable for many centuries after the dispersion of mankind. When we consider the low situation of the Delta, and the violent current of the tide from the coast of Phœnicia and Palestine towards that shore, we would be almost tempted to adopt this hypothesis; but the sacred records avouch the contrary. According to them, we find Egypt a populous, rich, and flourishing kingdom, as early as the age of Abraham. Had the Lower Egypt been a pool of stagnating water at any time after the general deluge, we think it could not have been drained, cleared, cultivated, and stocked with inhabitants, so early as the days of Abraham.

Chaldean Language, &c.

Diodorus Siculus, however, is positive that the Egyptians§ were a colony of Ethiopians; and this he endeavours to prove by the similarity of features, customs, laws, religious ceremonies, &c. between the two nations. That there was a constant intercourse of good offices between these two branches of the Hamites, cannot be questioned; and that they nearly resembled each other in many respects, is too evident to admit of contradiction. The excavations, originally dug out of the solid rocks of porphyry and marble, in which the natives resided before the plains were drained, have been observed by a most judicious traveller (G) very few years ago. At the same time, the most accurate and judicious travellers (H) who have visited that region in modern times, are generally of opinion that the land has gained nothing on the sea since the period when Herodotus wrote his description of that country; from which circumstance we may be led to conclude, that the idea of the inundation of the Delta is not founded in fact.

§ *Lib.* 13. *passim.*

But even admitting that the Egyptian Delta has acquired nothing from the sea since the age of Herodotus to the present, it certainly does not follow that the region in question was never overflown by that element; since there are, in many parts of the globe, large tracts of land, certainly once covered with sea, which have continued to this day in the very same situation in which they were 2000 years ago. We leave the decision of this point to the judgment of our readers.

We have already hinted our opinion of the nature of the Egyptian language; but because Egypt is generally thought to have been the native land of hieroglyphics, and because many are of opinion that hieroglyphical characters were prior to alphabetical, we shall hazard a few conjectures with respect to that species of writing.

68 Egyptian hieroglyphics.

The end of speech, in general, is to enable men to communicate their thoughts and conceptions one to another when present; the use of writing is to perform the same office when people are at so great a distance that vocal sounds cannot mutually reach them. Hieroglyphics are said to have been invented to supply this defect. The most ancient languages were everywhere full of tropes and figures borrowed from sensible objects. As in that stage of society men have not learned to abstract and generalize, all their ideas are borrowed from such objects as most forcibly strike their senses. This circumstance would naturally suggest to savages the idea of conveying their sentiments to each other, when absent, by delineations of corporeal objects. Thus, if a savage asked a loan of his

1 friend's

(G) See Mr Bruce's Travels, Vol. I.

(H) Mr Bruce, Dr Shaw, Bishop Pocock, Savary, Volney, &c.

Chaldean language, &c.

friend's horſe, he might find means to have conveyed to him the figure of that animal; and ſo of others. This was the very loweſt ſpecies of ideal communication, and has been ſtyled *picture-writing*.

Neceſſity would ſoon impel our ſavage correſpondents to fabricate a method more extenſively uſeful, which would likewiſe be ſuggeſted by the conſtant uſe of the metaphorical mode of ſpeech. Some ſavage leader, more ſagacious than the vulgar herd, would obſerve that certain ſenſible objects were fitted, according to the rules of analogy, to repreſent certain human paſſions, and even ſome abſtract ideas; and this would be readily enough adopted by the herd as a new improvement. In this caſe a *horn* might be the emblem of *power*, a *ſword* of *bravery*, a *lion* of *fury*, a *fox* of *cunning*, a *ſerpent* of *malice*, &c. By and by artificial ſigns might be contrived to expreſs ſuch ideas as could not readily be denoted by bodily objects. This might be called *ſymbolical writing*. Such was the foundation of the Chineſe characters; and hence that prodigious number of letters of which the written language of that people is compoſed. Farther they could not proceed, notwithſtanding their boaſted inventive powers; and farther, we believe, no nation ever did proceed, who had once upon a time no other characters but hieroglyphical. The Mexicans had arrived at the very loweſt ſtage of hieroglyphical writing, but had not taken one ſtep towards alphabetical. The Hurons employ hieroglyphical ſymbols, but never entertained a ſingle idea of alphabetical. Hieroglyphical characters are the images of objects conveyed to the mind by the organs of viſion; alphabetic are arbitrary artificial marks of ſound, accommodated by compact to convey to the mind the ideas of objects by the organs of hearing. In a word, we think that there is not the leaſt analogy between theſe two ſpecies to conduct from the one to the other: we are therefore of opinion, that hieroglyphical characters were never the vulgar channels of ideal conveyance among civilized people.

69 Were never the vulgar channel;

We know that in this point we differ from many learned, judicious, and ingenious writers; ſome of whom have taken much pains to inveſtigate the intermediate ſtages through which the fabricators of characters muſt have paſſed in their progreſs from hieroglyphical to alphabetical writing. Theſe writers have adopted a plan analogous to Biſhop Wilkins's project of an artificial language. In this theory, we own, we are led to ſuſpect that they ſuppoſed all mankind were once upon a time *ſavages*, and were left to hammer out words, as well as characters, by neceſſity, ingenuity, experience, practice, &c. For our part, we have endeavoured to prove, in our ſection on the Hebrew language, that alphabetical writing was an antediluvian invention; and we now lay it down as our opinion, that among all thoſe nations which ſettled near the centre of civilization, hieroglyphics were, comparatively, a modern fabrication.

The Orientals are, at this day, extravagantly devoted to allegory and fiction. Plain unadorned truth with them has no charms. Hence that extravagant medley of fables and romance with which all antiquity is replete, and by which all ancient hiſtory is diſguiſed and corrupted. Every doctrine of religion, every precept of morality, was tendered to mankind in parables and proverbs. Hence, ſays the Scripture, to underſtand a proverb, the words of the wiſe, and their dark ſayings. The eaſtern ſages involved their maxims in this enigmatical dreſs for ſeveral reaſons: to fix the attention of their diſciples; to aſſiſt their memory; to gratify their allegorical taſte; to ſharpen their wit and exerciſe their judgment; and ſometimes perhaps to diſplay their own acuteneſs, ingenuity, and invention.

Chaldean Language, &c.

It was among the ancients an univerſal opinion, that the moſt ſacred arcana of religion, morality, and the ſublime ſciences, were not to be communicated to *the uninitiated rabble*. For this reaſon every thing ſacred was involved in allegorical darkneſs.

Here, then, we ought to look for the origin of hieroglyphical or picture-writing among the civilized nations of the eaſt. They did not employ that ſpecies of writing becauſe they were ignorant of alphabetical characters, but becauſe they thought fit to conceal the moſt important heads of their doctrines under hieroglyphical figures. The Egyptian prieſts were moſt celebrated for their ſkill in deviſing thoſe emblematical repreſentations; but other nations likewiſe employed them. We learn from the fragments of Beroſus the Chaldean hiſtorian, preſerved by Syncellus and Alexander Polyhiſtor, that the walls of the temple of Belus at Babylon were covered all over with thoſe emblematical paintings. Theſe characters were called ιερα, becauſe they were chiefly employed to repreſent ſacred objects; and γραμματα, becauſe they were originally carved or engraved. Their name points to their original uſe. Inſtead of purſuing theſe obſervations, which the nature of our deſign will not permit, we muſt refer our readers to Herodotus, l. ii. Diodorus Sic. l. i. Strabo, l. xvii. Plut. Iſis and Oſiris; and among the Chriſtian fathers, to Clem. Alex. Euſeb. Præp. Evang.; but chiefly to Horapollo's Hieroglyphica.

70 But employed to conceal ſacred doctrines from the uninitiated;

From this deduction we would conclude, that this ſpecies of writing was an adventitious mode in Egypt, peculiar to the prieſts, and employed chiefly to exhibit things ſacred; and that among all civilized people it did not ſuperſede the uſe of alphabetical characters, nor did the uſe of the latter originate from the former. When alphabetical letters were invented, if indeed they were a human invention, they were antecedent to the other in uſe and extent. The Egyptian prieſts alone knew the true import of thoſe ſacred ſymbols; and communicated that knowledge firſt to their own children from generation to generation, then to the initiated, and laſt of all to the grandees of the nation, all of whom were indeed initiated. The hieroglyphics of Egypt were not then the ſymbols of any ſacred occult language; but ſigns invented by the prieſts and prophets or wiſe men, in order to repreſent their deities, the attributes and perfections of their deities, and the myſterious arcana of their religion, and many other circumſtances relating to objects of importance, which were deemed either too ſacred or too important to be imparted to the vulgar.

71 And poſterior in time to alphabetical characters.

The Egyptians aſcribed the invention of letters to a perſon whom they called *Thoth* *, *Theuth*, or *Thyoth*; the Greeks Ερμης; and the Romans *Mercurius*. Plato† calls him a god, or a godlike man; Diodorus ‡ makes him privy counſellor to Oſiris; Sanchoniathon

* *Euſeb. Præp. Ev.*

† *Phædrus.*

‡ Lib. i.

Chaldean Language, &c.

choniathon ap. Euseb. § connects him with the Phœnician Cronus or Saturn. To this Mercury the Egyptians ascribe the invention of all the arts and sciences. He was probably some very eminent inventive genius, who flourished during the first ages of the Egyptian monarchy, and who perhaps taught the rude savages the art of writing.

§ *Prep. Ev.*

72 Two kinds of alphabetical characters in Egypt.

According to Diodorus Siculus, the Egyptians had two kinds of letters ‖; the one sacred, the other common: the former the priests taught their own children, the latter all learned promiscuously. In the sacred characters the rites and ceremonies of their religion were couched; the other was accommodated to the ordinary business of life. Clem. Alexand. mentions three different styles of writing employed by the Egyptians *. "The pupils, who were instructed by the Egyptians, first learned the order and arrangement of the Egyptian letters, which is called *epistolography*, that is, the manner of writing letters; next, the sacred character, which the sacred scribes employed; lastly, the hieroglyphic character, one part of which is expressed by the first elements, and is called *Cyriologic*, that is, *capital*, and the other *symbolic*. Of the symbolic kind, one part explains properly by imitation; and the other is written tropically, that is, in tropes and figures; and a third by certain enigmatical expressions. Accordingly, when we intend to write the word *sun*, we describe a circle; and when the moon, the figure of that planet appearing horned, conformable to the appearance of that luminary after the change." In this passage we have an excellent description of the three different modes of writing used by the Egyptians; the common, the sacred, and the hieroglyphic. The last he describes according to its three divisions, in exact conformity to our preceding observations.

‖ Lib. 1.

* *Strom.* lib. 5.

73 The sacred letters and language of Egypt Chaldaic.

By the description above translated, it plainly appears, that the sacred character of the Egyptians was entirely different from the hieroglyphic; and by this consideration we are in a good measure justified, in supposing, as we have done all along, that the sacred letters of the Egyptians were actually the Chaldaic. The inscriptions on the obelisks mentioned by Cassiodorus, so often quoted, were certainly engraved in the sacred character; and the character in which they were drawn was that above mentioned. If the sacred letters were Chaldaic, the sacred language was probably the same.

The Egyptians pretended, that the Babylonians derived the knowledge of the arts and sciences from them; while, on the other hand, the Babylonians maintained, that the former had been tutored by them. The fact is, they both spoke the same language; used the same religious rites; had applied with equal success to astrology, astronomy, geometry, arithmetic, and the other sciences; of course a rivalship had arisen between the two nations, which laid the foundation of those opposite pretensions.

The most faithful specimen of the vulgar language of the Egyptians, is, we believe, still preserved in the Coptic, which, however, is so replete with Grecisms, that it must be difficult to trace it out.

Under the Ptolemies, the Greek was the language of the court, and consequently must have diffused itself over all the country. Hence, we believe, two-thirds of the Coptic are Greek words, diversified by their terminations, declensions, and conjugations only. To be convinced of the truth of this, our learned and curious readers need only consult Christian Scholtz's Egyptian and Coptic grammar and dictionary, corrected and published by Godfred Woide, Oxford, 1788.

Chaldean Language, &c.

74 The Egyptian and Phœnician languages the same.

The Egyptians and Phœnicians were in a manner cousin-germans, and consequently must have spoken the same language; that is, one of the sister dialects of the Hebrew, Chaldean, Arabian, Cushite, &c. — This is not a mere conjecture; it may be realized by almost numberless examples. It is true, that when Joseph's brethren went down to Egypt, and that ruler deigned to converse with them, they could not understand the Egyptian idiom which he spoke; nor would he, had he been actually an Egyptian, have understood them without an interpreter. The only conclusion from this circumstance is, that by this time the Egyptian had deviated considerably from the original language of mankind. The Irish and Welch, every body knows, are only different dialects of the Celtic tongue; and yet experience proves, that a native of Ireland and another of Wales cannot well comprehend each other's language, nor converse intelligibly without an interpreter. The Erse, spoken in the Highlands of Scotland, and the Irish, are known to be both branches of the old Celtic; yet a Scotch Highlander and an Irishman can hardly understand each other's speech. By a parity of reason, a Hebrew and an Egyptian might, in the age of Joseph, speak only different dialects of the same original tongue, and yet find it difficult to understand one another. The fact seems to be, the Hebrew dialect had been in a manner stationary, from the migration of Abraham to that period; whereas the Egyptian, being spoken by a powerful, civilized, and highly cultivated people, must have received many improvements, perhaps additions, in the course of near two centuries.

75 The vulgar letters of Egypt nearly the same with the Hebrew or Phœnician.

The descendants of Canaan and of Mizraim were strictly connected in their religious ceremonies: they worshipped the same objects, namely, the *Host of Heaven*; they mourned *Osiris* and *Adonis* in concert; they carried on a joint commerce, and, we think, spoke the same language; we may, therefore, conclude, that their vulgar letters were nearly the same, both in form, disposition, and number. Their original number was probably 16, viz. five vowels, six mutes, simple and middle, four liquids, and the solitary *s*.— With these, it is likely, was joined a mark of aspiration, or an *h*, such as we have in the Roman alphabet, and find on some Greek monuments. Cadmus was originally an Egyptian; that leader brought a new set of letters into Greece. These are generally deemed to be Phœnician. They were nearly the same with the ancient Pelasgic, as will be shown in the section of the *Greek language*. The latter, we think, were from Egypt, and consequently the former must have been from the same quarter. Danaus, Perseus, Lelex, &c. were of Egyptian extraction: they too adopted the Cadmean characters, without substituting any of their own.

The Jonim, or Ionians, emigrated from Gaza, a colony or Egyptians; and their letters are known to have differed very little from those of Cadmus and the Pelasgi.

Chaldean Language, &c.

Pelasgi. The conclusion, therefore, is, that the vulgar Egyptian letters were the same with the Phœnician.

We are abundantly sensible that there are found upon Egyptian monuments characters altogether different from those we have been describing. At what time, by what people, and to what language, these letters belonged, we will not pretend to determine. The Ethiopians, the Chaldeans, the Persians, the Greeks, the Romans, the Saracens, have, at different times, been sovereigns of that unhappy country. Perhaps other nations, whose memory is now buried in oblivion, may have erected monuments, and covered them with inscriptions composed of words taken from different languages, perhaps, upon some occasions, whimsically devised, with a view to perplex the curious antiquaries of future ages. Some of these are composed of hieroglyphics intermingled with alphabetical characters, artificially deranged, in order to render them unintelligible. These we do not pretend to develope; because the most inquisitive and sagacious antiquaries are not yet agreed as to their purport and signification.

76 Egyptian names of Hebrew original,

We shall now go on to show, that most part of the names of persons and places, &c. which have been conveyed down to us, may, in general, be reduced to a Hebrew, Phœnician, Syrian, or Chaldean original. As the first of these languages is most generally known, we shall employ it as our arch-type or standard, beginning with those terms which occur in Scripture.

The word *Pharaoh*, the title of the *melech* or king of Egypt, is, we think, compounded of two terms, which plainly discover a Hebrew original. According to an oriental tradition, the first who assumed this title was the sovereign of the *royal shepherds*; a race of people from Arabia and Phœnicia. They conquered Egypt at an early period, and kept possession of it for several centuries. They gloried in the title ὑκσοι, or ὑκσσοι, which, according to Josephus *con. Apion*, signifies "royal shepherds." The word *Pharaoh* seems to be compounded of פר *Phar*, "a bullock," and רעה *Rachah* "to feed;" hence פרעה *Pharachah*, as we think it ought to be written. The name given to Joseph is evidently of kin with the Hebrew; for *zuphnath* differs very little from the Hebrew verb *tzaphan*, which signifies "to hide, to keep secret;" *Paneah* or *Phaneah*, signifies much the same with the Hebrew *Phanah*, aspexit: so that the name actually intimates *one* who sees hidden things; which was certainly the very idea the prince intended to convey by giving him that name.

Potiphar, or *Potipherah*, the name of Joseph's father-in-law, has likewise a dialectical affinity with the Hebrew idiom. In that language *Patah* signifies "to open, to explain," which was one part of the sacerdotal office; and *Phar* imports "a bullock." Potiphar was then priest of the bullock, that is, the ox, *apis*, sacred to the *sun* (1). This person was priest or *prince of On*, which, according to Cyrillus on Hosea, was an Egyptian name of that luminary. The Hebrew word *hon* or *chon* signifies "power, wealth, sufficiency;" a very proper epithet for the *sun*, who was thought to bestow those blessings. The name of Joseph's wife was *Asenath* or *Asnath*, compounded of *Isshah* "a woman," and *Naith* or *Neit*, an Egyptian name of "Minerva, a votary of Minerva."

Chaldean Language, &c.

Almost all the names of cities belonging to Egypt which are mentioned in Scripture are evidently Hebrew. To be satisfied as to this position, our curious readers may consult Jamieson's *Specilegia*, an excellent book very little known. The names of most of the Egyptian deities are significant in the Hebrew tongue; and in that dialect the names appear to have been imposed with great judgment and propriety, plainly indicating some office assigned them, or pointing to some peculiar attribute. We shall produce a few instances.

77 And significant in that language.

Osiris was the great divinity of Egypt; he was certainly the *sun*. The Egyptians gave their deities a variety of names in allusion to their various offices and attributes. Jablonski has in a manner wearied himself with tracing the signification of this name. In Hebrew we have *Oshir* "to grow rich, to be enriched." The sun may be called the great enricher of nature, and therefore might properly be called by a name alluding to that quality. *Isis* was both the moon and the earth. *Isshah* is the Hebrew word for *woman*, and Horapollo assigns this very derivation. *Anubis* was one of the names of Mercury among the Egyptians: He was always figured with the head of a *dog*. He accompanied *Isis* in her peregrinations in quest of Osiris, and frighted away the wild beasts from attacking the princess. In Hebrew, *Nubah* signifies "to bark." Here the analogy, we think, is evident. Many Egyptian names begin with *Can*, such as *Canebus*, *Canopus*, &c. The Hebrew word *Cahen* or *Coken*, *Syr*, *Con* or *Chon*, intimates both a prince and a priest. *Ob* or *Aub*, in Hebrew, imports "a bottle, a flaggon," any thing round and prominent like the human belly. In the language of Egypt it was often applied to the sun, in allusion to his rotundity. In the temple of *Jupiter Ammon* or *Amon*, in the desert of Lybia, there was a statue of the god representing the *navel* of the human body, which was probably framed in allusion to this fancy. Hence the Pythoness, or people who, according to the Scripture, had familiar spirits, were said to prophecy by the inspiration of *Ob*, as the Delphic priestess did by that of Apollo. Again, many Egyptian names end with *siris*, as Calasiris, Termosiris. This termination is no doubt a cognate of the Hebrew and Chaldean *sar* or *zar*, signifying "a prince, or grandee, &c." The river Nile in the Ethiopic dialect is called *Siris*; that is, we believe, the *king of rivers*. The same flood seems to derive the name by which it is generally known, from the Hebrew *nehel*, "a valley, or torrent running down a valley." The same river was often called *Oceanus*, a word composed of *og*, or *oc*, or *och*, which signifies "a king, a leader," and the Hebrew *ein* "a fountain;" so that the word imports the *king of fountains*. The Hebrews always denominated the land of Egypt

(1) The Septuagint (Gen. xli. v. 45 and 50.) translate *On* by Ηλιουπολις.

Perſian Language.

the land of Mizraim; the Egyptians themſelves, in later times, ſeem to have called it Αιγυπτος *Ægyptus*, "Egypt," which ſome think is compounded of *Ai*, Hebrew, "an iſland, a country, a province," and *Copt* or *Cupt*, "a famous city in that country."

From this ſpecimen, we hope it will appear that the Egyptian language in the more early ages was one of thoſe dialects into which that of the deſcendants of the poſtdiluvian patriarchs was divided, and perhaps ſubdivided, a few centuries after the deluge. Among all thoſe, we believe, ſuch an affinity will be found, as plainly demonſtrates that they originally ſprang from one common ſtock. Here we might eaſily follow the Egyptian language into Greece; and there we are perſuaded we might trace a vaſt number of Egyptian terms into that tongue, which, however, the nature of this inquiry will not permit. If our learned readers ſhould incline to know more of the affinity of the Egyptian tongue with the others ſo often mentioned, they may conſult Bochart's *Chanaan*, Walton's *Proleg.* Gebelin's *Monde Prim.* Jameſon's *Spicilegia*, &c.

Sect. IV. *Of the Perſian Language.*

The Perſian language is divided into the ancient and modern; the former of which is at this day very imperfectly known, the latter is at preſent one of the moſt expreſſive, and at the ſame time one of the moſt highly poliſhed, in the world. We ſhall, in treating of this language, in compliance with the plan we have all along followed, begin with the ancient.

78 At the birth of Mohammed two languages prevalent in Perſia,

When Mohammed was born, and Anu'shi'rava'n, whom he calls the *juſt king*, ſat on the throne of Perſia, two languages were generally prevalent in that empire (k). The one was called *Deri*, and was the dialect of the court, being only a refined and elegant branch of the *Parſi*, ſo called from the province of which *Shiraz* is now the capital; and that of the learned, in which moſt books were compoſed, and which had the name of *Pahlavi*, either from the heroes who ſpake it in former times, or from *pahlu*, a tract of land which included ſome conſiderable cities of *Iran*: The ruder dialects of both were ſpoken by the ruſtics of ſeveral provinces; and many of theſe diſtinct idioms were vernacular, as happens in every kingdom of conſiderable extent. Beſides the *Parſi* and *Pahlavi*,

79 And a more ancient language than either known only to the prieſts.

a very ancient and abſtruſe tongue was known to the prieſts and philoſophers, called the language of the *zend*, becauſe a book on religious and moral duties which they held ſacred, and which bore that name, had been written in it; while the *Pazend* or comment on that work was compoſed in *Pahlavi*, as a more popular dialect. The letters of this book were called *zend*, and the language *aveſta*.

The *Zend* and the old *Pahlavi* are now almoſt extinct in *Iran*, and very few even of the Guebres can read it; while the *Parſi* remaining almoſt pure in *Shahnameh*, has, by the intermixture of Arabic words, and many imperceptible changes, now become a new language exquiſitely poliſhed by a ſeries of fine writers both in proſe and verſe, analogous to the different idioms gradually formed in Europe after the ſubverſion of the Roman empire.

Perſian Language.

So Parſi language and

The very learned and laborious Sir William Jones is confident that the *Parſi* abounds with words from the Shanſcrit, with no other change than ſuch as may be obſerved in the numerous dialects of India; that very many Perſian imperatives are the roots of Shanſcrit verbs; and that even the moods and tenſes of the Perſian verb ſubſtantive, which is the model of all the reſt, are deducible from the Shanſcrit by an eaſy and clear analogy. From this he infers that the *Parſi*, like the various idiom dialects, is derived from the language of the Bramins. This concluſion, we imagine, is not altogether juſt, ſince by the ſame train of reaſoning we may infer that the Shanſcrit is derived from the *Parſi*.

The ſame learned gentleman adds, that the multitude of compounds in the Perſian language proves that it is not of Arabic but Indian original. This is undoubtedly true; but though the *Parſi* is not of Arabic original, it does not neceſſarily follow that it is of Shanſcrit. We might with the ſame propriety, and with an equal ſhow of reaſon, conclude, that the Greek language is deſcended of the Shanſcrit, becauſe it too abounds with compounds. We may then reſt aſſured, that neither the one nor the other argument adduced by the ingenious preſident proves that the *Parſi* tongue is a deſcendant of the Shanſcrit.

The gentleman ſo often mentioned, aſſures us, that the Zend bears a ſtrong reſemblance to the Shanſcrit; which, however, it might do without being actually derived from it, ſince we believe every oriental ſcholar will find that all the languages from the Mediterranean to the utmoſt coaſt of Hindoſtan exhibit very ſtrong ſignatures of a common original. The Parſi, however, not being the original dialect of Iran or Perſia, we ſhall purſue it no farther at preſent, but return to give ſome account of the Pahlavi, which was probably the primitive language of the country. We have obſerved above, that the Pazend or comment on the Zend was compoſed in the Pahlavi for the uſe of the vulgar. This, according to Sir William, was a dialect of the Chaldaic; and of this aſſertion he exhibits the following proof.

81 The Pahlavi

By the nature of the Chaldean tongue, moſt words ended in the firſt long vowel, like *ſhemaiá* "heaven;" and that very word, unaltered in a ſingle letter, we find in the Pazend, together with *lailiá* "night," *meyá* "water," *nirá* "fire," *matrá* "rain," and a multitude of others, all Arabic or Hebrew, with a Chaldean termination; ſo *zamar*, by a beautiful metaphor from *pruning trees*, means in Hebrew to *compoſe verſes*, and thence, by an eaſy tranſition, to *ſing* them; now in Pahlavi we ſee the verb *zamarúniten* "to ſing," with its forms *zamaraunèmi* "I ſing," and *zamzunid* "he ſang;" the verbal terminations of the Perſian being added to the Chaldaic root. All theſe words are integral parts of the language; not adventitious like the Arabic nouns and verbals engrafted on modern Perſian.

From

(k) The moderns call the empire of Perſia *Iran*; a name unknown to the ancients.

Persian Language

From this reasoning it plainly appears, 1st, that Pahlavi was the ancient language of Persia; and, 2d, that the ancient Persian was a cognate dialect of the Chaldean, Hebrew, Arabic, Phœnician, &c. M. Anquetil has annexed to his translation of the *Zendavesta* two vocabularies in Zend and Pahlavi, which he found in an approved collection of *Rawayat* or *Traditional Pieces* in modern Persian. His vocabulary of the Pahlavi strongly confirms this opinion concerning the Chaldaic origin of that language. But with respect to the Zend, it abounded with vast numbers of pure Shanscrit words, to such a degree, that six or seven words in ten belonged to that language.

82 Derived from Chaldaic and Shanscrit, &c.

From this deduction it would appear, that the oldest languages of Persia were Chaldaic and Shanscrit: and that when they had ceased to be vernacular, the Pahlavi and Zend were deduced from them respectively, and the Parsi either from the Zend, or immediately from the dialect of the Brahmans: but all had perhaps a mixture of Tartarian; for the best lexicographers assert, that numberless words in ancient Persian are taken from the Cimmerians. With respect to the last of these, we cannot help being of opinion, that colonies of people from the neighbourhood of Persia did transport themselves into Crim Tartary, and perhaps into Europe. These colonists brought along with them those vocables which still occur in their dialect. Emigrants from those quarters must have found their way into Scandinavia, since numberless Persian words are still current in those regions. Perhaps Odin and his followers emigrated from the neighbourhood of Media and Persia, and brought with them the dialect of the nations from whose country they had taken their departure.

83 The Zend from the same source.

With respect to the Zend, it might well be a dialect of the Shanscrit, and was probably a sacred language; and if so, concealed from the vulgar, and reserved for the offices of religion. If Zoroastres, or Zaratusht as the orientals call him, travelled into Egypt, and was initiated in the mysteries of the Egyptian religion, as some pretend he was, he might be instructed in the sacred dialect of that people by the priests under whom he studied. When that philosopher returned into Persia, and became the apostle of a new religion, he might compose the volume of his laws and religious institutions in the sacred language of his Egyptian tutors. This language then became that of the Magi, who concealed it carefully from the knowledge of the uninitiated, as the priests did in Egypt and the Brahmans in Hindostan.

In our Section on the *Shanscrit* language, we shall give a detail of a number of particulars, which to us seem to furnish a presumption that the language in question was imported from Egypt into Hindostan. We confess there are not sufficient data to improve these presumptions into absolute certainty; but we hope the time is at hand when the worthy members of the Asiatic Society will discover abundant materials to ascertain the truth of this position. We are the rather inclined to adopt this hypothesis, when we consider the character of Zoroastres in connection with that of the Egyptian Cohens and of the Indian Brahmans.

If this opinion should one day appear to be well-founded, we believe the coincidence between the language of the Zend and the Shanscrit will be easily accounted for, without making the Hindoos masters of Iran or Persia, and then driving them back to the shores of the Ganges. That the nations of Turan or Scythia did actually over-run that country, and make themselves masters of a considerable part of it at different times, is vouched by the records and traditions of the Persians themselves. Upon those occasions a number of Tartarian words might be introduced into the country, and acquire a currency among the inhabitants. As the annals of ancient Persia have been long since destroyed and consigned to eternal oblivion, it is impossible to ascertain either the extent or duration of these irruptions. Indeed the nature of our design does not call for that investigation.

Persian Language.

In order to corroborate the cognation between the Chaldean and Pahlavi languages, we shall subjoin a few arguments derived from the Mosaic history, and the other writings of the Old Testament. These we believe will be admitted as irrefragable proofs of the position above advanced by such as admit the authenticity of those records.

84 Proofs from Scripture of the origin of the Pahlavi.

Elam is always allowed to have been the progenitor of the Persians. This patriarch was the eldest son of Shem the son of Noah; and according to the Mosaic account, his posterity settled in the neighbourhood of the descendants of Ashur, Arphaxad, Lud, and Aram, the other sons of Shem. The country where they settled was denominated *Elymais* * as late as the beginning of the Christian era. This name was retained till the Saracens conquered and took possession of that country. If this was the case, as it certainly was, the Elamites or Persians spoke a dialect of the primary language, which, in the first Section, we have proved to have been the Hebrew.

* *Strabo*, lib. 11.

When the four eastern monarchs invaded the five cities of the plain in Canaan †, Chedorlaomer king of Elam was at the head of the confederacy. Amraphel king of Shinar, that is Babylon or Chaldea, was one of the allies; Arioch king of Elafar was another; and Tidal, king of some scattered nations in the same neighbourhood, was the fourth. That Chedorlaomer was principal in this expedition, is obvious from the historian's detail of the second, where that prince is placed first, and the rest are named *the kings that were with him*. This passage likewise demonstrates, that Elam, Shinar, and Elazar, lay contiguous, and were engaged in the same cause. Wherever the country in question is mentioned in Scripture prior to the era of Daniel and Ezra, it is always under the name of *Elam*. To go about to prove this would be superfluous.

† Gen. chap. xiv.

According to Xenophon ‡, the Persians knew nothing of horsemanship before the age of Cyrus: but that historian informs us, that after that monarch had introduced the practice of fighting on horseback, they became so fond of it, that no man of rank would deign to fight on foot. Here it ought to be considered, that the historian above mentioned was now writing a moral, military, and political romance; and therefore introduces this anecdote, in order to exalt the character of his hero: so that we are not to suppose that the people under consideration were unacquainted with the art of horsemanship till that period.

‡ *Cyrop.* lib. 1.

The very name *Phars* or *Pharas* is certainly of He-

Persian Language

brew origin, and alludes to the skill that people professed in horsemanship. The original seems to be *Pharsah*, *ungula* "a hoof;" and in the Arabic *Pharas* intimates a *horse*, and *Pharis* a *horseman*. Consequently the people were denominated *Parsai*, and the country *Pars*, because they were trained from their infancy to ride the *great horse*, which indeed they deemed their greatest honour. This name was perhaps first imposed upon them by the neighbouring nations, and in process of time became their gentile appellation. *Mithras* is generally known to have been the chief divinity of the Persians; a name which is plainly derived from *Mither* "great." We find in Strabo the Persian god *Anamus*, which is plainly a cognate of *Hamah* the "sun or fire." Hence we believe comes *Hamarim*, the "hearths or chapels" where the fire sacred to the sun was kept burning; which, we believe, the Greeks called Πυραθεια or "fire-temples." Herodotus* mentions a custom among the Persians, according to which, when they came to engage an enemy, they cast a rope with a kind of gin at the end of it on their enemy, and by those means endeavoured to entangle and draw him into their power. The people of Persia who employed this net or gin were called *Sagartes*, from *sarags*, *sharag*, or *serig*, a word which in Hebrew, Arabic, and Chaldaic, signifies to "hamper or entangle:" hence perhaps the Greek word Σαγηνη, a "basket or net." *Sar* or *zar* in Hebrew, Phœnician, Syriac, &c. signifies "a lord, a prince," and hence we have the initial syllable of the far-famed *zar-tusht*, *Zoroastres*. In a word, most of the Persian names that occur in the Grecian histories, notwithstanding the scandalous manner in which they have been disguised and metamorphosed by the Greeks, may still with a little skill and industry be traced back to a Hebrew, Chaldaic, Syriac, or Phœnician origin. In the books of Daniel, Ezra, Nehemiah, and Esther, we find a number of Persian names which are all of a Hebrew or Chaldaic complexion: to investigate these at much greater length would be foreign to the design of the present article. If our curious reader should incline to be more fully satisfied as to this point, he may consult Bochart's *Chanaan*, D'Herbelot's *Bib. Orient.* Walton's *Proleg.* &c.

* Lib. 9. cap. 85.

It now appears, we hope, to the entire satisfaction of our readers, that the Pahlavi is a remnant of the old Persian, and that the latter is a cognate branch of the Hebrew, Chaldaic, Syriac, &c. We have likewise adduced some presumptive proofs that the Zend was copied from the sacred language of the Egyptians: we shall now endeavour to explain by what changes and revolutions the language first mentioned arrived at its present summit of beauty and perfection.

85 Progress of the Persian language.

We have observed above, that the Scythians, whom the old Persians called Σακαι *Sacæ*, and whom the modern call *Turan*, often invaded and over-ran Persia at a very early period. The consequence was, an infusion of Scythian or Tartarian terms, with which that language was early impregnated. This in all probability occasioned the first deviation from the original standard. The conquests of Alexander, and the dominion of his successors, must, one would imagine, introduce an inundation of Greek words. That event, however, seems to have affected the language in no considerable degree, at least very few Grecian terms occur in the modern Persian.

Persian Language.

The empire of the *Arsacidæ* or Parthians, we apprehend, produced a very important alteration upon the ancient Persian. They were a demi-Scythian tribe; and as they conquered the Persians retained the dominion of those parts for several centuries, and actually incorporated with the natives, their language must necessarily have given a deep tincture to the original dialect of the Persians. Sir William Jones has observed, that the letters of the inscriptions at *Istakhr* or Persepolis bear some resemblance to the old Runic letters of the Scandinavians. Those inscriptions we take to have been Parthian; and we hope, as the Parthians were a Tartarian clan, this conjecture may be admitted till another more plausible is discovered. The Persians, it is true, did once more recover the empire; and under them began the reign of the Deri and Parsi tongues: the former consisting of the old Persian and Parthian highly polished; the latter of the same languages in their uncultivated vernacular dress. In this situation the Persian language remained till the invasion of the Saracens in 636; when these barbarians overran and settled in that fine country; demolished every monument of antiquity, records, temples, palaces; every remain of ancient superstition; massacred or expelled the ministers of the Magian idolatry; and introduced a language, though not entirely new, yet widely differing from the old exemplar.

But before we proceed to give some brief account of the modern Persian, we must take the liberty to hazard one conjecture, which perhaps our adepts in modern Persian may not find themselves disposed to admit. In modern Persian we find the ancient Persian names wonderfully distorted and deflected from that form under which they appear in the Scripture, in Ctesias, Megasthenes, and the other Greek authors. From this it has been inferred, that not only the Greeks, but even the sacred historians of the Jews, have changed and metamorphosed them most unmercifully, in order to accommodate them to the standard of their own language. As to the Greeks, we know it was their constant practice, but we cannot believe so much of the Hebrews. We make no doubt of their writing and pronouncing the names of the Persian monarchs and governors of that nation nearly in the same manner with the native Persians. It is manifest, beyond all possibility of contradiction, that they neither altered the Tyrian and Phœnician names of persons and places when they had occasion to mention them, nor those of the Egyptians when they occurred in their writings. The Babylonian and Chaldaic names which are mentioned in the Old Testament vary nothing from the Chaldean original. No reason can be assigned why they should have transformed the Persian names more than the others. On the contrary, in Ezra, Nehemiah, and Esther, we find the Persian names faithfully preserved throughout.

86 Nothing now existing in Persic, except the Zend, older than the Saracen conquest.

The fact, we imagine, is this: Our modern admirers of the Persic have borrowed their names of the ancient kings and heroes of that country from romances and fabulous legends of more modern date and composition. The archives of Persia were destroyed by the Saracens: nothing of importance was written in that country till two centuries after the era of Mohammed. What succeeded was all fiction and romance.

4 The

Persian Language.

The authors of those entertaining compositions either forged names of heroes to answer their purpose, or laid hold on such as were celebrated in the ballads of their country, or preserved by vulgar tradition. The names were no doubt very different from those of the ancient kings and heroes of Persia; and probably many of them had undergone considerable changes during the continuance of the Parthian empire. Upon this foundation has the learned Mr Richardson erected a very irregular fabric, new, and, to use his own expression, we think built upon *pillars of ice*. He has taken much pains to invalidate the credit of the Grecian histories of the Persian empire, by drawing up in battle array against their records legions of romantic writers, who were not born till near a thousand years after the events had taken place; and to complete the probability, who lived 200 years after all the chronicles of the Medes and Persians had been finally destroyed by the fury of the Saracens.

After the decisive victory obtained over the Persians at Kadesia, their ancient government was overturned, their religion proscribed, their laws trampled under foot, and their civil transactions disturbed by the forcible introduction of the lunar for the solar kalendar; while, at the same time, their language became almost overwhelmed by an inundation of Arabic words; which from that period, religion, authority, and fashion, incorporated with their idiom.

From the seventh till the tenth century the Persian tongue, now impregnated with Arabic words, appears to have laboured under much discouragement and neglect. Bagdad, built by Almansor, became soon after the year 762 the chief residence of the khalifs, and the general resort of the learned and the ambitious from every quarter of the empire. At length the accession of the Buyah princes to the Persian throne marked in the tenth century the great epoch of the revival of Persian learning. About the year 977 the throne of Persia was filled by the great Azaduddawla; who first assumed the title of *Sultan*, afterwards generally adopted by eastern princes. He was born in Ispahan, and had a strong attachment to his native kingdom. His court, whether at Bagdad or in the capital of Persia, was the standard of taste and the favourite residence of genius. The native dialect of the prince was particularly distinguished, and became soon the general language of composition in almost every branch of polite learning. From the end of the tenth till the fifteenth century may be considered as the most flourishing period of Persian literature. The epic poet Firdausi, in his romantic history of the Persian kings and heroes, displays an imagination and smoothness of numbers hardly inferior to Homer. The whole fanciful range of Persian enchantment he has interwoven in his poems, which abound with the noblest efforts of genius. This bard has stamped a dignity on the monsters and fictions of the east, equal to that which the prince of epic poetry has given to the mythology of ancient Greece. His language may at the same time be considered as the most refined dialect of the ancient Persian, the Arabic being introduced with a very sparing hand: whilst Sadi, Jami, Hafez, and other succeeding writers, in prose as well as verse, have blended in their works the Arabic without reserve; gaining perhaps in the nervous luxuriance of the one language what may seem to have been lost in the softer delicacy of the other. Hence Ebn Fekreddin Anju, in the preface to the dictionary called *Farhang Jehanguiri*, says, that the Deri and the Arabic idioms were the languages of heaven; God communicating to the angels his milder mandates in the delicate accents of the first, whilst his stern commands were delivered in the rapid accents of the last.

87 The most flourishing period of Persian literature.

Persian Language.

For near 300 years the literary fire of the Persians seems indeed to have been almost extinguished; since, during that time, hardly any thing of that people which deserves attention has appeared in Europe: enough, however, has already been produced, to inspire us with a very high opinion of the genius of the east. In taste, the orientals are undoubtedly inferior to the best writers of modern Europe; but in invention and sublimity, they are excelled, perhaps equalled, by none. The Persians affect a rhetorical luxuriance, which to a European wears the air of unnecessary redundance. If to these leading distinctions we add a peculiar tone of imagery, of metaphor, of allusion, derived from the difference of government, of manners, of temperament, and of such natural objects as characterise Asia from Europe; we shall see, at one view, the great points of variation between the writers of the east and west. Amongst the oriental historians, philosophers, rhetoricians, and poets, many will be found who would do honour to any age or people; whilst their romances, their tales, and their fables, stand upon a ground which Europeans have not yet found powers to reach. We might here quote the Arabian Nights Entertainments, Persian Tales, Pilpay's Fables, &c.

88 The genius of the modern Persic.

We shall now annex a few strictures on the genius of that noble language; though it is our opinion that the province of the philologist is to investigate the origin, progress, and final improvement of a language, without descending to its grammatical minutiæ or peculiar idiomatic distinctions. We have already observed, that the tongue under consideration is partly Arabic and partly Persian, though the latter generally has the ascendant. The former is nervous, impetuous, and masculine; the latter is flowing, soft, and luxuriant. Wherever the Arabic letters do not readily incorporate with the Persian, they are either changed into others or thrown away. Their letters are the Arabic with little variation; these being found more commodious and expeditious than the old letters of the Deri and Parsi. Their alphabet consists of 32 letters, which, like the Arabic, are read from right to left; their form and order will be learned from any grammar of that language. The letters are divided into vowels and consonants as usual. The Arabic characters, like those of the Europeans, are written in a variety of different hands; but the Persians write their poetical works in the Talick, which answers to the most elegant of our Italic hands.

89 Resemblance between Persian and English.

There is a great resemblance between the Persian and English languages in the facility and simplicity of their form and construction: the former, as well as the latter, has no difference of terminations to mark the gender either in substantives or adjectives; all inanimate things are neuter; and animals of different sexes have either different names, or are distinguished by the words *nar* male, and *made* female. Sometimes indeed,

Persian Language.

deed a word is made feminine, after the manner of the Arabians, by having *a* added to it.

The Persian substantives have but one variation of case, which is formed by adding a syllable to the nominative in both numbers; and answers often to the dative, but generally to the accusative, case in other languages. The other cases are expressed for the most part by particles placed before the nominative. The Persians have two numbers, singular and plural; the latter is formed by adding a syllable to the former.

The Persian adjectives admit of no variation but in the degrees of comparison. The comparative is formed by adding *ter*, and the superlative by adding *terin* to the positive.

The Persians have active and neuter verbs like other nations; but many of their verbs have both an active and neuter sense, which can be determined only by the construction. Those verbs have properly but one conjugation, and but three changes of tense: the imperative, the aorist, and the preterite; all the other tenses being formed by the help of particles or of auxiliary verbs. The passive voice is formed by adding the tenses of the substantive verb to the participle of the active.

In the ancient language of Persia there were very few or no irregularities; the imperative, which is often irregular in the modern Persian, was anciently formed from the infinitive, by rejecting the termination *eeden*: for originally all infinitives ended in *den*, till the Arabs introduced their harsh consonants before that syllable, which obliged the Persians, who always affected a sweetness of pronunciation, to change the old termination of some verbs into *ten*, and by degrees the original infinitive grew quite obsolete; yet they still retain the ancient imperative, and the aorists which are formed from it. This little irregularity is the only anomalous part of the Persian language; which nevertheless far surpasses in simplicity all other languages ancient or modern.

With respect to the more minute and intricate parts of this language, as well as its derivations, compositions, constructions, &c. we must remit our readers to Mininskie's *Institutiones Linguæ Turcicæ cum rudimentis parallelis linguarum Arab. et Pers.* Sir William Jonea's Persian Grammar; Mr Richardson's Arabian and Persian Dictionary; D. Herbelot's *Bibl. Orient.* Dr Hyde *de Relig. vet. Pers.* &c. Our readers, who would penetrate into the innermost recesses of the Persian history, colonies, antiquities, connections, dialects, may consult the last mentioned author, especially chap. xxxv. *De Persia et Persarum nominibus, et de moderna atque veteri lingua Persica, ejusque dialectis.* In the preceding inquiry we have followed other authors, whose accounts appeared to us more natural, and much less embarrassing.

90 Utility of the Arabian and Persian languages.

To conclude this section, which might easily have been extended into a large volume, we shall only take the liberty to put our readers in mind of the vast utility of the Arabian and Persian languages. Numberless events are preserved in the writings of the orientals which were never heard of in Europe, and must have for ever lain concealed from the knowledge of its inhabitants, had not these two tongues been studied and understood by the natives of this quarter of the globe. Many of those events have been transmitted to posterity in poems and legendary tales like the Runic fragments of the north, the romances of Spain, or the Heroic ballads of our own country. Such materials as these, we imagine, may have suggested to Firdausi, the celebrated heroic poet of Persia, many of the adventures of his *Shahnamé*; which, like Homer when stript of the machinery of supernatural beings, is supposed to contain much true history, and a most undoubted picture of the superstition and manners of the times. The knowledge of these two languages has laid open to Europe all the treasures of oriental learning, and has enriched the minds of Britons with Indian science as much as the produce of these regions has increased their wealth and enervated their constitution.

Persian Language.

91 Persian poetry.

Before we conclude this section, we shall subjoin a few strictures on the nature of Persian poetry, in order to render our inquiry the more complete. The modern Persians borrowed their poetical measures from the Arabs: they are exceedingly various and complicated; they consist of 19 different kinds; but the most common of them are the *Iambic* or *Trochaic* measure, and a metre that chiefly consists of those compounded feet which the ancients called Ionics, which are composed of iambic and spondees alternately. In lyric poetry their verses generally consist of 12 or 16 syllables: they sometimes, but seldom, consist of 14. Some of their lyric verses contain 13 syllables: but the most common Persian verse is made up of 11; and in this measure are written all their great poems, whether upon heroic or moral subjects, as the works of Firdausi and Jami, the Bostar of Sadi, and the Mesnavi of Gelaleddin. This sort of verse answers to our common heroic rhyme, which was brought to so high a degree of perfection by Pope. The study of the Persian poetry is so much the more necessary, as there are few books or even letters written in that language, which are not interspersed with fragments of poetry. As to their prosody, nothing can be more easy and simple. When the student can read prose easily, he will with a little attention read poetry with equal facility.

Sect V. *Shanscrit and Bengalese Languages.*

92 The Shanscrit one of the most ancient languages in the world.

The Shanscrit, though one of the most ancient languages in the world, was little known even in Asia till about the middle of the present century. Since that period, by the indefatigable industry of the very learned and ingenious Sir William Jones and the other worthy members of that society of which he has the honour to be president, that noble and ancient language has at length been brought to light; and from it vast treasures of oriental knowledge will be communicated both to Europe and Asia; knowledge which, without the exertions of that happy establishment, must have lain concealed from the researches of mankind to the end of the world. In this section we propose to give to our readers such an account of that language as the limits of the present article, and the helps we have been able to procure, shall permit.

The Shanscrit language has for many centuries lain concealed in the hands of the bramins of Hindostan. It is by them deemed sacred, and is of consequence confined solely to the offices of religion. Its name imports

Shanſcrit and Bengaleſe Languages.

imports the *perfect language*, or, according to the eaſtern ſtyle, *the language of perfection*; and we believe no language ever ſpoken by man is more juſtly intitled to that high epithet.

The grand ſource of Indian literature, and the parent of almoſt every dialect from the Perſian gulph to the China ſeas, is the Shanſcrit; a language of the moſt venerable and moſt remote antiquity, which, tho' at preſent ſhut up in the libraries of the bramins, and appropriated ſolely to the records of their religion, appears to have been current over moſt of the oriental world. Accordingly traces of its original extent may be diſcovered in almoſt every diſtrict of Aſia. Thoſe who are acquainted with that language have often found the ſimilitude of Shanſcrit words to thoſe of Perſian and Arabic, and even of Latin and Greek; and that not in technical and metaphorical terms, which refined arts and improved manners might have occaſionally introduced, but in the main ground-work of language, in monoſyllables, the names of numbers, and appellations of ſuch things as would be firſt diſcriminated on the immediate dawn of civilization.

93 Traces of Shanſcrit in every diſtrict of Aſia and elſewhere.

The ancient coins of many different and diſtant kingdoms of Aſia are ſtamped with Shanſcrit characters, and moſtly contain alluſions to the old Shanſcrit mythology. Beſides, in the names of perſons and places, of titles and dignities, which are open to general notice, even to the fartheſt limits of Aſia, may be found manifeſt traces of the Shanſcrit. The ſcanty remains of Coptic antiquities afford little ſcope for compariſon between that idiom and this primitive tongue; but there ſtill exiſts ſufficient ground to conjecture, that, at a very early period, a correſpondence did ſubſiſt between theſe two nations. The Hindoos pretend, that the Egyptians frequented their country as diſciples, not as inſtructors; that they came to ſeek that liberal education and thoſe ſciences in Hindoſtan, which none of their own countrymen had ſufficient knowledge to impart. Perhaps we may examine the validity of this claim hereafter.

But though numberleſs changes and revolutions have from time to time convulſed Hindoſtan, that part of it which lies between the Indus and the Ganges ſtill preſerves that language whole and inviolate. Here they ſtill offer a thouſand books to the peruſal of the curious; many of which have been religiouſly handed down from the earlieſt periods of human exiſtence.

94 Number of books in that language.

The fundamental part of the Shanſcrit language is divided into three claſſes: *Dhaat*, or roots of verbs, which ſome call primitive elements; *Shubd*, or original nouns; and *Evya*, or particles. The latter are ever indeclinable, as in other languages; but the words comprehended in the two former claſſes muſt be prepared by certain additions and inflexions to fit them for a place in compoſition. And here it is that the art of the grammarian has found room to expand itſelf, and to employ all the powers of refinement. Not a ſyllable, not a letter, can be added or altered but by regimen; not the moſt trifling variation of the ſenſe, in the minuteſt ſubdiviſion of declenſion or conjugation, can be effected without the application of ſeveral rules: all the different forms for every change of gender, number, caſe, perſon, tenſe, mood, or degree, are methodically arranged for the aſſiſtance of the memory, according to an unerring ſcale. The number of the radical or elementary parts is about 700; and to theſe, as to the verbs of other languages, a very plentiful ſtock of verbal nouns owes its origin; but theſe are not thought to exceed thoſe of the Greek either in quantity or variety.

95 Characteriſtics of it.

To the triple ſource of words mentioned above, every term of truly Indian original may be traced by a laborious and critical analyſis. All ſuch terms as are thoroughly proved to bear no relation to any one of the Shanſcrit roots, are conſidered as the production of ſome remote and foreign idiom, ſubſequently ingrafted upon the main ſtock; and it is conjectured, that a judicious inveſtigation of this principle would throw a new light upon the firſt invention of many arts and ſciences, and open a freſh mine of philological diſcoveries. We ſhall now proceed to give as exact an account of the conſtituent parts of this language as the nature of our deſign will permit.

Shanſcrit and Bengaleſe Languages.

96 It is copious and nervous.

The Shanſcrit language is very copious and nervous. The firſt of theſe qualities ariſes in a great meaſure from the vaſt number of compound words with which it is almoſt overſtocked. "The Shanſcrit (ſays Sir William Jones), like the Greek, Perſian, and German, delights in compounds; but to a much higher degree, and indeed to ſuch exceſs, that I could produce words of more than 20 ſyllables; not formed ludicrouſly like that by which the buffoon in Ariſtophanes deſcribes a feaſt, but with perfect ſerioufneſs, on the moſt ſolemn occaſions, and in the moſt elegant works." But the ſtyle of its beſt authors is wonderfully conciſe. In the regularity of its etymology it far exceeds the Greek and Arabic; and, like them, has a prodigious number of derivatives from each primary root. The grammatical rules alſo are numerous and difficult, though there are not many anomalies. As one inſtance of the truth of this aſſertion, it may be obſerved, that there are ſeven declenſions of nouns, all uſed in the ſingular, the dual, and the plural numbers, and all of them differently formed, according as they terminate with a conſonant, with a long or a ſhort vowel; and again, different alſo as they are of different genders: not a nominative caſe can be formed to any one of theſe nouns without the application of at leaſt four rules, which vary likewiſe with each particular difference of the nouns, as above ſtated: add to this, that every word in the language may be uſed through all the ſeven declenſions, which is a full proof of the difficulty of the idiom.

The Shanſcrit grammars are called *Beeākĕrun*, of which there are many compoſed by different authors; ſome too abſtruſe even for the comprehenſion of moſt bramins, and others too prolix to be ever uſed but as references. One of the ſhorteſt, named the *Saraſootee*, contains between two and three hundred pages, and was compiled by Anoŏbhōōtēē Seroopĕnām Achārige, with a conciſeneſs that can ſcarcely be paralleled in any other language.

97 Shanſcrit alphabet.

The Shanſcrit alphabet contains 50 letters; and it is one boaſt of the bramins, that it exceeds all other alphabets in this reſpect: but it muſt be obſerved, that as of their 34 conſonants, near half carry combined ſounds, and that ſix of their vowels are merely the correſpondent long ones to as many which are ſhort, the advan-

Shanſcrit and Bengaleſe languages.

tage ſeems to be little more than fanciful. Beſides theſe, they have a number of characters which Mr Halhed calls connected vowels, but which have not been explained by the learned preſident of the Aſiatic Society.

* Plate CCCXC.

The Shanſcrit character uſed in Upper Hindoſtan * is ſaid to be the ſame original letter that was firſt delivered to the people by Brahma, and is now called *Diewnāgur*, or the language of angels, which ſhows the high opinion that the bramins have entertained of that character. Their conſonants and vowels are wonderfully, perhaps whimſically, modified and diverſified; to enumerate which, in this place, would contribute very little either to the entertainment or inſtruction of our readers. All theſe diſtinctions are marked in the *Beids* (1), and muſt be modulated accordingly; ſo that they produce all the effect of a laboured recitative: but by an attention to the muſic of the chant, the ſenſe of the paſſage recited equally eſcapes the reader and the audience. It is remarkable, that the Jews in their ſynagogues chant the Pentateuch in the ſame kind of melody; and it is ſuppoſed that this uſage has deſcended to them from the remoteſt ages.

98 Poetry.

The Shanſcrit poetry comprehends a very great variety of different metres, of which the moſt common are theſe:

The *munnee hurreneh chhund*, or line of 12 or 19 ſyllables, which is ſcanned by three ſyllables in a foot, and the moſt approved foot is the anapæſt.

The *cābee chhund*, or line of 11 ſyllables.

The *anŭſhtoſe chhund*, or line of eight ſyllables.

The poems are generally compoſed in ſtanzas of four lines, called *aſhlogues*, which are regular or irregular.

The moſt common aſhlogue is that of the *anŭſhtoſe chhund*, or regular ſtanza of eight ſyllables in each line. In this meaſure the greateſt part of the *Māhābāret* is compoſed. The rhyme in this kind of ſtanza ſhould be alternate; but the poets do not ſeem to be very nice in the obſervance of a ſtrict correſpondence in the ſounds of the terminating ſyllables, provided the feet of the verſe are accurately kept.

This ſhort *anŭſhtoſe aſhlogue* is generally written by two verſes in one line, with a pauſe between; ſo the whole then aſſumes the form of a long diſtich.

The irregular ſtanza is conſtantly called *anyāchhund*, of whatever kind of irregularity it may happen to conſiſt. It is moſt commonly compounded of the long line *cābee chhund* and the ſhort *anŭſhtoſe chhund* alternately; in which form it bears ſome reſemblance to the moſt common lyric meaſure of the Engliſh.

To purſue this ſubject to greater length is ſcarce poſſible for us, as matters ſtand at preſent. Our readers muſt ſuſpend their curioſity till more volumes of the *Aſiatic Reſearches* are publiſhed, where we make no doubt the whole myſtery of this extraordinary language will be plainly unfolded.

Perhaps our readers may feel a curioſity to be informed of the origin of this oriental tongue. If we believe the bramins themſelves, it was coeval with the race of man, as was obſerved towards the beginning of this ſection. The bramins, however, are not the only people who aſcribe a kind of eternity to their own particular dialect. We find that the Shanſcrit in its primitive deſtination was appropriated to the offices of religion. It is indeed pretended, that all the other dialects ſpoken in Hindoſtan were emanations from that fountain, to which they might be traced back by a ſkilful etymologiſt. This, we think, is an argument of no great conſequence, ſince we believe that all the languages of Europe, by the ſame proceſs, may be deduced from any one of thoſe current in that quarter of the globe. By a parity of reaſon, all the different dialects of Hindoſtan may be referred to the language in queſtion. Indeed, if we admit the authority of the Moſaic hiſtory, all languages whatſoever are derived from that of the firſt man. It is allowed that the language under conſideration is impregnated with Perſian, Chaldaic, Phœnician, Greek, and even Latin idioms. This, we think, affords a preſumption that the Shanſcrit was one of thoſe original dialects which were gradually produced among the deſcendants of Noah, in proportion as they gradually receded from the centre of population. What branch or branches of that family emigrated to Hindoſtan, it is not eaſy to determine. That they were a party of the deſcendants of Shem is moſt probable, becauſe the other ſepts of his poſterity ſettled in that neighbourhood. The ſum then is, that the Hindoos were a colony conſiſting of the deſcendants of the patriarch Shem.

Shanſcrit and Bengaleſe languages.

99 Origin of this tongue.

It appears, however, by almoſt numberleſs monuments of antiquity ſtill exiſting, that at a very early period a different race of men had obtained ſettlements in that country. It is now generally admitted, that colonies of Egyptians had peopled a conſiderable part of Hindoſtan. Numberleſs traces of their religion occur everywhere in thoſe regions. The very learned preſident himſelf is poſitive, that veſtiges of thoſe ſacerdotal wanderers are found in India, China, Japan, Tibet, and many parts of Tartary. Thoſe coloniſts, it is well known, were zealous in propagating their religious ceremonies wherever they reſided, and wherever they travelled. There is at the ſame time even at this day a ſtriking reſemblance between the ſacred rites of the vulgar Hindoos and thoſe of the ancient Egyptians. The prodigious ſtatues of Salſette and Elephanta fabricated in the Egyptian ſtyle; the vaſt excavations hewn out of the rock in the former; the wooly hair of the ſtatues, their diſtorted attitudes, their groteſque appearances, their triple heads, and various other configurations—plainly indicate a foreign original. Theſe phenomena ſuit no other people on earth ſo exactly as the ſons of Mizraim. The Egyptian prieſts uſed a ſacred character, which none knew but themſelves; none were allowed to learn except their children and the choice of the initiated. All theſe features mark an exact parallel with the bramins of the Hindoos. Add to this, that the dreſs, diet, luſtrations, and other rites of both ſects, bore an exact reſemblance to each other. Sir William Jones hath juſtly obſerved, that the letters of the Shanſcrit, ſtript of all adventitious appendages, are really the ſquare Chaldaic cha-

(1) The books which contain the religion of the bramins.

Shanſcrit and Bengaleſe Languages.

characters. We learn from Caſſiodorus * the following particulars: "The height of the obeliſks is equal to that of the circus; now the higher is dedicated to the ſun, and the lower to the moon, where the ſacred rites of the ancients are intimated by Chaldaic ſignatures by way of letters." Here then it is plain that the ſacred letters of the Egyptians were Chaldaic, and it is allowed that thoſe of the Bramins were of the ſame complexion; which affords a new preſumption of the identity of the Shanſcrit with thoſe juſt mentioned.

* Lib. iii. epiſt. 2. et 51.

That the Egyptians had at a very early period penetrated into Hindoſtan, is univerſally admitted. Oſiris, their celebrated monarch and deity, according to their mythology, conducted an army into that country; taught the natives agriculture, laws, religion, and the culture of the vine, &c. He is ſaid at the ſame time to have left colonies of prieſts, as a kind of miſſionaries, to inſtruct the people in the ceremonies of religion. Seſoſtris, another Egyptian potentate, likewiſe over-ran Hindoſtan with an army, and taught the natives many uſeful arts and ſciences. When the paſtor-kings invaded and conquered Egypt, it is probable that numbers of the prieſts, in order to avoid the fury of the mercileſs invaders who demoliſhed the temples and perſecuted the miniſters of religion, left their native country, and tranſported themſelves into India. Theſe, we ſhould think, were the authors both of the language and religion of the bramins. This dialect, as imported by the Egyptians, was probably of the ſame contexture with the ſacred language of that people, as it appeared many ages after. The Indians, who have always been an inventive and induſtrious race of men, in proceſs of time cultivated, improved, diverſified, and conſtructed that language with ſuch care and aſſiduity, that it gradually arrived at that high degree of perfection in which at preſent it appears.

Had the learned preſident of the Aſiatic Society (M), when he inſtituted a comparifon between the deities of Hindoſtan on the one ſide and of Greece and Italy on the other, examined the analogy between the gods of Hindoſtan and thoſe of Egypt, we think he would have performed a piece of ſervice ſtill more eminent. Having firſt demonſtrated the ſimilarity between the divinities of India and Egypt, he might then have proceeded to inveſtigate the reſemblance of the Egyptian and Phœnician with thoſe of Greece and Rome. By this proceſs a chain would have been formed which would have conducted his reader to comprehend at one view the identity of the Zabian worſhip almoſt throughout the world.

We foreſee that it will be objected to this hypotheſis, that all the dialects of Hindoſtan being clearly reducible to the Shanſcrit, it is altogether impoſſible that it could have been a foreign language. To this we anſwer, that at the early period when this event is ſuppoſed to have taken place, the language of the poſterity of the ſons of Noah had not deviated conſiderably from the primitive ſtandard, and conſequently the language of the Egyptians and the Hindoos was nearly the ſame. The Shanſcrit was gradually improved: the language of the vulgar, as is always the caſe, became more and more different from the original archetype; but ſtill retained ſuch a near reſemblance to the mother-tongue as proved the verity of its extraction.

Shanſcrit and Bengaleſe Languages.

100 Bengaleſe language derived from the Shanſcrit.

To the preceding account of the Shanſcrit language we ſhall annex a few ſtrictures on the language of Bengal, which we believe is derived from the other, and is in moſt common uſe in the ſouthern parts of Hindoſtan.

Though moſt of the ancient oriental tongues are read from right to left, like the Hebrew, Chaldaic, Arabic, &c. yet ſuch as properly belong to the whole continent of India proceed from left to right like thoſe of Europe. The Arabic, Perſian, &c. are the grand ſources whence the former method has been derived; but with theſe, the numerous original dialects of Hindoſtan have not the ſmalleſt connection or reſemblance.

The great number of letters, the complex mode of combination, and the difficulty of pronunciation, are conſiderable impediments to the ſtudy of the Bengal language; and the careleſſneſs and ignorance of the people, and the inaccuracy of their characters, aggravate theſe inconveniences. Many of their characters are ſpurious; and theſe, by long uſe and the hurry of buſineſs, are now almoſt naturalized into the language.

101 Bengal alphabet.

The Bengal alphabet, like that of the Shanſcrit, from which it is derived, conſiſts of 50 letters, whoſe form, order, and ſound, may be learned from Mr Halhed's grammar of the Bengal language. The vowels are divided into long and ſhort, the latter of which are often omitted in writing. Moſt of the oriental languages are conſtructed upon the ſame principle, with reſpect to the omiſſion of the ſhort vowel. The Hebrews had no ſign to expreſs it before the invention of the Maſoretic points; in Arabic it is rarely inſerted unleſs upon very ſolemn occaſions, as in the Koran; in the modern Perſian it is univerſally omitted: ſo to all the conſonants in the Shanſcrit, the ſhort vowel is an invariable appendage, and is never ſignified by any diacritical mark; but where the conſtruction requires that the vowel ſhould be dropped, a particular ſtroke is ſet under the letter. It is in vain to pretend, in a ſketch like this, to detail the ſound and pronunciation of theſe letters: this muſt be acquired by the ear and by practice.

102 Genders, &c. of this language.

In the Bengal language there are three genders, as in Greek, Arabic, &c. The authors of this threefold diviſion of genders, with reſpect to their precedence, appear to have conſidered the neuter as a kind of reſiduum reſulting from the two others, and as leſs worthy or leſs comprehenſive than either (ſee Section of the *Greek*). The terminations uſually applied upon this occaſion are *aa* for the maſculine, and *ee* for the feminine. In Shanſcrit, as in Greek and Latin, the names of all things inanimate have different genders, founded on vague and incomprehenſible diſtinctions: the ſame is the caſe with the Bengal.

(M) See that gentleman's diſcourſe, *Reſearches*, Vol. I.

Shanſcrit and Bengaleſe Languages.

A Shanſcrit noun, on its firſt formation from the general root, exiſts equally independent of caſe as of gender. It is neither nominative, nor genitive, nor accuſative; nor is impreſſed with any of thoſe modifications which mark the relation and connection between the ſeveral members of a ſentence. In this ſtate it is called an *imperfect* or *crude* noun. To make a nominative of a word, the termination muſt be changed and a new form ſupplied. Thus we ſee, that in the Shanſcrit, at leaſt, the nominative has an equal right with any other inflexion to be called a caſe. Every Shanſcrit noun has ſeven caſes, excluſive of the vocative; and therefore comprehends two more than even thoſe of the Latin. Mr Halhed above mentioned details all the varieties of theſe with great accuracy, to whoſe Grammar we muſt refer our readers. The Bengal has only four caſes beſide the vocative; in which reſpect it is much inferior to the other.

103 Peculiarities of Shanſcrit and Bengaleſe nouns.

It would be difficult to account for the variety of words which have been allotted to the claſs of pronouns by European grammarians. The firſt and ſecond perſon are chiefly worthy of obſervation: theſe two ſhould ſeem to be confined to rational and converſable beings only: the third ſupplies the place of every object in nature; wherefore it muſt neceſſarily be endued with a capacity of ſhifting its gender reſpectively as it ſhifts the ſubject; and hence it is in Shanſcrit frequently denominated an adjective. One of the demonſtratives *hic* or *ille* uſually ſerves for this purpoſe; and generally the latter, which in Arabic has no other name than *dhemeer el ghaayb*, "the pronoun of the abſentee," for whoſe name it is a ſubſtitute.

104 Bengaleſe pronouns.

In moſt languages where the verb has a ſeparate inflection for each perſon, that inflection is ſufficient to aſcertain the perſonality; but in Bengal compoſitions, though the firſt and ſecond perſons occur very frequently, nothing is more rare than the uſage of the pronoun of the third; and names of perſons are inſerted with a conſtant and diſguſting repetition, to avoid, as it ſhould ſeem, the application of the words HE and SHE. The ſecond perſon is always ranked before the firſt, and the third before the ſecond. The perſonal pronouns have ſeven caſes, which are varied in a very irregular manner. Leaving theſe to the Bengalian grammar, we ſhall proceed to the *verb*.

The Shanſcrit, the Arabic, the Greek and Latin verbs, are furniſhed with a ſet of inflections and terminations ſo comprehenſive and ſo complete, that by their form alone they can expreſs all the different diſtinctions both of perſons and time. Three ſeparate qualities in them are perfectly blended and united. Thus by their root they denote a particular act, and by their inflection both point out the time when it takes place and the number of the agents. In Perſian, as in Engliſh, the verb admits but of two forms, one for the preſent tenſe and one for the aoriſt; and it is obſervable, that while the paſt tenſe is provided for by a peculiar inflexion, the future is generally ſupplied by an additional word conveying only the idea of time, without any other influence on the act implied by the principal verb. It is alſo frequently neceſſary that the different ſtate of the action, as perfect or imperfect, be further aſcertained in each of the tenſes, paſt, preſent, and future. This alſo, in the learned languages, is performed by other variations of inflections, for which other verbs and other particles are applied in the modern tongues of Europe and Perſia.

Shanſcrit and Bengaleſe Languages.

Every Shanſcrit verb has a form equivalent to the middle voice of the Greek, uſed through all the tenſes with a reflective ſenſe, and the former is even the moſt extenſive of the two in its uſe and office: for in Greek the reflective can only be adopted intranſitively when the action of the verb deſcends to no extraneous ſubject; but in Shanſcrit, the verb is both reciprocal and tranſitive at the ſame time.

105 Middle voice of Shanſcrit verbs.

Neither the Shanſcrit, nor the Bengaleſe, nor the Hindoſtanic, have any word preciſely anſwering to the ſenſe of the verb *I have*, and conſequently the idea is always expreſſed by *eſt mihi*; and of courſe there is no auxiliary form in the Bengal verb correſpondent to *I have written*, but the ſenſe is conveyed by another mode. The verb ſubſtantive, in all languages, is defective and irregular, and therefore the Shanſcrit calls it a *ſemi-verb*. It is curious to obſerve that the preſent tenſe of this verb, both in Greek and Latin, and alſo in the Perſian, appears plainly to be derived from the Shanſcrit. In the Bengaleſe, this verb has but two diſtinctions of time, the preſent and the paſt; the terminations of the ſeveral perſons of which ſerve as a model for thoſe of the ſame tenſe in all other verbs reſpectively.

106 Characteriſtics of the Bengaleſe verbs.

Verbs of the Bengal language may be divided into three claſſes, which are diſtinguiſhed by their penultimate letter. The ſimple and moſt common form has an open conſonant immediately preceding the final letter of the infinitive. The ſecond is compoſed of thoſe words whoſe final letter is preceded by another vowel or open conſonant going before it. The third conſiſts entirely of cauſals derived from verbs of the firſt and ſecond conjugations. The reader will eaſily gueſs at the impoſſibility of proſecuting this ſubject to any greater length: we ſhall therefore conclude with a few remarks collected from the grammar ſo often mentioned, which we apprehend may be more amuſing, if not more inſtructing.

The Greek verbs in μι are formed exactly upon the ſame principle with the Shanſcrit conjugations, even in the minuteſt particulars. Inſtances of this are produced in many verbs, which from a root form a new verb by adding the ſyllable *mi*, and doubling the firſt conſonant. This mode furniſhes another preſumption of the Egyptian origin of the Shanſcrit. Many Greeks travelled into Egypt; many Egyptian colonies ſettled in Greece. By one or other of thoſe channels the foregoing innovation might have been introduced into the Greek language.

To form the paſt tenſe, the Shanſcrit applies a ſyllabic augment, as is done in the Greek: the future has for its characteriſtic a letter analogous to that of the ſame tenſe in the Greek, and it omits the reduplication of the firſt conſonant. It may be added, that the reduplication of the firſt conſonant is not conſtantly applied to the preſent tenſe of the Shanſcrit more than to thoſe of the Greek.

The natural ſimplicity and elegance of many of the Aſiatic languages are greatly debaſed and corrupted by the continual abuſe of auxiliary verbs; and this inconvenience has evidently affected the Perſian, the Hindoſtan, and the Bengal idioms.

The

Shanſcrit and Bengaleſe Languages.

The infinitives of verbs in the Shanſcrit and Bengaleſe are always uſed as ſubſtantive nouns. Every body knows that the ſame mode of arrangement very often occurs in the Greek.

In the Shanſcrit language, as in the Greek, there are forms of infinitives and of participles comprehenſive of time; there are alſo other branches of the verb that ſeem to reſemble the gerunds and ſupines of the Latin.

All the terms which ſerve to qualify, to diſtinguiſh, or to augment, either *ſubſtance* or *action*, are claſſed by the Shanſcrit grammarians under one head; and the word uſed to expreſs it literally ſignifies *increaſe* or *addition*. According to their arrangement, a ſimple ſentence conſiſts of three members; the *agent*, the *action*, the *ſubject*: which, in a grammatical ſenſe, are reduced to two; the *noun* and the *verb*. They have a particular word to ſpecify ſuch words as amplify the noun which imports quality, and anſwers to our *adjectives* or *epithets*: Such as are applied to denote relation or connection, are intimated by another term which we may tranſlate *prepoſition*.

107 Shanſcrit and Bengaleſe adjectives.

The adjectives in Bengaleſe have no diſtinction of gender or number; but in Shanſcrit theſe words preſerve the diſtinction of gender, as in the Greek and Latin.

Prepoſitions are ſubſtitutes for caſes, which could not have been extended to the number neceſſary for expreſſing all the ſeveral relations and predicaments in which a noun may be found, without cauſing too much embarraſſment in the form of a declenſion. Thoſe are too few in the Greek language, which occaſions much inconvenience. See ſect. *Greek*.

The Latin is leſs poliſhed than the Greek, and of conſequence bears a much nearer reſemblance to the Shanſcrit, both in words, inflections, and terminations.

The learned are now convinced that the uſe of numerical figures was firſt derived from India. Indeed the antiquity of their application in that country far exceeds the powers of inveſtigation. All the numerals in Shanſcrit have different forms for the different genders, as in Arabic. There appears a ſtrong probability that the European method of computation was derived from India, as it is much the ſame with the Shanſcrit, though we think the Europeans learned it from the Arabians. The Bengaleſe merchants compute the largeſt ſums by *fours*; a cuſtom evidently derived from the original mode of computing by the fingers.

The Shanſcrit language, among other advantages, has a great variety in the mode of arrangement; and the words are ſo knit and compacted together, that every ſentence appears like one complete word. When two or more words come together *in regimine*, the laſt of them only has the termination of a caſe; the others are known by their poſition; and the whole ſentence ſo connected, forms but one compound word, which is called a *foot*.

Sect. VI. *Of the Chineſe Language.*

108 Antiquity of the Chineſe.

The Chineſe, according to the moſt authentic accounts, are a people of great antiquity. Their ſituation was ſuch, as, in the earlieſt ages of the world, in a great meaſure ſecured them from hoſtile invaſion. Their little commerce with the reſt of mankind precluded them the knowledge of thoſe improvements which a mutual emulation had often generated among other nations, who were ſituated in ſuch a manner, with relation to each other, as ſerved to promote a mutual intercourſe and correſpondence. As China is a large and fertile country, producing all the neceſſaries, conveniencies, and even the luxuries of life, its inhabitants were not under the neceſſity of looking abroad for the two former, nor expoſed to the temptation of engaging in foreign commerce, in order to procure the latter. Perfectly ſatisfied with the articles which their own country produced, they applied themſelves entirely to the practice of agriculture and other arts connected with that profeſſion; and their frugality, which they retain even to this day, taught them the leſſon of being contented with little: of conſequence, though their population was almoſt incredible, the produce of their ſoil was abundantly ſufficient to yield them a ſubſiſtence. Their inventions were their own; and as they borrowed nothing from other people, they gradually began to deſpiſe the reſt of mankind, and, like the ancient Egyptians, branded them with the epithet of *barbarians*.

Chineſe Language.

Thoſe people had at an early period made amazing proficiency in the mechanical arts. Their progreſs in the liberal ſciences, according to the lateſt and indeed the moſt probable accounts, was by no means proportioned. In mathematics, geometry, and aſtronomy, their knowledge was contemptible; and in ethics, or moral philoſophy, the complexion of their laws and cuſtoms proves their ſkill to have been truly ſuperficial. They value themſelves very highly at preſent upon their oratorial talents; and yet of all languages ſpoken by any civilized people, theirs is confeſſedly the leaſt improved. To what this untowardly defect is owing, the learned have not yet been able to determine.

109 Their language an original tongue.

The language of the Chineſe is totally different from thoſe of all other nations, and bears very ſtrong ſignatures of an original tongue. All its words are monoſyllabic, and compoſitions and derivations are altogether unknown. Their nouns and verbs admit of no flexions: in ſhort, every thing relating to their idioms is peculiar, and incapable of being compared with any other dialect ſpoken by any civilized people. Moſt barbarous languages exhibit ſomething that reſembles an attempt towards thoſe diacritical modifications of ſpeech; whereas the Chineſe, after a ſpace of 4000 years, have not advanced one ſtep beyond the very firſt elements of ideal communication. This circumſtance, we think, is a plain demonſtration that they did not emigrate from that region where the primitive race of mankind is thought to have fixed its reſidence. Some have imagined, we believe with good reaſon, that they are a *Tartarian* race, which, breaking off from the main body of that numerous and widely extended people, directed their march towards the ſouth-eaſt. There, falling in with delightful and fertile plains which their poſterity now inhabit, they found themſelves accommodated ſo much to their liking, that they dropped all deſire of changing their habitations. The country of China is, indeed, ſo environed with mountains, deſerts, and ſeas, that

it

Chinese Language.

it would have been difficult for men in their primitive state to have emigrated into any of the neighbouring regions. Thus secluded from the rest of mankind, the Chinese, in all probability, were left to the strength of their own inventive powers to fabricate a language, as well as the other arts and improvements necessary for the support and convenience of life.

It is indeed obvious that their stock of vocables, when they emigrated from Tartary, was neither ample nor properly accommodated to answer the purposes of the mutual conveyance of ideas. With this slender stock, however, they seem to have been satisfied; for it does not appear that any additions were afterwards made to that which was originally imported. Instead of framing a new race of terms by compounding their primitive ones; instead of diversifying them by inflections, or multiplying them by derivatives, as is done in every other language; they rather chose to retain their primitive words, and by a variety of modifications, introduced upon their orthography or pronunciation, to accommodate them to a variety of significations. Were it possible to scrutinize all the Tartarian dialects, and to reduce them to their primitive monosyllabic character, perhaps the original language of the Chinese might be investigated and ascertained. We know that attempts have been made to compare it with some of the other Asiatic languages, especially the *Hebrew*: This labour has, however, proved unsuccessful, and no primeval identity has been discovered. Before this comparison could be instituted with the most distant prospect of success, the language last mentioned must be stripped of all its adventitious qualities; and not only so, but it must be reduced to the monosyllabic tone, and then contrasted with the Chinese monosyllables; an undertaking which we are persuaded would not be readily executed. After all, we are convinced that no resemblance of any importance would be discovered.

110 Process of its fabrication.

The Chinese language must then, in our opinion, have been a Tartarian dialect, as the people themselves were colonists from Tartary. We have observed above, that those people have not hitherto found out the art of composition of words. This is the more surprising, when we consider that, in the characters which form their written language, they employ many compositions. For example, the character by which they represent *misfortune*, is composed of one hieroglyphic which represents a *house*, and another which denotes *fire*; because the greatest misfortune that can befal a man is to have his house on fire. With respect to the language which they use in speech, though they very often employ many words to express one thing, yet they never run them together into one word, making certain changes upon them that they may incorporate the more conveniently, but always preserve them entire and unaltered.

111 Paucity of its words

The whole number of words in the Chinese language does not exceed 1200: the nouns are but 326. It must certainly appear surprising, that a people whose manners are so highly polished and refined, should be able to express so many things as must of necessity attend such a course of life by so small a number of words, and those too monosyllables. The difficulties which attend this singular mode must be felt almost every instant; circumstances which, according to the ordinary course of things, should have induced them to attempt both an augmentation of the number of their words and an extension of those which they had by composition and derivation. We learn from Du Halde† that the Chinese have two different dialects: the one vulgar, which is spoken by the vulgar, and varies according to the different provinces; the other is called the *Mandarin language*, and is current only among the learned. The latter is properly that which was formerly spoken at court in the province of *Kiang-nan*, and gradually spread among the polite people in the other provinces. Accordingly, this language is spoken with more elegance in the provinces adjoining to *Kiang-nan* than in any other part of the kingdom. By slow degrees it was introduced into all parts of the empire, and consequently became the universal language.

† *Hist. of China*, vol. ii.

Chinese Language.

It then appears that the modern language of China was originally the court dialect, and utterly unknown to the bulk of the people. From this circumstance we think it may fairly be concluded that this dialect was deemed the royal tongue, and had been fabricated on purpose to distinguish it from the vulgar dialects. We learn from Heliodorus, that the § Ethiopians had a royal language which was the same with the sacred idiom of the Egyptians. This Mandarin tongue was originally an artificial dialect fabricated with a view to enhance the majesty of the court, and to raise its very style and diction above that of the rest of mankind. The Chinese, a wonderfully inventive people, might actually contrive a language of that complexion, with an intention to render it obscure and enigmatical (N). Such a plan would excite their admiration, and would at the same time greatly exceed their comprehension. In process of time, when the Chinese empire was extended, the Mandarines who had been brought up at court, and understood nothing of the provincial dialects, found it convenient to have the most eminent persons in every province taught the language employed by themselves, in order to qualify them for transacting the affairs of government with them in a language which both understood. By this means the royal dialect descended to the vulgar, and in process of time became universal. The Tartar dialect formerly in use vanished; only a few vestiges of it remained; which gradually incorporating with the royal language, occasioned the variation of provincial tongues above-mentioned.

§ *Æthiop.* lib. vi.

We are therefore clearly of opinion, that the modern language of the Chinese was deduced from the original Mandarine, or court dialect, and that this last was an artificial speech fabricated by the skill and ingenuity of that wonderful people. The learned have long held it up as the primary dialect, because, say they, it bears

(N) An attempt of this nature, among a people like the Chinese, is by no means improbable; nor is its success less probable. For a proof of this, we need only have recourse to Bishop Wilkins's Artificial Language, and Psalmanazar's Dictionary of the language of Formosa.

Chinese Language.

bears all the ſignatures of an original unimproved language. In our opinion, nothing appears more ingeniouſly artificial. It is univerſally allowed that, in its ſtructure, arrangement, idioms, and phraſeology, it reſembles no other language. Is not every learned man now convinced that all the Aſiatic languages yet known, diſcover unequivocal ſymptoms of their cognation and family reſemblance? The Ethiopians, Chaldeans, Arabians, Perſians, Egyptians, Hebrews, Phœnicians, the Brahmans, Bengaleſe, the Hindoos bordering upon China, all ſpeak only different dialects of one language, varying from the original in dialect only, ſome in a greater ſome in a leſſer degree: why ſhould the Chineſe alone ſtand altogether inſulated and unallied?

The languages of the North all wear congenial features. The Tartar, or Tatar dialects of every clan, of every canton, of every denomination, exhibit the moſt palpable proofs of a near affinity: the Gothic and Sclavonian dialects, which pervade a great part of Europe and ſome parts of Aſia, are obviouſly brethren, and may eaſily be traced up to an Aſiatic original. Even ſome of the American jargon dialects contain vocables which indicate an Aſiatic or European original. Our readers, we flatter ourſelves, will agree with us, that had the language of the Chineſe been the original language, a reſemblance muſt have ſtill exiſted between it and its deſcendants. If it had originated from any other language, it would have retained ſome characteriſtic features of its parent archetype. As neither of theſe are to be found in the fabric of the language under conſideration, the concluſion muſt be, that it is a language entirely different from all other tongues; that it is conſtructed upon different principles, deſcended from different parents, and framed by different artiſts.

The Chineſe themſelves have a common and immemorial tradition, that their language was framed by *Yao* their firſt emperor, to whom they attribute the invention of every thing curious, uſeful, and ornamental. Traditional hiſtory, when it is ancient, uniform, and univerſal, is generally well founded: upon this occaſion we think the tradition above-mentioned may be fairly admitted as a collateral evidence.

112 A proof of its artificial ſtructure.

The paucity of vocables contained in this ſingular language, we think another preſumption of its artificial contexture. The Chineſe *Onomatheta* would find it an arduous taſk to deviſe a great number of new terms, and would therefore reſt ſatisfied with the ſmalleſt number poſſible. In other languages we find the like economy was obſerved. Rather than fabricate new words, men choſe ſometimes to adapt old words to new, and, upon ſome occaſions, even to contrary ſignifications. To ſpare themſelves the trouble of coining new terms, they contrived to join ſeveral old ones into one; whence aroſe a numerous race of compounds. Derivatives too were fabricated to anſwer the ſame purpoſe. By this proceſs, inſtead of creating new vocables, old ones were compounded, diverſified, deflected, ramified, metamorphoſed, and tortured into a thouſand different ſhapes.

The Greek is deſervedly eſteemed a rich and copious language; its radical words have been curiouſly traced by ſeveral learned men, who, after the moſt laborious and exact ſcrutiny, have found that they do not amount to more than 300. The Shanſcrit language is highly compounded; its radical terms, however, are very few in number. Upon the whole, we think we may conclude, that the more any language abounds in compounds and derivatives, the ſmaller will be the number of its radical terms. The Arabic admits of no compoſition, and of conſequence its words have been multiplied almoſt *in infinitum*; the Shanſcrit, the Perſian, and the Greek, abound with compounds, and we find their radicals are few in proportion.

Chineſe Language.

113 Three different methods of enriching a language.

There are, we think, three different methods which may be employed in order to enrich and extend the range of a language. 1ſt, By fabricating a multitude of words; the plan which has been purſued by the Arabs. 2d, By framing a multitude of compounds and derivatives; the artifice employed by the Greeks and the authors of the Shanſcrit. 3d, By varying the ſignification of words without enlarging their number; the method practiſed by the Chineſe and their coloniſts. The Arabians, we think, have ſhown the moſt fertile and inventive genius, ſince they have enriched their language by actually creating a new and a moſt numerous race of words. The fabricators of the Shanſcrit and the collectors of the Greek have exhibited art, but *comparatively* little fertility of genius. Leaving, therefore, the Arabians, as in juſtice we ought, maſters of the field in the conteſt relating to the formation of language, we may range the Greek and Shanſcrit on the one ſide, and the Chineſe on the other; and having made this arrangement, we may attempt to diſcover on which ſide the largeſt proportion of genius and invention ſeems to reſt.

The Greek and Shanſcrit (for we have ſelected them as moſt highly compounded) exhibit a great deal of art in modifying, arranging, and diverſifying their compounds and derivatives, in ſuch a manner as to qualify them for intimating complex ideas; but the Chineſe have performed the ſame office by the help of a race of monoſyllabic notes, ſimple, inflexible, invariable, and at the ſame time few in number. The queſtion then comes to be, whether more art is diſplayed in new-modelling old words by means of declenſions, conjugations, compounds, and derivatives; or by deviſing a plan according to which monoſyllabic radical terms, abſolutely invariable, ſhould, by a particular modification of ſound, anſwer all the purpoſes performed by the other. The latter appears to us much more ingeniouſly artificial. The former reſembles a complicated machine compoſed of a vaſt number of parts, congenial indeed, but looſely connected; the latter may be compared to a ſimple, uniform engine, eaſily managed, and all its parts properly adjuſted. Let us now ſee in what manner the people in queſtion managed their monoſyllabic notes, ſo as to qualify them for anſwering all the purpoſes of ſpeech.

114 That adopted by the Chineſe.

Though the number of words in the Chineſe language does not amount to above 1200; yet that ſmall number of vocables, by their artificial management, is ſufficient to enable them to expreſs themſelves with eaſe and perſpicuity upon every ſubject. Without multiplying words, the ſenſe is varied almoſt *in infinitum* by the variety of the accents, inflections, tones, aſpirations, and other changes of the voice and enunciation; circumſtances which make thoſe who do not

Chinese Language.

thoroughly understand the language frequently mistake one word for another. This will appear obvious by an example.

The word *teou* pronounced slowly, drawing out the *u* and raising the voice, signifies a *lord* or *master*. If it is pronounced with an even tone, lengthening the *u*, it signifies a *hog*. When it is pronounced quick and lightly, it imports a *kitchen*. If it be pronounced in a strong and masculine tone, growing weaker towards the end, it signifies a *column*.

By the same economy, the syllable *po*, according to the various accents, and the different modes of pronunciation, has eleven different significations. It signifies *glass*, *to boil*, *to winnow rice*, *wife or liberal*, *to prepare*, *an old woman*, *to break or cleave*, *inclined*, *a very little*, *to water*, *a slave or captive*. From these examples, and from almost numberless others which might be adduced, it is abundantly evident that this language, which at first sight appears so poor and confined, in consequence of the small number of the monosyllables of which it is composed, is notwithstanding very copious, rich, and expressive.

Again, the same word joined to various others, imports a great many different things; for example *mou*, when alone, signifies a *tree*, *wood*; but when joined with another word, it has many other significations. *Mou leou*, imports "wood prepared for building;" *mou lan*, is "bars, or wooden grates;" *mou hia*, "a box;" *mou fang*, "a chest of drawers;" *mou tsiang*, "a carpenter;" *mou eul*, "a mushroom;" *mou nu*, "a sort of small orange;" *mou sing*, "the planet Jupiter;" *mou mien*, "cotton," &c. This word may be joined to several others, and has as many different significations as it has different combinations.

Thus the Chinese, by a different arrangement of their monosyllables, can compose a regular and elegant discourse, and communicate their ideas with energy and precision; nay even with gracefulness and propriety. In these qualities they are not excelled either by the Europeans or Asiatics, who use alphabetical letters. In fine, the Chinese so naturally distinguish the tones of the same monosyllable, that they comprehend the sense of it, without making the least reflection on the various accents by which it is determined.

115 Consequences of this method on pronunciation.

We must not, however, imagine, as some authors have related, that those people cant in speaking, and make a sort of music which is very disagreeable to the ear; these different tones are pronounced so curiously, that even strangers find it difficult to perceive their difference even in the province of *Kiang-nan*, where the accent is more perfect than in any other. The nature of it may be conceived by the guttural pronunciation in the Spanish language, and by the different tones that are used in the French and Italian: these tones are almost imperceptible; they have, however, different meanings, a circumstance which gave rise to the proverb, that *the tone is all*.

If the fineness and delicacy of their tones are such as to be scarce perceptible to a stranger, we must suppose that they do not rise high, but only by small intervals; so that the music of their language must somewhat resemble the music of the birds, which is within a small compass, but nevertheless of great variety of notes. Hence it will follow, that strangers will find it very difficult, if not impossible, to learn this language; more especially if they have not a delicate ear and a flexible voice, and also much practice. The great difference then between the Chinese and Greek accents consists in this, that the Greeks had but two accents, the grave and acute, distinguished by a large interval, and that not very exactly marked: for the acute, though it never rises above a fifth higher than the grave, did not always rise so high, but was sometimes pitched lower according to the voice of the speaker. The Chinese must have many more accents, and the intervals between them must be much smaller, and much more carefully marked; for otherwise it would be impossible to distinguish them. At the same time, their language must be much more musical than the Greek, and perhaps more so than any language ought to be; but this becomes necessary for the purposes above-mentioned. Du Halde is positive, that notwithstanding the perpetual variation of accents in the Chinese tongue, and the almost imperceptible intervals between these tones, their enunciation does not resemble singing: many people, however, who have resided in China, are equally positive that the tone with which they utter their words does actually resemble *canting*; and this, when we consider the almost imperceptible intervals by which they are perpetually raising and lowering the tone of their voice, appears to us highly probable.

Chinese Language.

As the people of whose language we are treating at present communicate a variety of different significations to their monosyllabic words by their different accentuation, so they employ quantity for the very same purpose. By lengthening or shortening the vowels of their words, they employ them to signify very different things. The same they perform by giving their words different aspirations, as likewise by sounding them with different degrees of roughness and smoothness; and even sometimes by the different motion, posture, or attitude, with which their enunciation is accompanied. By these methods of diversifying their monosyllables (says Du Halde), they make 330 of them serve all the purposes of language, and these too not much varied in their termination; since all the words in that language either terminate with a vowel or with the consonant *n*, sometimes with the consonant *g* annexed.

From this account, we think it is evident that the Chinese, by a wonderful exertion of ingenuity, do, by different tones and prosodical modifications, by means of a very inconsiderable number of words, all invariable radicals, actually perform all that the most polished nations have been able to atchieve by their compounds, derivatives, &c. diversified by declensions, conjugations, and flexions of every kind; circumstances which, in our opinion, reflect the greatest honour on their inventive powers.

116 Grammar of the Chinese.

With respect to the grammar of this language, as it admits of no flexions, all their words being indeclinable, their cases and tenses are all formed by particles. They have no idea of genders; and even the distinction of numbers, which in almost all other languages, even the most unimproved, is marked by a particular word, is in the Chinese only indicated by a particle. They have only the three simple tenses, namely, the past, present, and future; and for want of different

Chinese Language.

different terminations, the same word stands either for the verb or the verbal substantive, the adjective or the substantive derived from it, according to its position in the sentence.

The Chinese language being composed of monosyllables, and these indeclinable, can scarce be reduced to grammatical rules: we shall, however, attempt to lay before our readers as much of the texture of that singular dialect as may enable them to form some vague idea of its genius and constitution. We shall begin with the letters, and proceed regularly to the remaining parts as they naturally succeed each other.

117 Chinese letters or characters

The art of joining the Chinese monosyllables together is extremely difficult, and requires a very long and laborious course of study. As they have only figures by which they can express their thoughts, and have no accents in writing to vary the pronunciation, they are obliged to employ as many different figures or characters as there are different tones, which give so many different significations to the same word. Besides, some single characters signify two or three words, and sometimes even a whole period. For example, to write these words, *good morrow, Sir*, instead of joining the characters which signify *good* and *morrow* with that of *Sir*, a different character must be used, and this character alone expresses these three words. This circumstance greatly contributes to multiply the Chinese characters.

This method of joining the monosyllables is indeed sufficient for writing so as to be understood; but it is deemed trifling, and is used only by the vulgar. The style that is employed, in order to shine in composition, is quite different from that which is used in conversation, though the words are in reality the same. In writings of that species, a man of letters must use more elegant phrases, more lofty expressions, and the whole must be dignified with tropes and figures which are not in general use, but in a peculiar manner adapted to the nature of the subject in question. The characters of Cochin china, of Tong-king, of Japan, are the same with those of the Chinese, and signify the same things; though, in speaking, these nations do not express themselves in the same manner: of consequence the language of conversation is very different, and they are not able to understand each other; while, at the same time, they understand each other's written language, and use all their books in common.

The learned must not only be acquainted with the characters that are employed in the common affairs of life, but must also understand their various combinations, and the numerous and multiform dispositions and arrangements which of several simple strokes make the compound characters. The number of their characters amounts to 80,000; and the man who knows the greatest number of them is of course the most learned. From this circumstance we may conclude, that many years must be employed to acquire the knowledge of such a prodigious number of characters, to distinguish them when they are compounded, and to remember their shape and import. After all, a person who understands 10,000 characters may express himself with tolerable propriety in this language, and may be able to read and understand a great number of books. The generality of their learned men do not understand above 15,000 or 20,000, and few of their doctors have attained to the knowledge of above 40,000. This prodigious number of characters is collected in their great vocabulary called *Hai-pien*. They have radical letters, which show the origin of words, and enable them to find out those which are derived from them: for instance, the characters of mountains, of trees, man, the earth, of a horse, under which must be sought all that belongs to mountains, trees, man, &c. In this search one must learn to distinguish in every word those strokes or figures which are above, beneath, on the sides, or in the body of the radical figure.

118 Exceedingly numerous,

Chinese Language.

Clemens Alexandrinus (see Section *Chaldean*, &c.) informs us, that the Egyptians employed three sorts of characters: The first was called the *epistolary*, which was used in writing letters; the second was denominated *sacred*, and peculiar to the sacerdotal order; the last *hieroglyphical*, which was appropriated to monumental inscriptions and other public memorials. This mode of representation was twofold: one, and the most simple, was performed by describing the picture of the object which they intended to represent, or at least one that resembled it pretty nearly; as when they exhibited the sun by a circle and the moon by a crescent: the other was properly symbolic; as when they marked *eternity* by a serpent with his tail in his mouth, the *air* by a man clothed in an azure robe studded with stars, &c.

The Chinese, in all probability, had the same variety of characters. In the beginning of their monarchy, they communicated their ideas by drawing on paper the images of the objects they intended to express; that is, they drew the figure of a bird, a mountain, a tree, waving lines, to indicate birds, mountains, forests, rivers, &c.

There were, however, an infinite number of ideas to be communicated, whose objects do not fall under the cognizance of the senses; such as the soul, the thoughts, the passions, beauty, deformity, virtues, vices, the actions of men and other animals, &c. This inconvenience obliged them to alter their original mode of writing, which was too confined to answer that purpose, and to introduce characters of a more simple nature, and to invent others to express those things which are the objects of our senses.

119 And truly hieroglyphical.

These modern characters are, however, truly hieroglyphical, since they are composed of simple letters which retain the signification of the primitive characters. The original character for the sun was a circle, thus ⊙; this they called *ga*: They now represent that luminary by the figure |☲|, to which they still give the original name. But human institutions having annexed to these last framed characters the very same ideas indicated by the original ones, the consequence is, that every Chinese letter is actually significant, and that it still retains its significancy, though connected with others. Accordingly the word *tsai*, which imports "misfortune, calamity," is composed of the letter *mien* "a house," and the letter *ho* "fire;" so that the symbolical character for misfortune is the figure of a house on fire. The Chinese characters, then, are not simple letters without any signification, like those of the Europeans and other Asiatics; but when they are joined together, they are so many hieroglyphics, which form images and express thoughts.

Upon the whole, the original characters of the Chi-

Chinese Language.

nese were real pictures (see Section of the *Egyptian* language); the next improvement was the symbolical character; the third and last stage is the present mode, in which artificial signs have been fabricated, in order to represent such thoughts or ideas as could not be represented by one or other of the methods above described. Du Halde, Vol. II. p. 400, *et seq.* has furnished us with rules for pronouncing the Chinese vowels and consonants; a piece of information which, we apprehend, would be of little consequence to our readers, and which we shall therefore pass over, and proceed to give a brief account of their grammar. As the whole language is composed of monosyllables, and these indeclinable, its grammatical structure must be simple and obvious: we shall only mention what to us appears singular and important.

120 Peculiarities of the Chinese parts of speech.

In the Chinese language there is no diversity of genders or cases, and of consequence no declensions. Very often the noun is not distinguished from the verb; and the same word which in one situation is a substantive, in another may become an adjective, and even a verb.

The adjective always goes before the substantive; but if it follows it, it becomes a substantive.

The cases and numbers are known only by the composition. The plural number is distinguished by the particle *men*, which is common to all nouns; but when the noun is preceded by some word that signifies number, the particle *men* is not annexed.

The Chinese genitive, both singular and plural, when it comes after nouns, is often made by *ti*; and there is no other case in that language. The same particle is sometimes placed after pronouns, as if they were derivatives.

The comparative degree is formed by adding the particle *keng*, which is always set before the noun, and signifies *much*. The particle *to* is sometimes used, which likewise imports *much*.

The Chinese have only three personal pronouns, *ngo* "I," *ni* "thou," and *ta* "he:" these become plural by adding the syllable *men*. They are made possessive by adding the syllable *ti*, as *ngo ti* "mine," *ni ti* "thine," *ta ti* "his." The patronymics are formed by putting the name of the city, country, &c. after the pronoun: *chon* is the pronoun relative *who*, *what*, *which*.

Chinese verbs have only three tenses, the preterperfect, the present, and the future. When there is no particle added to the verb, it is the present: the preterperfect is made by adding the particle *leao*: to distinguish the future tense they use the particle *tsiang* or *hoei*; and these are all the varieties incident to their verbs.

The Chinese language has no words that are properly adverbs; they only become so by custom, or by the place they possess in discourse. They are often obliged to employ several words to express the adverbs of other languages: they have none that are demonstrative, or proper for calling or exhorting; but in their stead they are obliged to use nouns and verbs.

121 Their numerals.

Perhaps our readers may wish to know the Chinese numerals; and may imagine that they bear a resemblance to those of the European or other Asiatic dialects. In this, however, they will be disappointed.

Chinese Language.

They stand as follows:

Y	One
Eut	Two
San	Three
Sace	Four
Ou	Five
Lou	Six
Tsi	Seven
Po	Eight
Kieou	Nine
Che	Ten
Che y	Eleven
Eut che	Twelve
San che	Thirteen
Pe	One hundred
Eut pe	Two hundred
Y tsien	One thousand
Y ouan	Ten thousand
Che ouan	Twenty thousand
Eut ouan	One hundred thousand
Che ouan	Two hundred thousand
Y pe ouan	One million.

There are a great many particles proper to numbers in the Chinese language: they are frequently used, and in a way peculiar to it; for every numeral has a particle importing the object to which it is attached. Thus *co* is used for man, and *y co* for a woman, &c. *hoei* is used for illustrious men; *tche* or *tchi* is used for ships, dogs, hens; *mey* is used for pearls and precious things; *pen* is used for books; *teng* is appropriated to oxen and cows; *too* is used for letters and little bundles of paper; *oo* is employed for corn and pulse. Those distinctions indicate a language manufactured on purpose to be employed by people who were too high and too haughty to converse with the vulgar.

122 Style of the Chinese writers.

The style of the Chinese, in their elaborate compositions, is mysterious, concise, and allegorical, after the eastern manner. It is often obscure to those who do not understand the language thoroughly; and it requires a considerable degree of skill to avoid mistakes in reading an author of elegance and sublimity. Their writers express a great deal in few words; and their expressions are lively, full of spirit, intermingled with bold comparisons and lofty metaphors. They affect to insert in their compositions many sentences borrowed from their five canonical books; and as they compare their books to pictures, so they liken these quotations to the five principal colours employed in painting; and in this their eloquence chiefly consists.

They prefer a beautiful character to the most finished picture; and nothing is more common than to see a single page covered with old characters, if they happen to be fair and elegant, sold at a very high price. They honour their characters in the most common books; and when they happen to light by chance upon a printed leaf, they gather it up with the greatest care and respect.

In China there are three varieties of language; that of the common people, that of the people of fashion, and that employed in writing books. Though the first is not so elegant as either of the other two, it is not however inferior to our European languages; though those who are but superficially acquainted with

Chinese Language.

the Chinese may, in fact, imagine it uncouth and barbarous. This low and rude language is pronounced and written many different ways, as is generally the case in other countries.

But a more polished, and at the same time a much more energetic, language, is employed in an almost infinite number of novels; some perhaps true, but many more the vehicles of fiction. These are replete with lively descriptions, characters highly finished, morality, variety, wit, and vivacity, in such a degree as to equal in purity and politeness the most celebrated authors of Europe. This was the language of the Mandarines; and though exquisitely beautiful in its kind, was still inferior to the language of books. This last might be styled the *hypersublime*; and of this there are several degrees and intervals before an author can arrive at what they call the language of the *kings*. This mode of writing cannot be well understood without looking upon the letters; but when understood, it appears easy and flowing. Each thought is generally expressed in four or six characters: nothing occurs that can offend the nicest ear; and the variety of the accents with which it is pronounced produces a soft and harmonious sound.

The difference between the *king* and their other books consists in the difference of the subjects upon which they are written. Those of the former are always grand and sublime, and of course the style is noble and elevated: those of the latter approach nearer to the common affairs and events of life, and are of consequence detailed in the Mandarin tongue. In writing on sublime subjects no punctuations are used. As these compositions are intended for the learned only, the author leaves to the reader to determine where the sense is complete; and those who are well skilled in the language readily find it out.

The copiousness of the Chinese language is in a great measure owing to the multitude of its characters. It is likewise occasioned, in some degree, by the difference of their signification, as also by the artificial method of their conjunction, which is performed most commonly by uniting them two and two, frequently three and three, and sometimes four and four.

123 Their books numerous and bulky.

Their books are very numerous and bulky, and of course exceedingly cumbrous. A dictionary of their language was compiled in this century. It consisted of 95 large volumes. An appendix was annexed of 25 volumes. Their other books are voluminous in proportion. The Chinese, one may say, are a nation of learned men. Few people of rank neglect the belles lettres; for ignorance in a man of any degree of eminence is deemed an indelible stain on his character.

For their manner of writing, the implements with which they write, and the materials upon which they draw their characters, we must remit our readers to the article WRITING. It would, we believe, afford our readers some pleasure, could we discover and explain the reasons which have hitherto prevented the Chinese from adopting the letters employed from time immemorial by the other nations of Europe and Asia.

The Chinese have ever looked upon themselves as greatly superior to the rest of mankind. In ancient times they entertained such contemptible notions of foreigners, that they scorned to have any further commerce with them than to receive their homage. They were indeed, at a very early period, highly revered by the Indians, Persians, and Tartars. In consequence of this veneration, they looked upon themselves as the favourites of heaven. They imagined they were situated in the middle of the earth, in a kind of paradise, in order to give laws to the rest of mankind. Other men they looked upon with contempt and disdain, and deemed them deformed in body and defective in mind, cast out into the remote corners of the world as the dross and refuse of nature. They boasted that themselves only had received from God rational souls and beautiful bodies, in order to qualify them for being sovereigns of the species.

Chinese Language.

124 Obstacles to their improvement in science and literature.

Such are the sentiments of the Chinese; and with such sentiments it is by no means surprising that their improvements in *language*, in *writing*, and other appendages of the belles lettres, have not been proportioned to their progress in mechanics. When people are once fully persuaded that they have already arrived at the summit of perfection, it is natural for them to sit down contented, and solace themselves with the idea of their own superior attainments. The Chinese had early entertained an exalted opinion of their own superiority to the rest of mankind; and therefore imagined that they had already carried their inventions to the *ne plus ultra* of perfection; the consequence was, that they could make no exertions to carry them higher.

The Chinese, for the space of 3000 years, had almost no intercourse with the rest of mankind. This was the consequence of their insulated situation.—They, of course, *compared themselves with themselves*; and finding that they excelled all their barbarian neighbours, they readily entertained an opinion that they excelled all the rest of mankind in an equal proportion. This conceit at once stifled the emotions of ambition, and deprived them of all opportunities of learning what was going forward in other parts of the world.

They despised every other nation. People are little disposed to imitate those whom they despise; and this perhaps may be one reason why they are at this day so averse from adopting the European inventions.

A superstitious attachment to the customs of the ancients, is the general character of the Asiatic nations. This is evidently a kind of diacritical feature among the Chinese. The institutions of *Fohi* are looked up to among them with equal veneration as those of *Thoth* were among the Egyptians. Among the latter, there was a law which made it capital to introduce any innovation into the music, painting, or statuary art, instituted by that legislator. We hear of no such law among the former; but custom established, and that invariably, for a space of 3000 years, might operate as forcibly among them as a positive law did among the people first mentioned. An attachment to ancient customs is often more powerful and more coercive than any law that can be promulgated and enforced by mere human authority. These reasons, we think, may be assigned as the impediments to the progress of the Chinese in the belles lettres, and perhaps in the cultivation of the other sciences.

Though the language of the Chinese is confessedly different from all the other known languages in its

Chinese Language.

125 Chinese words found in various other languages.

character and construction, it contains, however, a great number of words evidently of the same origin with those which occur in other dialects, used by people who, according to the natural course of things, could never have been connected with that remote country. A few of those we shall produce before we conclude this section. We shall begin with the import of the name *China*.

China, or, as the orientals write it, *Sin*, is perhaps the Latin *sinus*, "the bosom, the heart, the middle." The Chinese actually imagine that their country is situated in the very middle of the earth, and of consequence call it *Cham*, "the middle, the heart;" a denomination which exactly suits their opinion.

Tu, in Chinese, intimates every thing that falls under the cognizance of the senses, every thing that strikes the sight; in Latin, *tueor*.

Ta, a table, a plank, a figure that renders every thing sensible: 2. To see, to look upon, to appear; Greek ταν ταινω, whence τεινω, *tendo*.

Tue, to examine attentively, to inspect carefully.

Tui, the most apparent, chief, principal, first; 2. Lightning, thunder.

Teu, a sign by which to know one, letter of acknowledgment. All these ideas are contained in the Hebrew ת, *thu*, *signum*, which we believe has produced the Egyptian *theuth*, the god or godlike man who invented letters, geometry, music, astronomy, &c.

Tai, a dye, a theatre; Greek of old Θιαω, then Θιασμαι, "to see, to look."

Tam, Latin *tantum*, "so much."

Tan, land, country, region, a syllable annexed to the end of a great number of words. *Aqui tan*, *Aquitania*, "a land of water;" *Mauri tan*, *Mauritania*, "the land of the Moors." The orientals prefix *s*, whence *Farsistan*, *Farsistan*, "the land or country of the Persians;" *Chusistan*, *Chusistan*, "the country of Chuz;" *Turquestan*, *Turquestan*, "the land of the Turks."

Ti, a chief, an emperor, a title of dignity; whence the Greek τιω "to honour;" hence, too, the word *di*, "bright, glorious;" whence Δις "Jupiter, "Διος "divine;" the Latin *Dius*, now *Deus*, "God", and *Divus*, with the *digamma Æolicum* inserted; the Celtic *Dhia*, &c. It signified originally "bright, glorious," and was an epithet of the Sun.

Tum, Latin *tumeo*, "to swell."

Liven, "to love;" Hebrew לב, *leb*, "the heart;" Latin, *libet*. This word pervades all the dialects of the Gothic tongue, still retaining either the same or a nearly analogous signification.

Li, "letters;" Latin, *lino*, "to daub," as the Chinese actually do in forming their letters.

Lo, "to contain, that which contains;" Celtic, *log*; French, *loge*, *logis*, *loger*.

Lim, "a rule;" hence Latin, *linea*, "a line."

Su, "with;" Greek, συν, "with;" Celtic, *syn*, *sym*; whence Latin, *cum*, *con*, &c.

Xim, "very high, elevated, sacred, perfect;" Latin, *eximius*.

Sin, "the heart;" Persian, *Sin*, "the heart."

Sien, "chief, first;" Celtic, *can*, *cean*, *san*, "the head;" metaphorically, the chief, the first, the principal; Thibet, "*sen*, or *ken*, "great, elevated;" Arabic, *sume*, "to be elevated or raised."

Sim, or *Sing*, "a constellation, a star, an element;" Hebrew, *shem*; Greek, σημειον, σημα; Latin, *signum*. Greek Language.

Sie, "a man of learning;" Goth. Sax. Engl. "see; to see, seer."

Cem, "a priest;" Hebr. *cohen*; Syr. *con*; Egypt. *can*, *cun*.

Quin, "a king; Celtic, *ken*, *kend*, "head, chief;" Gothic, *konnig*; Germ. Flem. Eng. *king*, also *queen*.

Hu, "a door;" Goth. Germ. Engl. *hus*, *hausen*, *house*.

Min, "a river;" Welch, *men*, "the water of a river;" Latin, *mano*, "to flow," and perhaps *amvenus*, "pleasant."

Hen, "hatred;" Greek, αινος "cruel, horrible, odious."

Kiven, "a dog;" Greek κυων, *id*.

Ven, "beauty;" Latin, *Venus*, *venustas*; Iceland. Swed. *wen*, "pleasant;" Scotch, *winsome*.

Han, "the soul, breath;" Greek, ανεμος; Latin, *anima*, *animus*.

To these instances of the analogy between the Chinese language and those of the other people of Asia and Europe many more might be added; but the preceding, it is hoped, will serve as a specimen, which is all that can be expected from an inquiry of the nature of the present.

Sect. VII. *Of the Greek Language.*

126 Origin of the Greeks.

Before we enter upon the consideration of the essential and constituent parts of this noble language, we must beg leave to settle a few preliminaries, which, we trust, will serve to throw some light upon many points which may come under consideration in the course of the following disquisition.

The Greeks, according to the most authentic accounts, were descended of Javan or Jon, the fourth son of Japhet, the eldest son of the patriarch Noah. The Scriptures of old, and all the orientals to this day, call the Greeks *Jonim*, or *Jaunam*, or *Javenoth*. We have already observed, in the beginning of the article concerning the Hebrew language, that only a few of the descendants of Ham, and the most profligate of the posterity of Shem and Japhet, were concerned in building the tower of Babel. We shall not now resume the arguments then collected in support of that position; but proceed to investigate the character of that branch of the posterity of Javan which inhabited Greece and the neighbouring regions.

At what period the colonists arrived in these parts cannot be certainly determined; nor is it of great importance in the question before us. That they carried along with them into their new settlements the language of Noah and his family, is, we think, a point that cannot be controverted. We have endeavoured to prove that the Hebrew, or at least one or other of its sister-dialects, was the primæval language of mankind. The Hebrew, then, or one of its cognate branches, was the original dialect of the Jonim or Greeks.

Be that as it may, before these people make their appearance in profane history, their language deviates very widely from this original archetype. By what means, at what period, and in what length of time

Greek Language.

this change was introduced, is, we believe, a matter not easy to be elucidated. That it was progressive, is abundantly certain both from the rules of analogy and reason.

The colonies, which traversed a large tract of country before they arrived at their destined settlements, must have struggled with numberless difficulties in the course of their peregrinations. The earth, during the periods which immediately succeeded the universal deluge, must have been covered with forests, intersected with swamps, lakes, rivers, and numberless other impediments. As the necessaries, and a few of the conveniences of life, will always engross the first cares of mankind, the procuring of these comforts will, of necessity, exclude all concern about arts and sciences which are unconnected with these pursuits. Hence we think it probable, that most of those colonies which migrated to a very great distance from the plains of Shinar, which we believe to have been the original seat of mankind, in a great measure neglected the practice of the polite but unnecessary modes of civilization which their ancestors were acquainted with, and practised before the era of their migration. Certain it is, that those nations which continued to reside in the neighbourhood of that centre of civilization, always appear in a cultivated state; while, at the same time, the colonists who removed to a considerable distance appear to have sunk into barbarism, at a period more early than the annals of profane history can reach.—This appears to have been the situation of the primary inhabitants of Greece. Their own historians, the most partial to their own countrymen that can well be imagined, exhibit a very unpromising picture of their earliest progenitors. Diodorus Siculus, in delineating the character of the original men, we believe sketches his draught from the first inhabitants of Greece ‡. He represents them as absolute savages, going out in small parties to make war upon the wild beasts of the field, which (according to him) kept them in continual alarm. "Necessity obliged them to band together for their mutual security; they had not sagacity enough to distinguish between the wholesome and poisonous vegetables; nor had they skill enough to lay up and preserve the fruits of autumn for their subsistence during the winter." The scholiast on Pindar describes the situation of the inhabitants of Peloponnesus in the following manner ‖. "Now some have affirmed that the nymphs, who officiated in performing the sacred rites, were called *Melissæ*. Of these Mnaseas of Patara gives the following account. They prevailed upon men to relinquish the abominable practice of eating raw flesh torn from living animals, and persuaded them to use the fruits of trees for food.—Melissa, one of them, having discovered bee-hives, ate of the honey-combs, mingled the honey with water for drink, and taught the other nymphs to use the same beverage. She called bees Μελισσαι *Melissæ*, from her own name, and bestowed much care on the management of them.

"These things (says he) happened in Peloponnesus; nor is the temple of Ceres honoured without

127 Who were long a barbarous people.

‡ *Lib.* i.

‖ *Python.* Ode 4.

128 Progress of their civilization.

nymphs, because they first pointed out the mode of living on the fruits of the earth, and put an end to the barbarous practice of feeding on human flesh. The same ladies, too, from a sense of decency, invented garments made of the bark of trees."

Hecatæus the Milesian, treating of the Peloponnesians, affirms *, "that before the arrival of the Hellenes, a race of barbarians inhabited that region; and that almost all Greece was, in ancient times, inhabited by barbarians †. In the earliest times (says Pausanias) (o) barbarians inhabited most part of the country called *Hellas*." The original Greeks, if we may believe an author of deep research and superior ingenuity ‡, were strangers to all the most useful inventions of life. Even the use of fire was unknown till it was found out and communicated by Prometheus, who is thought to have been one of the first civilizers of mankind. Hence Æschylus ‖, introduces Prometheus commemorating the benefits which he had conferred upon mankind by his inventions, in a strain that indicates the uncultivated state of the world prior to the age in which he flourished. For the entertainment of our readers, we shall translate as much of that passage as suits our present purpose.

* *Strabo*, lib. 7.

† *Id.* lib. 1.

‡ *Plin. Nat. Hist.*

‖ *Prometh.* verse 44 &c.

——"Of the human race
Now hear the tale, how fooliſh erſt they were:
I taught them thought and exerciſe of reaſon;
If aught they ſaw before, they ſaw in vain.
Hearing, they heard not; all was ſhapeleſs dreams
For a long ſpace of time, at random mixt
In wild confuſion: for they neither knew
Tile-cover'd houſes ſtanding in the ſun,
Nor timber work; but, like the earth-bred ant,
They lodg'd in ſunleſs caves dug under ground:
No certain ſign had they of winter cold,
Nor of the flow'ry ſpring, or ſummer ſtore,
But I blindly manag'd all; till I them taught
What time the ſtars appear, what time they ſet,
Hard to be ſcan'd: then arithmetic rare,
That queen of arts, by dint of patient thought
Deſery'd, I taught them; and how vocal ſounds
From letters join'd aroſe."

This character, though applied to mankind in general, was in reality that of the most ancient Greeks. These forbidding features had been transmitted to the poet by tradition as those of his ancestors: he was a Greek, and of consequence imputes them to all mankind without distinction.

Phoroneus, the son and successor of Inachus §, is said to have civilized the Argives, and to have taught them the use of some new inventions. This circumstance raised his character so high among the savage aborigines of the country, that succeeding ages ¶ deemed him the first of men. Pelasgus obtained the like character, because he taught the Arcadians to live upon the fruit of the *fagus*, to build sheds to shelter them from the cold, and to make garments of the skins of swine.

§ *Plato.*

¶ *Pausan.* lib. 8. c. 1.

But what clearly demonstrates the unpolished character of the most ancient Greeks is, the extravagant

(o) The Greeks borrowed this contemptuous epithet from the Egyptians. See *Herod.* l. ii. cap. 158.

Greek Language.

gant honours laviſhed by them upon the inventors of uſeful and ingenious arts. Moſt of theſe were advanced to divine honours, and became the objects of religious worſhip to ſucceeding generations. The family of the Titans afford a moſt ſtriking inſtance of this ſpecies of adulation. Jupiter, Juno, Mars, Apollo, Venus, Diana, &c. were ſprung of this family. By the uſeful inventions which theſe perſonages communicated to the uncultivated nations of Greece, they obtained ſuch laſting and ſuch extravagant honours, that they juſtled out the ſidereal divinities of the country, and poſſeſſed their high rank as long as Paganiſm prevailed in thoſe regions. To theſe teſtimonies of the ſavagiſm of the original Greeks, others almoſt without number might be added; but thoſe adduced in the preceding part of this inquiry will, we hope, ſatisfy every candid reader as to the truth of the poſition advanced.

129 A new colony arrives in Greece called *Pelaſgi*,

While matters were in this ſituation with reſpect to the primitive Jonim or Greeks, a new colony arrived in thoſe parts, which in a few years conſiderably changed the face of affairs. The people who compoſed this colony were called *Pelaſgi*; concerning whoſe origin, country, character, and adventures, much has been written, and many different opinions exhibited by the learned. It is not our province to enter into a detail of their arguments and ſyſtems; we ſhall only inform our readers, that the general opinion is, that they were natives either of Egypt or Phœnicia. We have ſeen a diſſertation in manuſcript upon this ſubject, from which we are allowed to extract the following particulars.

The author, we think, has proved by very plauſible arguments, that theſe people could not be deſcendants of the Egyptians nor Phœnicians. He maintains, that the Pelaſgi were a great and numerous tribe; that they overſpread all the coaſt of Aſia Minor from Mount Mycale to Troas; that they were maſters at one time of all the Aſiatic and Grecian iſlands; that they over-ran Greece and many of the neighbouring countries; and all this in leſs than half a century.—Theſe facts he ſeems to have proved from Homer, Herodotus, Diodorus Siculus, Pauſanias, and other Greek authors of approved authenticity. He ſhows, that they were a civilized generation; that they were well acquainted with military affairs, legiſlation, agriculture, navigation, architecture, letters, &c. He inſiſts, that Phœnicia could not at any given period have furniſhed ſuch a numerous body of emigrants, even ſuppoſing the whole nation had emigrated, and left their native country a deſert. He believes that this event took place before the invaſion of Canaan by the Iſraelites; that conſequently the Pelaſgic migration was not occaſioned by that cataſtrophe. He has ſhown, we think by very probable arguments, that the Egyptians in the earlieſt ages were averſe to foreign expeditions, eſpecially by ſea; becauſe that people hated this element, and beſides could be under no temptation to emigrate: add to this, they were accuſtomed to live on ſmall matters, and their country was exceedingly fertile and eaſily cultivated. It appears (ſays he) from Herodotus, that the Pelaſgi were not acquainted with the religion of the Zabians, which could not have been the caſe had they emigrated from either of theſe countries. He makes it appear, at leaſt to our ſatisfaction, that Herodotus is miſtaken when he ſuppoſes that the deities of Greece were derived from Egypt. He demonſtrates, that the names of the greateſt part of thoſe deities are of Phœnician extraction; and this opinion he eſtabliſhes by a very plauſible etymological deduction. He aſſerts, that had the Pelaſgi been natives of either of the countries above-mentioned, it would be abſurd to ſuppoſe them ignorant of the names and religious rites of their reſpective nations. He finds, that the Egyptian and Phœnician colonies, which afterwards ſettled in Greece, were enemies to the Pelaſgi, and either ſubdued or expelled them the country, which, he imagines, could ſcarce have been the caſe had both parties ſprung from the ſame anceſtors. After ſettling theſe points, he concludes, that the people in queſtion were the progeny of the Arabian ſhepherds, who, at a very early period, invaded and ſubdued both the Lower and Upper Egypt. After poſſeſſing that country about a century and a half, they were conquered by Amenophis king of the Upper Egypt, who drove them out of the country. Upon this the fugitives retired to Paleſtine, where Manecho the Egyptian hiſtorian loſes ſight of them, and either through malice or ignorance confounds them with the Iſraelites. This writer ſuppoſes that thoſe fugitives gradually directed their courſe for the weſt and north-weſt coaſts of Aſia Minor, whence they conveyed themſelves over to Greece.

Such are the arguments by which the author of the diſſertation above-mentioned ſupports his hypotheſis. It is, for aught we know, altogether new, and to us it appears by no means improbable. If our curious readers ſhould wiſh to know more of this ſubject, they may conſult Gebelin's preliminary Diſcourſe to his Greek Dictionary, Lord Monboddo's Inquiry into the Origin and Progreſs of Language, vol. i. towards the end, and Mr Bryant's Analyſis of Ancient Mythology, *paſſ.*

Be this as it may, nothing is more certain than that the Pelaſgi were the firſt people who in ſome degree civilized the ſavages of ancient Greece. It is not our buſineſs at preſent to enumerate the many uſeful inventions which they communicated to the Greeks, at that time worſe than barbarians. We deem it, however, abſolutely neceſſary as an introduction to our ſubject, to hazard a few conjectures on the language and letters of thoſe adventurers; a point ſtrictly connected with the ſubject ſoon to fall under conſideration.

130 Who introduce letters into that country.

Whether we ſuppoſe the Pelaſgi to have been the offſpring of the Phœnicians, Egyptians, or Arabian ſhepherds, it will make little difference as to their language; every man of learning and reſearch is convinced that thoſe three nations, eſpecially at that early period, ſpoke a dialect of the Hebrew. The Pelaſgi, then, muſt have ſpoken a dialect of that language when they arrived in Greece. Perhaps it might have undergone ſeveral changes, and acquired ſome new modifications, during ſo many years as had paſſed ſince they began to be a ſeparate nation, and in the courſe of ſo many peregrinations. Some monuments of theirs ſtill extant prove this fact beyond all contradiction. As theſe people incorporated with the aborogines of Greece, the remains of the original language of mankind,

Greek language.

kind, or at leaſt ſo much of it as had been retained by them, gradually coaleſced with that of the new ſettlers. From this, we think, it is obvious, that prior to the arrival of the new coloniſts from the Eaſt, the language now current among the two united tribes muſt have been a dialect of the Phœnician, Arabian, Hebrew, &c. Be that as it may, Herodotus ‖ affirms that the Pelaſgi in his time ſpoke a barbarous language, quite unintelligible to the modern Greeks.

The reaſon of this difference between the language of the Hellenes or Greeks in the age of Herodotus and that of the remains of the Pelaſgi at that period, ſeems to be this: Prior to the time of that hiſtorian, the Greek language had, from time to time, undergone many changes, and received vaſt improvements; whereas, on the contrary, that of the remnant of the Pelaſgi, who were now reduced to a very low ſtate, had remained ſtationary, and was then juſt in the ſame predicament in which it had been perhaps a century after their arrival in the country.

As the Pelaſgi, as was obſerved above, were a people highly civilized and well inſtructed in the various arts at that time known in the eaſtern world, they were ſkilled in agriculture, architecture, muſic, &c. (P): The preſumption then is that they could not be unacquainted with alphabetical writing. This moſt uſeful art was well known in the countries from which they emigrated; and of courſe it is impoſſible to imagine that they did not export this art as well as the others above-mentioned. Diodorus Siculus imagines that § the Pelaſgi knew not the uſe of alphabetical letters, but that they received them from Cadmus and his Phœnician followers; that thoſe letters were afterwards called *Pelaſgic*, becauſe the Pelaſgi were the firſt people of Greece who adopted them. This account muſt go to the ſcore of national vanity, ſince very ſoon after he acknowledges * that Linus wrote the exploits of the firſt Bacchus and ſeveral other romantic fables in Pelaſgic characters; and that Orpheus, and Pronapides the maſter of Homer, employed the ſame kind of letters. Zenobius likewiſe informs us † that Cadmus ſlew Linus for teaching characters differing from his. Theſe letters could be none other than the Pelaſgic ‡.

Pauſanias, in his Attics, relates ‖, that he himſelf ſaw an inſcription upon the tomb of Corœbus, who lived at the time when Crotopus, who was contemporary with Deucalion, was king of the Argives. This inſcription then was prior to the arrival of Cadmus; and conſequently letters were known in Greece before they were introduced by this chief. It likewiſe appears from Herodotus himſelf, that the Ionians were in poſſeſſion of alphabetical characters before the coming of the Phœnicians. "For (ſays he) * the Ionians having received letters from the Phœnicians, changing the figure and ſound of ſome of them, ranged them with their own, and in this manner continued to uſe them afterwards." If, then, the Ionians (Q) ranged the Phœnician characters with their own, it is obvious that they had alphabetical characters of their own.

Greek language.

Beſides theſe hiſtorical proofs of the exiſtence of Pelaſgic characters, monuments bearing inſcriptions in the ſame letters have been diſcovered in ſeveral parts of Greece and Italy, which place this point beyond the reach of controverſy. What characters theſe were may be eaſily determined. As the Pelaſgi emigrated from Arabia, the preſumption is that their letters were Phœnician. They are ſaid by Dr Swinton to have been 13 in number, whereas the Phœnician alphabet conſiſts of 16. The three additional letters were probably invented by the latter people after the Pelaſgi had left the eaſtern quarters. The Phœnician letters imported by the Pelaſgi were, no doubt, of a coarſe and clumſy contexture, unfavourable to expedition in writing, and unpleaſant to the ſight. Beſides, the Phœnician characters had not as yet received their names; and accordingly the Romans, who derived their letters from the Arcadian Pelaſgi †, had no names for theirs. The probability is, that prior to this era the Pelaſgic letters had not been diſtinguiſhed by names. They were of courſe no other than the original letters of the Phœnicians in their firſt uncouth and irregular form: and for this reaſon they eaſily gave way to the Cadmean, which were more beautiful, more regular, and better adapted to expedition.

† *Livii* lib. 1. c. 7.

Plate IX.

Hitherto we have ſeen the Pelaſgi and the Ionim incorporated, living under the ſame laws, ſpeaking the ſame language, and uſing the ſame letters. But another nation, and one too of vaſt extent and populouſneſs, had at an early period taken poſſeſſion of a conſiderable part of the country afterwards diſtinguiſhed by the name of *Hellas* or *Greece*. The Thracians were a great and mighty nation; inferior to none except the Indians *, ſays the father of Grecian hiſtory. Theſe people, at a very early period, had extended their quarters over all the northern parts of that country. They were, in ancient times, a learned and poliſhed nation. From them, in ſucceeding ages, the Greeks learned many uſeful and ornamental ſciences. Orpheus (R) the muſician, the legiſlator, the poet, the philoſopher, and the divine, is known to have been of Thracian extraction. Thamyris and Linus were his diſciples, and highly reſpected among the Greeks for their learning and ingenuity. That theſe people ſpoke the ſame language with the Greeks, is abundantly evident from the connection between them and theſe Thracian bards. The Thracian language, then, whatever it was, contributed in a great proportion towards forming that of the Greeks. From the remains of the Thracian dialect there appears to have been a very ſtrong reſemblance between it and the

* *Herod.* lib. 5. cap. 3.

The Thracians a powerful nation at a very early period.

(P) The Arcadians, who were a Pelaſgic tribe, were higly celebrated for their ſkill in muſic. They introduced this art into Italy. See *Dion. Halicar.* L. 1.

(Q) The Athenians were originally called *Ionians*.

(R) Orpheus ſeems to be compounded of two oriental words, *or* "light," and *phi* "the mouth." Though ſome deduce it from the Arabian *arif* "a learned man."

Greek language.

the Chaldean. This poſition we could readily ſupport by the moſt plauſible etymological deduction, did the limits preſcribed us in this article adn it ſuch an inquiry. It appears, however, that the ‡ Thracians, Getæ, and Daci or Davi, ſpoke nearly the ſame language. The Goths, ſo much celebrated in the annals of the lower empire, were the deſcendants of the Getæ and Daci, and conſequently retained the dialect of their anceſtors. The reader, therefore, muſt not be ſurpriſed, if in tracing the materials of which the Greek language is compoſed, we ſhould ſometimes have recourſe to the remains of the Gothic.

‡ *Strabo*, lib. 1 & 7

132 The Greek language compoſed of three different dialects.

We have now found out three branches of the Greek language; that of the Ionim or *Aborigines*, that of the Pelaſgic tribe, and that of the Thracians. Theſe three, we imagine, were only different dialects of the very ſame original tongue. This aſſertion we could readily prove by the compariſon of a great number of words taken from the two laſt, were this a proper place for ſuch a diſcuſſion.

133 Arrival of Cadmus in Greece.

Some centuries after the arrival of the Pelaſgi, Cadmus, an Egyptian (s) by birth, and a ſojourner in Phœnicia, arrived in Bœotia with a multitude of followers. This colony chief and his countrymen introduced letters and ſeveral other uſeful improvements into the country in queſtion. As theſe people were natives of Phœnicia and its environs, their alphabet was that of their native country, conſiſting of 16 letters. That the Phœnician alphabet was nearly the ſame with the Samaritan and Hebrew, has been ſo often and ſo clearly demonſtrated by the learned of this and the former century, that it would be altogether ſuperfluous to inſiſt upon it in this ſhort inquiry. The Phœnicians, as is generally known, wrote from right to left, and the old Grecian characters inverted, exactly reſemble the other.

† *Scaliger.*

The names of the Cadmean characters are Syrian †, which ſhows the near reſemblance between that language and the Phœnician. They ſtand thus: *alpha*, *betha*, *gamla*, *delta* &c. The Syrians uſed to add *a* to the Hebrew vocables; hence alph becomes alpha, beth, betha or beta, &c. In the Cadmean alphabet we find the vowel letters, which is an infallible proof that this was the practice of the Phœnicians in the age of Cadmus; and this very circumſtance furniſhes a preſumption that the Jews did the ſame at the ſame period.

133 The letters introduced by him.

After all, it is evident that the oldeſt Greek letters, which are written from right to left, differ very little from thoſe of the Pelaſgi. The four double letters θ, φ, ξ, χ, are ſaid to have been added by Palamedes about 20 years before the war of Troy. Simonides is generally ſuppoſed to have added the letters ζ, η, ψ, though it appears by ſome ancient inſcriptions that ſome of theſe letters were uſed before the days of Palamedes and Simonides.

In the year of our Lord 1456 ſeven brazen tables were diſcovered at Engubium, a city of Umbria in the Apennines, of which five were written in Pelaſgic or Etruſcan characters and two in Latin. The firſt of theſe tables is thought to have been compoſed about 168 years after the taking of Troy, or 1205 years before Chriſt. By comparing the inſcription on theſe tables with the old Ionic characters, the curious have been enabled to diſcover the reſemblance.

Greek language.

134 The old Ionic character.

The old Ionic character wrote from right to left continued in general uſe for ſeveral centuries: It was compoſed of the Cadmean and Pelaſgic characters, with ſome variations of form, poſition, and ſound. The Athenians continued to uſe this character till the year of Rome 350. The old Ionic was gradually improved into the new, and this quickly became the reigning mode. After the old Ionic was laid aſide the * (Βουστροφηδον) Buſtrophodon came into cuſtom, which goes backwards and forwards as the ox does with the plough. They carried the line forward from the left, and then back to the right. The words were all placed cloſe together, and few ſmall letters were uſed before the fourth century. If our curious readers would wiſh to know more of letters and alphabets, we muſt remit them to Chiſhul, Morton, Poſtelius, the great Montfaucon, Gebelin, Aſſle, &c. For our part we are chiefly concerned at preſent with the Phœnician and Cadmean ſyſtems; and on theſe perhaps we may have dwelt too long. Having now, we hope, ſufficiently proved that the Greek alphabet was derived from the Phœnician, in order to convince our curious but illiterate readers of the certainty of our poſition, as it were by ocular demonſtration, we ſhall annex a ſcheme of both alphabets, to which we ſhall ſubjoin ſome ſtrictures upon ſuch letters of the Greek alphabet as admit any ambiguity in their nature and application.

* *Pauſan.* lib 5. cap. 17.

135 The Greek alphabet derived from the Phœnician.

Α, *alpha*, had two ſounds, the one broad like *a* in the Engliſh word *all*; the other ſlender, as *e* in *end*, *ſpend*, *defend*. The Hebrews certainly uſed it ſo, becauſe they had no other letter to expreſs that ſound; the Arabs actually call the firſt letter of their alphabet *elif*; and they as well as the Phœnicians employ that letter to expreſs both the ſound of A and E promiſcuouſly. The Greeks call their letter E ψιλον, that is, E ſlender, which ſeems to have been introduced to ſupply the place of A ſlender.

Η, *eta*, was originally the mark of the *ſpiritus aſper*, and no doubt anſwered to the Hebrew ח. It is ſtill retained in that capacity in the word Ημισεον, and in words with the *ſpiritus aſper* beginning books, chapters, ſections, &c. E originally marked both the ſound of Ελιλον and Ητα; that is, it was ſometimes ſounded ſhort as at preſent, and ſometimes long, where it is now ſupplied by H. As it was found convenient to diſtinguiſh theſe two different quantities of ſound by different letters, they adopted H, the former *ſpiritus aſper*, to denote the long ſound of E, and ſubſtituted the preſent *ſpiritus aſper* [᾽] in its place.

Ι, *iota*, is the Hebrew or Phœnician *jod* or *yod*. We imagine it originally ſerved the purpoſe of both iota and ypſilon. It had two different ſounds; the one broad and full, the other weak and ſlender. The latter had the ſound of the modern υψιλον. That this was actually the caſe, appears in ſeveral monumental inſcriptions: And upon this depends the variation of ſome caſes

(s) Joſeph Scaliger's account of the origin of the Ionic letters. *Euſeb. Chron.*

Greek Language

cases of the demonstrative pronoun and of the second declension.

Greek Language.

Ο, *omicron* or small *o*, in the original Greek had three different sounds. It sounded *o* short, as at present; and likewise *o* long, now denoted by Ω or large *O*. It likewise marked the sound of the improper diphthong ου, sounded like the English diphthong *oo*. The Ω was taken from the Phœnician vau or *V*.

Υ, *ypsilon*, we have observed before, was adopted to supply a mark for the sound of I slender.

Ζ, *zeta*, is compounded of δς Dion. Halic. however, informs us that this letter should be pronounced σδ, according to the Doric plan.

Θ, *theta*, was not known in the old Greek. It is compounded of τ and the *spiritus asper*, both which were of old written separately thus TH.

Ξ, *xi*, is compounded of γς, κς, χς. These letters, too, were originally written separately.

Φ, *phi*. This letter is compounded of β, π, and the *spiritus asper*; thus BH, PH.

Χ, *chi*, like the foregoing, is compounded of γ, κ, and the *spiritus asper* as above.

Ψ, *psi*, like some of the rest, is made up of βς, πς, which, too, were originally written in separate characters.

These observations are thrown together purely for the use of students who may not choose to penetrate into the *minutiæ*. We are sorry that the nature of the work will not permit us to extend our researches to greater length. The reader will find an ancient inscription on Plate CCCXC, in which the powers of the letters are exemplified as they were in the first stage of the Greek language. Every language, we believe, was originally composed of inflexible words; the variations which now distinguish nouns and verbs were the effects of progressive improvements. What might have been the state of the Greek language with respect to these variations in its original form, it is not now possible to discover. That it was rude and irregular, will not, we imagine, be controverted. One of the first attempts towards forming the variations, now denominated *declensions* and *conjugations*, would probably be made upon the *demonstrative* article and the *substantive* verb. This observation will be found to hold good in most polished languages. In the Greek tongue, this was evidently the method.

136 Origin and extension of the article.

The original Greek article was imported from the east. It was the Hebrew or Phœnician ה *ha*. This particle sometimes signifies *one*, and sometimes it answers to our demonstrative *the*; both in its adverbial and demonstrative capacity it imports demonstration. In the earliest stages of the two oriental languages, it was probably written apart, as *ha-melech* "the king." In process of time it came to be joined with the following word, as *Hammelech*. From this we think the Greek article was deduced. It is still retained in the Doric dialect in its pristine character. The difference between *ho* and *ha* in the eastern language is nothing. Here then we have the articles ὁ masculine and ἡ feminine. Upon these several changes were superinduced, in order to render them more useful for the purposes of language. For those changes we know of no archetype.

The Greeks then having adopted the Hebrew, or Phœnician, or Chaldean article *ha*, and changed it into *ho* for the masculine, seem to have arranged its variations in the following manner:

	Sing.	*Plu.*
Nom.	ὁ	οἱ
Gen.	τοῦ	τῶν
Dat.	τῷ	τοῖς
Acc.	τὸν	τοὺς

137 Its use in the flexion of nouns of the first and second declensions.

In the earliest stages of the Greek language, ι and υ were sounded in the same manner, or nearly so, as was observed above. The accusative was at first like the nominative; for distinction's sake it was made to terminate in ν, which letter was likewise adopted to characterize the genitive plural; ς was annexed to the dative plural, to distinguish it from the dative singular. The radical word was still without inflexion.

When the article was inflected in this manner, the process stood as follows: we take λογος for an example.

	Sing.	*Plu.*
Nom.	ὁ λογ *speech*	οἱ λογ *speeches*
Gen.	τοῦ λογ *of speech*	τῶν λογ *of speeches*
Dat.	τῷ λογ *to speech*	τοῖς λογ *to speeches*
Acc.	τὸν λογ *speech*	τοὺς λογ *speeches*

In this arrangement our readers will observe, that in the time under consideration, ω was not yet introduced; and therefore ομικρον or little ο was the same letter in the genitive plural as in the accusative singular; but in the latter case it was sounded long by way of distinction.

The article *ha*, which is still retained in the Doric dialect, was varied as follows:

	Sing.	*Plu.*
Nom.	ἁ	αἱ
Gen.	ἁς	ἁν
Dat.	ἁι	αἱς
Acc.	ἁν	ἁς

These variations differ a little from those of the masculine; and they were no doubt made for the sake of distinction, as is usual in such cases. We shall now give an example of the feminine as it must have stood before variations were introduced. We shall employ τιμη.

	Sing.	*Plu.*
Nom.	ἁ τιμ *honour*	αἱ τιμ *honours*
Gen.	ἁς τιμ *of honour*	ἁν τιμ *of honours*
Dat.	ἁι τιμ *to honour*	αἱς τιμ *to honours*
Acc.	ἁν τιμ *honour*	ἁς τιμ *honours*

Afterwards, when the Chaldean article *da* was adopted for the neuter gender, the letter ד or *d* was changed into τ, and prefixed to it; and then the Greeks, who, in their declension of adjectives, always followed the neuter gender, began to prefix it to the oblique cases.

In this manner we think the Greek nouns stood originally; the only change being made upon the article. At length, instead of prefixing that word, and expressing it by itself, they found it convenient to affix a fragment of it to the noun, and so to pronounce both with more expedition. Thus ὁς-λογ, *e.g.* became λογ-ος, τοῦ λογ became λογ-ου, and of course λογοις and λογων, &c. The *spiritus asper*, or rough breathing, was thrown away, in order to facilitate the coalition. Nouns of the neuter gender, as was necessary, were distinguished by using ν instead of ς. In Oriental words the Greeks often change ς into ν, and *vice versa*.

In this case the Greeks seem to have copied from an

Greek Language.

an eaſtern archetype. In Hebrew we find an arrangement exactly ſimilar. To ſupply the place of the pronouns poſſeſſive, they affix fragments of the perſonals: Thus, they write *ben-i* "my ſon," inſtead of *ben-ani*, and *debir-nu* "our words," inſtead of *debir-anu*, &c. The perſons of their verbs are formed in the ſame manner. In this way, in our opinion, the variations of the firſt and ſecond declenſions were produced.

138 In this mode of flexion the Greeks copied from the Orientals.

139 Formation of the third declenſion, and of its caſes.

After that a conſiderable number of their nouns were arranged under theſe two claſſes, there remained an almoſt infinite number of others which could not conveniently be brought into theſe arrangements; becauſe their terminations did not readily coaleſce with the articles above-mentioned. Theſe, like nouns of the neuter gender, were in a manner ſecluded from the ſociety of the two other claſſifications. It is probable that theſe for a long time continued indeclinable. At laſt, however, an effort was made to reduce them into a claſs as well as the others. All theſe excluded nouns originally terminated with ς, which appears from their genitives as they ſtand at preſent. By obſerving this caſe, we are readily conducted to the termination of the priſtine vocable. The genitive always ends in ος, which ending is formed by inſerting ο between the radical word and ς. By throwing out ο we have the ancient nominative: Thus, Τιταν, genitive Τιτανος; taking out ο we have Τιτανς, the original inflexible termination. Ανερ, genitive Ανδρος; throw out ο and you have Ανδρς. Παλλας, genitive Παλλαδος; take away ο and there remains παλλαδς. Ορνις, genitive Ορνιθος; by throwing out ο we have Ορνιθς. Αναξ, genitive Ανακτος, Ανακτς. Κρατος, genitive Κρατος, Κρατς; originally Κρατις, becauſe originally ι had the ſound of ϝ, as was obſerved above. Μιλι, genitive Μιλιτος, Μιλιτς. Ειδος, genitive Ειδος, Ειδς, the old noun. In ſhort, the genitive is always formed by inſerting ο immediately before ς, which is always the termination of the nominative; and by this rule we eaſily diſcover the noun ſuch as it was in its original form.

The dative of this declenſion was cloſed with ι *aſcriptum*; the ſame with that of the ſecond, namely, ι *ſubſcriptum*. The accuſative commonly terminates with α; but was originally ended with ν. The Romans imitated the Æolian dialect, and they commonly ended it with *em* or *im*. The Greeks, perhaps, in this imitated their progenitors, for *a* was their favourite vowel. The nominative plural ended in ες, which nearly reſembles the Engliſh plural, and was poſſibly borrowed from the Thracians. The genitive plural in all the declenſions ends in ων; the dative ends in σι, the σ being inſerted to diſtinguiſh it from the dative ſingular. When a ſtrong conſonant, which would not eaſily coaleſce with ς, comes immediately before it, that conſonant is thrown out to avoid a harſh or difficult ſound. The ſum then is; the caſes of nouns of the firſt and ſecond declenſions conſiſt of the radical word with fragments of the articles annexed, and theſe were the firſt claſſifications of nouns. The other nouns were left out for ſome time, and might be denominated *neuters*; at length they too were claſſified, and their variations formed as above. In this proceſs the Greeks deviated from the oriental plan; for theſe people always declined their nouns by particles prefixed. Whether the Greeks were gainers by this new proceſs, we will not pretend poſitively to determine. We are, however, inclined to imagine that they loſt as much in perſpicuity as they gained by variety.

Greek Language.

140 Greek ablative.

It is generally believed that the Greeks have no ablative; to this opinion, however, we cannot aſſent. It is true, that the dative, and what we would call the *ablative*, are always the ſame: yet we think there is no more reaſon to believe that the latter is wanting in Greek, than that the ablative plural is wanting in Latin, becauſe in that language both theſe caſes are always alike.

In the eaſtern languages there are only two genders, analogous to the eſtabliſhed order of nature, where all animals are either male or female. But as the people of the Eaſt are, to this day, ſtrongly addicted to perſonification, they ranged all objects of which they had occaſion to ſpeak, whether animate or inanimate, under one or other of theſe two claſſes. Hence aroſe what is now called the *maſculine* and *feminine* genders. The orientals knew nothing of a neuter gender, becauſe, indeed, all objects were comprehended under the foregoing claſſes. The Phœnician feminine was formed from the maſculine, by adding את, *ah*. In this the Greeks in many caſes imitated them. The Greeks and Latins left a vaſt number of ſubſtantives, like a kind of outcaſts, without reducing them to any gender; this proceſs gave riſe to the neuter gender, which imports, that ſuch ſubſtantives were of *neither gender*. This has the appearance of a defect, or rather a blemiſh, in both. Sometimes, too, they make words neuter, which, according to the analogy of grammar, ought to be either maſculine or feminine. And again, they range words under the maſculine or feminine, which by the ſame rule ought to have been neuter. In ſhort, the doctrine of generical diſtribution ſeems to have been very little regarded by the fabricators of both tongues. The beauty which ariſes from variety ſeems to have been their only object.

141 Genders.

The uſe of the article in the Greek language is, we think, rather indeterminate; it is often prefixed to proper names, where there is no need of demonſtration nor generical diſtinction. On the contrary, it is often omitted in caſes where both the one and the other ſeem to require its aſſiſtance. In ſhort, in ſome caſes it ſeems to be a mere expletive. Though both Lord Monboddo and Mr Harris have treated of this part of ſpeech, neither the one nor the other has aſcertained its proper uſe. (*See Orig. and Progr. of Language*, vol. ii. p. 53. *Hermes*, page 214. *et ſeq*).—We know not any objection to the early uſe of articles among the Greeks ſo plauſible as the total neglect of them among the Romans. But it ought to be conſidered, that after the flexions were introduced, the uſe of the article was in a great meaſure neglected. Accordingly, Lord Monboddo obſerves that it is very ſeldom uſed as ſuch by Homer, but commonly in place of the relative pronoun, ὁς, ἡ, ὁ.—Thus it would appear, that at the time when the Roman language was reduced to the Grecian ſtandard, the article was not commonly uſed by the Greeks; and of courſe the Latins never employed it. There can be no doubt but the pronoun *who*, in the northern languages, is the ſame with the Greek ὁ, and the Hebrew *hua*. This among the northern people is always

142 Farther obſervations on the article.

Greek Language.

ways a relative, which affords a presumption that the Greeks originally used the article in the same manner as we do at present. The fact is, that the articles having once got into vogue, were often positively used as mere expletives to fill up a gap; and that, on the other hand, when there was no occasion for pointing out an object, it being fully determined by the tenor of the discourse, it was often omitted.

143 Adjectives

In forming adjectives, they followed the same plan that they had done with substantives. Their great effort was to make their adjectives agree with their substantives in gender, number, and case. This arrangement improved the harmony of speech; and nothing could be more natural than to make the word expressing the quality correspond with the subject to which it belonged.

As adjectives denote qualities, and thus are susceptible of degrees, nature taught them to invent marks for expressing the difference of these degrees. The qualities may exceed or fall below each other by almost numberless proportions; it was, however, found convenient to restrict these increases and decreases to two denominations. The positive is, properly speaking, no degree of comparison at all; therefore we need only point out the formation of the comparative and superlative.

The former is generally thought to be fabricated, by first adding the Hebrew word יתר, *excellent*, to the positive, and then affixing the Greek termination ος; and the latter, by affixing the Syrian word *tath* and the syllable ος, in the same manner.

144 Greek numerals.

Every nation, even the most uncivilized, have early acquired the notion of number. Numerical characters and names are the same in many different languages. These terms were discovered, and in use, long before grammar came to any perfection; and therefore remain either inflexible or irregular. The first way of computing among the Greeks was by the letters of the alphabet; so that Α signified *one* and Ω *twenty-four*: in this manner the rhapsodies of Homer are numbered; and so are the divisions of some of the Psalms, as is generally known. But a more artificial plan of computation was obviously necessary. They divided the letters of the alphabet into *decades* or tens, from A to I = 10. To express the number 6, they inserted Ϛ *baw* = 6; so that by this means the first decade amounted to 10. In the next decade every letter increased by tens, and so P denoted 100. In this decade they inserted ϟ κοππα = 90. In the third, every letter rose by 100; so that ϡ σαμπι = 900. By inserting these three Phœnician characters they made their alphabet amount to 900. To express chiliads or thousands, they began with the letters of the alphabet as before; and to make the distinction, they placed a dot under each character, as the units, tens, hundreds, were distinguished by an acute accent over them.

But in monumental inscriptions, and in public instruments, a larger and more lasting numerical character was fabricated. They began with I, and repeated that letter till they arrived at Π = 5. This is the first letter of πεντε 5. Then they proceeded, by repeating I till they came to 10 Δ, the first letter of δεκα, 10. Then they repeated Δ over and over, so that four Δ = 40. To express 50, they used this method; they inclosed Δ in the belly of Π = 50, Π[H] = 500, Π[M] = 50,000, &c. Often, however, X signifies 1000, and then we have δις χιλιοι, 2000, τρις χιλιοι 3000; and so of the rest.

Greek Language.

145 Pronouns.

The word *pronoun* signifies a word placed instead of a noun or name; and indeed the personal pronouns are really such: this needs no explication. The pronoun of the first person is one of those words which have continued invariable in all languages; and the other personals are of the same character. The relatives, possessives, demonstratives, and gentiles, are generally derived from these, as may be discerned by a very moderate adept in the language. Our readers will therefore, we hope, easily dispense with our dwelling upon this part of speech.

146 Greek verbs, how formed.

Verb. In most ancient languages, verbs, according to the order of nature, have only three tenses or times, namely, the *past*, *present*, and *future*. The intermediate tenses were the invention of more refined ages.— The Greek, in the most early periods, had no other tenses but those above-mentioned. The manner of forming these we shall endeavour to point out, without touching upon the nature of the rest, since an idea of them may be acquired from any common grammar.

We have observed above, that the flexion of nouns of the first and second declensions are formed by annexing fragments of the articles to the radical words; and that the variation of the tenses were produced by joining the substantive-verb, according to the same analogy. Every Greek verb was originally an inflexible biliteral, triliteral, quadriliteral or dissyllabic radix. The variations were formed a long while after in the manner above intimated.

The Greeks had their substantive or auxiliary verb, from the Phœnician or Chaldean verb היה, *fuit*. This verb, taking away the gentle aspirate from both beginning and end, actually becomes ει. This vocable the Greeks brought along with them from the East, and manufactured after their own manner, which appears to have been thus:

Pref. εω, εεις, εε, εομεν, εετε, εοσι,
Cont. ω, εις, ει, ουμεν, ειτε, ουσι,
Fut. εσω, εσεις, εσει, εσομεν, &c.

We place οσι in the third person plural, because for many centuries ομικρον supplied the sound of the diphthong ου. By these variations it will appear that the radical verb was rendered capable of inflexion. We have observed that Greek verbs were a collection of biliteral, triliteral, or quadriliteral, radical words.— The following may serve for examples: τι, λεγ, Μαθ, τυπ, ϕαν, ταν, ϕατ, Δαμ, Δηλ, Δικ.

These radicals are taken at random; and we believe our Grecian student, by adding the terminations, will readily find them all significant verbs. With these radicals, then, and the substantive-verb, we suppose the present and future tenses were formed.

147 Original present that which is now the second future.

But it is now generally admitted that the modern present was not the original one of the verb. The second, or Attic future, appears plainly to have been the most ancient present. When the language was improved, or rather in the course of being improved, a new present was invented, derived indeed from the former, but differing widely from it in its appearance and complexion. Upon this occasion, the old present

Greek Language.

was degraded, and inſtead of intimating what was *doing at preſent*, was made to import what was immediately to be done hereafter. By this means, γραφω, contracted into γραφῶ, *I am writing*, came to intimate *I am juſt going to write*. This change was probably made for the ſake of enriching the language, for variety, for energy. Thus, τυπτω contracted τυπτῶ became τυπτω, τιπῶ, τιπτω, &c. According to this theory, we find, that ſuch verbs as now have no ſecond future retain their original form, only the circumflex has been removed in order to accommodate them to the general ſtandard. Grammarians have now choſen the three characteriſtic letters of active verbs from the preſent, firſt future, and perfect. The true characteriſtic of the original verb was that of the preſent ſecond future. Many verbs are now deſtitute of that tenſe, becauſe, ſince the invention of the new preſent, thoſe have fallen into diſuſe.

148 Formation of the modern preſent,

Let us now take the verb λεγω, *dico*, in order to make a trial; and let us write the radix and the auxiliary, firſt ſeparately, and then in conjunction: Thus,

λεγ-ω, λεγ-εις, λεγ-ει, λεγ-ομεν, λεγ-ετε, λεγ-ουσι. Then we will have contracted λεγῶ, λεγεῖς, λεγεῖ, λεγοῦμεν, λεγεῖτε, λεγοῦσι. Here, we believe, every thing is ſelf-evident.

The Engliſh would run thus: Saying *I am*, ſaying *thou art*, ſaying *he is*, &c. At firſt the radix and the auxiliary were pronounced ſeparately, as we do our helping verbs in Engliſh, and would have been written in the ſame manner had words been then diſtinguiſhed in writing.

149 Firſt future, and

The preſent firſt future occupied the ſame place that it now does, and concurred in its turn to complete the future in conjunction with the radix. That the ſubſtantive verb was inflected in the manner above laid down, is obvious from its future middle ἐσομαι, and from the future of the Latin verb *ſum*, which was of old *eſo*, *eſis*. &c. Verbs in λω, μω, νω, ρω, often take σω in the firſt future. See *Fæd. Cret. ap. Marm. Oxon.* I. 67. Verbs in λω and ρω aſſume σ by analogy, as κελλω, κελσω, *Eurip. Hecub.* v. 1057. κελσαι *Hom. Od.* x. v. 511. τιλλω, τιλσω, *unde* τιλσον, *Il.* x. v. 707. ορω, ορσομαι, *Pind. Nem. Od.* 9. *Duolec.* 2. τειρω, τειρσει, *Theoc. Idyll.* 22. v 62. In fine, the Æolic dialect after the liquids often inſerts σ.

It muſt be obſerved, that the Greeks, in order to accelerate the pronunciation, always throw out the ε and ο, except in verbs ending in αω, ιω, ουω: where they generally change them into η and ω. When the laſt letter of the radix can coaleſce with σ after ε is thrown out, they transform it, ſo as to anſwer that purpoſe; if not, they ſometimes throw it out. We ſhall once more take λεγω for an example:

λεγ-εσω, λεγ-εσεις, λεγ-εσει, &c.

Throwing out ε, it would ſtand λεγ-σω, λεγ-σεις, &c. by changing γς into ξ it becomes λεξω. Λ θ and σ cannot coaleſce with σ, therefore they throw them out: thus, λαθω, future firſt ασω; πλησθω, future firſt πλησω; λυτω, λυσω, &c.

Theſe are the general rules with reſpect to the formation of the preſent and future of active verbs in the earlieſt ſtages of the Greek language. The limits preſcribed will not allow us to purſue theſe conjectures; but the reader may, if he thinks proper, carry them a great way.

Greek Language.

150 Præterite tenſes.

The præterite tenſe falls next under conſideration. If we may truſt analogy, this, as well as the other two, muſt have owed its conformation to the radix of the verb, and ſome other word fitted to eke out its terminations. It has been thought by ſome critics, that this addition was taken from the Hebrew word היה; and we ſhould be of the ſame opinion did not another auxiliary preſent itſelf nearer home, which appears to us much more congruous to ſuch a purpoſe. Perhaps, indeed, the people from whom we ſuppoſe it borrowed, derived it from the eaſtern quarters. We have already obſerved, that the Thracians were maſters of a great part of Greece in the very earlieſt ages. At that time they were a polite and learned people. From them a conſiderable part of the Greek language was derived. If, therefore, we ſhould find a word in their language employed for the ſame purpoſe, and accommodated to coaleſce with the radical verb, we feel ourſelves very much inclined to prefer ſuch a word.

151 Origin of the auxiliary verb.

The word *ha* pervades many different languages as an auxiliary verb. From it we have the Italian *ho*, the Spaniſh *he*, the French *ai*; and in one ſhape or other it appears in all the German and Scandinavian dialects. It is the Gothic auxiliary; and, we believe, it forms the termination of the perfect active of the firſt conjugation in the Latin tongue: For there *am* is the radix of *amo*; in the præterite *am-avi*, *amavi*: and the præterperfect *am hav eram*, i. e. *amaveram*, compounded of *am*, *hov*, and *eram*, the imperfect of the indicative of the ſubſtantive verb. This proceſs, in the formation of the præterite of Latin verbs, will ſcarce be queſtioned, and forms certainly a preſumptive proof that the Greeks purſued the ſame line. From this verb is likewiſe derived the Latin *habeo*, by changing *v* into *b*, which are indeed the ſame letter. Our readers, after this detail, will not be ſurpriſed if we ſhould now hazard a conjecture, and declare it as our opinion, that this ſame Gothic auxiliary *ha* is actually the additional part of the præterite of Greek verbs, and that part upon which the conjugation depends.

In forming this combination between the radix and the auxiliary, the Greeks were obliged to fabricate ſeveral devices. As often as the laſt letter of the radix could not unite with the aſpirate in *ha*, they metamorphoſed it into one of the double letters, which are capable of coaleſcing with it. In the verb λεγω, γ was changed into χ; thus, λεγ *ha* became λεχα, τυπτω præterite τυπ *ha*, was combined into τυφα. In verbs which had a radix that would not admit this conjunction, they hardened the *h* into κ, as in τιω, præterite τι-κα, Ακου-κα. Many other ways were contrived to facilitate this reunion. Theſe are detailed in every Greek grammar, and ſo need not be mentioned.—What has been ſaid with reſpect to this configuration, we offer as a pure conjecture, without the moſt remote intention of obtruding it upon our readers.

If it is admitted, that the auxiliary *ha* formed the conjugating termination of the active verb among the Greeks, it will likewiſe be admitted, that the radical verb and the other made originally two diſtinct words: that, according to this ſcheme, the præterite would

Greek Language.

proceed thus, λιγ *ha*, ſaid *I have*; λιγ *has*, ſaid *thou haſt*; λιγ *he*, ſaid *he hath*, &c. This proceſs to us appears rational, elegant, and advantageous. The pluperfect was not then invented, and therefore it does not come under our conſideration. The other tenſes were all deduced from thoſe deſcribed; and in forming theſe intermediate diſtinctive tenſes, we believe that both critics and grammarians, and perhaps philoſophers too, were employed. See GRAMMAR.

The eaſtern nations have diverſified their verbs, by affixing fragments of the perſonal pronouns to the radix, by which they gained only the advantage of exhibiting the genders of the perſons engaged in being, acting, and ſuffering; but a perpetual repetition of theſe was unavoidable. The Greeks, by their artificial combination of the radix with the two auxiliaries, avoided the neceſſity of repeating their perſonal pronouns, as we and the other modern inhabitants of Europe are obliged to do; and at the ſame time, by diverſifying the terminations of their nouns and verbs, wonderfully improved the beauty and harmony of their language. The arrangement above inſiſted on is ſo very different from that of the orientals, and ſo entirely Gothic, that we think there can be no doubt that the Greeks borrowed this manœuvre from the Thracians. Every perſon moderately acquainted with the Greek language will, upon examination, diſcover a wonderful coincidence between the ſtructure, idioms, and phraſeology, of the Engliſh and Greek languages: ſo many congenial features muſt engender a ſtrong ſuſpicion that there once ſubſiſted a pretty intimate relation between them.

In the preceding deduction, we find ourſelves obliged once more to differ from the very learned author of the *Origin and Progreſs of Language*. As we took the liberty to queſtion his originality of the Greek language, and at the ſame time preſumed to attack the goodly ſtructure raiſed by philoſophers, critics, and grammarians; ſo we now totally differ from that learned writer as to his theory of the creation of verbs out of the inhabile matter of αω, ιω, &c. This whole fabric, in our opinion, leans on a feeble foundation.

The apparatus of intermediate tenſes, of augments, derivation of tenſes, with their formation, participles, and idiomatical conſtructions, and other eſſentials or appendages, we omit, as not coming within the verge of the diſquiſition.

157 Derivation and formation of the middle voice,

The derivation and formation of the middle and paſſive voices, would certainly afford matter of curious ſpeculation; but the labour neceſſary to inveſtigate this connection would greatly overbalance the benefit expected.

However, to complete our plan, we ſhall ſubjoin a few ſtrictures with reſpect to the formation of the middle-voice, which was, in our opinion, immediately formed from the active.

We have ſeen already, that the active voice in its original ſtate was formed by annexing fragments of the ſubſtantive or auxiliary verb to the radix. The ſame economy was obſerved in fabricating the flexible parts of the verb of the middle voice. To demonſtrate this, we ſhall firſt conjugate the preſent tenſe of the auxiliary paſſive upon the principles above laid down.

Greek Language.

Preſent, Εμαι, ισαι, ιται, ιμεθα ιεσθε, ιονται. Such was the paſſive-preſent of the auxiliary. We ſhall now take our example from the verb τυπτω; ſecond future τυτ-ισομαι, *ſtruck I am*, τυτ-ισαι, *ſtruck thou art*, τυτ-ιται, *ſtruck he is*, &c. contracted τυτουμαι, τυτη, τυτιται. The conjunction and formation here is obvious. Perhaps, in the ſecond perſon, σ was inſerted, which, however, is thrown out in the proceſs of the perſons. The future middle is clearly formed, by affixing the future paſſive of the verb ειμι, only as η was introduced into the language for ι long, it was generally (τ) ſubſtituted inſtead of that vowel in verbs ending in αω and ιω, and ω for ο in verbs ending in οω; the two vowels ι and ο being originally long as well as ſhort, till η was adopted to denote the long ſound of the former, and ω that of the latter. In many verbs, before the conjunction of the radix and auxiliary, ι was thrown out: thus, τυτ-ισομαι became τυψομαι, λιγ-ισομαι, λιξομαι, &c. Plate CCCLXC.

The præterite was deduced from that of the active by a very ſlight variation, ſo trifling, indeed, that it need not be mentioned; only we may obſerve, that the aſpirate *h* is never retained in this tenſe, which originally ſeems to have been the only diſtinguiſhing character by which that tenſe of the middle-voice differed from the ſame tenſe of the active.

From the ſtrict analogy between the mode of forming the three primary tenſes of the active and middle voice, we are led to ſuſpect that what is now the middle was originally the paſſive voice.

The immediate formation of the former, by annexing the paſſive auxiliary, is obvious. The middle voice ſtill partakes of the paſſive ſignification, ſince it has ſometimes a paſſive, though more frequently an active. There are ſeveral parts of the preſent paſſive quite analogous to the ſame tenſes in the middle: and, laſtly, it is the common progreſs, in the courſe of improvement, to proceed ſtep by ſtep, and by approximation. What is moſt ſimple and eaſy is the firſt object, then ſucceeds what is only a little more difficult, and ſo on till we arrive at the laſt ſtage, when human ingenuity can go no farther. Now, it will readily be admitted, that the paſſive voice is much more embarraſſed and intricate in its texture than the middle; and, therefore, the former ſhould have been poſterior in point of time to the latter.

We are well aware, that the very learned Kuſter, and moſt other moderns, deeply ſkilled in the origin, progreſs, and ſtructure, of the Greek language, have thought otherwiſe. The general opinion has been, that the Greek middle voice anſwered exactly to the Hebrew conjugation *hithpachal*, and in its priſtine ſignification imported a reciprocality, or when the *agent acts upon itſelf*. For our part, we only intended a few hints upon the ſubject, which our learned readers may purſue, approve, or reject, at pleaſure.

If we might pretend to inveſtigate the formation of the paſſive voice, we ſhould imagine that the modern

(τ) We ſay generally, becauſe in verbs ending in ιω, the ι is ſometimes retained, as τιλιω, τιλισω, αχθ-ισω.

Greek Language.

dern present was formed from the ancient one, by inserting such letters as were found necessary for beauty, variety, energy, &c.; the first future from the second future middle of the verb τιπτω, once θιω. This future is θησομαι; and, joined to the radix, always occupies that place, τυ-θησομαι, τυλιθησομαι, γλιχ-θησομαι, τυρθησομαι, and so of the rest: whether μαι, σαι, ται, which occur so frequently as the terminations of the middle and passive voices, are fragments of some obsolete verb, we will not pretend to determine.

153 And of the passive.

From verbs in αω, εω, οω, υω, are formed verbs in μι; which in the present, imperfect, and second aorist, as it is called, only have a different form, by assuming αι with a long vowel preceding it, in the present active; which vowel is preserved in each person singular. This collection of irregular verbs seems to be formed from the verb υημι, which in some dialects might be νημι. Indeed the imperfect νν, ης, ν, seems to imply as much: in this, however, we dare not be positive.

In the whole of this analysis of the formation of verbs, we have laid down what to us appears most plausible. That metaphysical critics may discover inaccuracies in the preceding detail we make no doubt; but our candid readers will doubtless reflect, that no language was ever fabricated by philosophers, and that the elements of language were hammered out by peasants, perhaps by savages. Critics have created a philosophy of language we admit, and have a thousand times discovered wonderful acuteness and ingenuity in the mechanism of words and sentences, where the original onomathetæ never apprehended any, and which possibly never existed but in their own heated imagination. If our more enlightened readers should find any thing in the preceding detail worthy their attention, so much the better; if the contrary should happen, we presume they will take up with the hackneyed system. We have all along neglected the dual number, because it regularly follows the type of the other numbers.

Be that as it may, before we drop this subject we must take the liberty to subjoin an observation or two with respect to the consequences of the practice of new-modelling the present, and of course the imperfect, tenses of verbs. 1st, After this arrangement they commonly retained all the other tenses exactly as they had stood connected with the primitive verb: this needs no example. 2d, They often collected the tenses of verbs, whose present and imperfect were now obsolete, in order to supply this defect. Thus we have ειπ-ον, ενεγκα, ηνεγκα. 3d, They often formed present and imperfect tenses without any other tenses annexed: The poets in particular seem to have fabricated these two tenses at pleasure.

If this procedure was convenient for the poets, it was certainly most incommodious with respect to the vulgar, as well as to foreigners who had an inclination to learn the language. The vulgar, some ages after Homer and Hesiod, must have found it as difficult to understand their poems as our people do to comprehend those of Chaucer and Spenser. By this disposition, too, the etymology of verbs was almost entirely confounded. The present second future being, as has been observed, the ancient present, the attention of the curious etymologist was naturally diverted to the modern present, where it was utterly impossible to discover the radical word. A few examples will elucidate this point: τειν-ω, *to stretch, to extend*, old present τανυω; ταν is the radix, which at once appears to be a Persian word signifying *a large tract of country*. Hence *Mauritania* "the land of the Maur," Aquitania, Bretania; and with s prefixed Hindo-stan, Chusi-stan, Turque-stan. The obsolete verb οτω, whence οπτομαι, is evidently derived from *oph*, an Egyptian name of the moon: φαινω, second future φανω, *to shew*, from the Egyptian word *phan* or *pan*, a name of the sun: τυπτω, future second τυπω; τυπ is obviously the offspring of בן *thph*, "a drum or timbrel," from beating or striking, &c. In such etymological researches, the student must be careful to turn the Ionic η into the Doric α; because the Dores were latest from the coast of Palestine, and consequently retained the largest share of the Phœnician dialect: thus χαιρω, *to rejoice*, turning η into α becomes χαιρω. This word, throwing away the termination, becomes *gath*, plainly signifying a *wine press* (u). It is likewise to be observed, that the Æolians often change α into υ, as συρξ instead of σαρξ, &c.

Greek Language.

It is not our intention to enter into the arrangement and peculiar constructions of the Greek language. There is, however, one, which we cannot well pass over in silence. As that tongue is destitute of those words which the Latins call *gerunds*, to supply this defect they employ the infinitive with the article prefixed; thus, Εις το ειναι αυτους φιλους, *in order to their being friends*; απο τω ἑλεσθαι αυτους βασιλεα, *from their having elected a king*; Εκ τη απο φευγειν αυτης εκτης πολεος, *from their flying out of the city*. In these phrases the infinitive is said to assume the nature of a substantive noun; agreeing with the article before it, exactly as if it were a noun of the neuter gender. Idioms of this kind occur in our own tongue; only with us the verb, instead of being expressed in the infinitive, is turned into the participle. According to this arrangement, the first of the preceding phrases, which, according to the Greek, would stand *toward to be friends*, in English is, *in order to their being friends*. This anomaly, then, if indeed it be such, is of no manner of consequence. The French, if we are not mistaken, would express it in the very same manner with the Greek, that is, *pour etre amis*.

154 Greek infinitives used as nouns.

From treating of verbs, we should naturally proceed to the consideration of adverbs, which are so denominated, because they are generally the concomitants of verbs. Every thing relating to that part of speech, in the Greek tongue, may be seen in the Port Royal or any other Greek grammar. Instead therefore of dwelling upon this beaten topic, we shall hazard a conjecture upon a point to which the critics in the Greek tongue, as far as we know, have not hitherto adverted.

The most elegant and most admired writers of Greece, and especially Homer, and after him Hesiod, abound with small particles, which appear to us pure expletives, created as it were to promote harmony, or fill up a blank without sense or signification. How those

155 Greek particles of oriental extraction.

(u) Hence it came to signify rejoicing, from the mirth and revelry attending the treading of the vine-press.

thoſe expletive particles ſhould abound in that language beyond any other, we think, is a matter not eaſy to account for. It has been ſaid by the Zoili, that if you extract theſe nonentities from the poems of that bard, *qui ſolus meruit dici poeta*, a *magnum inane*, a mighty blank would be left behind. We would willingly do juſtice to that pigmy race of words, and at the ſame time vindicate the prince of poets from that groundleſs imputation. Plato likewiſe, the prince of philoſophers, has been often accuſed of too frequently employing theſe ſuperfluous auxiliaries.

Thoſe particles were no doubt imported from the eaſt. It would be ridiculous to imagine that any deſcription of men, however enthuſiaſtically fond they might be of harmonious numbers, would ſit down on purpoſe to fabricate that race of monoſyllables purely to eke out their verſes; mere ſounds without ſignificancy. In the firſt place, it may be obſerved, that there is a very ſtrict connection among the particles of all cognate languages. To this we may add, that the not underſtanding the nature, relations, ſignification, and original import of thoſe ſeemingly unimportant terms, has occaſioned not only great uncertainty, but numberleſs errors in tranſlating the ancient languages into the modern. The Greek language in particular loſes a conſiderable part of its beauty, elegance, variety, and energy, when theſe adverbial particles with which it is replete are not thoroughly comprehended. An exact tranſlation of theſe ſmall words, in appearance inſignificant, would throw new light not only on Homer and Heſiod, but even upon poets of a much poſterior date. Particles, which are generally treated as mere expletives, would often be found energetically ſignificant. It is, however, altogether impoſſible to ſucceed in this attempt without a competent ſkill in the Hebrew, Chaldaic, Arabian, Perſian, and old Gothic languages. We ſhall here take the liberty to mention a few of theſe particles which are moſt familiar, one or other of which occur in almoſt every line of Homer, and which we believe are either not underſtood or miſunderſtood. Such are Δα, δη μεν νυτοι, μαν, γε, ιρι, αεα, ρα, γων. Δα is nothing elſe but the Chaldaic particle δα, the parent of the Engliſh *the*. It likewiſe ſignifies *by turns, in your turn:* δη is the ſame word in the Ionic dialect; μεν is a particle of the Hebrew affirmative אמן *amen, fides, veritas.* Μαν, a kind of oath by the moon called *mana*, almoſt over all the eaſt; hence Dor. μανα; γε, an oath by γεα, that is, *the earth;* αεα, another oath by the ſame element, probably from the oriental word of the ſame import; ρα is a fragment of αρα mentioned before; γων, of για the *earth*, and Ον or Ων, an Egyptian name of the ſun; Ως *as*, a particle which pervades all the dialects of the Gothic language. In this manner we believe all theſe ſmall words that occur ſo frequently in the Greek tongue, and which have hitherto been held inexplicable, may be eaſily rendered in ſignificant terms: and were this done, we believe they would add both beauty and energy to the clauſes in which they ſtand. But this diſcuſſion muſt be left to more accompliſhed adepts.

156 Prepoſitions,

We ſhall not explain the nature of prepoſitions, becauſe we are convinced that few people will take the trouble to peruſe this diſquiſition who are not already acquainted with their import in language. The Greek prepoſitions are eighteen in number, which need not be enumerated here. Moſt of theſe might be eaſily ſhown to be particles, or fragments deduced from oriental or Gothic words. The uſe of theſe words is to connect together terms in diſcourſe, and to ſhow the relation between them. In languages where, as in Engliſh, all theſe relations are expreſſed without any change on the termination of the nouns to which they are prefixed, the proceſs is natural and eaſy. The whole is performed by juxtapoſition. But in the Greek and Latin tongues, this effect is produced, partly by prefixing prepoſitions and partly varying the terminations of nouns. Had the Greeks been able to intimate all thoſe relations by varying the terminations, or had they multiplied their prepoſitions to ſuch a number as would have enabled them to expreſs theſe relations without the caſual variations, as the northern languages have done; in either caſe their language would have been leſs embarraſſing than it is in its preſent ſtate. According to the preſent arrangement both prepoſitions and the caſual variations are uſed promiſcuouſly to anſwer that purpoſe; a method which appears to us not altogether uniform. Though this plan might occaſion little embarraſſment to natives, it muſt, in our opinion, have proved ſomewhat perplexing to foreigners. The difficulty would be, as to the latter, when to adopt the one and when the other expedient.

Another inconveniency ariſes from the exceeding ſmall number of prepoſitions in that language, which bear too ſmall a proportion to the great variety of relations which they are appropriated to intimate. This deficiency obliged them often to employ the ſame prepoſition to denote different relations: For inſtance, Επι intimates, 1ſt, *upon;* as επι τυ λιθυ, *upon the ſtone;* and then it takes the genitive. 2d, It denotes *near upon;* as επι τῳ λιθῳ, and then it governs the dative. 3d, The ſame prepoſition ſignifies *motion towards;* as Επεσεν επι τον λιθον, *he fell upon the ſtone.* In theſe inſtances the ſame prepoſition intimates three different relations; and, which is ſtill more embarraſſing, each of theſe requires a different caſe. The difficulty in this inſtance is ſo conſiderable, that even the moſt accurate of the Greek writers themſelves often either forget or neglect the true application. Many examples of this might be adduced, did the limits aſſigned us admit ſuch illuſtrations. Every man who has carefully peruſed the Grecian authors will readily furniſh himſelf with examples.

157 Irregularly uſed,

Again, ſome prepoſitions, which indicate different relations, are prefixed to the ſame caſe. Thus, Εξ ſignifies *from;* as, εκ Διος Αρχωμεσθα, *from Jupiter we begin;* απ εμου βιου, *from my life*, or *my courſe of life;* προ των θυρων, *before the doors;* προ νικης εγκωμιον, *an encomium before the victory:* Αντι αγαθων αποδιδοναι κακα, *to render evil for good:* αντι σου, *againſt you.* In theſe examples, and indeed every where, thoſe prepoſitions intimate different relations, and yet are prefixed to the ſame caſes. Sometimes the ſame prepoſition ſeems to aſſume two oppoſite ſignifications: this appears from the prepoſition αντι juſt mentioned, which intimates both *for, inſtead of*, and *againſt* or *oppoſite to.*

What has been obſerved with reſpect to the prepoſitions above mentioned, the reader will readily enough apply to Κατα, Μετα, Δια, περι. Theſe incongruities certainly imply ſomething irregular; and ſeem to intimate

Greek Language.

mate that thoſe anomalies were ſo deeply incorporated with the conſtitution of the language, that the ſubſequent improvers found it impoſſible to correct them. Indeed to prefix a prepoſition to a caſe already diſtinguiſhed by the affixed termination, appears to us a ſuperfluity at leaſt, if not an abſurdity; for certainly it would have been more natural to have ſaid ἐκ Διὸς ἀρχόμεθα, than ἐκ Διὸς ἀρχόμεθα. Some very learned men, who have inquired into *the origin of language*, have been of opinion that prepoſitions were the laſt invented ſpecies of words. If this opinion is well founded, we may ſuppoſe (and we think that this ſuppoſition is not altogether improbable) that the caſual terminations of the Greek language were firſt affixed to the radix, in the manner above exhibited; and that prepoſitions were afterwards fabricated and prefixed to the caſes already in uſe.

The ſyntax or conſtruction of the Greek language does not, according to our plan, come within the compaſs of our preſent inquiry. This the curious Greek ſtudent will eaſily acquire, by applying to the grammars compoſed for that purpoſe. We have already hazarded a few conjectures with reſpect to the formation of the moſt important and moſt diſtinguiſhed claſſes of words into which it has been divided by the moſt able grammarians, without, however, deſcending to the minutiæ of the language. As prepoſitions are the chief materials with which its other words, eſpecially verbs, are compounded, we ſhall briefly conſider the order in which they probably advanced in this proceſs.

158 Uſed in compoſition.

Complex ideas are compounded of a certain number or collection of ſimple ones. Of thoſe complex notions, ſome contain a greater and ſome a ſmaller number of ſimple conceptions. In language, then, there are two ways of expreſſing thoſe complex ideas, either by coining a word to expreſs every ſimple idea ſeparately, according to the order in which they ſtand in the mind; or by trying to combine two or more ſimple terms into one, and by that method to intimate one complex idea by one ſingle word. The Arabians, notwithſtanding all the boaſted excellencies of their language, have never arrived at the art of compounding their words, in order to anſwer this noble purpoſe; and the ſiſter dialects are but ſlenderly provided with this ſpecies of vocables. The Greeks, of all other nations (except perhaps thoſe who ſpake the Shanſcrit language), are unrivalled in the number, variety, propriety, elegance, energy, and expreſſion of their compound terms. The Greeks, like the Arabians, in the earlieſt ſtages of their language, had only a collection of radical diſjointed words, conſiſting of the jargons of the aboriginal Greeks, of the Pelaſgi, Thracians, &c. How theſe words were arranged and conſtructed, we have no data remaining upon which we can found a critical inveſtigation. We muſt therefore remain ſatisfied with ſuch probable conjectures as the nature of the caſe, and the analogy of the language, ſeem to ſuggeſt.

The prepoſitions were originally placed before the nouns, whoſe relations they pointed out. For example, let us take the ξυγκατέθνησκετο τοις ἄλλοις, *he died along with the reſt*, or *he died out of hand along with the others*. Theſe words were arranged thus: ἀνεθνησκεν συν τοις ἄλλοις; and ἀπο-θνησκειν συν τοις ἄλλοις. In this manner the parts of every compound word were placed ſeparately, at leaſt as much as other words which had no connection.

Greek Language.

159 The firſt compound words in Greek.

The firſt compound words of the Greek language were the radical nouns with the article, and the radical part of the ſubſtantive or auxiliary verb. The ſucceſs of this experiment encouraged them to attempt the ſame in other words. By this noble invention they found themſelves able to expreſs, in one word, with eaſe and ſignificancy, what in other languages, and formerly in their own, required a tedious ambages or circumlocution. In proceſs of time, as their language was gradually mellowed, they increaſed the number of their compounds, till their language, in that reſpect, infinitely excelled all its parent dialects. In this proceſs they were careful to unite ſuch letters as not only prevented aſperity and difficulty of pronunciation, but even promoted harmony and elegance. But this was the labour of poſterior ages.

The Greeks were entirely ignorant of the derivation or etymology of their language: for this we need only conſult Plato's Cratylus, Ariſtotle's Rhetoric, Demetrius Phalereus, Longinus, &c. In deducing patronymics, abſtracts, poſſeſſives, gentiles, diminutives, verbals, &c. from radicals of every kind, they have ſhown the greateſt art and dexterity. Examples of this occur almoſt in every page of every Greek author. But this extended no farther than their own language; every foreign language was an abomination to the Greeks. But more of this in the ſequel.

160 Original materials of the Greek language;

The original materials of the Greek tongue were undoubtedly rough and diſcordant, as we have deſcribed them above. They had been collected from different quarters, were the produce of different countries, and had been imported at very diſtant periods. It would therefore be an entertaining, if not an inſtructing, ſpeculation, if it were poſſible to diſcover by what men and by what means this wonderful fabric was founded, erected, and carried to perfection. The writers of Greece afford us no light. Foreigners were unacquainted with that originally inſignificant canton. Every thing beyond Homer is buried in eternal oblivion. Orpheus is indeed reported to have compoſed poems; but theſe were ſoon obliterated by the hand of time. The verſes now aſcribed to that philoſophical hero are none of his *. Linus wrote, in the Pelaſgic dialect, the atchievements of the firſt Bacchus; Thamyris the Thracian wrote; and Pronapides the maſter of Homer was a celebrated poet. The works of all theſe bards did not long ſurvive; and it is a certain fact that the Greek tongue was highly poliſhed even more early than the age in which theſe worthies flouriſhed. Homer, no doubt, imitated their productions, and ſome are of opinion that he borrowed liberally from them. The Greeks knew no more of the original character of their language than of the original character and complexion of their progenitors. They allowed, indeed, that their language was originally barbarous and uncouth; but by what means or by what perſons it was poliſhed, enriched, and finally arranged, was to them an impenetrable ſecret.

* *Pauſan.* lib. 1. cap. 22.

We have already demonſtrated that the Ionim or aborigines of Greece were a race of barbarians; that conſequently their language, or rather their jargon, was of the ſame contexture. The Pelaſgi found both the

Greek Language.

the people and their ſpeech in this uncultivated ſtate. Theſe people arrived in Greece about the year before Chriſt 1760. It was then that the language of Greece began to be cultivated. Before the age of Homer the work ſeems to have been completed. Nothing of conſequence was afterwards added to the original ſtock; on the contrary, not a few moieties were deducted from the Homeric treaſure. The Pelaſgi, as was ſaid before, arrived in Greece *an. ant. Chr.* 1760. Homer is thought to have been born *an. ant. Chr.* 1041; conſequently the cultivation of the Greek tongue was completed in a period of about 700 years. But upon the ſuppoſition that Orpheus, Linus, Tamyris, &c. wrote long before Homer, as they certainly did, that language was arrived nigh the ſtandard of perfection two centuries before; by which computation the period of its progreſs towards its ſtationary point is reduced to 500 years. But as the Pelaſgi were a colony of foreigners, we ought to allow them one century at leaſt to ſettle and incorporate with the natives, and to communicate their language, laws, manners, and habits, to the aborigines of the country. By this deduction we ſhall reduce the term of cultivation to leſs than four centuries.

161 Which was carried to its utmoſt perfection at a very early period.

During this period Greece was furiouſly agitated by tumults and inſurrections. That country was divided into a number of independent ſtates, which were perpetually engaged in quarrels and competitions. The profeſſion of arms was abſolutely neceſſary for the protection and preſervation of the ſtate; and the man of conduct and proweſs was honoured as a demigod, and his exploits tranſmitted with eclat to poſterity. The Greek tongue was then rough and unpoliſhed; becauſe, like the ancient Romans, the braveſt men were more diſpoſed to act than to ſpeak. Every language will take its colour from the temper and character of thoſe who employ it; and had it not been owing to one claſs of men, the Greek tongue would have continued equally rough to the era of Homer as it had been a century after the arrival of the Pelaſgi.

There has appeared among barbarous or half-civilized people a deſcription of men whoſe profeſſion it has been to frequent the houſes or palaces of the great, in order to celebrate their atchievements, or thoſe of their anceſtors, in the ſublimeſt ſtrains of heroic poetry. Accordingly we find that the Germans had their *bards*, the Gauls their *fads*, the Scandinavians their *ſcalds* or *ſcaldres*, the Iriſh their *ſileas*, all retained for that very purpoſe. They lived with their chieftains or patrons; attended them to battle; were witneſſes of their heroic deeds; animated them with martial ſtrains; and celebrated their proweſs if they proved victorious; or, if they fell, raiſed the ſong of woe, and chanted the mournful dirge over their ſepulchres. Theſe bards were always both poets and muſicians. Their perſons were held ſacred and inviolable. They attended public entertainments, and appeared in all national conventions. The chief of them were employed in the temples of the gods; and the leſs illuſtrious, like our minſtrels of old, ſtrolled about from place to place, and exerciſed their functions wherever they found employment.

162 By the poets, who made a

Among the ancient Greeks there was a numerous tribe of men of the very ſame deſcription, who were at once poets and muſicians, and whoſe office it was to celebrate the praiſes of the great, and to tranſmit their exploits to poſterity in the moſt exaggerated encomiums. Theſe poetical vagrants were ſtyled Ἀοιδοὶ or ſongſters. Some of theſe lived in the houſes of great men; while others, leſs ſkilful or leſs fortunate, ſtrolled about the country in the manner above deſcribed. The more illuſtrious of thoſe Ἀοιδοὶ who were retained in the temples of the gods, were certainly the firſt improvers of the language of the Greeks. Among the Hebrews, we find the firſt poetical compoſitions were hymns in honour of Jehovah, and among the pagans the ſame practice was eſtabliſhed. In Greece, when all was confuſion and devaſtation, the temples of the gods were held ſacred and inviolable. There the Ἀοιδοὶ improved their talents, and formed religious anthems on thoſe very models which their progenitors had chanted in the eaſt.

Greek Language.

The language of the Greeks was yet rugged and unmellowed: their firſt care was to render it more ſoft and more flexible. They enriched it with vocables ſuited to the offices of religion; and theſe we imagine were chiefly imported from the eaſt. Homer every where mentions a diſtinction between the language of gods and men. The language of gods imports the oriental terms retained in the temples, and uſed in treating of the ceremonies of religion; the language of men intimates the ordinary civil dialect which ſprung from the mixed dialects of the country. The prieſts, no doubt, concurred in promoting this noble and important purpoſe. From this ſource the ſtrolling Ἀοιδοὶ drew the rudiments of their art; and from theſe laſt the vulgar deduced the elements of a poliſhed ſtyle.

163 Diſtinction between the language of Gods and of men.

To theſe Ἀοιδοὶ of the ſuperior order we would aſcribe thoſe changes mentioned in the preceding part of this inquiry, by which the Greek tongue acquired that variety and flexibility, from which two qualities it has derived a great ſhare of that eaſe, beauty, and verſatility, by which it now ſurpaſſes moſt other languages. The diverſity of its terminations furniſhes a moſt charming variety, while at the ſame time the ſenſe is communicated to the reader or hearer by the relation between them. By this economy the poet and the orator are left at liberty to arrange their vocables in that order which may be moſt ſoothing to the ear, and beſt adapted to make a laſting impreſſion on the mind.

Few colonies have emigrated from any civilized country without a detachment of prieſts in their train. The ſupreme powers, whoever they were, have always been worſhipped with muſic and dancing. The Hebrews, Phœnicians, and Egyptians, delighted in theſe muſical and jocund feſtivals. The prieſts who attended the Ions, Dores, Æolians, Thebans, Athenians, &c. from the eaſt, introduced into Greece that exquiſite taſte, thoſe delicate muſical feelings, which diſtinguiſhed the Greeks from all the neighbouring nations. Hence that numerous race of onomatapœas, by which the Greek language is inveſted with the power of expreſſing almoſt every paſſion of the human ſoul, in ſuch terms as oblige it to feel and actually to aſſimulate to the paſſion it would excite. Numberleſs inſtances of this occur in every page of Homer, Heſiod, Pindar, Sophocles, Euripides, and even of Ariſtophanes: to quote inſtances would be to inſult the Greek ſtudent.

Greek Language.

Every body knows that the practice of writing in verſe was antecedent to the date of proſaic compoſition. Here, then, the Aëdoi and the miniſters of religion chiefly diſplayed their ſkill and diſcernment. By a judicious mixture of ſhort and long ſyllables; by a junction of conſonants which naturally ſlide into each other; by a careful attention to the rythm, or harmony reſulting from the combination of the ſyllables of the whole line—they completed the metrical tone of the verſe, guided by that delicacy of muſical feeling of which they were poſſeſſed before rules of proſody were known among men.

Much liberty was certainly uſed in tranſpoſing letters, in varying terminations, in annexing prefixes and affixes, both to nouns and other kinds of words where ſuch adjuncts were poſſible: and upon this occaſion we think it probable, that thoſe particles of which we have ſpoken above were inſerted like filling ſtones thruſt in to ſtop the gaps or chinks of a building. Verſes were then clumſy and irregular, as the quantity of vowels was not duly aſcertained, and the collision of heterogeneous conſonants not always avoided. Probably theſe primitive verſes differed as widely from the finiſhed ſtrains of Homer and his ſucceſſors, as thoſe of Chaucer and Spenser do from the ſmooth poliſhed lines of Dryden and Pope.

16. Earlieſt poet of Greece.

The poetical compoſitions of the earlieſt Greeks were not, we think, in the hexameter ſtyle. As they were chiefly calculated for religious ſervices, we imagine they reſembled the Hebrew iambics preſerved in the ſong of Aaron and Miriam, Deborah and Barak, Pſalms, Proverbs, &c. which were indeed calculated for the ſame purpoſe. Archilochus perhaps imitated theſe, though the model upon which he formed his iambics was not generally known. The later dramatic poets ſeem to have copied from the ſame archetypes. Hexameters, it is probable, were invented by Orpheus, Linus, Pamyris, Muſæus, &c. The firſt of theſe travelled into Egypt, where he might learn the hexameter meaſure from that people, who uſed to bewail *Maneros* and *Oſiris* in elegiac ſtrains. This ſpecies of metre was firſt conſecrated to theology, and the moſt profound ſciences of moral and natural philoſophy; at length it was brought down to celebrate the exploits of kings and heroes.

Res geſtas regumque, ducumque et fortia bella,
Quo ſcribi poſſent numero monſtravit Homerus.

We have hazarded a conjecture above, importing that the earlieſt poetical compoſitions of the Greeks were conſecrated to the ſervice of the gods. We ſhall now produce a few facts, which will furniſh at leaſt a preſumptive evidence of the probability of that conjecture.

165 Orpheus.

Orpheus begins his poem with ancient chaos, its tranſformations and changes, and purſues it through its various revolutions. He then goes on to deſcribe the offſpring of Saturn, that is time, the æther, love, and light. In ſhort, his whole poem is ſaid to have been an oriental allegory, calculated to inſpire mankind with the fear of the gods, and to deter them from murder, rapine, unnatural luſts, &c.

166 Muſæus.

Muſæus was the favourite ſcholar of Orpheus, or perhaps his ſon. He compoſed prophecies and hymns, and wrote ſacred inſtructions, which he addreſſed to his ſon. He preſcribed atonements and luſtrations; but his great work was a Theogony, or Hiſtory of the Creation, &c.

Greek Language.

167 Melampus,

Melampus brought the myſteries of Proſerpine from Egypt into Greece. He wrote the whole hiſtory of of the diviſters of the gods. This ſeer is mentioned by Homer himſelf.

168 Olen.

Olen came from Lycia and compoſed the firſt hymn that was ſung in Delos at their ſolemnities; he probably emigrated from Patara a city of Lycia, where Apollo had a celebrated temple and oracle.

The Hyperborean damſels uſed to viſit Delos, where they chanted ſacred hymns in honour of the Delian god.

169 Homer and Heſiod.

To theſe we add the great Homer himſelf, if indeed the hymns commonly annexed to the Odyſſey are his compoſition. Heſiod's Theogony is too well known to need to be mentioned.

From theſe inſtances we hope it appears, that the origin of the poetry of Greece is to be found in the temples; and that there, its meaſure, numbers, rythm, and other appendages were originally fabricated

The Grecian poets, however, enjoyed another advantage which that claſs of writers have ſeldom poſſeſſed, which aroſe from the different dialects into which their language was divided. All thoſe dialects were adopted indifferently by the prince of poets; a circumſtance which enabled him to take advantage of any word from any dialect, provided it ſuited his purpoſe. This, at the ſame time that it rendered verſification eaſy, diffuſed an agreeable variety over his compoſition. He even accommodated words from Macedonia, Epirus, and Illyricum, to the purpoſes of his verſification: Beſides, the laws of quantity were not then clearly aſcertained; a circumſtance which afforded him another convenience. Succeeding poets did not enjoy theſe advantages, and conſequently have been more circumſcribed both in their diction and numbers.

170 Different dialects, with their origin.

The Greek language, as is generally known, was divided into many different dialects. Every ſept, or petty canton, had ſome peculiar forms of ſpeech which diſtinguiſhed it from the others. There were, however, four different dialectical variations which carried it over all the others. Theſe were the Attic, Ionic, Æolic, and Doric. Theſe four dialectical diſtinctions originated from the different countries in the eaſt from which the tribes reſpectively emigrated. The Attics conſiſted, 1ſt, of the barbarous aborigines; 2d, of an adventitious colony of Egyptian Saites; 3d, a branch of Ionians from the coaſt of Paleſtine. Theſe laſt formed the old Ionian dialect, from which ſprung the Attic and modern Ionic. The Æolians emigrated from a different quarter of the ſame coaſt; the inhabitants of which were a remnant of the old Canaanites, and conſequently different in dialect from the two firſt mentioned colonies. The Dores ſprang from an unpoliſhed race of purple fiſhers on the ſame coaſt, and conſequently ſpoke a dialect more coarſe and ruſtic than any of the reſt. Theſe four nations emigrated from different regions; a circumſtance which, in our opinion, laid the foundation of the different dialects by which they were afterwards diſtinguiſhed.

It

Greek Language

It is impoſſible in this ſhort ſketch to exhibit an exact view of the diſtinguiſhing features of each dialect. Such an analyſis would carry us far beyond the limits of the article in queſtion. For entire ſatisfaction on this head, we muſt refer the Grecian ſtudent to Mattaire's *Græcæ Linguæ Dialecti*, where he will find every thing neceſſary to qualify him for underſtanding that ſubject. We ſhall content ourſelves with the few obſervations following.

The Athenians being an active, briſk, volatile race, delighted in contractions. Their ſtyle was moſt exquiſitely poliſhed. The moſt celebrated authors who wrote in that dialect were the following: Plato, Thucidydes, Xenophon, Demoſthenes, and the other orators; Æſchylus, Euripides, Sophocles, Ariſtophanes, Menander, Diphilus, with the other comic and tragic poets. That dialect was either ancient or modern. The ancient Attic was the ſame with the Ionic.

The Ionic, as was ſaid, was the ancient Attic; but when that nation emigrated from Attica and ſettled on the coaſt of Aſia Minor, they mingled with the Carians and Pelaſgi and of courſe adopted a number of their vocables. They were an indolent, luxurious, and diſſolute people; of courſe their ſtyle was indeed eaſy and flowing, but verboſe, redundant, and without nerves. This, however, is the leading ſtyle in Homer; and after him a prodigious number of writers on every ſubject have uſed the ſame dialect, ſuch as Herodotus of Halicarnaſſus the celebrated hiſtorian; Cteſias of Cnidus the hiſtorian of Perſia and India; Hecataeus of Miletus; Megaſthenes the hiſtorian, who lived under Seleucus Nicator; Hippocrates the celebrated phyſician of Coos; Hellanicus the hiſtorian often mentioned with honour by Polybius; Anacreon of Teia; Alcæus, Sappho of Leſbos, excellent poets; Pherecydes Syrus the philoſopher, and a multitude of other perſons of the ſame profeſſion, whom it would be ſuperfluous to mention upon the preſent occaſion.

The Æolic and Doric were originally cognate dialects. When the Dorians invaded Peloponneſus and ſettled in that peninſula, they incorporated with the Æolians, and their two dialects blended into one produced the new Doric. The original Dores inhabited a rugged mountainous region about Oſſa and Pindus, and ſpoke a rough unpoliſhed language ſimilar to the ſoil which they inhabited. Andreas Schottus, in his obſervations on poetry, l. 2. cap. 50. proves from an old manuſcript of "Theocritus, that there were two dialects of the Doric tongue, the one ancient and the other modern; that this poet employed Ionic and the modern Doric; that the old Doric dialect was rough and cumbrous; but that Theocritus has adopted the new as being more ſoft and mellow." A prodigious number of poets and philoſophers wrote in this dialect, ſuch as Epicharmus the poet; Ibycus the poet of Rhegium; Corinna the poeteſs of Theſpis, or Thebes, or Corinth, who bore away the prize of poetry from Pindar; Erynna a poeteſs of Leſbos; Moſchus the poet of Syracuſe; Sappho the poeteſs of Mitylene; Pindarus of Thebes the prince of lyric-poets; Archimedes of Syracuſe the renowned mathematician; and almoſt all the Pythagorean philoſophers. Few hiſtorians wrote in that dialect; or if they did, their works have not fallen into our hands. Moſt of the hymns ſung in temples of the gods were compoſed in Doric; a circumſtance which evinces the antiquity of that dialect, and which, at the ſame time, proves its affinity to the oriental ſtandard.

Greek Language

171 The partiality of the Greeks to their own tongue, and its evil conſequences.

After that the Greek tongue was thoroughly poliſhed by the ſteps which we have endeavoured to trace in the preceding pages, conſcious of the ſuperior excellency of their own language, the Greeks, in the pride of their heart, ſtigmatized every nation which did not employ their language with the contemptuous title of *barbarians*. Such was the delicacy of their pampered ears, that they could not indure the untutored voice of the people whom they called Βαρβαροφωνοι. This extreme delicacy produced three very pernicious effects; for, 1ſt, it induced them to metamorphoſe, and ſometimes even to mangle, foreign names, in order to reduce their ſound to the Grecian ſtandard: and, 2d, it prevented their learning the languages of the eaſt, the knowledge of which would have opened to them an avenue to the records, annals, antiquities, laws, cuſtoms, &c. of the people of thoſe countries, in compariſon of whom the Greeks themſelves were of yeſterday, and knew nothing. By this unlucky bias, not only they, but even we who derive all the little knowledge of antiquity we poſſeſs through the channel of their writings, have ſuffered an irreparable injury. By their transformation of oriental names they have in a manner ſtopped the channel of communication between the hiſtories of Europe and Aſia. This appears evident from the fragments of Cteſias's Perſian hiſtory, from Herodotus, Xenophon, and all the other Grecian writers who have occaſion to mention the intercourſe between the Greeks and Perſians. 3d, It deprived them of all knowledge of the etymology of their own language, without which it was impoſſible for them to underſtand its words, phraſeology, and idioms, to the bottom. We mentioned Plato's Cratylus above. In that dialogue, the divine philoſopher endeavours to inveſtigate the etymology of only a few Greek words. His deductions are abſolutely childiſh, and little ſuperior to the random conjectures of a ſchool-boy. Varro, the moſt learned of all the Romans, has not been more ſucceſsful. Both ſtumbled on the very threſhold of that uſeful ſcience; and a ſcholar of very moderate proficiency in our days knows more of the origin of theſe two noble languages, than the greateſt adepts among the natives did in theirs. By prefixes, affixes, tranſpoſitions of letters, new conjunctions of vowels and conſonants for the ſake of the muſic and rythm, they have ſo diſguiſed their words, that it is almoſt impoſſible to develope their original. As a proof of this, we remember to have ſeen a manuſcript in the hands of a private perſon where the firſt twelve verſes of the Iliad are carefully analyſed; and it appears to our ſatisfaction that almoſt every word may be, and actually is, traced back to a Hebrew, Phœnician, Chaldean, or Ægyptian original: And we are convinced that the ſame proceſs will hold good in the like number of verſes taken from any of the moſt celebrated poets of Greece. This inveſtigation we found was chiefly conducted by reducing the words to their original invariable ſtate, which was done by ſtripping them of

Greek Language

prefixes, affixes, &c. These ſtrictures are, we think, well founded; and conſequently need no apology to protect them.

172 Beauty of the Greek language.

These imperfections, however, are counterbalanced by numberleſs excellencies: and we are certainly much more indebted to that incomparable people for the information they have tranſmitted to us through the medium of their writings, than injured by them in not conveying to us and to themſelves more authentic and more ample communications of ancient events and occurrences. Without fatiguing our readers with ſuperfluous encomiums on a language which has long ago been extolled perhaps to an extravagant degree by the labours of men of the moſt enlarged capacity and the moſt refined taſte, we ſhall now proceed to make a few obſervations on *ſpirits* and *accents*; which being rather appendages than eſſentials of the language, we have on purpoſe reſerved for the laſt place.

173 The ſpiritus aſper and lenis.

Every word in the Greek language beginning with a vowel is marked with a ſpirit or breathing: This aſpiration is double, namely *lenis et aſper*, "the gentle, and rough or aſpirated." The gentle accent, though always marked, is not now pronounced, though in the earlieſt periods of the language it was undoubted enounced, though very ſoftly. Both theſe aſpirations were imported from the eaſt. They were actually the Hebrew ה *he* and ח *heth*. The former denoted the *ſpiritus lenis*, and the latter the *ſpiritus aſper*. The Hebrew prefixed *ha* or *he* to words beginning with a vowel, and of courſe the Greeks followed their example. Theſe people ſeem to have delighted in aſpirates; and of conſequence the letter σ is, ſome think, rather too often affixed to the terminations of their words. Every word beginning with ρ had the aſpirate joined to ρ, probably with a deſign to render the aſpiration ſtill more rough.

174 The accents.

The Greek accents are three in number; the acute, the grave, and the circumflex. The acute raiſes and ſharpens the voice; the grave depreſſes and flattens it; the circumflex firſt raiſes and ſharpens the voice, and then depreſſes and flattens it. It is obviouſly compoſed of the other two. The learned author of the *Origin and Progreſs of Language* has taken much pains to prove that theſe accents were actually muſical notes, invented and accommodated to raiſe, depreſs, and ſuſpend the voice, according to a ſcale of muſical proportions. It is ſcarce poſſible, we think, for a modern Greek ſcholar to comprehend diſtinctly the ancient theory of accents. Theſe the native Greeks learned from their infancy, and that with ſuch accuracy, that even the vulgar among the Athenians would have hiſſed an actor or actreſs off the ſtage or an orator off the pulpitum ‡, on account of a few miſtakes in the enunciation of thoſe notes.

‡ See *Pulpitum*.

Theſe elevations, depreſſions, and ſuſpenſions of the voice upon certain ſyllables, muſt have made the language ſound in the ears of foreigners ſomewhat like recitative, or ſomething nearly reſembling *cant*. But the little variety of thoſe ſyllabic tones, and the voice not reſting upon them, but running them on without interruption, ſufficiently diſtinguiſhed them from muſic or cant. Be that as it may, we think it highly probable, that the wonderful effects produced by the harangues of the orators of Greece on the enraptured minds of their hearers, were owing in a good meaſure to thoſe artificial muſical tones by which their ſyllables were ſo happily diverſified. Greek Language.

To this purpoſe we ſhall take the liberty to tranſcribe a paſſage from Dion. Halic. *De Structura Orationis*, which we find tranſlated by the author of the *Origin and Progreſs of Language*, vol. ii. book 3d, part ii. chap. 7. page 381. "Rhetorical compoſition is a kind of muſic differing only from ſong or inſtrumental muſic, in the degree, not in the kind; for in this compoſition the words have melody, rythm, variety, or change, and what is proper or becoming: So that the ear in it, as well as in muſic, is delighted with the melody, moved by the rythm, is fond of variety, and deſires with all theſe what is proper and ſuitable. The difference, therefore, is only of greater and leſs."

With reſpect to accents, it may be obſerved that only one ſyllable of a word is capable of receiving the acute accent, however many there be in the word. It was thought that the raiſing the tone upon more than one ſyllable of the word, would have made the pronunciation too various and complicated, and too like chanting.

The *grave accent* always takes place when the acute is wanting. It accords with the level of the diſcourſe; whereas the acute raiſes the voice above it.

The *circumflex accent* being compoſed of the other two, is always placed over a long ſyllable, becauſe it is impoſſible firſt to elevate the voice and then to depreſs it on a ſhort one. Indeed among the Greeks a long ſyllable was pronounced like two ſhort ones; and we apprehend it was ſometimes written ſo, eſpecially in later times. It is altogether obvious from two learned Greek authors, Dion. Halic. and Ariſtoxenus, that the Greek accents were actually muſical notes, and that theſe tones did not conſiſt of loud and low, or ſimply elevating and depreſſing the voice; but that they were uttered in ſuch a manner as to produce a melodious rythm in diſcourſe.

In a word, the acute accent might be placed upon any ſyllable before the antepenult, and roſe to a *fifth* in the diatonical ſcale of muſic; the grave fell to the third below it. The circumflex was regulated according to the meaſure of both, the acute always preceding. The grave accent is never marked except over the laſt ſyllable. When no accent is marked, there the grave alwaya takes place. Some words are called *enclitics*. Theſe have no accent expreſſed, but throw it back upon the preceding word. The circumflex, when the laſt ſyllable is ſhort, is often found over the penult, but never over any other ſyllable but the laſt or the laſt but one.

175 The ancient Greeks had no accentual marks.

The ancient Greeks had no accentual marks. They learned thoſe modifications of voice by practice from their infancy; and we are aſſured by good authority, that in pronunciation they obſerve them to this day. The accentual marks are ſaid to have been invented by a famous grammarian, Ariſtophanes of Byzantium, keeper of the Alexandrian library under Ptolemy Philopater, and Epiphanes, who was the firſt likewiſe who is ſuppoſed to have invented punctuation. Accentual marks, however, were not in common uſe till about the ſeventh century; at which time they are found in manuſcripts. If our curious readers would wiſh to enter more deeply into the theory of accents, we muſt

Greek Language.

must remit them to Origin of Language, vol ii. l. 2. *passim*; and to Mr Foster's Essay on the different Nature of Accent and Quantity.

Such, in general, are the observations which we thought the nature of our design obliged us to make on the origin and progress of the Greek language. Some of our more learned readers may perhaps blame us for not interspersing the whole disquisition with quotations from the most celebrated writers in the language which has been the object of our researches. We are well aware that this is the general practice in such cases. The books were before us, and we might have transcribed from them more quotations than the nature of an article of this kind would permit. In the first part there were no books in that language to quote from, because the Greeks knew nothing of their own origin, nor of that of their language, and consequently have recorded nothing but dreams and fictions relating to that subject. Even when we had made considerable progress in our inquiry, the nature of the plan we have adopted excluded in a great measure the use of quotations. When we drew near the conclusion, we imagined that our learned readers would naturally have recourse to the passages alluded to without our information, and that the unlearned would not trouble themselves about the matter. The Greek student who intends to penetrate into the depths of this excellent language, will endeavour to be thoroughly acquainted with the books after mentioned.

176 Books to be studied by every one who wishes to be a master of this language.

Aristotle's Rhetoric and Poetics, his book *De Interpretatione*, especially with Ammonius's Commentary. Ammonius was a native of Alexandria, and by far the most acute of all the ancient grammarians.

Dion. Halic. *De Structura Orationis*, where, amidst abundance of curious and interesting observations, will be found the true pronunciation of the Greek letters.

Demetrius Phalereus *De Elocutione*; a short essay indeed, but replete with instruction concerning the proper arrangement of words and members in sentences.

Longinus, the prince of critics, whose remains are above commendation. Theodorus Gaza‡ and the other refugees from Constantinople, who found an hospitable reception from the munificent family of the Medici, and whose learned labours in their native language once more revived learning and good taste in Europe. These, with some other critics of less celebrity, but equal utility, will unlock all the treasures of Grecian erudition, without however disclosing the source from which they flowed. To these one might add a few celebrated moderns, such as Monf. Fourmont the Elder, Monf. Gebelin, Abbé Pezron, Salmasius, and especially the learned and industrious Lord Monboddo.

‡ See *Gaza*.

We shall now give a very brief account of the vast extent of the Greek language even before the Macedonian empire was erected; at which period, indeed, it became in a manner universal, much more than ever the Latin language could accomplish notwithstanding the vast extent of the Roman empire.

177 Vast extent of the Greek language.

Greece, originally Hellas, was a region of small extent, and yet sent out many numerous colonies into different parts of the world. These colonies carried their native language along with them, and industriously diffused it wherever they formed a settlement. The Iones, Æoles, and Dores, possessed themselves of all the west and north-west coast of the Lesser Asia and the adjacent islands; and there even the barbarians learned that polished language. The Greek colonies extended themselves along the south coast of the Euxine sea as far as Sinope, now Trebizund, and all the way from the west coast of Asia Minor: though many cities of barbarians lay between, the Greek tongue was understood and generally spoken by people of rank and fashion.

There were Greek cities on the north coast of the Euxine sea to the very eastern point, and perhaps beyond even those limits; likewise in the Taurica Chersonesus, or Crim Tartary; and even to the mouth of the Danube, the straits of Caffa, &c. In the neighbourhood of all these colonies, the Greek language was carefully propagated among the barbarians, who carried on commerce with the Greeks.

A great part of the south of Italy was planted with Greek cities on both coasts; so that the country was denominated *Magna Græcia*. Here the Greek tongue universally prevailed. In Sicily it was in a manner vernacular. The Ionians had sent a colony into Egypt in the reign of Psammitichus; and a Greek settlement had been formed in Cyrenia many ages before. The Phocians had built Massilia or Marseilles as early as the reign of Cyrus the Great, where some remains of the Greek language are still to be discovered. Cæsar tells us, that in the camp of the Helvetii registers were found in Greek letters. Perhaps no language ever had so extensive a spread, where it was not propagated by the law of conquest.

178 Greek spoken at present.

The Greek tongue, at this day, is confined within very narrow limits. It is spoken in Greece itself, except in Epirus, and the western parts of Macedonia. It is likewise spoken in the Grecian and Asiatic islands in Candia or Crete, in some parts of the coast of Asia Minor, and in Cyprus: but in all these regions, it is much corrupted and degenerated.

As a specimen, we shall insert a modern Greek song, and the advertisement of a quack medicine, which, with other plunder, was brought by the Russians from Choesim or Chotzim in 1772.

Song in modern Greek.

ΜΙ δυστυχίαις πολεμῶ μὲ βάσανα ὡς τὸ λαιμό
  Εἶμαι, και κιντινεύω, καὶ νὰ χαθῶ κοντεύω
Στο πέλαγος των συμφορῶν με ἐπικινδυνον καιρον
  Μ'ανέμους ὀλαθρίους σφοδροὺς και εναντιους.
Με κύματα πολλῶν καὶ μὲν τρφαιὶ ανασεισμῶν.
  Θαλασσα φυσκομένη, πολλα ἀγριομένη,
Ὅπου ἀφριζει καὶ φτσὰ με σαγανάκια περισσά
  Σύνεφα σκοτισμένα καὶ κατασυγχισμενα,
Και νὰ φανῆ μια σωτηρία, νὰ ἰδοῦν τα μάτια μου ξηρά.
  Γλιχα νερα νὰ εὕρω, κασχα και δεν ηξευρω,
Ν' ἀραξω και δεν ἠμπορῶ γιατι λιμένα δεν θωρῶ.
  Μ' ανελπιστίαν θρέχω στα ἄρμενα τοῦ ἰχν.
Πῶ μὲ αὐτὰ κὰν νὰ πνιγῶ ἢ σηλαμετινα εὑγῶ,
  Κὰὶ τουτα ἂν βασταξουν, ἐμποροῦν νὰ μὲ φυλαξουν.

Translation.

With dire misfortunes, pains, and woes,
O'erwhelm'd, ingulph'd, I struggling fight;
  O'er my frail bark proud billows close
To plunge her deep in lasting night.

Greek Language.

Rough seas of fils inceſſant roar,
Fierce winds adverſe, with howling blaſt,
Heave ſurge on ſurge. Ah! far from ſhore
My found'ring ſkiff ſhall ſink at laſt.
Involv'd in low'ring darkſome clouds,
'Mid ſultry fogs, I pant for breath;
Huge foaming billows rend my ſhrouds,
While yawning gulphs extend beneath.
From burſting clouds loud thunders roll,
And deaf'ning peals terrific ſpread;
Red lightnings dart from pole to pole,
And burſt o'er my devoted head.
When ſhall the friendly dawning rays
Guide me to pleaſures once poſſeſt;
And breezy gales, o'er peaceful ſeas,
Waft to ſome port of endleſs reſt?
In dark deſpair, with tempeſts toſt,
I veer my ſail from ſide to ſide.
Conduct me, Heav'n! to yond' fair coaſt,
Or plunge me in the 'whelming tide.

The Quack Bill.

ΒΑΛΣΑΜΟΝ ΤΗΣ ΙΕΡΟΥΣΑΛΗΜ, ΑΠΟ ΤΑΙΣ, ΚΑΙ ΝΟΥΡΙΑΙΣ, ΚΑΙ ΠΑΛΕΑΙΣ ΡΕΤΖΕΤΑΙΣ.

ΤΟΥΤΟ τὸ μπαλσαμον ὠφιλεῖ εις τὸ ἀδυνατόν ϛομάχι, ϗ βοηθᾶ τὴν χωνευσιν δυναμώνει τὴν καρδιαν. συκώνει ὁλας τας ἐμβρέξεις της κοιλιας ωφελεῖ εἰς τὴν ϛασιν ϗ βῆχα παλαιὸν. Ἰατρέυει τὰς ἐσωτερικὰς πληγὰς τὲ ϛόθος, ϗ τὰ πνεύμονος ἤγουν πλεμονίν. κινεῖ τα καταμήνια τῶν ϒυναικῶν. Εἰς τὰς ἐξωτερικὰς πληγὰς πρέπει νὰ βάζεται μὲ το ξανδὸ τόσον εἰς παλαιας. Οτον ϗ ἰσιτας, καθὼς εἶναι ἡ οπαθιάς, καὶ μαχαιριὰς, ϗ ἄλλα κοψίματα ἰατρεύει κάθελογῆς Φίσολα, ϗ ὁλας τὰς βρομερὰς πληγὰς ὁπὲ ἔφθασαν εἰς τὸ κοκαλον θαυμάσιως, ὠφιλεῖ εἰς τὰ ἀυτία ὁπὲ τρέχουν ἴμπυον νὰ ϕαζεται δὺο ἢ τρεῖς κόμπες ἤχουν ϕαλαγματιας μὲβαμπάκι βριμμένον εἰς ἄυτο, βάνεται εἰς τὰς πληγωμενὰς δυντοκοιλιαῖς ϗ θέλουν ἰατρευθῆ. ϗ ἀκομι δυναμώνει τὰ ὀδοντια ὁπὲ κινοῦνται δὲ θέλουν νὰ πέσουν. βοηθᾶ ϗ ἀπὸ τὴν παυθκλαι.

Ἡ δοσις ἐσωτερικὸς ἃς εἶναι δεκα ἢ ϗ δώδεκα κόμπες εἰς ὀλίγον κρασὶ, ἢ καὶ νερον, τὸ καθε ταχυ ϗ βράδυ. ἃς το ἀνταχειρίζεται, καὶ ἵνα θαυμάσιον μὲτὴν δοκιμὴν βεβαιωμένον.

Ἀληθὲς Ϭάλσαμον τῶ Βασιλεως.

Inſtead of giving a literal and bald tranſlation of this advertiſement, which runs exactly in the ſtyle of other quack bills, it may be ſufficient to obſerve, that the medicine recommended is ſaid, when taken inwardly, to raiſe the ſpirits, remove coſtiveneſs and inveterate coughs; to cure pains of the breaſt and bellyaches; to aſſiſt reſpiration, and remove certain female obſtructions. When applied externally, it cures wounds and ſores, whether old or freſh, removes ringing of the ears, faſtens the teeth when looſe, and ſtrengthens the gums.

All this, and much more, it is ſaid to do in a wonderful manner; and is declared to be the true royal balſam of Jeruſalem, and an univerſal ſpecific.

It is indeed next to a miracle that ſo many monuments of Grecian literature are ſtill to be found among men. Notwithſtanding the burning of the famous library of Alexandria, and the almoſt numberleſs wars, maſſacres, and devaſtations, which have from time to time in a manner deſolated thoſe countries where the Greek language once flouriſhed; we are told that there ſtill remain about 3000 books written in that language. Greek Language.

We ſhall now conclude this ſection with a brief detail of the moſt diſtinguiſhed ſtages and variations through which this noble tongue made its progreſs from the age of Homer to the taking of Conſtantinople, *an. ant. Chr.* 1453; a period of more than 2000 years. 179 Diſtinguiſhed ſtages of the Greek language.

Homer gave the Greek poetry its colour and conſiſtency, and enriched, as well as harmonized, the language. It ſeems, from the coincidence of epithets and cadence in Homer and Heſiod, that the Greek heroic verſe was formed ſpontaneouſly, by the old Ἀοιδοι, a ſort of *improviſatori*; and that Homer and his firſt followers adopted their verſification. The Iliad and Odyſſey have much of the air of extempore compoſitions; an epithet is never wanting to fill up a verſe; and a ſet of expreſſions are mechanically annexed to ſuch ideas as were of frequent recurrence. Hence that copiouſneſs and waſte of words in the old Greek bard, which forms ſuch a contraſt to the condenſed and laboured compoſition of Virgil.

The Greek proſe was of a more difficult ſtructure; and it may be diſtributed into different ſtyles or degrees of purity. Of the proſe authors now extant, the firſt and beſt ſtyle is that of Herodotus, and of Plato in the florid or mixed kind, of Xenophon in the pure and ſimple, of Thucydides and Demoſthenes in the auſtere. Nothing, perhaps, is ſo conducive to form a good taſte in compoſition as the ſtudy of theſe writers.

The ſtyle of Polybius forms a new epoch in the hiſtory of the Greek language: it was the idiotic or popular manner of expreſſion, eſpecially among military men, in his time, about the 150th Olympiad. It became the model of ſucceeding writers, by introducing a ſimple unſtudied expreſſion, and by emancipating them from the anxious labour of the old Greeks reſpecting the cadence and choice of words. The ſtyle of the New Teſtament, being plain and popular, frequently reſembles that of Polybius, as has been ſhown by Raphelius, and by Kirchmaier, *de paralleliſmo. N. T. et Polybii*, 1725.

Before this hiſtorian, the Alexandrian Jews had formed a new or Helleniſtic ſtyle, reſulting from the expreſſion of oriental ideas and idioms in Greek words, after that language had loſt of its purity, as it gained in general uſe, by the conqueſts of Alexander. The Helleniſtic is the language of the Septuagint, the Apocrypha, the New Teſtament, and partly of Philo and Joſephus. This mixture in the ſtyle of the evangeliſts and apoſtles, is one credential of the authenticity of the beſt of all books, a book which could not have been written but by Jewiſh authors in the firſt century. See the fine remarks of Biſhop Warburton, Doctrine of Grace, book i. ch. 8—10. Critics loſe their labour in attempting to adjuſt the Scripture-Greek to the ſtandard of Atticiſm.

The diction of the Greek hiſtorians, and geographers of the Auguſtan age, is formed on that of Polybius; but improved and modernized, like the Engliſh of the preſent age, if compared with that of Clarendon or Bacon. More perſpicuous than refined, it was well ſuited to ſuch compilations as were then written by men of letters, ſuch as Dionyſius, Diodo-

rus,

Greek Language.

rus, and Strabo, without much experience or rank in public life.

The eccleſiaſtical ſtyle was cultivated in the Chriſtian ſchools of Alexandria, Antioch, and Conſtantinople; rank and luxuriant, full of oriental idioms, and formed in a great meaſure on the Septuagint verſion. Such is, for inſtance, the ſtyle of Euſebius. After him, the beſt Chriſtian writers poliſhed their compoſitions in the ſchools of rhetoric under the later Sophiſts. Hence the popular and flowing purity of St Chryſoſtome, who has more good ſenſe than Plato, and perhaps as many good words.

On the Greek of the Byzantine empire, there is a good diſſertation by Ducange, *de cauſis corruptæ Græcitatis*, prefixed to his Gloſſary, together with Portius's Grammar of the modern Greek. This laſt ſtage of the Greek language is a miſerable picture of Turkiſh barbariſm. And, which is moſt ſurpriſing, there is no city of Greece where the language is more different from the ancient than at Athens. The reaſon of that is, becauſe it has been long inhabited by a mixed multitude of different nations.

To conclude, the Greeks have left the moſt durable monuments of human wiſdom, fortitude, magnificence, and ingenuity, in their improvement of every art and ſcience, and in the fineſt writings upon every ſubject neceſſary, profitable, elegant, or entertaining.

The Greeks have furniſhed the brighteſt examples of every virtue and accompliſhment, natural or acquired, political, moral, or military: they excelled in mathematics and philoſophy; in all the forms of government, in architecture, navigation, commerce, war: as orators, poets, and hiſtorians, they ſtand as yet unrivalled, and are like to ſtand ſo for ever; nor are they leſs to be admired for the exerciſes and amuſements they invented, and brought to perfection, in the inſtitution of their public games, their theatres, and ſports.

180 No perfect tranſlation of any Greek author.

Let us further obſerve, that in vain our readers will look for theſe admired excellencies in any of the beſt tranſlations from the Greek: they may indeed communicate ſome knowledge of what the originals contain; they may preſent you with propoſitions, characters, and events: but allowing them to be more faithful and more accurate than they really are, or can well be, ſtill they are no better than copies, in which the ſpirit and luſtre of the originals are almoſt totally loſt. The mind may be inſtructed, but will not be enchanted: The picture may bear ſome faint reſemblance, and if painted by a maſterly hand give pleaſure; but who would be ſatisfied with the canvas, when he may poſſeſs the real object? who would prefer a piece of coloured glaſs to a diamond? It is not poſſible to preſerve the beauties of the original in a tranſlation.—The powers of the Greek are vaſtly beyond thoſe of any other tongue. Whatever the Greeks deſcribe is always felt, and almoſt ſeen; motion and muſic are in every tone, and enthuſiaſm and inchantment poſſeſs the mind:

Graiis ingenium, Graiis dedit ore rotundo,
Muſa loqui. Hor.

Latin Language.

Sect. VIII. *Of the Latin Language.*

This language, like every other ſpoken by barbarians, was in its beginning rough and uncultivated.—What people the Romans were, is a point in which antiquarians are not yet agreed. In their own opinion they were ſprung from the Trojans *; Dion. Halicar. derives them from the Greeks †; and Plutarch informs us ‡ that ſome people imagined that they were ſprung from the Pelaſgi. The fact is, they were a mixture of people collected out of Latium and the adjacent parts, which a variety of accidents had drawn together, to eſtabliſh themſelves on that mountainous region, in order to ſecure their own property, and plunder that of their neighbours. They were in all probability compoſed of Arcadians, Siculi, Latins, Hetruſcans, Umbrians, Oſcans, Pelaſgi, &c.; and if ſo, their language muſt have been a mixture of the different dialects peculiar to all theſe diſcordant tribes.

181 Origin of the Romans, and of their language.

* *Tit. Liv.* lib. i. cap. 1. &c.

† *Antiq. Rom.* lib. i.

‡ *Vita Romul.*

The Latin language ought then to be a mingled maſs of the Arcadian, that is, the Æolian || Greek, the Pelaſgic, Hetruſcan, and Celtic dialects. Theſe jarring elements, like the people to whom they belonged reſpectively, gradually incorporated, and produced what was afterwards called the *Latin* tongue.

|| *Strabo*, lib. v. *Dionyſ. Halicarn. Antiq.* lib. i.

The Arcadians were a Pelaſgic § tribe, and conſequently ſpoke a dialect of that ancient Greek produced by the coalition of this tribe with the ſavage aborigines of Greece. This dialect was the groundwork of the Latin. Every ſcholar allows, that the Æolian Greek, which was ſtrongly tinctured with the Pelaſgic, was the model upon which the Latin language was formed. From this deduction it appears, that the Latin tongue is much more ancient than the modern Greek; and of courſe we may add, that the Greek, as it ſtood before it was thoroughly poliſhed, bore a very near reſemblance to that language. Hence we think we may conclude, that the knowledge of the Latin language is neceſſary in order to underſtand the Greek. Let us not then expect to find the real ingredients of the Greek tongue in the academic groves of Athens, or in Smyrna, or in Rhodope, or in Hæmos; but on the banks of the Tiber and on the fields of Laurentum.

§ *Strabo de Heraclitis.*

A very conſiderable part of the Latin tongue was derived from the Hetruſcan. That people were the maſters of the Romans in every thing ſacred. From them they learned the ceremonies of religion, the method of arranging games and public feſtivals, the art of divination, the interpretation of omens, the method of luſtrations, expiations, &c. It would, we believe, be eaſy to prove, that the Pelaſgi * and Hetruſci (x) were the ſame race of people; and if this was the caſe, their languages muſt have differed in dialect only.

* *Thucyd.* lib. iv.

The Umbrian or Celtic enters deeply into the compoſition of the Latin tongue. For proof of this, we need only appeal to *Pelloutier*, *Bullet's Memoires de la Langue Celtique*, *partie premiere*, *Abbé Pezron's Origin of*

(x) The Hetruſci were variouſly denominated by the Greeks and Romans. The former called them τυρρηνοι;

Latin Language

of Ancient Nations, &c. Whether the old Celtic differed essentially from the Pelasgic and Hetruscan, would be a matter of curious investigation, were this a proper subject for the present article.

The Latin abounds with oriental words, especially Hebrew, Chaldaic, and Persian. These are certainly remains of the Pelasgic and Hetruscan tongues, spoken originally by people who emigrated from regions where those were parts of the vernacular language.—The Greeks, in polishing their language, gradually distorted and disfigured vast numbers of the rough eastern vocables, which made a very great part of it. (See the preceding section).

The Romans, of less delicate organs, left them in their natural state, and their natural air readily bewrays their original. We had collected a large list of Latin words still current in the east; but find that Thomassin † and Ogerius (y), and especially Monf. Gebelin, in his most excellent Latin Dictionary, have rendered that labour superfluous.

† *Glossary.*

In this language, too, there are not a few Gothic terms. How these found their way into the Latin, it is not easy to discover, unless, as Pelloutier supposes, the Celtic and Gothic languages were originally the same: or perhaps we may conjecture, that such words were parts of a primitive language, which was at one time universal.

182 How far the Latin resembles the Greek.

There are, besides, in the Latin a great number of obsolete Greek words, which were in process of time obliterated, and others substituted in their room; so that, upon the whole, we are persuaded, that the most effectual method to distinguish the difference between the early and modern Greek, would be to compare the ancient Latin with the latter; there being, we imagine, very little difference between the ancient Greek and Latin in the earliest periods.

However that may be, it is certain that the Roman letters were the same with the ancient Greek.—*Formæ literis Latinis quæ veterrimis Græcorum*, says Tacitus * ; and Pliny † says the same thing, and for the truth of his assertion he appeals to a monument extant in his own times.

* *Tacitus, Annal.* lib. ii.
† *Nat. Hist.* lib. vii. cap. 58.

These old Greek letters were no other than the Pelasgic, which we have shown from Diodorus Siculus (see preceding Section) to have been prior to the Cadmean. For the figure of these letters, see Astle, Postellus, Montfaucon, Palæographia Græca, Munf. Gebelin, and our Plates IX and X.

That the Latins borrowed the plan of their declensions from the Greeks, is evident from the exact resemblance of the terminations of the cases throughout the three similar declensions. In nouns of the first declension, the resemblance is too palpable to stand in need of illustration. In the second, the Greek genitive is ου. In Latin the *o* is thrown out, and the termination becomes *i*. In the Greek section, we have observed, that the sounds of ι and υ differed very little; therefore the Latins used ι instead of υ. The Latin dative ends in *o*, which is the Greek dative, throwing away ι *subscriptum*, which was but faintly sounded in that language. No genuine Greek word ended in ω or *m*.

Latin Language.

The Hellens seemed to have abhorred that bellowing liquid; it is, however, certain that they imported it from the east, as well as the other letters, and that they employed it in every other capacity, except in that of closing words. In the termination of flexions, they changed it into ν.

The Latins retained *m*, which had been imported to them as a terminating letter at an era before the Greek language had undergone its last refinement.—Hence the Latin accusative in *um*, instead of the Greek ον. The vocative case, we imagine, was in this declension originally like the nominative. The Latins have no dual number, because, in our opinion, the Æolian dialect, from which they copied, had none. It would be, we think, a violent stretch of etymological exertion, to derive either the Latin genitive plural of the second declension from the same case of the Greek, or that of the latter from the former; we therefore leave this anomaly, without pretending to account for its original formation. The third declensions in both languages are so exactly parallel, that it would be superfluous to compare them. The dative plural here is another anomaly, and we think a very disagreeable one, which we leave to the conjectures of more profound etymologists.

For the other peculiarities of Latin nouns, as they are nearly similar to those of the Greek, we must beg leave to remit our readers to that section for information.

183 Deficiency of articles.

The Latins have no articles, which is certainly a defect in their language. The Pelasgic, from which they copied, had not adopted that word in the demonstrative sense. Homer indeed seldom uses it; and the probability is, that the more early Greek used it less frequently, at least in the sense above-mentioned. Thus in Latin, when I say, *video hominem*, it is impossible to find out by the bare words whether the word *hominem* intimates "a man," or "the man;" whereas in Greek it would be βλεπω ἀνθρωπον, *I see a man*, βλεπω τον ἀνθρωπον, *I see the man*. Hence the first expression is indefinite, and the second definite.

184 Origin of the substantive verb.

The substantive verb *sum* in Latin seems to be partly formed from the Greek and partly not. Some of the persons of the present tense have a near resemblance to the Greek verb ειμι or εἰμι, while others vary widely from that archetype. The imperfect præterite and

τυρσηνοι; which was their true name, for they actually emigrated from Tarshish, or the western coast of Asia Minor, and consequently Herodotus everywhere calls them τυρσηνοι. The Æolians changed α into υ; hence in that dialect they were called τυρσηνοι, from *Tarsus*. The Romans styled them *Tusci*, probably from the Greek verb θυω, *sacrifico*, alluding to the skill which that people professed in the ceremonies of religion. They called their country *Hetruria*, we think from the Chaldaic word *heretum*, "a magician or sorcerer;" a name deduced from their skill in divination.

(y) *Græca et Latina lingua Hebraizantes*, Venice 1763. If these books are not at hand, Dr Littleton's Dictionary will, in a good measure, supply their place.

Latin Language.

and præterperfect have nothing common with the Greek verb, and cannot, we think, be forced into an alliance with it. The future *ero* was of old *eſo*, and is indeed genuine Greek. Upon the whole, in our apprehenſion the Latin ſubſtantive verb more nearly reſembles the Perſian verb *heſten* than that of any other language we are acquainted with.

185 And of other verbs.

From what exemplar the Latin verbs were derived, is not, we think, eaſily aſcertained. We know that attempts have been made to deduce them all from the Æolic Greek, and that the Romans themſelves were extremely fond of this chimera; but the almoſt numberleſs irregularities, both in the formation and conjugation of their verbs, induce us to believe that only a part of them were formed upon that model. We are apt to think that the terminations in *bam*, *bas*, *bat*, *bamus*, &c. are produced by their union with a fragment of ſome obſolete verb, which is now wholly loſt. In the verb *amo*, *e.g.* we are ſure that the radix *am* is the Hebrew word *mother*; but how *am-abam*, *am-abo*, *am-arem* were fabricated, and connected with the radical *am*, is not ſo eaſily determined. That Latin verbs are compoſed of an inflexible radix and another flexible verb, as well as the Greek, cannot be doubted; but what this flexible auxiliary was, we think, cannot now be clearly aſcertained. It is not altogether improbable that ſuch parts of the verbs as deviate from the Greek archetype were ſupplied by fragments of the verb *ha*, which pervades all the branches of the Gothic language, and has, we think, produced the Latin verb *habeo*. When the Greeks began to etymologize, they ſeldom overpaſſed the verge of their own language: the Latins purſued nearly the ſame courſe. If their own language preſented a plauſible etymology, they embraced it; if not, they immediately had recourſe to the Greek; and this was the *ne plus ultra* of their etymological reſearches. Cicero, Quintilian, Feſtus, &c. and even Varro, the moſt learned of all the Romans, ſtop here; all beyond is either doubt or impenetrable darkneſs. The opinion above-mentioned we offer only as a conjecture; the deciſion we leave to more able critics

186 Deficiencies in Latin verbs.

The want of aoriſts or indefinite tenſes ſeems to us a palpable defect in the Latin language. The uſe of theſe among the Greeks enabled the writer to expreſs the ſpecific variations of time with more accuracy and preciſion than the Latins, who never attempted to ſpecify them by any other tenſes but the imperfect and pluperfect. Indeed we ſhould imagine, that both the Greeks and Latins were much inferior to the Engliſh in this reſpect. The Latin word *lego*, for example, may be tranſlated into Engliſh three different ways: 1ſt, *I read*; 2d, *I do read*; 3d, *I am reading*.

187 Irregularities in the conjugations.

The Latins, in reducing verbs to their four conjugations, formed their inflexions in a very irregular manner. Many verbs of the firſt claſs inflect their præterite and ſupine like thoſe of the ſecond: thus *domo*, inſtead of giving *avi* and *atum*, has *ui* and *itum*, like *monui* and *monitum*. Again, not a few verbs of the third conjugation have *ivi* and *itum*, as if they belonged to the fourth; e. g. *peto*, *petivi*, *petitum*. Then, ſome verbs have *io* in the preſent, *ivi* in the præterite, and *itum* in the ſupine, while, contrary to the rules of analogy, they in reality belong to the third: ſuch are *cupio*, *cupivi*, *cupitum*, *cupere*, &c. Some verbs of the ſecond conjugation have their præterite and ſupine as if they belonged to the third; thus, *jubeo*, *juſſi*, *juſſum*, *jubere*; *augeo*, *auxi*, *auctum*, *augere*. Some verbs, which are actually of the fourth conjugation, have their præterite and ſupine as if they were of the third; thus *ſentio*, *ſenſi*, *ſenſum*, *ſentire*; *hauris*, *hauſi*, *hauſtum*, *haurire*, &c. If theſe are not manifeſt irregularities, we cannot ſay what deſerves the name. The fact ſeems to ſtand thus: The Romans were originally a banditti of robbers, bankrupts, runaway ſlaves, ſhepherds, huſbandmen, and peaſants of the moſt unpoliſhed character. They were engaged in perpetual broils and quarrels at home, and ſeldom enjoyed repoſe abroad. Their profeſſion was robbery and plunder. Like old Iſhmael, their hands were againſt every man, and every man's hand againſt them. In ſuch a ſtate of ſociety no time was left for cultivating the ſciences. Accordingly the arts of war and government were their ſole profeſſion. This is ſo true, that their own poet characterizes them in the following manner:

Latin Language.

Excudunt alii ſpirantia mollius æra, &c.

188 The Latin deficient in participles.

Another blemiſh in the Latin tongue is occaſioned by its wanting a participle of the præterite tenſe in the active voice. This defect is perpetually felt, and is the cauſe of an aukward circumlocution wherever it happens to preſent itſelf. Thus, "The general having croſſed the river, drew up his army;" *Imperator, cum tranſiiſſet flumen, aciem inſtruxit.* Here *cum tranſiiſſet flumen* is a manifeſt circumlocution, which is at once avoided in the Greek διαβαντος περασας τον ποταμον, &c. This muſt always prove an incumbrance in the caſe of active intranſitive verbs. When active deponent verbs occur, it is eaſily avoided. Thus, "Cæſar having encouraged the ſoldiers, gave the ſignal for joining battle;" *Cæſar cohortatus milites, prælii committendi ſignum dedit.*

Another palpable defect in this language ariſes from the want of a participle of the preſent paſſive. This again muſt produce an inconveniency upon many occaſions, as will be obvious to every Latin ſtudent almoſt every moment.

189 Supines and gerunds.

The two ſupines are univerſally allowed to be ſubſtantive-nouns of the fourth declenſion. How theſe aſſumed the nature of verbs it is not eaſy to determine. When they are placed after verbs or nouns, the matter is attended with no difficulty; but how they ſhould acquire an active ſignification, and take the caſe of the verb with which they are connected, implies, we ſhould think, a ſtretch of prerogative.

The Latin gerunds form another unnatural anomaly. Every Latin ſcholar knows that theſe words are nothing but the neuters of the participles of the future paſſive. The fabricators of the Latin tongue, however, elevated them from their primary condition, giving them upon many occaſions an active ſignification. In this caſe we muſt have recourſe to

——————————*Si volet uſus,*
Quem penes arbitrium eſt et jus et norma loquendi.

Another inconveniency, perhaps more ſeverely felt than any of the preceding, ariſes from the want of the uſe of the preſent participle of the verb *ſum*. Every body knows what a conveniency is derived from the frequent uſe of the participle ων in Greek; and indeed it appears to us ſomewhat ſurpriſing that the

Latin Language.

Latins neglected to introduce the participle *ens* into their language. In this we believe they are ſingular. Here again a circumlocution becomes neceſſary in ſuch a caſe as the following: "The ſenate being at Rome, paſſed a decree." Inſtead of ſaying *ſenatus ens Romæ, legem tulit*, we are obliged to ſay *cum ſenatus Romæ eſſet*, &c. If the words *ens* or *exiſtens* had been adopted, as in the Greek, this odious circumlocution would have been avoided.

Many other defects of the like kind will occur to every perſon who ſhall chooſe to ſearch for them, and thoſe in the moſt approved claſſical authors. Perhaps our mentioning ſo many may be deemed invidious by the admirers of that language; but we write from conviction, and that muſt be our apology.

190 Different genius of the Latin and Greek languages.

If one take the trouble to compare the ſtructure of the Greek and Latin languages, he will, we think, quickly be convinced that their characteriſtic features are extremely different. The genius of the former ſeems eaſy and natural; whereas that of the latter, notwithſtanding the united efforts of poets, orators, and philoſophers, ſtill bears the marks of violence and reſtraint. Hence it appears that the Latin tongue was preſſed into the ſervice, and compelled almoſt againſt its will to bend to the laws of the Grecian model. Take a ſentence of Hebrew, Chaldean, Arabian, &c. and try to tranſlate it into Greek without regarding the arrangement of the words, and you will find it no difficult attempt; but make the ſame trial with reſpect to the Latin, and you will probably find the labour attended with conſiderable difficulty. To tranſlate Greek into Engliſh is no laborious taſk; the texture of the two languages is ſo congenial, that the words and phraſes, and even the idiomatic expreſſions, naturally ſlide into each other. With the Latin the caſe is quite otherwiſe; and before elegant Engliſh can be produced, one muſt deviate conſiderably from the original. Should we attempt to tranſlate a piece of Engliſh into Greek, and at the ſame time into Latin, the tranſlation of the former would be attended with much leſs difficulty than that of the latter, ſuppoſing the tranſlator equally ſkilled in both languages.

191 Cauſes of this difference.

This incongruity ſeems to ſpring from the following cauſe. Before any man of conſiderable abilities, either in the capacity of a poet, grammarian, or rhetorician, appeared at Rome, the language had acquired a ſtrong and inflexible tone, too ſtubborn to be exactly moulded according to the Grecian ſtandard. After a language has continued ſeveral centuries without receiving a new poliſh, it becomes like a full grown tree, incapable of being bent to the purpoſes of the mechanic. For this reaſon, it is highly probable, that the tongue in queſtion could not be forced into a complete aſſimilation with the Greek. Notwithſtanding all theſe obſtructions, in proceſs of time it arrived at ſuch an exalted pitch of perfection, as to rival, perhaps to excel, all the other European languages, the Greek only excepted. Had men of the taſte, judgment, and induſtry of Ennius, Plautus, Terence, Cicero, and the worthies of the Auguſtan age, appeared in the early ſtages of the Roman commonwealth, we may believe that their language would have been thoroughly reduced to the Grecian archetype, and that the two dialects might have improved each other by a rivalſhip between the nations who employed them.

Latin Language.

Without pretending to entertain our readers with a pompous and elaborate account of the beauties of that imperial language which have been detailed by writers almoſt without number, we ſhall endeavour to lay before them as briefly as poſſible its priſtine character, the ſteps and ſtages by which it gradually roſe to perfection, the period when it arrived at the ſummit of its excellence, and by what means it degenerated with a rapid career till it was loſt among thoſe very people to whom it owed its birth.

192 The Latin tongue compoſed chiefly of Pelaſgic and Celtic words.

We have obſerved already, that the Latin tongue was a *colluvies* of all the languages ſpoken by the va-grant people who compoſed the firſt elements of that republic. The prevailing dialects were the Pelaſgic or Hetruſcan, which we think were the ſame; and the Celtic, which was the aboriginal tongue of Italy. Hence the primary dialect of the Romans was compoſed of diſcordant materials, which in our opinion never acquired a natural and congenial union. Be that as it may, this motley mixture was certainly the original dialect of the Romans. The Pelaſgic or Hetruſcan part of it retained a ſtrong tincture of the oriental ſtyle. The Celtic part ſeems to have been prevalent, ſince we find that moſt of the names of places (z), eſpecially in the middle and northern parts of Italy, are actually of Celtic original. It is therefore clear that the ſtyle of the firſt Romans was compoſed of the languages above-mentioned. Who thoſe firſt Romans were, we believe it is impoſſible to determine with any degree of certainty. The Roman hiſtorians afford us aa little information upon that ſubject, as their etymologiſts do upon the origin of their language. Their moſt celebrated writers upon this point were Ælius Gallus, Quintus Cornificius, Nonius Marcellus, Feſtus, and ſome others of leſs note. At the head of theſe we ought to place Terentius Varro, whom Cicero ſtyles the moſt learned of all the Romans. From theſe writers we are to expect no light. Their etymologies are generally childiſh and futile. Of the language of the moſt ancient Romans we can only reaſon by analogy; and by that rule we can diſcover nothing more than what we have advanced above.

In the firſt place we may reſt aſſured that the dual number, the articles, the participle above-mentioned, the aoriſts, and the whole middle voice, never appeared in the Latin tongue; and accordingly were not current in thoſe languages from which it was copied, at leaſt at the time when it was firſt fabricated.

Beſides all this, many circumſtances concur to make it highly probable that, in the earlieſt periods of the language, very few inflexions were introduced. 1ſt, When the Pelaſgi left Greece, the Greek language itſelf was not fully poliſhed. 2d, The Arcadians were never thoroughly cultivated. They were a ruſtic paſtoral people, and little minded the refinements of a civilized

(z) For proof of this our readers may conſult Abbé Pezron, Pelloutier, Bullet's *Mem.* Gebelin *Pref. Dict. Lat.* and many others.

Latin Language.

vilized ſtate; conſequently the language they brought into Italy at that era muſt have been of a coarſe and irregular contexture. 3d, When the Theſſalian* Pelaſgi arrived in Italy about the time of Deucalion, the Greek itſelf was rude and barbarous; and, which is ſtill of more conſequence, if we may credit Herodotus quoted in the former Section, that people had never adopted the Hellenic tongue. Hence it appears, that the part of the Latin language derived from the Pelaſgic or Hetruſcan (for thoſe we believe to have been the ſame) muſt have taken a deep tincture from the oriental tongues (See preceding Section). If we may judge of the Celtic of that age by that of the preſent, the ſame character muſt likewiſe have diſtinguiſhed its ſtructure.

* *Dion. Halicar. lib. 1.*

193 Hence little inflected in its original ſtate.

From theſe circumſtances, we think it appears that the earlieſt language of the Romans was very little diverſified with inflexions. It nearly reſembled the oriental exemplar, and conſequently differed widely from the modern Latin. The effect of this was, that the modern Romans could not underſtand the language of their early progeniters. Polybius*, ſpeaking of the earlieſt treaty between the Romans and Carthaginians, makes the following obſervation: "Believe me (ſays he), the Roman language has undergone ſo many changes ſince that time (A) to the preſent, that even thoſe who are moſt deeply ſkilled in the ſcience of antiquities cannot underſtand the words of that treaty but with the greateſt difficulty."

* *Lib. 3. ab initio.*

From this ſource we make no doubt has flowed that vaſt number of oriental words with which the Latin language is impregnated. Theſe were originally inflexible, like their brethren of the eaſt. They were not diſguiſed as they now are with prefixes, affixes, metatheſes, ſyncopas, antitheſes, &c. but plain and unadorned in their natural dreſs.

194 Went afterwards into the Grecian model.

After the Romans became acquainted with the Æolian Greeks, who gradually ſeized upon both coaſts of Italy towards the ſouth, which they called *Magna Græcia*, they began to affect a Grecian air, and to torture their language into that foreign contexture. It appears, however, that at firſt the Grecian garb ſat rather awkwardly, and ſeveral marks of violence were eaſily diſcerned. The moſt ancient ſpecimen of this kind that we can recollect conſiſts of the remains of the *twelve tables*. Here every thing is rude and of a clumſy caſt; for though by this time conſiderable progreſs had been made in refinement, and the language of Rome had begun to appear in a Grecian uniform, ſtill thoſe changes were not altogether natural. Soon after appeared Marcus Fabius Pictor and Siſenna; hiſtorians often quoted by Livy, but whoſe works are long ſince irrecoverably loſt. The Faſti Capitolini are often mentioned; but they too periſhed in the burning of the Capitol during the civil wars between Marius and Sylla. Had thoſe monuments eſcaped the ravages of time, we ſhould have been able to mark the progreſs of the Latin tongue from ſtage to ſtage, and to aſcertain with the greateſt accuracy its gradual configuration in the conſe of its progreſs towards the Grecian ſtandard. We muſt therefore leave the Latin tongue during thoſe periods rude and barbarous, and deſcend to others better known and more characteriſtically marked. Thoſe commenced after that

Latin Language.

Græcia capta ferum victorem cepit et artes
Intulit agreſti Latio.

195 The principal authors by whom it was gradually poliſhed.

In this period we find Ennius, who wrote a Roman hiſtory in hexameter verſe in 18 books, which he called *Annals*; moſt part of which is now loſt. He likewiſe tranſlated *Euhemerus de Origine Deorum*; a work often mentioned by the Chriſtian fathers in their diſputes with the Pagans. It is ſometimes quoted by Cicero. Then followed Caius Lucilius the famous ſatyriſt, and a number of other writers, ſuch as Accius, Valerius, Ædituus, Alpinus, &c. whoſe fragments were publiſhed by the Stephens, Paris, 1564. All theſe imitated the writers of Greece or tranſlated from them. By their perſeverance and active exertions the ſpirit of theſe authors was transfuſed into the Latin tongue, and its ſtructure accommodated to the Grecian plan.

Plautus and Terence, by tranſlating the comedies of Menander and Diphilus into their own language, taught the Latin muſes to ſpeak Attic Greek. To ſpeak that language was then the *ton* of the times, as it is now with us to chatter French. Greek tutors were retained in every reputable family; and many Romans of the firſt rank were equally qualified to ſpeak or write both in Greek and Latin. The original jargon of Latium was now become obſolete and unintelligible; and Cato the Ancient condeſcended to learn the Greek language at 80.

195 The golden age of Rome.

To pretend to enumerate the various, and we may add inimitable, examples of the Auguſtan or golden age of the Roman tongue, would be an inſult to the underſtanding of our readers: we ſhall only take the liberty to tranſlate a few lines from a moſt excellent hiſtorian*, who, had his honeſty been equal to his judgment, might have rivaled the moſt celebrated writers of his country. Having obſerved, that the Greek authors, who excelled in every province of literature, had all made their appearance nearly about the ſame ſpace of time, confined within very narrow limits, he adds, "Nor was this circumſtance more conſpicuous among the Greeks than among the Romans; for unleſs we go back to the rough and unpoliſhed times, which deſerve commendation only on account of their invention, the Roman tragedy is confined to Accius and the period when he flouriſhed. The charming wit of Latin elegance was brought to light by Cecilius, Terentius, and Afranius, nearly in the ſame age. As for our hiſtorians (to add Livy alſo to the age of the former), if we except Cato and ſome old obſcure ones, they were all confined to a period of 80 years; ſo neither has our ſtock of poets extended to a ſpace much backward or forward. But the energy of the bar, and the finiſhed beauty of proſe eloquence, ſetting aſide the ſame Cato (by leave of P. Craſſus, Scipio, Lælius, the Gracchi, Fannius, and Ser. Galba, be it ſpoken), broke out all at once under Tully the prince of

* *Velleius Paterculus, lib. 1. cap. ult.*

(A) This treaty, according to the ſame hiſtorian, was concluded in the conſulſhip of Lucius Junius Brutus and Marcus Valerius, 28 years before Xerxes made his deſcent upon Greece.

Latin Language.

his profession; so that one can be delighted with none before him, and admire none except such as have either seen or were seen by that orator."

From this quotation it plainly appears, that the Romans themselves were convinced of the short duration of the golden age of their language. According to the most judicious critics, it commenced with the era of Cicero's oratorical productions, and terminated with the reign of Tiberius, or perhaps it did not reach beyond the middle of that prince's reign. It is generally believed that eloquence, and with it every thing liberal, elevated, and manly, was banished Rome by the despotism of the Cæsars. We imagine that the transition was too instantaneous to have been entirely produced by that unhappy cause. Despotism was firmly established among the Romans about the middle of the reign of Augustus; and yet that period produced such a group of learned men as never adorned any other nation in so short a space of time. Despotism, we acknowledge, might have affected the eloquence of the bar; the noble and important objects which had animated the republican orators being now no more: but this circumstance could not affect poetry, history, philosophy, &c. The style employed upon these subjects did not feel the fetters of despotism. The age of Louis XIV. was the golden period of the French tongue; and we think that age produced a race of learned men, in every department superior in number and equal in genius to the literati who flourished under the noble and envied constitution of Britain during the same age, though the latter is universally allowed to have been the golden period of this country. The British isles, we hope, enjoy still as much liberty as ever; yet we believe few people will aver, that the writers of the present age are equal either in style or in genius to that noble group who flourished from the middle of the reign of Charles I. to the middle of the reign of George II. and here despotism is quite unconcerned.

197 Causes of the degeneracy of the Latin tongue.

In the east the same observation is confirmed. The Persians have long groaned under the Mohammedan yoke; and yet every oriental scholar will allow, that in that country, and under the most galling tyranny, the most amazing productions of taste, genius, and industry, that ever dignified human nature, have been exhibited. Under the Arabian caliphs, the successors of Mohammed, appeared writers of a most sublime genius, though never was despotism more cruelly exercised than under those fanatics. The revival of letters at the era of the reformation was chiefly promoted and cherished by petty despotical princes.

We cannot therefore be persuaded to agree, that the despotism of the Cæsars banished eloquence and learning from Rome. Longinus indeed has attributed this misfortune to that cause, and tells us, θρεψαι τε γαρ ικανη τα φρονηματα των Μεγαλοφρονων ἡ ΕΛΕΥΘΕΡΙΑ, &c. "It is liberty that is formed to nurse the sentiments of great geniuses, to push forward the propensity of contest, to inspire them with hopes, and the generous ambition of being the first in rank." When Longinus wrote this, he did not reflect that he himself was a striking instance of the unsoundness of his observation.

As to science, the fact is undoubtedly on the other side. That Seneca was superior to Cicero in philosophy, cannot be reasonably contradicted. The latter had read, and actually abridged, the whole extent of Grecian philosophy: this displayed his reading rather than his learning. The former had addicted himself to the stoic sect; and though he does not write with the same flow of eloquence as Tully, he thinks more deeply and reasons more closely. Pliny's Natural History is a wonderful collection, and contains more useful knowledge than all the writings of the Augustan age condensed into one mass. We think the historical annals of Tacitus, if inferior to Livy in style and majesty of diction, much superior in arrangement and vigour of composition. In short, we discover in these productions a deep insight into human nature, an extensive knowledge of the science of government, a penetration which no dissimulation could escape, together with a sincere attachment to truth both with respect to events and characters; nor is he inferior in the majesty, energy, and propriety of his harangues, wherever an equal opportunity presents itself. Quintilian, Pliny the younger, Suetonius, Petronius Arbiter, and Juvenal, deserve high esteem; nor are they inferior to their immediate predecessors. We think there is good reason to conclude, that the loss of liberty among the Romans did not produce the extinction of eloquence, science, elevation of sentiment, or refinement of taste. There were, we believe, other circumstances which chiefly contributed to produce that revolution.

Latin Language.

198 The writers of the silver age greater masters of science than their predecessors.

The same Velleius Paterculus whom we have quoted assigns some plausible and very judicious reasons for this catastrophe. "Emulation (says he) is the nurse of genius; and one while envy, and another admiration, fires imitation. According to the laws of nature, that which is pursued with the greatest ardour mounts to the top: but to be stationary in perfection is a difficult matter; and by the same analogy, that which cannot go forward goes backward. As at the outset we are animated to overtake those whom we deem before us, so when we despair of being able to overtake or to pass by them, our ardour languishes together with our hope, and what it cannot overtake it ceases to pursue; and leaving the subject as already engrossed by another, it looks out for a new one upon which to exert itself. That by which we find we are not able to acquire eminence we relinquish, and try to find out some object *elsewhere* upon which to employ our intellectual powers. The consequence is, that frequent and variable transitions from subject to subject proves a very great obstacle to perfection in any profession."

This perhaps was the case with the Romans. The heroes of the Augustan age had borne away the prize of eloquence, of history, of poetry, &c. Their successors despaired of being able to equal, much less to surpass them, in any of these walks. They were therefore laid under the necessity of striking out a new path by which they might arrive at eminence. Consequently Seneca introduced the *stile coupé*, as the French call it; that is, a short, sparkling, figurative diction, abounding with antitheses, quaintnesses, witticisms, embellished with flowers and meretricious ornaments; whereas the style of the Augustan age was natural, simple, solid, unaffected, and properly adapted to the nature of the subject and the sentiments of the author.

The historian Sallust laid the foundation of the unnatural

Latin Language.

natural ſtyle above mentioned. Notwithſtanding all the excellencies of that celebrated author, he every where exhibits an affectation of antiquity, an antithetical caſt, an air of auſterity, an accuracy, exactneſs, and regularity, contrary to that *air degagé* which nature diſplays in her moſt elaborate efforts. His words, his clauſes, ſeem to be adjuſted exactly according to number, weight, and meaſure, without exceſs or defect. Velleius Paterculus imitated this writer; and, as is generally the caſe with imitators, ſucceeded beſt in thoſe points where his archetype had failed moſt egregiouſly. Tacitus, however excellent in other reſpects, deviated from the Auguſtan exemplars, and is thought to have imitated Salluſt; but affecting brevity to exceſs, he often falls into obſcurity. The other contemporary writers employ a cognate ſtyle; and becauſe they have deviated from the Auguſtan ſtandard, their works are held in leſs eſtimation, and are thought to bear about them marks of degeneracy.

That degeneracy, however, did not ſpring from the deſpotic government under which theſe authors lived, but from that affectation of ſingularity into which they were led by an eager but fruitleſs deſire of ſignalizing themſelves in their mode, as their predeceſſors had done in theirs. But the miſchiefs of this rage for innovation did not reach their ſentiments as it had done their ſtyle; for in that point we think they were ſo far from falling below the meaſure of the writers of the former age, that in many inſtances they ſeem to have ſurpaſſed them.

With reſpect to ſentiment and mental exertions, the authors in queſtion preſerved their vigour, till luxury and effeminacy, in conſequence of power and opulence, enervated both the bodies and minds of the Romans. The contagion ſoon became univerſal; and a liſtleſſneſs, or intellectual torpor, the uſual concomitant of luxury, ſpread indolence over the mental faculties, which rendered them not only averſe to, but even incapable of, induſtry and perſeverance. This lethargic diſpoſition of mind ſeems to have commenced towards the concluſion of the ſilver age; that is, about the end of the reign of Adrian. It was then that the Roman eagles began to ſtoop, and the genius of Rome, as well in arts as in arms, began to decline. Once more, the declenſion of the intellectual powers of the writers of that nation did not ariſe from the form of the government, but from the cauſes above ſpecified.

As the Roman genius, about that period, began to decline, ſo the ſtyle of the ſilver age was gradually vitiated with barbariſms and exotic forms of ſpeech. The multitudes of barbarians who flocked to Rome from all parts of the empire; the ambaſſadors of foreign princes, and often the princes themſelves, with their attendants; the prodigious numbers of ſlaves who were entertained in all the conſiderable families of the capital, and over all Italy; the frequent commerce which the Roman armies upon the frontiers carried on with the barbarians; all concurred to vitiate the Latin tongue, and to interlard it with foreign words and idioms. In ſuch circumſtances, it was impoſſible for that or any other language to have continued pure and untainted.

This vitiated character both of ſtyle and ſentiment became more and more prevalent, in proportion as it deſcended from the reign of Adrian towards the era of the removal of the imperial ſeat from Rome to Conſtantinople. Then ſucceeded the iron age, when the Roman language became abſolutely rude and barbarous.

Latin Language.

199 Writers of great talents during the ſilver and brazen ages.

Towards the cloſe of the ſilver, and during the whole courſe of the brazen age, there appeared, however, many writers of no contemptible talents. The moſt remarkable was Seneca the ſtoic, the maſter of Nero, whoſe character both as a man and a writer is diſcuſſed with great accuracy by the noble author of the *Characteriſtics*, to whom we refer our readers.

About the ſame time lived Perſius the ſatyriſt, the friend and diſciple of the ſtoic Cornutus; to whoſe precepts, as he did honour by his virtuous life, ſo his works, though ſmall, ſhow an early proficiency in the ſcience of morals.

Under the mild government of Adrian and the Antonines lived Aulus Gellius, or (as ſome call him) Agellius; an entertaining writer in the miſcellaneous way, well ſkilled in criticiſm and antiquity. His works contain ſeveral valuable fragments of philoſophy, which are indeed the moſt curious part of them.

With Aulus Gellius we may range Macrobius; not becauſe a contemporary (for he is ſuppoſed to have lived under Honorius and Theodoſius), but from his near reſemblance in the character of a writer. His works, like thoſe of the other, are miſcellaneous; filled with mythology and ancient literature, with ſome philoſophy intermixed.

In the ſame age with Aulus Gellius flouriſhed Apuleius of Madaura in Africa; a Platonic writer, whoſe matter in general far exceeds his perplexed and affected ſtyle, too conformable to the falſe rhetoric of the age when he lived.

Boethius was deſcended from one of the nobleſt of the Roman families, and was conſul in the beginning of the ſixth century. He wrote many philoſophical works; but his ethic piece on the Conſolation of Philoſophy deſerves great encomiums, both for the matter and the ſtyle; in which latter he approaches the purity of a far better age than his own. By command of Theodoric king of the Goths this great and good man ſuffered death; with whom the Latin tongue, and the laſt remains of the Roman dignity, may be ſaid to have ſunk in the weſtern world.

There were beſides a goodly number both of poets and hiſtorians who flouriſhed during this period; ſuch as Silius Italicus, Claudian, Auſonius, &c. poets and hiſtorians to a very great number, for whom our readers may conſult *Joh. Alberti Fabricii Bibl. Lat.*

200 Ecclesiastical writers in Latin.

There flouriſhed, too, a number of eccleſiaſtical writers, ſome of whom deſerve great commendation. The chief of theſe is Lactantius, who has been deſervedly dignified with the title of the *Chriſtian Cicero*.

The Roman authors amount to a very ſmall number in compariſon of the Greek. At the ſame time, when we conſider the extent and duration of the Roman empire, we are juſtly ſurpriſed to find ſo few writers of character and reputation in ſo vaſt a field. We think we have good reaſon to agree with the prince of Roman poets in the ſentiment quoted p. 562.

Upon the whole, the Latin tongue deſerves our attention beyond any other ancient one now extant. The grandeur of the people by whom it was ſpoken; the

Celtic Language.

201 Excellency and usefulness of the Latin tongue.

the lustre of its writers; the empire which it still maintains among ourselves; the necessity we are under of learning it in order to obtain access to almost all the sciences, nay even to the knowledge of our own laws, of our judicial proceedings, of our charters; all these circumstances, and many others too numerous to be detailed, render the acquisition of that imperial language in a peculiar manner at once improving and highly interesting. Spoken by the conquerors of the ancient nations, it partakes of all their revolutions, and bears continually their impression. Strong and nervous while they were employed in nothing but battles and carnage, it thundered in the camps, and made the proudest people to tremble, and the most despotic monarchs to bend their stubborn necks to the yoke. Copious and majestic, when, weary of battles, the Romans inclined to vie with the Greeks in science and the graces, it became the learned language of Europe, and by its lustre made the jargon of savages disappear who disputed with it the possession of that quarter of the globe. After having controlled by its eloquence, and humanized by its laws, all those people, it became the language of religion. In short, the Latin language will be studied and esteemed as long as good sense and fine taste remain in the world.

Sect. IX. *Celtic, Gothic, and Sclavonian Languages.*

§ 1. *Of the Celtic Language.*

In treating of the origin of the Latin tongue (see Section VIII.), we observed that a great part of it is derived from the Celtic. We shall now endeavour to give some account of the origin and extent of that ancient language; still leaving the *minutiæ* to grammars and dictionaries, as we have done with respect to the other dialects which have fallen under our consideration. Our candid readers, it is hoped, will remember, that we are acting in the character of philologers, not in that of grammarians and lexicographers.

202 Origin of the Celts.

The descendants of Japhet having peopled the western parts of Asia, at length entered Europe. Some broke into that quarter of the globe by the north, others found means to cross the Danube near its mouth. Their posterity gradually ascended towards the source of that river; afterwards they advanced to the banks of the Rhine, which they passed, and thence spread themselves as far as the Alps and the Pyrenean hills.

These people, in all probability, were composed of different families; all, however, spoke the same language; their manners and customs bore a near resemblance; there was no variety among them but that difference which climate always introduces. Accordingly they were all known, in the more early times, by the general name of *Celto-scythæ*. In process of time, becoming exceedingly numerous, they were divided into several nations, which were distinguished by different names and territorial appellations. These who inhabited that large country bounded by the ocean, the Mediterranean, the Rhine, the Alps, and the Pyrenees, were denominated *Gauls* or *Celts*. Those people multiplied so prodigiously in the space of a few centuries, that the fertile regions which they then occupied could not afford them the means of subsistence. Some of them now passed over into Britain; others crossed the Pyrenees, and formed settlements in the northern parts of Spain. Even the formidable barriers of the Alps could not impede the progress of the Gauls: they made their way into Italy, and colonized those parts which lie at the foot of the mountains; whence they extended themselves towards the centre of that rich country.

203 Part of whom were denominated *Gauls*

Celtic Language.

By this time the Greeks had landed on the eastern coast of Italy, and founded numerous colonies in those parts. The two nations vying as it were with each other in populousness, and always planting colonies in the course of their progress, at length rencountered about the middle of the country. This central region was at that time called *Latium*. Here the two nations formed one society, which was called *the Latin people*. The languages of the two nations were blended together; and hence, according to some, the Latin is a mixture of Greek and Gaelic.

As the Gauls were a brave and numerous people, they certainly maintained themselves in their pristine possessions, uninvaded, unconquered, till their civil animosities and domestic quarrels exposed them as a prey to those very Romans whom they had so often defeated, and sometimes driven to the brink of destruction. They were not a people addicted to commerce; and, upon the whole, considering their situation both in their primary seats and afterwards in Italy, they had little temptation or opportunity to mingle with foreigners. Their language, therefore, must have remained unmixed with foreign idioms. Such as it was when they settled in Gaul, such it must have continued till the Roman conquests. If therefore there is one primitive language now existing, it must be found in the remains of the Gaelic or Celtic. It is not, then, surprising, that some very learned men, upon discovering the coincidence of very great numbers of words in some of the Greek dialects with other words in the Celtic, have been inclined to establish a strict affinity between those languages. The ancient Pelasgic and the Celtic at least must have nearly resembled each other, admitting a dialectical difference only, and that discrimination which climate and a long period of time must always produce.

204 Resemblance between their language and that of the Pelasgi.

Some have thought that the Gauls lost the use of their native language soon after their country was conquered by the Romans; but *Monsieur Bullet*, in his *Memoires de la Langue Celtique*, has proved almost to a demonstration, that the vulgar among those people continued to speak it several centuries after that period. When a great and populous nation has for many ages employed a vernacular tongue, nothing can ever make them entirely relinquish the use of it, and adopt unmixed that of their conquerors.

Many learned men, among whom is the lexicographer above-mentioned, have shown that all the local names in the north of Italy are actually of Celtic extraction. These names generally point out or describe some circumstances relating to the nature of their situation; such as exposure, eminence, lowness, moistness, dryness, coldness, heat, &c. This is a very characteristic feature of an original language; and in the Celtic it is so prominent, that the Erse names of places all over Scotland are, even to this day, peculiarly distinguished by this quality. We have heard a gentleman, who was well skilled in the dialect of the Celtic still spoken

Celtic Language

in the Highlands of Scotland, propoſe to lay a bet, at very great odds, that if one ſhould pronounce the name of any village, mountain, river, gentleman's ſeat, &c. in the old Scottiſh dialect, he ſhould be able, by its very name, to give a pretty exact deſcription of its local ſituation.

To diſcover the ſources from which the Celtic tongue is derived, we muſt have recourſe to the following expedients.

1. We muſt conſult the Greek and Latin authors, who have preſerved ſome Gaelic or Celtic terms in their writings.

2. We muſt have recourſe to the Welſh and *Baſſe Bretagne* dialects; in which, indeed, there are many new words, but theſe are eaſily diſtinguiſhed from the primitive ſtock.

3. If one would trace another ſource of the Celtic, he muſt converſe with the country people and peaſants, who live at a diſtance from cities, in thoſe countries where it was once the vernacular tongue. We have been credibly informed, that a Highland gentleman, croſſing the Alps for Italy, accidentally fell in with an old woman, a native of thoſe parts, who ſpoke a language ſo near akin to his native Erſe, that he could underſtand her with little difficulty; and that ſhe, on the other hand, underſtood moſt of his words. That an event of this nature ſhould actually take place is by no means ſurpriſing, when we conſider that the Erſe ſpoken in the Highlands of Scotland is perhaps the moſt genuine remnant of the Celtic now exiſting, and at the ſame time reflect that there may be ſome remote cantons among thoſe wild and inacceſſible mountains, the Alps, where ſome remains of that tongue may be ſtill preſerved.

205 The moſt genuine remains of the Celtic in the Highlands of Scotland.

4. We have ſaid, that the moſt genuine remains of the Gaelic tongue are to be found in the Highlands of Scotland; and the reaſon is obvious. The Scottiſh Highlanders are the unmixed unconquered poſterity of the ancient Britons, into whoſe barren domains the Romans never penetrated; not, we imagine, becauſe they were not able, ſince they ſubdued both North and South Wales, equally inacceſſible, but becauſe they found no ſcenes there either to fire their ambition or allure their avarice. Amidſt all the revolutions that from time to time ſhook and convulſed Albion, thoſe mountainous regions were left to their primitive lords, who, like their ſouthern progenitors, hoſpitable in the extreme, did not, however, ſuffer ſtrangers to reſide long among them. Their language, accordingly, remained unmixed, and continues ſo even to this day, eſpecially in the moſt remote parts and unfrequented iſlands.

The Norwegians ſubdued the weſtern iſlands of Scotland at a time when the Scottiſh monarchy was ſtill in its minority. They erected a kind of principality over them, of which the iſle of *Man* was the capital. Though they maintained the ſovereignty of thoſe iſlands for ſome centuries, built many forts, and ſtrengthened them with garriſons, and in fine were the lawgivers and adminiſtrators of juſtice among the natives; yet we have been informed by the moſt reſpectable authority, that there is not at this day a ſingle vocable of the Norſe or Daniſh tongue to be found among thoſe iſlanders. This fact affords a demonſtration of that ſuperſtitious attachment with which they were devoted to their vernacular dialects.

Celtic Language.

206 The Welſh dialect not pure, nor the Iriſh.

The Welſh dialect cannot we think be pure and unſophiſticated. The *Silures* were conquered by the Romans, to whom they were actually ſubject for the ſpace of three centuries. During this period, a multitude of Italian exotics muſt have been tranſplanted into their language; and indeed many of them are diſcernible at this day. Their long commerce with their Engliſh neighbours and conquerors hath adulterated their language, ſo that a great part of it is now of an Engliſh complexion. The Iriſh is now ſpoken by a race of people whoſe morality and ingenuity are nearly upon a level. Their lateſt hiſtorians have brought them from the confines of Aſia, through a variety of adventures, to people an iſland *extra anni ſoliſque vias*. However this genealogical tale may pleaſe the people for whom it was fabricated, we muſt ſtill ſuſpect that the Iriſh are of Celtic extraction, and that their foreſathers emigrated from the weſtern coaſt of Britain at a period prior to all hiſtorical or even traditional annals. Ireland was once the *native land of ſaints*. The chief actors on this ſacred ſtage were Romaniſts, and deeply tinctured with the ſuperſtition of the times. They pretended to improve the language of the natives; and whatever their ſucceſs was, they improved it in ſuch a manner as to make it deviate very conſiderably from the original Celtic; ſo that it is not in Ireland that we are to look for the genuine characters of the dialect under conſideration.

Though the Hibernian tongue, in our opinion, differs conſiderably from the original Celtic, ſome very ingenious eſſays have been lately publiſhed by the learned and laborious members of the *Antiquarian Society of Dublin*; in which the coincidence of that tongue, with ſome of the oriental dialects, has been ſupported by very plauſible arguments. In a diſſertation publiſhed in the year 1772, they have exhibited a collection of *Punico-Malteſe* words compared with words of the ſame import in Iriſh, where it muſt be allowed the reſemblance is palpable. In the ſame diſſertation they have compared the celebrated *Punic* ſcene in Plautus with its tranſlation into the Iriſh; in which the words in the two languages are ſurpriſingly ſimilar. If thoſe criticiſms are well founded, they will prove that the Celtic is coeval and congenial with the moſt ancient languages of the eaſt; which we think highly probable. Be that as it may, the Danes and Norwegians formed ſettlements in Ireland; and the Engliſh have long been ſovereigns of that iſland. Theſe circumſtances muſt have affected the vernacular idiom of the natives; not to mention the neceſſity of adopting the language of the conquerors in law, in ſciences, in the offices of religion.

207 Coincidence between the Celtic and Phœnician.

The inhabitants of the highlands and iſlands of Scotland are the deſcendants of thoſe Britons who fled from the power of the Romans, and ſheltered themſelves among the fens, rocks, and faſtneſſes of thoſe rugged mountains and ſequeſtered glyns. They preferred theſe waſtes and wilds, with liberty and independence, to the pleaſant and fertile valleys of the ſouth, with plenty embittered by ſlavery. They no doubt carried their language along with them; that language was a branch of the Celtic. With them, no doubt, fled a number of the druidical prieſts, who unqueſtionably knew their native dialect in all its beauties

and

Celtic Language.

and varieties. Theſe fugitives in proceſs of time formed a regular government, elected a king, and became a conſiderable ſtate. They were ſequeſtered by their ſituation from the reſt of the world. Without commerce, without agriculture, without the mechanical arts, and without objects of ambition or emulation, they addicted themſelves wholely to the paſtoral life as their buſineſs, and to hunting and fiſhing as their diverſion. Thoſe people were not diſtinguiſhed by an innovating genius; and conſequently their language muſt have remained in the ſame ſtate in which they received it from their anceſtors. They received it genuine *Celtic*, and ſuch they preſerved it.

When the Scots became maſters of the low country, and their kings and a great part of the nobility embraced the Saxon manners, and adopted the Saxon language, the genuine Caledonians tenaciouſly retained their native tongue, dreſs, manners, clanſhips, and feudal cuſtoms, and could never cordially aſſimilate with their ſouthern neighbours. Their language, therefore, could not be polluted with words or idioms borrowed from a people whom they hated and deſpiſed. Indeed it is plain from the whole tenor of the Scottiſh hiſtory, that neither Caledonian chieftains, nor their vaſſals, were ever ſteadily attached to the royal family after they fixed their reſidence in the low country, and became *Saxons*, as the Highlanders called them by way of reproach. Indeed the commerce between them and thoſe of the ſouth, till about a century and a half ago, was only tranſient and accidental; nor was their native dialect in the leaſt affected by it.

Their language, however, did not degenerate, becauſe there exiſted among them a deſcription of men whoſe profeſſion obliged them to guard againſt that misfortune. Every chieftain retained in his family a bard or poet laureat, whoſe province it was to compoſe poems in honour of his lord, to commemorate the glorious exploits of his anceſtors, to record the genealogy and connections of the family; in a word, to amuſe and entertain the chief and his gueſts at all public entertainments and upon all ſolemn occaſions. Thoſe profeſſors of the Parnaſſian art uſed to vie with each other; and the chiefs of families often aſſembled their reſpective bards, and encouraged them by conſiderable premiums to exert their poetic talents. The victor was rewarded and honoured; and the chieftain deemed it an honour to himſelf to entertain a bard who excelled his peers. The ancient Gauls, as we learn from Diodorus Siculus, Strabo, Tacitus, Lucan, &c. entertained perſons of that profeſſion; and certainly the ancient Britons did the ſame. Thoſe bards were highly revered; their perſons were deemed ſacred; and they were always rewarded with ſalaries in lands or cattle (See ſection *Greek.*) Thoſe poetic geniuſes muſt have watched over their vernacular dialect with the greateſt care and anxiety; becauſe in their compoſitions no word was to be loſt, but as many gained as poſſible.

208 Cauſes of the purity of the Scotch dialect of this ancient language.

The uſe of letters was not known among the ancient *Celtæ*: their druidical clergy forbade the uſe of them. All their religious rites, their philoſophical dogmas, their moral precepts, and their political maxims, were compoſed in verſes which their pupils were obliged to commit to memory. Accordingly letters were unknown to the Caledonian Scots, till they learned them either from their ſouthern neighbours or from the Romans. The Iriſh, indeed, pretend to have letters of a very ancient date; the Highlanders of the country in queſtion make no claim to the uſe of that invention. Their bards, therefore, committed every thing to memory; and of courſe the words of their language muſt have been faithfully preſerved. We find that the celebrated poems of Oſſian, and others of an inferior character, or at leaſt fragments of ſuch poems (ſee OSSIAN), have thus been preſerved from father to ſon for more than 1000 years. The beauty, ſignificancy, harmony, variety, and energy of theſe verſes, ſtrike us even in a proſe tranſlation: how infinitely more charming muſt they appear in their native form and poetical attire!

Celtic Language.

In order to exhibit the genius of the Celtic in as ſtriking a light as the nature of our preſent deſign will permit, we ſhall lay before our readers a very contracted ſketch of the Gaelic or Caledonian dialect as it now ſtands; which we hope will go a great way to convince them that this is the genuine offspring of the other. In doing this we ſhall borrow many hints from a gentleman * whoſe learning ſeems to equal his zeal for his native language; which, in compliance with the modern practice, we ſhall for the future diſtinguiſh by the name of *Gaelic*.

* *Eſſays*, &c. by James Grant, Eſq; advocate.

The Gaelic is not derived from any other language as far as we know, being obviouſly reducible to its own roots. Its combinations are formed of ſimple words of a known ſignification; and thoſe words are reſolvable into the ſimpleſt combinations of vowels and conſonants, and even into ſimple ſounds. In ſuch a language we may expect that ſome traces will be found of the ideas and notions of mankind living in a ſtate of primeval ſimplicity; and if ſo, a monument is ſtill preſerved of the primitive manners of the Celtic race while as yet under the guidance of ſimple nature, without any artificial reſtraint or controul.

The ſudden ſenſations of heat and cold, and bodily pain, are expreſſed by articulate ſounds, which, however, are not uſed in this language to denote heat, cold, or bodily pain. A ſudden ſenſation of heat is denoted by an articulate exclamation *hait*; of cold, by *id*; of bodily pain, by *oich*. All theſe ſounds may be called *interjections*, being parts of ſpeech which diſcover the mind to be ſeized with ſome paſſion. Few of the improved languages of Europe preſent ſo great a variety of ſounds which inſtantaneouſly convey notice of a particular paſſion, bodily or mental feeling.

The pronouns *he* and *ſhe* are expreſſed by the ſimple ſounds *e* and *i*, and theſe are the marks of the maſculine and feminine genders; for a neuter gender is unknown in the *Gaelic*. The compoſitions of rude and barbarous ages are univerſally found to approach to the ſtyle and numbers of poetry; and this too is a diſtinguiſhing character of the *Gaelic*. Bodily ſubſiſtence will always be the principal concern of an uncultivated people. Hence *ed* or *eid* is uſed upon diſcovery of any animal of prey or game: it is meant to give notice to the hunting companion to be in readineſs to ſeize the animal: and hence we believe *edo* "to eat" in Latin, and *ed* in Iriſh, ſignifies "cattle;" likewiſe in Scotch *edal* "cattle," literally ſignifies "the

Celtic Language

"the offspring or generation of cattle." *Coed* or *cued*, "ſhare or portion of any ſubject of property," literally "common food." *Faad* "hunting," literally "gathering of food." *Edra* "the time of the morning when cattle are brought home from paſture to give milk," literally "meal-time." Theſe are words importing the ſimplicity of a primitive ſtate, and are common in the Gaelic idiom.

Traces of imitative language remain in all countries. The word uſed for *cow* in the Gaelic language is *bo*, plainly in imitation of the lowing of that animal.

In joining together original roots in the progreſs of improving language and rendering it more copious, its combinations diſcover an admirable juſtneſs and preciſion of thought, which one would ſcarce expect to find in an uncultivated dialect. It will, however, be found, upon examination, that the Gaelic language, in its combination of words, ſpecifies with accuracy the known qualities, and expreſſes with preciſion the nature and properties which were attributed to the object denominated.

269 Excellency of Gaelic compound

An appears to have been a word of frequent uſe in this language, and ſeems to have been originally a name applied indefinitely to any object. According to *Bullet*, it was uſed to ſignify "a planet;" hence the *ſun* had the name of *grian*, which is a compound of *gri* "hot," and *an* "a planet." *Re* ſignifies originally and radically "diviſion." The changes of the moon and the variety of her phaſes were early employed to point out the diviſions of time. The preſent name for the *moon* is *geulach*; a word derived from her whiteneſs of colour. To theſe we might add a vaſt number more whoſe ſignification preciſely indicates their ſhape, colour, effects, &c. Many of theſe would be found exactly ſimilar to Greek and Latin words of the ſame ſound and ſignification. In order to ſatisfy our curious readers, we ſhall annex a few, though ſome of them may perhaps be queſtionable.

The *Venus* of the Latins is ſaid to be a compound of *ben* and *jus*, which literally ſignify "the firſt woman," the letter *b* in Gaelic being ſoftened into *v*. Εδαϱ and ὠδαϱ ſignify "food." Theſe words are compounded of the Gaelic words *ed* or *eid* and *ar*; the former denotes *food* ſimply, and the latter *ploughed land*. Theſe are the roots of the Greek and Latin words ἐδω *edo*, ἀϱοω *aro*. Εδϱα, which ſignifies "a ſeat," has an evident reference to food. It is compounded of two Gaelic words *ed* and *ira*, which literally ſignify "meal-time." Εδνα, which ſignifies "the preſents which a bridegroom made to his bride," is a compound of two Gaelic words *ed* and *na* or *nuah*, literally ſignifying "raw food." From *ar* there are many Greek derivatives. Ἀϱουϱα ſignifies "ploughed land," alſo "crop of corn;" Ἀϱτος "bread." In Gaelic *a crop of corn and bread* are expreſſed by *arbhar*, commonly pronounced *arar* and *aran*; all being equally derivatives of the root *ar*. So the Greek and Latin words ἀϱοτες, *arabilis*, "arable;" ἀϱοτϱον, *aratrum*, "a plough;" ἀϱοτηϱ, *arator*, "a ploughman;" and many others, are evidently derived from the ſame ſource. We would not, however, ſuggeſt, in conſequence of this coincidence, that either the Greek or Latin languages were derived from the Gaelic; we rather believe that theſe are remains of a primeval tongue, which are ſtill retained in all the three; and we produce them upon the preſent occaſion as preſumptions that the Gaelic is an original, underived language, and of courſe the moſt pure and unadulterated relick of the Celtic now exiſting. If our readers ſhould incline to know more of this ſubject, they may conſult Pezron's *Origin of Ancient Nations*, Bullet's *Mem. de la Langue Celtique*, Parſon's *Rem. of Japhet*, Gebelin, *Monde prim.* &c.

Celtic Language

210 Copiouſneſs and antiquity of the Celtic.

When the Celtic language was generally ſpoken over Europe, it ſeems to have been amazingly copious. By conſulting *Bullet's Memoires*, it appears that its names for the common and various objects of nature were very numerous. The words denoting water, river, wood, foreſt, mountain, lake, &c. were moſt preciſely accommodated to ſpecify each modification and variety, with ſuch peculiar exactneſs as even the Greek, with all its boaſted idiomatical preciſion and copiouſneſs, has not been able to equal. The appearances which diverſify the viſible face of inanimate nature, arreſt the attention of men in an uncultivated ſtate. Unaccuſtomed to thought and abſtract reaſoning, their minds expand and exerciſe their powers upon ſenſible objects, and of courſe mark every *minutia* and almoſt imperceptible diſtinction with an accuracy to us ſeemingly impoſſible.

We hope it now appears to every reader, that the Celtic was one of the dialects of the primitive language; that it once overſpread by far the greateſt part of Europe; that the Gaelic now ſpoken in the northern parts of Scotland and the adjacent iſlands is the moſt pure and unmixed relick of that tongue now anywhere exiſting. We would willingly refer our readers to ſome well compoſed grammar of that language; but indeed we know of none that deſerves our recommendation. Some years ago we were flattered with the proſpect of ſeeing one publiſhed by a gentleman whoſe deep ſkill in that language is univerſally acknowledged. We have likewiſe heard of an intended dictionary of the ſame tongue; but hitherto our hopes have been diſappointed.

We are, however, happy to find that there is now publiſhing an excellent tranſlation of both the Old and New Teſtaments into Gaelic, which has hitherto been a deſideratum among thoſe who ſpeak this language. Such a tranſlation will at once contribute to preſerve that ancient tongue, and diſſeminate the knowledge of the truth among the natives of that country.

Every aſſiſtance towards acquiring the knowledge of a tongue which was once univerſal over a great part of Europe, will certainly be an acceptable preſent to the public. The antiquary, who is deſirous of tracing the affinity of languages, and wiſhes to mark the migrations of people, ought certainly to apply himſelf to the ſtudy of its remaining branches; and, if we miſtake not, he will ſoon be convinced, that they all breathe a ſpirit congenial to the manners and ſentiments of a people who are juſt entering upon the firſt ſtage of improvement and civilization.

211 Origin of the words *Gael* and *Gal.*

Perhaps it may be expected, that, before we conclude this ſhort ſketch of the Celtic tongue, we ſhould give

Celtic Language.

give some account of the origin of the words *Gaul* and *Gal*, the two names by which this people was distinguished by the Greeks and Romans. Mr M'Pherson imagines, that the appellation of *Celt* is an adjective derived from *Gael*, the aboriginal name of the inhabitants of ancient Gaul. For our part, we can see no connection between *Gael* and *Kelt*, nor do we think that the latter is an adjective. We believe that those people called themselves *Cael* and not *Gael*. We are sure that *Caledonia*, or *Cal-don* or *dun*, was an ancient name of the mountainous parts of Scotland.

Though many different opinions have been advanced with relation to the etymology of this word, we imagine that none is so probable as that which supposes that it is compounded of the two Celtic words *Cal* or *Kal*, that is, "Gal or Gaul," and *dun*, which signifies "a hill or mountain." Upon this ground, the Caledonii will import the Gauls of the mountains, or, which is the same, the Highland Gauls. The Irish and Highlanders reciprocally denominate themselves by the general title of *Cael*, *Gael*, or *Gauls*. They also distinguish themselves, as the Welch originally did, and as the Welch distinguish them both at present, by the appellation of *Guidhill*, *Guethel*, and *Gathel*. The intermediate *th*, they say, is left quiescent in the pronunciation, as it is in many words of the British language; in which case *Gathel* would immediately be formed into *Gael*; and Gathel is actually founded like *Gael* by both the Irish and Highlanders at present. The appellation of *Gathel*, therefore, say they, was originally the same with *Gael*, and the parent of it. The quiescent letters in British are frequently transferred from the middle to the conclusion of the word; by which manœuvre, *Gathel* is changed into *Galath*, *Galat*, *Galt*, and *Celt*. It is true, that *Gael* of the continent is universally denominated *Galatæ* and *Celtæ* by the Grecians, and *Gailt* and *Gallta* by the Irish. The appellations, therefore, of *Gathel-i*, *Gall-i*, *Gallat-æ*, *Calet-es*, *An-calit-es*, and *Celt-æ*, are all one and the same denomination, only varied by the astonishing ductility of the *Celtic*, and disguised by the alterations ever incident to a language that has been merely oral for ages.

It may perhaps appear presumptuous in us to differ from two such respectable authorities as M'Pherson and Whitaker: we must, however, acknowledge, that neither the one nor the other appears to us well founded. Besides, they convey no idea of the signification of the words, though in the Celtic language they must have been significant. The name *Cael*, the same with *Gal*, was probably given them in the East from the Greek καλ, which in many oriental languages denotes *fair*; and Γαλατια may be easily derived from καλ or καλαθ, *Gal* or *Galath*.—This denomination might be given them by their neighbours, in allusion to their fair complexion.

§ 2. *Of the Gothic Language.*

Gothic Language.

212 Ancient Gothic.

The Celtic and Gothic tongues at one time divided Europe between them. Both were of equal antiquity, both originated in Asia, both were dialects of the original language of mankind. The Celtic, however, was first imported into Europe. The Gauls or Celts had penetrated farthest towards the west; a circumstance which plainly intimates the priority of their arrival. In the population of countries, we believe it may be held as a maxim, that the colonies who emigrated first were generally impelled by succeeding emigrants; and that of consequence the most early were pushed forward to the parts most distant. The Celts, then, having overspread the most western parts of Europe, must have arrived more early in those regions.

213 The same with the language of the Thracians.

The Goths and Getæ were the same race of people, according to Procopius *, *de bello Goth.*; and Strabo † (B) informs us, that they spoke the same language with the Thracians, from whose confines they had spread themselves northward as far as the western banks of the Danube. Vopiscus, in the History of Probus, tells us, that this emperor ‡ obliged "the Thracians, and all the Getic tribes, either to surrender or accept of his friendship." This expression indicates, that the Thracians and the Getic tribes were deemed the same race of people. From this deduction it is clear, that the Getæ and Thracians were brethren; that they spoke the same language: and that their laws, manners, customs, and religious tenets, were the same, might easily be shown, were this a proper place for an inquiry of that nature.

* Lib. i. cap. 2. † Lib. ii. cap. 23. ‡ Lib. 7.

The Thracian language, as might be demonstrated from names of persons, offices, places, and customs, among that people, was nearly related to the Chaldean and other oriental languages.

They are thought to have been the descendants of Tiras, one of the sons of Japhet, and consequently must have preserved the speech of the Noachic family. The Gothic language abounds with *Pahlavi*, or old Persic words, which are no doubt remains of the primeval dialect of mankind. The Thracians peopled a considerable part of the northern coast of Asia Minor; and consequently we meet with many names of cities, mountains, rivers, &c. in those parts, exactly corresponding with many names in Europe, evidently imposed by our Gothic progenitors. Any person tolerably acquainted with the remains of the Gothic tongue, will be able to trace these with little difficulty.

214 Origin of the Goths.

We learn from Herodotus ‖, that Darius in his expedition against the wandering Scythians who lived on the other side of the Ister or Danube, in his progress subdued the Getæ; and in the same passage the historian informs us, that these people held the immortality of the human soul, and that they were the bravest and most just of all the Thracians. After this period, we find them mentioned by almost every Greek writer, even familiarly; for Getæ in the comedies of that nation, is a common name for a slave. The Getæ then occupied all that large tract of country

‖ Lib. 4. *passim.*

(B) Lib. vii. page 295, B.; ibid. page 305. G. (Casaubon). From this passage it appears, that the Greeks were of opinion that the Getæ were Thracians. *Plin. Nat. Hist.* l. iv. cap. 11. mentions a tribe of the Getæ called *Gaudæ*.

Gothic Language.

try which extended from the confines of Thrace to the banks of the Danube: were a brave and virtuous people; and spoke the same language with the Thracians, with whom they are often confounded both by Greek and Roman historians.

But the name of *Goths* is by no means so ancient. It was utterly unknown both to the ancient Greeks and Romans. The first time that the name *Goth* is mentioned is in the reign of the Emperor Decius, about the year of Christ 250. About that time they burst out of Getia, and rushing like a torrent into the empire, laid waste every thing with fire and sword. The name of their leader or king was *Cneva*. Decius, endeavouring to expel them Thrace, was vanquished and slain.

After this irruption, we find them frequently in the Latin authors under the name of *Getæ* or *Gothi*; tho' the Greeks generally denominate them *Scythæ*. Torfæus tells us, that *get* ‡ and *got* is actually the same word, which anciently, according to him, denoted a "soldier." *Got* in Icelandic signifies a "horse or horseman," and *gata* a "wanderer;" and this last was perhaps the import of the term *Geta*, they being originally an unsettled vagrant people. As nations generally assume to themselves some high auspicious denomination, we may believe the Goths did the same. We may therefore rest satisfied, that the Getæ assumed the Icelandic name above mentioned as their national one: or perhaps, notwithstanding their Greek denomination, they called themselves *Gets* or *Goths* from the beginning.

‡ *History of Norway*, lib. i.

215 Their primary seat.

The original seat of the Goths was the country now called *Little Tartary*, into which they had extended themselves from the frontiers of Thrace. This country was called *Little Scythia* by the Greek writers; and it was the station whence those innumerable swarms advanced, which, in conjunction with the Alani and other barbarous tribes, at length overran and subverted the western empire. One part of the Gothic nation was allowed by Constantine to settle in Mœsia. Before the year 420 most of the Gothic nations who had settled within the limits of the Roman empire had been converted to the Christian faith; but, unhappily, the greater part of the apostles by whom they had been proselyted, were Arians, which proved fatal to many of the orthodox Christians; for the Arian Goths persecuted them with unrelenting cruelty.

216 Remains of genuine Gothic.

About the year 367, Ulphilas bishop of the Mœsian Goths, translated the New Testament into the Gothic language. The remains of this translation furnish a genuine, and at the same time venerable, monument of the ancient Gothic dialect. No more is now extant of that valuable translation than the four Gospels, and another fragment containing part of the epistle to the Romans. The Gospels have been repeatedly published since the first edition by Junius 1665, down to that of Mr Lye. Other fragments of the Gothic language have also been found, which our curious readers may see in Lye's Notes to his Edition of the Gothic Gospels. The fragment of the Epistle to the Romans was lately discovered in the library at Wolfenbottle, and published by Knitel archdeacon of Wolfenbottle.

The Goths, prior to the age of Ulphilas, were ignorant of the use of alphabetical characters. The bishop fabricated an alphabet for them, which is a medley of Greek and Roman letters, but rather inclining to the former.

Gothic Language.

217 Gothic alphabet.

This alphabet consists of 25 letters (see PLATE IX). Junius has carefully analysed those letters, and pointed out their powers and sounds in his Gothic alphabet, prefixed to his *Glossarium Gothicum*. They were long retained in all the European languages derived from the Gothic source, which will be enumerated in the sequel.

What kind of language the ancient Gothic was, is plain from the fragments above mentioned; but in what respects it agrees with the oriental tongues, or differs from them, is not easy to ascertain with precision. We have observed in our section on the Greek, that a considerable part of that language must have been derived from the Thracian; which, according to Strabo there quoted, was the same with the Getic or Gothic. The Thracian tongue will, we are convinced upon comparison, be found analogous to the Chaldean or Syrian. The German, which is a genuine descendant of the Gothic, is full of Persian words: the old Persian or Pahlavi appears to be a dialect of the Chaldean. The learned Junius, near the beginning of his Gothic alphabet, remarks, that a very considerable part of the language in question is borrowed from the most ancient Greek.

218 Gothic language derived from the Chaldean, &c.

Both the learned Ihre in his *Glossarium Suio Gothicum*, and Wachter in his excellent German and Latin Dictionary, often remark the coincidence of Gothic and German words with oriental vocables of the like sound and of the same signification. In the old Saxon, which is another ramification of the Gothic tongue, numberless terms of the very same complexion appear. From this deduction we hope it will follow, that the Gothic tongue, in its original unmixed state as it was spoken by the ancient Getæ, was a dialect of the primeval language; that language which the sons of Tiras brought with them from the plains of Shinar or from Armenia, or from any other region where the primitive mortals had fixed their residence. To confirm this position, we shall annex a few instances.

The Thracian tribes, in all probability, first took possession of those parts of Asia Minor which stretch towards the east. Thence they crossed the Hellespont, and spread themselves far and wide northward. Strabo supposes that they first settled in the regions to the north of those straits, and thence transported numerous colonies into Asia Minor. The reverse was probably the case. Population, we think, proceeded northward: but be that as it may, it is universally agreed, that both sides of the Hellespont were peopled with Thracians.

In Asia Minor we meet with the city Perge, which, throwing away the *a*, is *Perg*. In every tongue descended from the Gothic, the word *Berg* signifies a "rock," and metaphorically a "town or burgh;" because towns were originally built on rocks for the sake of defence. Hence likewise *Pergamos*, the fort or citadel of Troy. *Beira* in Thracian signified a "city;" the Chaldaic and Hebrew word *Beer* imports a "well," and is possibly the original of the Gothic word *beer*, *ale*. In ancient times, especially in

Gothic Language.

the Eaſt, it was cuſtomary to build cities in the neighbourhood of fountains. The ancients called the Phrygians Βρυγες, *Bryges* or *Bruges*; the Gothic word coinciding is obvious. *Dyndymus*, the name of a city ſacred to Cybele, is compounded of two Gothic words *dun* and *dum*, both ſignifying "a height, an eminence;" and hence *a town*, *an incloſure*. The word *tros* ſeems to be the very Gothic *troſh*, "brave, valiant." The words *fader*, *mader*, *dochter*, *bruder*, are ſo obviouſly Perſian, that every etymologiſt has aſſigned them to that language.

Many futile etymologies have been given of the ſacred name *God*, which is in reality the Perſian word *Chodi*, commonly applied by them to their *Hormazd* or *Oromazes*. The Perſian *bad* or *bod* ſignifies a "city;" the ſame word in Gothic imports a "houſe, a manſion, an abode." *Band*, in Perſic, a "ſtrait place;" in Gothic, "to bend." *Heim* or *ham*, "a houſe," is generally known to be of Perſian original. Much critical ſkill has been diſplayed in tracing the etymology of the Scotch and old Engliſh word *Yule*, "Chriſtmas." *Yule*, derived from *iul*, was a feſtival in honour of the ſun, which was originally celebrated at the winter ſolſtice. *Wick* or *wich* is a Gothic term ſtill preſerved in many names of towns; it ſignifies "a narrow corner, or ſmall ſtrip of land jutting into the ſea, or into a lake or river:" hence Latin *vicus*, and the Greek οικος. In Spaniſh, we have many old Gothic words; among others *hijo* a "ſon," the ſame with the Greek υιος. In ſome places of Scotland, we call any thing that is little, ſmall, *wee*; originally ſpelt *wi*, if we miſtake not, from the very ſame word.

Theſe few examples we have thrown together, without any regard to order, perſuaded that almoſt every word of the language, truly Gothic, may with a little pains and judgment be traced to ſome oriental root or cognate. We may obſerve in paſſing, that many Gothic nouns end in *a*, like the Chaldaic and Syriac; that their ſubſtantive verb very much reſembles that of the Perſian, Greek, and Latin; and that their active and auxiliary verb has furniſhed the common præterperfect tenſe of Greek verbs in the active voice: that verb is *haban*, but originally *ha*, as the common people pronounce it at this day, eſpecially in the north of Scotland, and among the Swedes, Danes, Norwegians, and Icelanders.

219 Modern tongues deduced from the Gothic.

We ſhall now leave the other inferior arrangements of this ancient language to grammarians and lexicographers, and proceed to inquire what modern tongues are deduced from it as their ſtock, and which of them makes the neareſt approaches to its ſimplicity and ruſticity.

We have already obſerved that the Goths, formerly Getæ, were poſſeſſed of a vaſt extent of country, reaching from the frontiers of Thrace to the banks of the Iſter or Danube. We have ſeen that a colony of them ſettled in Mœſia under Conſtantine II. They then ſpread themſelves into Dacia, and from thence into Germany. All theſe countries were ſituated in ſuch a manner, that the progreſs of population was forward, and according to the natural courſe of emigration. From Germany they extended themſelves into Scandinavia, that is, Sweden, Denmark, and Norway. Their whole ancient *Edda*, *Sagas*, "Chronicles," ſhow that the Goths arrived in Scandinavia by this route, without, however, fixing the era of that event with any tolerable degree of accuracy. By the Germans, we believe the ancients underſtood all the nations eaſtward, weſtward, and northward, reaching from the Danube on the ſouth up to the extremity of Scandinavia on the Northern Ocean; and from the Rhine and German Ocean on the weſt, to the river Chronus or Niemen on the eaſt. All thoſe nations ſpoke one or other of the Gothic dialects, ſome approaching nearer, and others deviating farther from, the parent language.

Gothic Language.

The Francic is a dialect of the Teutonic, *Tudeſque*, or old German; and the Goſpels of Ulphilas bear ſuch a reſemblance to the Francic, fragments of which are preſerved in the early French hiſtorians, that ſome learned men have pronounced thoſe Goſpels to be part of an old Francic verſion; but others of equal reſpectability have refuted this opinion, both from hiſtory and compariſon of the dialects. Schilter has given us large monuments of the Tudeſque or old German from the ſeventh century, which evidently prove that the Gothic of Ulphilas is the ſame language. Wachter's learned Gloſſary of the ancient German likewiſe confirms this poſition. Mr Ihre, after heſitating whether the Goſpels of Ulphilas bear moſt reſemblance to the German or Scandinavian dialect of the Gothic, declares at laſt in favour of the former. The Anglo-Saxon is alſo known to be a venerable dialect of the Tudeſque; and is ſo intimately connected with the Goſpels, that ſome valuable works on this ſubject are wholly built upon that ſuppoſition.

The Icelandic is the oldeſt relict of the Scandinavian. It begins with Arius Frode in the eleventh century, and is a dialect of the German. The remains we have of it are more modern by four centuries than thoſe of the German: they are more poliſhed than the other. The words are ſhortened, not only becauſe they are more modern than the German, but becauſe the Icelandic was poliſhed by a long ſucceſſion of poets and hiſtorians almoſt equal to thoſe of Greece and Rome. Hence the Icelandic, being a more poliſhed language than the German, has leſs affinity with the parent Gothic. The Swediſh is more nearly related to the Icelandic than either the Daniſh or Norwegian. That the Swediſh is the daughter of the Gothic, is fully ſhown by Mr Ihre above mentioned in his *Gloſſarium Suio-Gothicum*. There is, therefore, no manner of doubt as to the identity of the Gothic, preſerved in Ulphilas and other ancient remains, with the German and Scandinavian tongue.

The modern German, a language ſpoken in a far greater extent than any other of modern Europe, reſembles the Gothic Goſpels more than the preſent Daniſh, Norwegian, or Swediſh; and has certainly more ancient *ſtamina*. Its likeneſs to the Aſiatic tongues, in harſhneſs and inflexible thickneſs of ſound, is very apparent.

Buſbequius ſhows, that the clowns of Crim Tartary, remains of the ancient Goths, ſpeak a language almoſt German. Theſe clowns were no doubt deſcendants of the ancient Goths, who remained in their native country after the others had emigrated. It is therefore apparent from the whole of this inveſtiga-

Sclavonian Language.

tion, that the Gothic was introduced into Europe from the Eaſt, and is probably a dialect of the language originally ſpoken by men.

§ 3. *Of the Sclavonian Language.*

220 Sclavonic language,

THERE is another language which pervades a conſiderable part of Europe, and this, like the Gothic, ſeems to have originated in the Eaſt. The language we mean is the Sclavonic or rather Slevonic, which prevails far and wide in the eaſtern parts of this diviſion of the globe. It is ſpoken by the Dalmatians, by the inhabitants of the Danubian provinces, by the Poles, Bohemians, and Ruſſians. The word *ſlaf*, that is, "ſlave" (whence the French word *eſclave*, and our word *ſlave*), ſignifies "noble, illuſtrious;" but becauſe, in the lower ages of the Roman empire, vaſt multitudes of theſe people were ſpread over all Europe in the quality of ſlaves, that word came to denote the ſervile tribe by way of diſtinction, in the ſame manner as the words *Geta*, *Dacus*, and *Syrus*, did among the Greeks at a more early period.

221 Spoken by the Slavi one of the tribes of the Sarmatians,

The Slavi dwelt originally on the banks of the Boryſthenes, now the Dnieper or Nieper. They were one of the tribes of the European Sarmatians who in ancient times inhabited an immenſe tract of country, bounded on the weſt by the Viſtula, now the Weiſel; on the ſouth eaſt by the Euxine Sea, the Boſphorus Cimmerius, the Palus Mœotis, and the Tanais or Don, which divides Europe from Aſia.

In this vaſt tract of country, which at preſent comprehends Poland, Ruſſia, and a great part of Tartary, there dwelt in ancient times many conſiderable tribes. To enumerate theſe, we believe, would not much edify our readers: we ſhall only inform them, that among theſe Sarmatian clans were the Roxolani, now the Ruſſians, and likewiſe the Slavi, who dwelt near the Boryſthenes, as was obſerved above.

The Slavi gradually advanced towards the Danube; and in the reign of Juſtinian having paſſed that river, they made themſelves maſters of that part of Illyricum which lies between the Drave and the Save, and is to this day from them called *Sclavonia*. Theſe barbarians by degrees over-ran Dalmatia, Liburnia, the weſtern parts of Macedonia, Epirus; and on the eaſt they extended their quarters all along to the weſtern bank of the Danube, where that river falls into the Euxine. In all theſe countries, the Sclavonian was deeply impregnated with the Greek, which was a thing of courſe, ſince the barbarian invaders ſettled in thoſe regions, and mingled with the aborigines, who ſpoke a corrupt dialect of that language.

222 The Poles,

The Poles are the genuine deſcendants of the ancient Sarmatæ (c), and conſequently ſpeak a dialect of their language, but much adulterated with Latin words, in conſequence of the attachment the Polanders have long profeſſed to the Roman tongue.

223 Sileſians, and

The Sileſians and Bohemians have corrupted their dialects in the very ſame manner. In thoſe countries, then, we are not to ſearch for the genuine remains of the ancient Sarmatian.

The modern Ruſſians, formerly the Rhoxani or Roxolani, are the poſterity of the Sarmatæ, and are a branch of the Slavi: they inhabit a part of the country which that people poſſeſſed before they fell into the Roman provinces; they ſpeak the ſame language, and wear the very ſame dreſs; for, on the hiſtorical pillar at Conſtantinople, the Sclavonians are dreſſed like the Ruſſian boors. If then the Slavi are Sarmatæ, the Ruſſians muſt of courſe be the deſcendants of the ſame people. They were long a ſequeſtered people, and conſequently altogether unconnected with the other nations of Europe. They were ſtrangers to commerce, inhoſpitable to ſtrangers, tenacious of ancient uſages, averſe to improvements of every kind, wonderfully proud of their imaginary importance; and, in a word, a race of people juſt one degree above abſolute ſavagiſm. A people of this character are, for the moſt part, enemies to innovations; and if we may believe the Ruſſian hiſtorians, no nation was ever more averſe to innovations than the one in queſtion. From the ninth century, at which era they embraced Chriſtianity, it does not appear that they moved one ſtep forward towards civilization, till Peter the Great, not a century ago, in conſequence of his deſpotic authority, compelled them to adopt the manners and cuſtoms of their more poliſhed neighbours.

Sclavonian Language.

224 Ruſſians, deſcended from the Slavi.

We may then conclude, that the Ruſſians made as little change in their language during that period, as they did in their dreſs, habits, and manner of living. Whatever language they ſpoke in the ninth century, the ſame they employed at the beginning of the 18th. They were, indeed, according to *Appian de bel. Mithrid.* once conquered by Diophantus, one of Mithridates's generals; but that conqueſt was for a moment only: they were likewiſe invaded, and their country over-run, by the great Timor or Tamerlane; but this invaſion was like a torrent from the mountains, which ſpreads devaſtation far and wide while it rages, but makes little alteration on the face of the country.

We find likewiſe, that upon ſome occaſions they made incurſions upon the frontiers of the Roman empire; but we hear of no permanent ſettlements formed by them in theſe quarters. Upon the whole, we take the Ruſſians to have been, with reſpect to their language, in the very ſame predicament with the Highlanders and Iſlanders of Scotland, who, according to the general opinion, have preſerved the Celtic dialect pure and entire, in conſequence of their having never mingled with foreigners.

225 The Ruſſian language genuine Sclavonic.

From this deduction we may infer two things; firſt, that the Ruſſian language is the genuine Sclavonian; and, ſecondly, that the latter is the ſame, or nearly the ſame, with the ancient Sarmatian.

In the Ruſſian, there are found a great number of words reſembling the old ſimple roots of the Greek both in ſound and ſignification; its grammatical genius is nearly the ſame: and we are informed by the very beſt authority, that there is in this language a tranſlation of Epictetus, in which there are whole pages, in both original and tranſlation, without one ſingle

(c) This appears by their character, their laws, their manners, their form of government, their military equipage, their impetuoſity, their ariſtocratic ſplendor.

Sclavonian language.

single transposition. Monsr. Leveque, who has published a translation of a history of Russia, is so entirely convinced of the strict analogy between the ancient Greek and the modern Russe, that he is positive that the former is derived from the latter. Monsr Freret, a very learned French academician, is clearly of the same opinion. We are, however, persuaded that this opinion is ill founded. We rather imagine, that those coincidences arise from the relicks of the primitive language of mankind; vestiges of which, we believe, are to be found almost in every tongue now existing.

It is, however, we allow, uncommonly difficult to render a reason for the syntaxical analogy of the two languages, without admitting the truth of the one or the other hypothesis. We have examined with some care a good number of Russian vocables, and compared them with Greek ones of the same signification.

226 Resemblance between Russian and oriental words.

We have not, however, found such a resemblance as we think necessary to support the position advanced above. We have indeed found a very strong resemblance between the former and many oriental words, especially Hebrew, Chaldean, and old Persian, of which we could produce several instances, did the nature of our present inquiry admit such a deviation. Every body knows that the Sarmatæ were divided into two great nations, the Asiatic and European; the former extended very far eastward, behind the mountain Caucasus, the northern shore of the Euxine Sea, and so forth. These, we may believe, derived their language from the original tongue long before the Greek language existed. This, in comparison of the Hebrew, Phœnician, Egyptian, Arabian, Chaldean, &c. was but of yesterday. The Greek, most learned men are now convinced, was a late composition of many different dialects, incorporated with the jargon of the aboriginal Ionim or Greeks. The Sarmatian, on the contrary, was the tongue of a great and populous nation, civilized, in all appearance, long before the Greeks began to emerge from a state of savagism. We are, therefore, by no means disposed to allow, either that the Greek is derived from the Russian, or the Russian from the Greek. We believe there is just the same reason for this conclusion, that the Abbé Pezron and Monsr. Gebelin pretend to have discovered, in order to support their position that the Greek is derived from the Celtic. Certain it is, that the resemblance among the oriental languages, of which we take the Sarmatian to have been one, is so palpable, that any person of a moderate capacity who is perfectly master of one, will find little difficulty in acquiring any other. If, therefore, the coincidence between the Greek and Russian should actually exist, we think this circumstance will not authenticate the supposition, that either of the two is derived from the other.

In the course of this argument, our readers will be pleased to observe, that we all along suppose, that the Sclavonian, of which we think the Russian is the most genuine remain, is the same with the old Sarmatian. We shall now take the liberty to hazard a conjecture with respect to the syntaxical coincidence of that language with the Greek; for we acknowledge that we are not so profoundly versed in the Russian dialect of the Sclavonian as to pretend to pronounce a definitive sentence.

Sclavonian language.

As the Russians were a generation of savages, there is no probability that they were acquainted with the use of letters and alphabetical writing till they acquired that art by intercourse with their neighbours. It is certain, beyond all contradiction, that few nations had made less proficiency in the fine arts than that under consideration: and we think there is little appearance of their having learned this art prior to their conversion to Christianity. Certain it is, that the Slavi, who settled in Dalmatia, Illyria, and Liburnia, had no alphabetical characters till they were furnished with them by St Jerome. The Servian character, which very nearly resembles the Greek, was invented by St Cyril; on which account the language written in that character is denominated *Chiurilizza*. These Sclavonic tribes knew nothing of alphabetic writing prior to the era of their conversion. The Mœsian Goths were in the same condition till their Bishop Ulphilas fabricated them a set of letters.

227 Origin of the syntaxical coincidence between this language and the Greek.

If the Slavi and Goths, who resided in the neighbourhood of the Greeks and Romans, had not learned alphabetical writing prior to the era of their conversion to Christianity, it must hold *à fortiori*, that the Russians, who lived at a very great distance from those nations, knew nothing of this useful art antecedent to the period of their embracing the Christian faith.

The Russians pretend that they were converted by St Andrew; but this is known to be a fable. Christianity was first introduced among them in the reign of the grand Duke Wolodimar, who marrying the daughter of the Grecian emperor Basilius, became her convert about the year 989. About this period, we imagine, they were taught the knowledge of letters by the Grecian missionaries, who were employed in teaching them the elements of the Christian doctrines. Their alphabet consists of 31 letters, with a few obsolete additional ones; and these characters resemble those of the Greeks so exactly, that there can be no doubt of their being copied from them. It is true, the shape of some has been somewhat altered, and a few barbarian ones have been intermingled. The Russian liturgy, every body knows, was copied from that of the Greeks; and the best specimen of the old Russian is the church offices for Easter, in the very words of Chrysostom, who is called by his name *Zlato ustii*, "golden-mouthed." The power of the clergy in Russia was excessive; and no doubt their influence was proportioned to their power. The first race of clergy in that country were undoubtedly Greeks. We know how active and industrious those people were in propagating their language as well as their religion. The offices of religion might be at first written and pronounced in the Greek tongue, but it would soon be found expedient to have them translated into Russian. The persons employed in this work must have been Greeks, who understood both languages.

As it is confessedly impossible that a people so dull and uninventive as the Russians originally were, could ever have fabricated a language so artificially constructed as their present dialect; and as it is obvious, that, till Christianity was introduced among them by the Greeks, they could have no correspondence with that

Sclavonian language.

people—it must appear surprising by what means their language came to be fashioned so exactly according to the Greek model. We have observed above, that the Russian letters must have been invented and introduced into that country by the Greek missionaries. We think it probable, that those apostles, at the same time that they taught them a new religion, likewise introduced a change into the idiom of their language. The influence of these ghostly teachers over a nation of savages must have been almost boundless; the force of their precepts and example almost incontrollable. If the savage converts accepted a new religion from the hands of those Grecian apostles, they might with equal submission adopt improvements in their language. Such of the natives as were admitted to the sacerdotal function must have learned the Greek language, in order to qualify them for performing the offices of their religion. A predilection for that language would be the immediate consequence. Hence the natives, who had been admitted into holy orders, would co operate with their Grecian masters in improving the dialect of the country; which, prior to the period above mentioned, must have greatly deviated from the original standard of the Sarmatian tongue.

Upon this occasion, we imagine the Greek apostles, in conjunction with their Russian disciples, reduced the language of the country to a resemblance with the Greek idiom. They retained the radical vocables as they found them; but by a variety of flexions, conjugations, derivations, compositions, and other modifications, transformed them into the Grecian air and apparel. They must have begun with the offices of the church; and among a nation of savages newly converted, the language of the new religion would quickly obtain a very extensive circulation. When the Grecian garniture was introduced into the church, the laity would in process of time assume a similar dress. The fabric of the Grecian declensions, conjugations, &c. might be grafted upon Russian stocks without affecting the radical parts of the language. If the dialect in question, like most others of a very ancient date, laboured under a penury of vocables, this manœuvre would contribute exceedingly to supply that defect. By this expedient the Greek language itself had been enlarged from about 300 radical terms to the prodigious number of words of which it now consists.

The Latin tongue we have seen above in its original constitution differed widely from the Greek; and notwithstanding this incongruity, the improvers of the former have pressed it into a very strict agreement with the latter. This, we think, was still a more difficult task; as, in our opinion, the genius of the Latin differs in a much greater degree than that of the Russian does from the Greek. We know, that the genius of the Gothic tongue and those of all its descendants are much more in unison with the Greek than with that of the Latin. The Spanish, Italian, and French, have cudgelled many of their Gothic, Teutonic, and Celtic verbs, into a kind of conjugations, imitating or rather aping those of the Latin. The Persians have formed most elegant and energetic declensions and conjugations, upon inflexible roots, borrowed from the Pahlavi and Deri, and even from Tartar originals.

Upon the grounds above-mentioned we have taken the liberty to hazard the following conjectures, which we cheerfully submit to the cognizance of our more enlightened readers.

1. That the Sarmatian was a dialect of the original language of mankind.

2. That the Sclavonian was a dialect of the Sarmatian.

3. That the Russe is the most genuine unsophisticated relick of the Sclavonian and Sarmatian.

4. That the Russians had no alphabetic characters prior to the era of the introduction of Christianity, that is towards the end of the tenth century.

5. That they were converted by Grecian missionaries.

6. That those missionaries copied their present letters from those of Greece; and in conjunction with the more enlightened natives, reduced the original unimproved Russe to its present resemblance to the Greek standard

228 Russian nouns.

The Russian language, like most others, contains eight parts of speech, noun, pronoun, &c. Its nouns have three genders, masculine, feminine, and neuter; it has also a common gender for nouns, intimating both sexes. It has only two numbers, singular and plural. Its cases are seven, nominative, genitive, dative, accusative, vocative, instrumental, and prepositive. These cases are not formed by varying the termination, as in Greek and Latin; but generally by placing a vowel after the word, as, we imagine, was the original practice of the Greeks (See *Greek* Section). Thus in Russe, рукъ *ruk*, "hand;" nominative, рукъ-а "the hand;" genitive, рукъ-и "of the hand," &c. See *Les Elem. de la Langue Russe par Charpentier*. Nouns substantive are reduced to four declensions, and adjectives make a fifth. These agree with their substantives in case, gender, and number. They have three degrees of comparison, as is common in other languages; the positive, comparative, and superlative. The comparative is formed from the feminine of the nominative singular of the positive, by changing *a* into *ie*, that is, *aie* in English; the superlative is made by prefixing *naï*, *pre*, before the positive. These rules are general; for the exceptions, recourse must be had to the Russian grammar abovementioned.

229 Adjectives.

The numeral adjectives in Russe have three genders like the rest, and are declined accordingly. Their pronouns have nothing peculiar, and are divided and arranged in the same manner as in other languages. Verbs in the Russian language are comprehended under two conjugations. The moods are only three; the indicative, the imperative, and the infinitive: the subjunctive is formed by placing a particle before the indicative. Its tenses are eight in number; the present, the imperfect, the preterite simple, the preterite compound, the pluperfect, the future indeterminate, the future simple, the future compound. The verbs have their numbers and persons as in other languages. To enter into a detail of their manner of conjugating their verbs would neither be consistent with our plan, nor, we are persuaded, of much consequence to our readers. Their other parts of speech differ nothing from those of other languages. Their syntax nearly resembles that of the Greek and Latin. All these articles must be learned from a grammar of the language. Whether there is any grammar of the Russian language compo-

sed

Sclavonian Language.

ſed in Engliſh we know not. That of Monſ. Chargentier in French, printed at Peterſburgh in 1768, is the only one we have ſeen, and which appears to us a very excellent one. We could wiſh to be able to gratify our readers with a more authentic account of the origin of the Sclavonian language; but this we find impoſſible, in conſequence of the want of memorials relating to the ſtate of the ancient Sarmatæ. Towards the era of the ſubverſion of the weſtern empire, the nations who inhabited the countries in queſtion were ſo blended and confounded with each other, and with Huns and other Scythian or Tartar emigrants, that we believe the moſt acute antiquarian would find it impoſſible to inveſtigate their reſpective tongues, or even their original reſidence or extraction. We have ſelected the Ruſſe as the moſt genuine branch of the old Sclavonian, and to this predilection we were determined by the reaſons above mentioned. We are ſorry that we are not ſo well acquainted with the idiom of the Ruſſian language as to be able to compare it with thoſe of the eaſt; but upon ſuch a compariſon, we are perſuaded that the radical materials of which it is compoſed would be found to have originated in the oriental regions. The word *Tſar*, for example, is probably the Phœnician and Chaldean *Sar* or *Zar*, "a prince, a grandee." Diodorus Siculus calls the queen of the Maſſagetæ, who, according to Cteſias, cut off Cyrus's head, *Zarina*; which was not many years ago the general title of the empreſs of all the Ruſſias. Herodotus calls the ſame princeſs *Tomyris*, which is the very name of the famous Timor or Tamur, the conqueror of Aſia. The former ſeems to have been the title, and the latter the proper name, of the queen of the Maſſagetæ. In the old Perſian or Pahlavi, the word *Gard* ſignifies "a city;" in Ruſſian, *Gorad* or *Grad* intimates the very ſame idea: hence *Conſtantinople* in old Ruſſe is called *Tſargrad* or *Tſargorad*. Theſe are adduced as a ſpecimen only; an able etymologiſt might, we believe, diſcover a great number.

231 Phœnician and Chaldean words in Ruſſe.

The Sclavonian language is ſpoken in Epirus, the weſtern part of Macedonia, in Boſnia, Servia, Bulgaria, in part of Thrace, in Dalmatia, Croatia, in Poland, Bohemia, Ruſſia, and Mingrelia in Aſia, whence it is frequently uſed in the ſeraglio at Conſtantinople. Many of the great men of Turkey underſtand it, and frequently uſe it; and moſt of the janizaries having been ſtationed in garriſons in the Turkiſh frontiers in Europe, uſe it as their vulgar tongue. The Hungarians, however, and the natives of Wallachia, ſpeak a different language: and this language bears evident ſignatures of the Tartarian dialect, which was the tongue of the original Huns. Upon the whole, the Sclavonian is by much the moſt extenſive language in Europe, and extends far into Aſia.

Sect. X. *Modern Languages.*

If we call all the different dialects of the various nations that now inhabit the known earth, languages, the number is truly great; and vain would be his ambition who ſhould attempt to learn them, though but imperfectly. We will begin with naming the principal of them: There are four, which may be called original or mother-languages, and which ſeem to have given birth to all that are now ſpoken in Europe. Theſe are the *Latin*, *Celtic*, *Gothic*, and *Sclavonian*. It will not, however, be imagined, from the term *original* given to theſe languages, that we believe them to have come down to us, without any alteration, from the confuſion of tongues at the building of the tower of Babel. We have repeatedly declared our opinion, that there is but one truly original language, from which all others are derivatives variouſly modified. The four languages juſt mentioned are original only as being the immediate parents of thoſe which are now ſpoken in Europe.

Modern Languages

232 Parent dialects of Europe, with their reſpective offſpring.

I. From the *Latin* came,

1. The Portugueſe.
2. Spaniſh.
3. French.
4. Italian.

From the *Celtic*,

5. The Erſe, or Gaelic of the Highlands of Scotland.
6. The Welſh.
7. The Iriſh.
8. Baſſe-Bretagne.

From the *Gothic*,

9. The German.
10. The Low Saxon or Low German.
11. The Dutch.
12. The Engliſh; in which almoſt all the noun-ſubſtantives are German, and many of the verbs French, Latin, &c. and which is enriched with the ſpoils of all other languages.
13. The Daniſh.
14. The Norwegian.
15. Swediſh.
16. Icelandic.

From the *Sclavonian*,

17. The Polonete.
18. The Lithuanian.
19. Bohemian.
20. Tranſylvanian.
21. Moravian.
22. The modern Vandalian, as it is ſtill ſpoken in Luſatia, Pruſſian Vandalia, &c.
23. The Croatian.
24. The Ruſſian or Muſcovite; which, as we have ſeen, is the pureſt dialect of this language.
25. The language of the Calmucs and Coſſacs.
26. Thirty-two different dialects of nations who inhabit the north-eaſtern parts of Europe and Aſia, and who are deſcended from the Tartars and Huno-Scythians. There are polyglott tables which contain not only the alphabets, but alſo the principal diſtinct characters of all theſe languages.

II. The languages at preſent generally ſpoken in Aſia are, 233 Aſiatic languages.

27. The Turkiſh and Tartarian, with their different dialects.
28. The Perſian.
29. The Georgian or Iberian.
30. The Albanian or Circaſſian.
31. The Armenian.

} Theſe languages are ſpoken by the Greek Chriſtians in Aſia, under the patriarch of Conſtantinople.

32.

Modern languages.

32. The modern Indian.
33. The Formoſan.
34. The Indoſtanic.
35. The Malabarian.
36. The Warugian.
37. The Talmulic or Damulic.

} The Daniſh miſſionaries who go to Tranquebar, print books at Hall in theſe languages.

38. The modern Arabic.
39. The Tanguſian.
40. The Mungalic.
41. The language of the Nigarian or Akar Nigarian.
42. The Gruſinic or Gruſinian.
43. The Chineſe.
44. The Japoneſe.

We have enumerated here thoſe Aſiatic languages only of which we have ſome knowledge in Europe, and even alphabets, grammars, or other books that can give us information concerning them. There are doubtleſs other tongues and dialects in thoſe vaſt regions and adjacent iſlands; but of theſe we are not able to give any account.

234 frican nguage.

III. The principal languages of Africa are,

45. The modern Egyptian.
46. The Fetuitic, or the language of the kingdom of Fetu.
47. The Moroccan; and,
48. The jargons of thoſe ſavage nations who inhabit the deſert and burning regions. The people on the coaſt of Barbary ſpeak a corrupt dialect of the Arabic. To theſe may be added the Chilhic language, otherwiſe called *Tamazeght*; the Negritian, and that of Guinea; the Abyſſinian; and the language of the Hottentots.

235 merican nguages.

IV. The languages of the American nations are but little known in Europe. Every one of theſe, though diſtant but a few days journey from each other, have their particular language or rather jargon. The languages of the Mexicans and Peruvians ſeem to be the moſt regular and poliſhed. There is alſo one called *Poconchi* or *Pocomana*, that is uſed in the bay of Honduras and toward Guntimal, the words and rules of which are moſt known to us. The languages of North America are in general the Algonbic, Apalachian, Mohogic, Savanahamic, Virginic, and Mexican: and in South America, the Peruvian, Caribic, the language of Chili, the Cairic, the Tucumanian, and the languages uſed in Paraguay, Braſil, and Guiana.

236 eneral re- ctions on odern nguages.

V. We have already ſaid, that it would be a vain and ſenſeleſs undertaking for a man of letters to attempt the ſtudy of all theſe languages, and to make his head an univerſal dictionary; but it would be ſtill more abſurd in us to attempt the analyſis of them in this place: ſome general reflections therefore muſt here ſuffice. Among the modern languages of Europe, the French ſeems to merit great attention; as it is elegant and pleaſing in itſelf; as it is become ſo general, that with it we may travel from one end of Europe to the other without ſcarce having any occaſion for an interpreter; and as in it are to be found excellent works of every kind, both in verſe and proſe, uſeful and agreeable. There are, beſides, grammars and dictionaries of this language which give us every information concerning it, and very able maſters who teach it; eſpecially ſuch as come from thoſe parts of France where it is ſpoken correctly; for with all its advantages, the French language has this inconvenience, that it is pronounced ſcarce anywhere purely but at Paris and on the banks of the Loire. The language of the court, of the great world, and of men of letters, is moreover very different from that of the common people; and the French tongue, in general, is ſubject to great alteration and novelty. What pity it is, that the ſtyle of the great Corneille, and that of Moliere, ſhould already begin to be obſolete, and that it will be but a little time before the inimitable *chefs d'œuvres* of thoſe men of ſublime genius will be no longer ſeen on the ſtage! The moſt modern ſtyle of the French, moreover, does not ſeem to be the beſt. We are inclined to think, that too much conciſeneſs, the epigrammatic point, the antitheſis, the paradox, the ſententious expreſſion, &c. diminiſh its force; and that, by becoming more poliſhed and refined, it loſes much of its energy.

Modern languages.

VI. The German and Italian languages merit likewiſe a particular application; as does the Engliſh, perhaps above all, for its many and great excellencies (See LANGUAGE). Authors of great ability daily labour in improving them; and what language would not become excellent, were men of exalted talents to make conſtant uſe of it in their works? If we had in Iroquois books like thoſe which we have in Engliſh, Italian, French, and German, ſhould we not be tempted to learn that language? How glad ſhould we be to underſtand the Spaniſh tongue, though it were only to read the Araucana of Don Alonzo D'Ercilia, Don Quixote, ſome dramatic pieces, and a ſmall number of other Spaniſh works, in the original; or the poem of Camoens in Portugueſe.

VII. The other languages of Europe have each their beauties and excellencies. But the greateſt difficulty in all living languages conſtantly conſiſts in the pronunciation, which it is ſcarce poſſible for any one to attain unleſs he be born or educated in the country where it is ſpoken: and this is the only article for which a maſter is neceſſary, as it cannot be learned but by teaching or by converſation: all the reſt may be acquired by a good grammar and other books. In all languages whatever, the poetic ſtyle is more difficult than the proſaic: in every language we ſhould endeavour to enrich our memories with great ſtore of words (*copia verborum*), and to have them ready to produce on all occaſions: in all languages it is difficult to extend our knowledge ſo far as to be able to form a critical judgment of them. All living languages are pronounced rapidly, and without dwelling on the long ſyllables (which the grammarians call *moram*): almoſt all of them have articles which diſtinguiſh the genders.

VIII. Thoſe languages that are derived from the Latin have this further advantage, that they adopt without reſtraint, and without offending the ear, Latin and Greek words and expreſſions, and which by the aid of a new termination appear to be natives of the language. This privilege is forbidden the Germans, who in their beſt tranſlations dare not uſe any foreign word, unleſs it be ſome technical term in caſe of great neceſſity.

Philomathes || Philopœmen.

PHILOMATHES, a lover of learning or ſcience.

PHILOMELA, in fabulous hiſtory, was a daughter of Pandion king of Athens, and ſiſter to Procne, who had married Tereus king of Thrace. Procne ſeparated from Philomela, to whom ſhe was much attached, ſpent her time in great melancholy till ſhe prevailed upon her huſband to go to Athens and bring her ſiſter to Thrace. Tereus obeyed; but he had no ſooner obtained Pandion's permiſſion to conduct Philomela to Thrace, than he fell in love with her, and reſolved to gratify his paſſion. He diſmiſſed the guards whom the ſuſpicions of Pandion had appointed to watch him; offered violence to Philomela; and afterwards cut out her tongue, that ſhe might not diſcover his barbarity, and the indignities ſhe had ſuffered. He confined her in a lonely caſtle; and having taken every precaution to prevent a diſcovery, he returned to Thrace, and told Procne that Philomela had died by the way, and that he had paid the laſt offices to her remains. At this ſad intelligence Procne put on mourning for the loſs of Philomela; but a year had ſcarcely elapſed before ſhe was ſecretly informed that her ſiſter was not dead. Philomela, in her captivity, deſcribed on a piece of tapeſtry her misfortunes and the brutality of Tereus, and privately conveyed it to Procne. She was going to celebrate the orgies of Bacchus when ſhe received it, but ſhe diſguiſed her reſentment; and as during thoſe feſtivals ſhe was permitted to rove about the country, ſhe haſtened to deliver her ſiſter Philomela from her confinement, and concerted with her on the beſt meaſures of puniſhing the cruelty of Tereus. She murdered her ſon Itylus, then in the ſixth year of his age, and ſerved him up as food before her huſband during the feſtival. Tereus, in the midſt of his repaſt, called for Itylus; but Procne immediately informed him that he was then feaſting on his fleſh, when Philomela, by throwing on the table the head of Itylus, convinced the monarch of the cruelty of the ſcene. He drew his ſword to puniſh Procne and Philomela; but as he was going to ſtab them to the heart, he was changed into a hoopoe, Philomela into a nightingale, Procne into a ſwallow, and Itylus into a pheaſant. This tragedy happened at Daulis in Phocis; but Pauſanias and Strabo, who mention the whole of the ſtory, are ſilent about the transformation; and the former obſerves, that Tereus, after this bloody repaſt, fled to Megara, where he laid violent hands on himſelf. The inhabitants of the place raiſed a monument to his memory, where they offered yearly ſacrifices, and placed ſmall pebbles inſtead of barley. It was on this monument that the birds called hoopoes were firſt ſeen; hence the fable of his metamorphoſis. Procne and Philomela died through exceſs of grief and melancholy; and as the nightingale's and the ſwallow's voice is peculiarly plaintive and mournful, the poets have embelliſhed the fable by ſuppoſing that the two unfortunate ſiſters were changed into birds.

PHILONIUM, in pharmacy, a kind of ſomniferous anodyne opiate, taking its name from Philo the inventor.

PHILOPŒMEN, a celebrated general of the Achæan league, was born in Megalopolis, a city of Arcadia, in Peloponneſus: and from his very infancy diſcovered a ſtrong inclination to the profeſſion of arms. He was nobly educated by Caſſander of Mantinea; a man of great probity, and uncommon abilities. He was no ſooner able to bear arms than he entered among the troops which the city of Megalopolis ſent to make incurſions into Laconia, and in theſe inroads never failed to give ſome remarkable inſtance of his prudence and valour. When there were no troops in the field, he uſed to employ his leiſure time in hunting and ſuch other manly exerciſes. When Cleomenes king of Sparta attacked Megalopolis, Philopœmen diſplayed much courage and greatneſs of ſoul. He ſignalized himſelf no leſs ſome time after, in the battle of Sellaſia, where Antigonus gained a complete victory over Cleomenes. Antigonus, who had been an eye-witneſs of his prudent and intrepid behaviour, made very advantageous offers to gain him over to his intereſt; but he rejected them, having an utter averſion to a court life, which he compared to that of a ſlave, ſaying, that a courtier was but a ſlave of a better condition. As he could not live idle and inactive, he went to the iſle of Crete, which was then engaged in war, and ſerved there as a volunteer till he acquired a complete knowledge of the military art; for the inhabitants of that iſland were in thoſe days accounted excellent warriors, being ſcarce ever at peace among themſelves. Philopœmen, having ſerved ſome years among the troops of that iſland, returned home, and was upon his arrival appointed general of the horſe; in which command he behaved ſo well, that the Achæan horſe, heretofore of no reputation, became in a ſhort time famous all over Greece. He was ſoon after appointed general of all the Achæan forces, when he applied himſelf to the re-eſtabliſhing of military diſcipline among the troops of the republic, which he found in a very low condition, and univerſally deſpiſed by their neighbours. Aratus, indeed, was the firſt that raiſed the Achæan ſtate to that pitch of power and glory to which it arrived; but the ſucceſs of his enterpriſes was not ſo much owing to his courage and intrepidity as to his prudence and politics. As he depended on the friendſhip of foreign princes, and their powerful ſuccours, he neglected the military diſcipline at home; but the inſtant Philopœmen was created prætor, or commander in chief, he roufed the courage of his countrymen, in order to put them into a condition to defend themſelves without the aſſiſtance of foreign allies. With this view he made great improvements in the Achæan diſcipline; changing the manner of their exerciſe and their arms, which were both very defective. He had thus, for the ſpace of eight months, exerciſed his troops every day, making them perform all the motions and evolutions, and accuſtoming them to manage with dexterity their arms, when news was brought him that Machanidas was advancing, at the head of a numerous army, to invade Achaia. He was glad of this opportunity to try how the troops had profited by his diſcipline; and accordingly, taking the field, met the enemy in the territories of Mantinea, where a battle was fought. Philopœmen, having killed Machanidas with his own hand, ſtruck off his head, and carried it from rank to rank, to encourage his victorious Achæans, who continued the purſuit, with great ſlaughter, and incredible ardour, to the city of Tegea, which they entered together with the fugitives. The Lacedæmonians loſt on

Philopœmen.

Ancient Univerſal Hiſtory, vol. vi.

Philopœmen.

on this occaſion above 8000 men, of which 4000 were killed on the ſpot, and as many taken priſoners. The loſs of the Achæans was very inconſiderable, and thoſe that fell were moſtly mercenaries. This happened about the year before Chriſt 204.

But what moſt of all raiſed the fame and reputation of Philopœmen was his joining the powerful city of Lacedæmon to the Achæan commonwealth; by which means the Achæans came to eclipſe all the other ſtates of Greece. This memorable event happened in the year 191. In this tranſaction we cannot help taking notice of one circumſtance, which, in our opinion, reflects greater luſtre on Philopœmen than all his warlike exploits. The Lacedæmonians, overjoyed to ſee themſelves delivered from the oppreſſions they had long groaned under, ordered the palace and furniture of Nabis to be ſold; and the ſum accruing from thence, to the amount of 120 talents, to be preſented to Philopœmen, as a token of their gratitude. Deputies therefore were to be appointed, who ſhould carry the money, and deſire Philopœmen, in the name of the ſenate, to accept of the preſent. On this occaſion it was that the virtue of the generous Achæan appeared in its greateſt luſtre; for ſo great was the opinion which the Spartans had of his probity and diſintereſtedneſs, that no one could be found who would take upon him to offer the preſent: ſtruck with veneration, and fear of diſpleaſing him, they all begged to be excuſed. At laſt they obliged, by a public decree, one Timolaus, who had formerly been his gueſt, to go to Megalopolis, where Philopœmen lived, and offer him this teſtimony of their regard. Timolaus, with great reluctance, ſet out for Megalopolis, where he was kindly received and entertained by Philopœmen. Here he had an opportunity of obſerving the ſtrictneſs of his whole conduct, the greatneſs of his mind, the frugality of his life, and the regularity of his manners; which ſtruck him with ſuch awe, that he did not dare once to mention the preſent he was come to offer; inſomuch that, giving ſome other pretence to his journey, he returned home with the money. The Lacedæmonians ſent him again; but he could no more prevail upon himſelf now, than the firſt time to mention the true cauſe of his journey. At laſt, going a third time, he ventured, with the utmoſt reluctance, to acquaint Philopœmen with the offer he had to make in the name of the Lacedæmonians. Philopœmen heard him with great calmneſs; but the inſtant he had done ſpeaking, he ſet out with him for Sparta, where, after having acknowledged his obligation to the Spartans, he adviſed them to lay out their money in reforming or purchaſing thoſe miſcreants who divided the citizens, and ſet them at variance by means of their ſeditious diſcourſes; to the end that, being paid for their ſilence, they might not occaſion ſo many diſtractions in the government: "for it is much more adviſable (ſaid he) to ſtop an enemy's mouth than a friend's; as for me, I ſhall always be your friend, and you ſhall reap the benefit of my friendſhip without expence." Such was the diſintereſtedneſs of this noble Achæan!

About two years after this the city of Meſſene withdrew itſelf from the Achæan league. Philopœmen attacked them; but was wounded, taken priſoner, and poiſoned by the magiſtrates. Thus died one of the greateſt heroes that Greece or any other country ever produced. He was no way inferior in valour, military knowledge, and virtue, to any of the boaſted heroes of Rome. Had Achaia been nearer to an equality with Rome, he would have preſerved his country from the yoke which the Roman republic forced it to bear. Both the Greek and Roman writers put him upon the level with Hannibal and Scipio, who were his contemporaries, and happened to die the ſame year. They allow him to have been not only one of the greateſt commanders, but alſo one of the greateſt ſtateſmen of his age. To his valour and prudence Achaia owed her glory, which upon his death began to decline, there being none after him in that republic able to oppoſe her enemies with the like ſteadineſs and prudence: whence Philopœmen was called the laſt of the Greeks, as Brutus was afterwards ſtyled the laſt of the Romans.

Philoſopher, Philoſopher's Stone.

PHILOSOPHER, a perſon verſed in philoſophy; or one who makes profeſſion of, or applies himſelf to, the ſtudy of nature and morality.

Philosopher's Stone, the greateſt object of alchemy, is a long ſought-for preparation, which, when found, is to convert all the true mercurial part of metal into pure gold, better than any that is dug out of mines or perfected by the refiner's art.

Some Greek writers in the fourth and fifth centuries ſpeak of this art as being then known; and towards the end of the 13th century, when the learning of the Eaſt had been brought hither by the Arabians, the ſame pretenſions began to ſpread through Europe. It is ſuppoſed that this art, called *alchemy*, was of Egyptian origin; and that, when the ancient Greek philoſophers travelled into Egypt, they brought back ſome of the allegoric language of this Egyptian art, ill underſtood, which afterwards paſſed into their mythology. Alchemy was the earlieſt branch of chemiſtry, conſidered as a philoſophical ſcience: in the other parts of chemical knowledge, facts preceded reaſoning or ſpeculation; but alchemy was originally ſpeculative. See TRANSMUTATION.

The alchemiſts ſuppoſed the general principals of metals to be chiefly two ſubſtances, which they called mercury and ſulphur; they apprehended alſo, that the pure mercurial, ſulphureous, or other principles of which they imagined gold to be compoſed, were contained ſeparately in other bodies: and theſe principles, therefore, they endeavoured to collect, and to concoct and incorporate by long digeſtions: and by thus conjoining the principles of gold, if they could be ſo procured and conjoined, it might be expected that gold would be produced. But the alchemiſts pretend to a product of a higher order, called *the elixir, the medicine for metals, the tincture, the philoſopher's ſtone;* which, by being projected on a large quantity of any of the inferior metals in fuſion, ſhould change them into fine gold; which being laid on a plate of ſilver, copper, or iron, and moderately heated, ſhould ſink into the metal, and change into gold all the parts to which it was applied; which, on being properly heated with pure gold, ſhould change the gold into a ſubſtance of the ſame nature and virtue with itſelf, ſo as thus to be ſuſceptible of perpetual multiplication; and which, by continued coction, ſhould have its power more and

Philoſopher's Stone.

more exalted, ſo as to be able to tranſmute greater and greater quantities of the inferior metals, according to its different degrees of perfection.

Alchemiſts have attempted to arrive at the making of gold by three methods: the firſt by ſeparation; for every metal yet known, it is affirmed, contains ſome quantity of gold; only, in moſt, the quantity is ſo little as not to defray the expence of getting it out.

The ſecond is by maturation; for the alchemiſts think mercury is the baſis and matter of all metals; that quickſilver purged from all heterogeneous bodies would be much heavier, denſer, and ſimpler, than the native quickſilver; and that by ſubtilizing, purifying, and digeſting it with much labour, and long operations, it is poſſible to convert it into pure gold.

This method is only for mercury. With reſpect to the other metals, it is ineffectual, 1. Becauſe their matter is not pure mercury, but has other heterogeneous bodies adhering to it; and, 2. Becauſe the digeſtion, whereby mercury is turned into gold, would not ſucceed in other metals, becauſe they had not been long enough in the mines.

Weight is the inimitable character of gold, &c. Now mercury, they ſay, has always ſome impurities in it, and theſe are lighter than mercury. Could they be purged away, which they think is not impoſſible, mercury would be as heavy as gold; and what is as heavy as gold is gold, or at leaſt might very eaſily be made gold.

The third method is by tranſmutation, or by turning all metals readily into pure gold, by melting them in the fire, and caſting a little quantity of a certain preparation into the fuſed matter; upon which the feces retire, are volatilized and burnt, and carried off, and the reſt of the maſs is turned into pure gold. That which works this change in the metals is called the *philoſopher's ſtone*. See TRANSMUTATION.

Whether this third method be poſſible or not, it is difficult to ſay. We have ſo many teſtimonies of it from perſons who on all other occaſions ſpeak truth, that it is hard to ſay they are guilty of direct falſehood, even when they ſay that they have been maſters of the ſecret. We are told, that it is only doing that by art which nature does in many years and ages. For as lead and gold differ but little in weight, therefore there is not much in lead beſide mercury and gold. Now, if we had any body which would ſo agitate all the parts of lead as to burn all that is not mercury therein, and had alſo ſome ſulphur to fix the mercury, would not the maſs remaining be converted into gold? There is nothing in nature ſo heavy as lead except gold, mercury, and platina, which was not known to theſe reaſoners; it is evident, therefore, there is ſomething in lead that comes very near to gold. But in lead there is likewiſe ſome heterogeneous matter different both from mercury and gold. If therefore 19 ounces of lead be diſſolved by the fire, and 8 ounces be deſtroyed by theſe means, it is argued that we ſhall have the reſt good gold; the ratio of lead to gold being as 11 to 19. If then the philoſopher's ſtone can purify the mercurial matter in lead, ſo as that nothing ſhall remain but the pure mercurial body, and you can fix and coagulate this by means of ſulphur, out of 19 ounces of lead you will have 11 of gold: or, if you reduce the lead from 18 to 14, you will then have converted it into mercury; and if you farther purify this mercury to the proper ſtandard, you will have gold; provided you have but a ſulphur with which to fix and coagulate it. Such is the foundation of the opinion of the philoſopher's ſtone; which the alchemiſts contend to be a moſt ſubtile, fixed, concentrated fire, which, as ſoon as it melts with any metal, does, by a magnetic virtue, immediately unite itſelf to the mercurial body of the metal, volatilize and cleanſe off all that is impure therein, and leave nothing but a maſs of pure gold. Many frauds and artifices have unqueſtionably been practiſed in this operation, and there might be political reaſons why princes and others ſhould encourage thoſe who pretended to a power of furniſhing this inexhauſtible ſource of wealth; but it would be wrong to cenſure as impoſtors all thoſe who have declared themſelves convinced, from their own experiments, of the tranſmutability of baſe metals into gold. There are ſtrong reaſons, however, to believe that the authors have been deceived themſelves by fallacious appearances. Mr Boyle gives an account of a proceſs by which he imagines part of the ſubſtance of gold to have been tranſmuted into ſilver. He alſo relates a very extraordinary experiment, under the title of the degradation of gold by an anti-elixir, which was publiſhed in his own life-time, and ſince reprinted in 1739. Hence many have been led to conclude in favour of the alchemical doctrine of the tranſmutability of metals See an account of this experiment, with remarks upon it by Dr Lewis, in his *Commerce of Arts*, ſect. 12. p. 297, &c.

Philoſopher's Stone.

Characters of the Kings and Queens of England.

"The opinion (ſays Holt) that one metallic or other foreign ſubſtance might be changed into another, was, it ſeems, at this time (reign of Henry VI. of England) propagated by certain chemiſts, whoſe obſervations on the ſurpriſing effects and alterations produced in certain ſubſtances by the force of heat carried their imaginations beyond what ſound judgment might warrant. The firſt inſtance of which on record is in vol. xi. p. 68. of the *Fœdera*; wherein Henry VI. grants a licence to John Cobbe, freely to work in metals; he having, by philoſophical art, found out a method of transferring imperfect metals into perfect gold and ſilver.

"This pretended ſecret, known afterwards by the name of the *philoſopher's ſtone* or *powder*, was encouraged by four licences, granted to different projectors during this reign, and at ſundry times after, during this century particularly, and in ſucceeding times, all over Europe. The frenzy has not entirely ceaſed even to this day, although it meets with neither public encouragement nor countenance from men of ſober reaſon; the projectors having yet found nothing from their airy ſchemes in this mode of ſearch but certain ruin to their property."

The ſame author, when ſpeaking of the commerce of the kingdom, and the wonderful increaſe and riches of commercial cities, ſpeaks thus: "This is the true philoſopher's ſtone, ſo much ſought after in former ages, the diſcovery of which has been reſerved to genius, when ſtudying to improve the mechanic arts. Hence a pound of raw materials is converted into ſtuffs of fifty times its original value. And the metals too are not, indeed, tranſmuted into gold—they are more:

for

Philoſophic. for the labour of man has been able to work the baſer metal, by the ingenuity of art, ſo as to become worth more than many times its weight in gold"

PHILOSOPHIC, or PHILOSOPHICAL, ſomething belonging to PHILOSOPHY.

PHILOSOPHICAL EGG, among chemiſts, a thin glaſs body or bubble, of the ſhape of an egg, with a long neck or ſtem, uſed in digeſtions. Philoſophical, Philoſophizing.

PHILOSOPHIZING, rules of. See *NEWTONIAN Philoſophy*, n° 16. and the following article.

PHILOSOPHY,

1 Definitions of philoſophy.

IS a word derived from the Greek, and literally ſignifies the *love of wiſdom* (A). In its uſual acceptation, however, it denotes a ſcience, or collection of ſciences, of which the univerſe is the object; and of the term thus employed many definitions have been given, differing from one another according to the different views of their ſeveral authors. By Pythagoras, philoſophy is defined επιστημη των οντων, "the knowledge of things exiſting;" by Cicero, after Plato, *ſcientia rerum divinarum et humanarum cum cauſis;* and by the illuſtrious Bacon, *interpretatio naturæ*. Whether any of theſe definitions be ſufficiently preciſe, and at the ſame time ſufficiently comprehenſive, may be queſtioned; but if philoſophy in its utmoſt extent be capable of being adequately defined, it is not here that the definition ſhould be given. "Explanation (ſays an acute writer *), is the firſt office of a teacher; definition, if it be good, is the laſt of the inquirer after truth; but explanation is one thing, and definition quite another." It may be proper, however, to obſerve, that the definition given by Cicero is better than that of Pythagoras, becauſe the chief object of the philoſopher is to aſcertain the *cauſes* of things; and in this conſiſts the difference between his ſtudies and thoſe of the natural hiſtorian, who merely enumerates phenomena, and arranges them into ſeparate claſſes.

* *Tatham's Chart and Scale of Truth*, v. i. p. 8.

2 Its objects.

The principal objects of philoſophy are, God, nature, and man. That part of it which treats of God is called *theology;* that which treats of nature, *phyſics* and *metaphyſics;* and that which treats of man, *logic* and *ethics*. That theſe are not ſeparate and independent ſciences, but, as Bacon expreſſes it (B), branches from the ſame trunk, we ſhall endeavour to ſhow, after we have given, agreeably to our uſual plan, a ſhort hiſtory of philoſophy from the earlieſt ages to the preſent day.

To attempt to aſſign an *origin* to philoſophy, would be ridiculous; for every man endeavours to aſcertain the cauſes of thoſe changes which he obſerves in nature; and even children themſelves are inquiſitive after that which produces the ſound of their drums and their rattles. Children, therefore, and the moſt illiterate vulgar, have in all ages been philoſophers. But the firſt people among whom philoſophy was cultivated as a profeſſion, was probably the Chaldeans. We certainly read of none earlier; for though we have more authentic accounts of the Hebrews than of any other nation of remote antiquity, and have reaſon to believe that no people was civilized before them, yet the peculiar circumſtances in which they were placed, rendered all philoſophical inveſtigation to them uſeleſs, and even tended to ſuppreſs the very ſpirit of enquiry. The Egyptians indeed pretended to be the firſt of nations, and to have ſpread the bleſſings of religion and the light of ſcience among every other people; but, from the earlieſt records now extant, there is reaſon to believe that the Chaldeans were a civilized and powerful nation before the Egyptian monarchy was founded. Hiſtory of Philoſophy.

3 Philoſophy of the Chaldeans.

Of the Chaldean philoſophy much has been ſaid, but very little is known. Aſtronomy ſeems to have been their favourite ſtudy; and at the era of Alexander's conqueſt of their country, they boaſted that their anceſtors had continued their aſtronomical obſervations through a period of 470,000 years. Extravagant claims to antiquity have been common in all nations (C). Caliſthenes, who attended the Macedonian conqueror, was requeſted by Ariſtotle to inform himſelf concerning the origin of ſcience in Chaldea; and upon examining into the grounds of this report, he found that their obſervations reached no farther backwards than 1903 years, or 2234 years before the Chriſtian era. Even this is a remoter antiquity than Ptolemy allows to their ſcience; for he mentions no Chaldean obſervations prior to the era of Nabonaſſar, or

(A) The origin uſually attributed to the term *philoſophy* has been already aſſigned in the article PHILOLOGY. M. Chauvin gives it a turn ſomewhat different. According to him, the term is derived from φιλεω, *deſire* or *ſtudy*, and σοφια, *wiſdom;* and therefore he underſtands the word to mean *the deſire or ſtudy of wiſdom;* for (ſays he) Pythagoras, conceiving that the application of the human mind ought rather to be called *ſtudy* than *ſcience*, ſet aſide the appellation of *wiſe* as too aſſuming, and took that of *philoſopher*.

(B) Convenit igitur partiri *philoſophiam* in *doctrinas* tres; *doctrinam* de *numine*, *doctrinam* de *naturâ*, *doctrinam* de *homine*. Quoniam autem partitiones *ſcientiarum* non ſunt lineis diverſis ſimiles, quæ coeunt ad unum angulum; ſed potius ramis arborum, qui conjunguntur in uno trunco, qui etiam truncus ad ſpatium nonnullum integer eſt et continuus, antequam ſe partiatur in ramos. *De aug. Scient.* lib. iii. cap 1.

(C) This claim of the Babylonians is thus rejected with contempt by Cicero; "Contemnamus Babylonios, et eos, qui e Caucaſo cœli ſigna ſervantes, numeris, et motibus, ſtellarum curſus perſequuntur: Condemnemus, inquam, hos aut *ſtultitiæ*, aut *vanitatis*, aut *imprudentiæ*, qui 470 millia annorum, ut ipſi dicunt, monumentis comprehenſa continent, et mentiri judicemus, nec *ſeculorum* reliquorum *judicium*, quod de ipſis futurum ſit, *pertimeſcere*. *De Divinatione*, lib. i. § 19.

History of Philosophy.

or 747 years before Christ. That they cultivated something which they called philosophy at a much earlier period than this, cannot be questioned; for Aristotle ‡, on the credit of the most ancient records, speaks of the Chaldean magi as prior to the Egyptian priests, who were certainly men of learning before the time of Moses. For any other science than that of the stars, we do not read that the Chaldeans were famous; and this seems to have been cultivated by them merely as the foundation of judicial astrology. Persuading the multitude that all human affairs are influenced by the stars, and professing to be acquainted with the nature and laws of this influence, their *wise men* pretended to calculate nativities, and to predict good and bad fortune ||. This was the source of idolatry and various superstitions; and whilst the Chaldeans were given up to such dotages, true science could not be much indebted to their labours. If any credit be due to Plutarch and Vitruvius, who quote Berosus, (see BEROSUS), it was the opinion of the Chaldean *wise men* that an eclipse of the moon happens when that part of its body which is destitute of fire is turned towards the earth. "Their cosmogony, as given by Berosus, and preserved by Syncellus, seems to be this, that all things in the beginning consisted of darkness and water; that a divine power dividing this humid mass, formed the world; and that the human mind is an emanation from the Divine nature *".

|| *Sext. Emp. ad Matth.* l. 5. § 2 *Strabo*, lib. 16. *Cic. de Div.* lib. 1. § 1.

* *Enfield's Hist. Phil.* v. i.

The large tract of country which comprehended the empires of Assyria and Chaldea, was the first peopled region on earth. From that country, therefore, the rudiments of science must have been propagated in every direction through the rest of the world; but what particular people made the earliest figure, after the Chaldeans, in the history of philosophy, cannot be certainly known. The claim of the Egyptians is probably best founded; but as their science was the immediate source of that of the Greeks, we shall defer what we have to say of it on account of the connection between the parent and the offspring, and turn our attention from Chaldean to Indian philosophy, as it has been cultivated from a very early period by the Brachmans and Gymnosophists. We pass over Persia, because we know not of any science peculiar to that kingdom, except the doctrines of the magi, which were religious rather than philosophical; and of them the reader will find some account under the words MAGI, POLYTHEISM, and ZOROASTER.

4 Indian philosophy

From whatever quarter India received its wisdom, we are certain that its philosophers were held in high repute at a period of very remote antiquity, since they were visited by Pythagoras and other sages of ancient Greece, who travelled in pursuit of knowledge. Yet they seem to have been in that early age, as well as at present, more distinguished for the severity of their manners than for the acquisition of science; and, as Dr Enfield observes, to have more resembled modern monks than ancient philosophers. The brachmans or bramins, it is well known, are all of one tribe; and the most learned of them are in their own language called *Pundits* or *Pandits*. The Greek writers, however, mention a society called *Samanæans*, who, voluntarily devoting themselves to the study of divine wisdom, gave up all private property, committed their children to the care of the state, and their wives to the protection of their relations. This society was supported at the public expence; and its members spent their time in contemplation, in conversation on divine subjects, or in acts of religion.

History of Philosophy.

5 Ingrafted on religion.

The philosophy of the Indians has indeed from the beginning been ingrafted on their religious dogmas, and seems to be a compound of fanatic metaphysics and extravagant superstition, without the smallest seasoning of rational physics. Very unlike the philosophers of modern Europe, of whom a great part labour to exclude the agency of mind from the universe, the Pandits of Hindostan allow no powers whatever to matter, but introduce the Supreme Being as the immediate cause of every effect, however trivial. "Brehm, *the Spirit of God*, (says one of their most revered Bramins), is absorbed in self-contemplation. The same is the mighty Lord, who is present in every part of space, whose omnipresence, as expressed in the Reig Beid or Rigveda, I shall now explain. Brehm is one, and to him there is no second; such is truly Brehm. His omniscience is self inspired or self-intelligent, and its comprehension includes every possible species. To illustrate this as far as I am able; the most comprehensive of all comprehensive faculties is omniscience; and being self-inspired, it is subject to none of the accidents of mortality, *conception*, *birth*, *growth*, *decay*, or *death*; neither is it subject to passion or vice. To it the three distinctions of time, *past*, *present*, and *future*, are not. To it the three modes of being (D) are not. It is separated from the universe, and independent of all. This omniscience is named *Brehm*. By this omniscient Spirit the operations of God are enlivened. By this Spirit also the 24 powers (E) of nature are animated. How is this? As the eye by the sun, as the pot by the fire, as iron by the magnet (F), as variety of imitations by the mimic, as fire by the fuel, as the shadow by the man, as dust by the wind, as the arrow by the spring of the bow, and as the shade by the tree; so by this Spirit the world is endued with the powers of intellect, the powers of the will, and the powers of action: so that if

(D) To be awake, to sleep, and to be absorbed in a state of unconsciousness—a kind of trance.

(E) The 24 powers of nature, according to the Bramins, are the five elements, *fire*, *air*, *earth*, *water*, and *akash* (a kind of subtile æther); the five members of action, the *hand*, *foot*, *tongue*, *anus*, and *male-organ of generation*; the five organs of perception, the *ear*, *eye*, *nose*, *mouth*, and *skin*; the five senses, which they distinguish from the organs of sensation; the three dispositions of the mind, *desire*, *passion*, and *tranquillity*; and the power of *consciousness*.

(F) If the work from which this extract is quoted be of as great antiquity as Mr Halhed supposes, the Bramins must have been acquainted with the phenomena of magnetism at a much earlier period than any other philosophers of whom history makes mention.

if it emanates from the heart by the channel of the ear, it causes the perception of sounds; if it emanates from the heart by the channel of the skin, it causes the perception of touch; if it emanates from the heart by the channel of the eye, it causes the perception of visible objects; if it emanates from the heart by the channel of the tongue, it causes the perception of taste; if it emanates from the heart by the channel of the nose, it causes the perception of smell. This also invigorating the five members of action, and invigorating the five members of perception, and invigorating the five elements, and invigorating the five senses, and invigorating the three dispositions of the mind, &c. causes the creation or the annihilation of the universe, while itself beholds every thing as an indifferent spectator *."

Preliminary Disc. Halhed's Intoo rws.

From this passage it is plain that all the motions in the universe, and all the perceptions of man, are, according to the Bramins, caused by the immediate agency of the Spirit of God, which seems to be here considered as the soul of the world. But it appears from some papers in the Asiatic Researches, that the most profound of these oriental philosophers, and even the authors of their sacred books, believe not in the existence of matter as a separate substance, but hold an opinion respecting it very similar to that of the celebrated Berkeley. The Védantis (says Sir William Jones), unable to form a distinct idea of brute matter independent of mind, or to conceive that the work of Supreme Goodness was left a moment to itself, imagine that the Deity is ever present to his work, and constantly supports a series of perceptions, which in one sense they call *illusory*, though they cannot but admit the reality of all created forms, as far as the happiness of creatures can be affected by them.

6 dmits not e separate istence of atter, and

This is the very immaterialism of Berkeley; and in proof that it is the genuine doctrine of the Bramins, the learned president quotes the *Bhágavat*, which is believed to have been pronounced by the Supreme Being, and in which is the following sentence:

"Except the *first cause*, whatever may appear, and may not appear, in the mind, know that to be the mind's *Máyá*, or "delusion," as light, as darkness."

7 aches the etempsy- osis.

We have shown elsewhere (see METAPHYSICS, n° 269.) that the metaphysical doctrines of the Bramins, respecting the human soul, differ not from those of Pythagoras and Plato; and that they believe it to be an emanation from the great soul of the world, which, after many transmigrations, will be finally absorbed in its parent substance. In proof of their believing in the metempsychosis, Mr Halhed gives us the following translation of what (he says) is a beautiful stanza in the Gēētā: "As throwing aside his old clothes, a man puts on others that are new; so our lives, quitting the old, go to other newer animals."

8 ysics of Bra- as.

From the Bramins believing in the soul of the world not only as the *sole agent*, but as the *immediate* cause of every motion in nature, we can hardly suppose them to have made any great progress in that science which in Europe is cultivated under the name of *physics*. They have no inducement to investigate the laws of nature; because, according to the first principles of their philosophy, which, together with their religion, they believe to have been revealed from heaven, every phenomenon, however regular, or however anomalous, is produced by the voluntary act of an intelligent mind. Yet if they were acquainted with the use of fire-arms 4000 years ago, as Mr Halhed seems to believe, he who made that discovery must have had a very considerable knowledge of the powers of nature; for though gunpowder may have been discovered by accident in the East, as it certainly was in the West many ages afterwards, it is difficult to conceive how mere accident could have led any man to the invention of a gun. In astronomy, geometry, and chronology too, they appear to have made some proficiency at a very early period. (See ASTRONOMY, n° 4.) Their chronology and astronomy are indeed full of those extravagant fictions which seem to be essential to all their systems; but their calculation of eclipses, and their computations of time, are conducted upon scientific principles.

9 Their astronomy.

"It is sufficiently known (says Mr Davis †) that the Hindoo division of the ecliptic into signs, degrees, &c. is the same as ours; that their astronomical year is sidereal, or containing that space of time in which the sun, departing from a star, returns to the same; that it commences on the instant of his entering the sign Aries, or rather the Hindoo constellation Mésha; that each astronomical month contains as many even days and fractional parts as he stays in each sign; and that the civil differs from the astronomical account of time only in rejecting those fractions, and beginning the year and month at sunrise, instead of the intermediate instant of the artificial day or night. Hence arises the unequal portion of time assigned to each month dependent on the situation of the sun's apsis, and the distance of the vernal equinoctial colure from the beginning of Mésha in the Hindoo sphere; and by these means they avoid those errors which Europeans, from a different method of adjusting their kalendar by intercalary days, have been subject to."

† *Asiatic Researches*, vol. ii.

Mr Davis observes, that an explanation of these matters would have led him beyond his purpose, which was only to give a general account of the method by which the Hindoos compute eclipses, and to show that the science of astronomy is as well known among them now as ever it was among their ancestors. This he does very completely; but in the present short historical sketch, we can neither copy nor abridge his memoir. Suffice it to say, that he has shown the practical part of the Hindoo astronomy to be founded on mathematical principles; and that the learned Pandits appear to have truer notions of the form of the earth, and the economy of the universe, than those which are ascribed to their countrymen in general.

The same writer shows likewise, that the prodigious duration which the Hindoos attribute to the world, is the result of a scientific calculation, founded indeed on very whimsical principles. "It has been common with astronomers to fix on some epoch, from which, as from a radix, to compute the planetary motions; and the ancient Hindoos chose that point of time counted back, when, according to their motions as they had determined them, they must have been in conjunction in the beginning of Mésha or Aries, and coeval with which circumstance they supposed the *creation*. This, as it concerned the planets only, would have produced a moderate term of years compared with the enormous antiquity that will be hereafter

History of Philosophy.

stated: but having discovered a slow motion of the nodes and apsides also, and taken it into the computation, they found it would require a length of time corresponding with 1955884890 years now expired, when they were so situated, and 2364115110 years more before they would return to the same situation again, forming together the grand anomalistick period denominated a *Calpa*, and fancifully assigned as the day of Brahmá."

But though the mathematical part of the astronomy of the Pandits is undoubtedly respectable, their physical notions of the universe are in the highest degree ridiculous and extravagant. In the Vedas and Puranas, writings of which no devout Hindoo can dispute the divine authority, eclipses are said to be occasioned by the intervention of the monster *Rahu*; and the earth to be supported by a series of animals. "They suppose (says Mr Halhed) that there are 14 spheres, seven below and six above the earth. The seven inferior worlds are said to be altogether inhabited by an infinite variety of serpents, described in every monstrous figure that the imagination can suggest. The first sphere above the earth is the immediate vault of the visible heavens, in which the sun, moon, and stars, are placed. The second is the first paradise, and general receptacle of those who merit a removal from the lower earth. The third and fourth are inhabited by the souls of those men who, by the practice of virtue and dint of prayer, have acquired an extraordinary degree of sanctity. The fifth is the reward of those who have all their lives performed some wonderful act of penance and mortification, or who have died martyrs for their religion. The highest sphere is the residence of Brahma and his particular favourites, such as those men who have never uttered a falsehood during their whole lives, and those women who have voluntarily burned themselves with their husbands. All these are absorbed in the divine essence."

10 Strange notions of the universe.

11 Ethics of the Hindoos.

On ethics, the Hindoos have nothing that can be called philosophy. Their duties, moral, civil, and religious, are all laid down in their *Vedas* and *Shasters*; and enjoined by what they believe to be divine authority, which supersedes all reasoning concerning their fitness or utility. The business of their Pandits is to interpret those books, which are extremely ancient, and written in a language that has long been unintelligible to every other order of men; but no Pandit will alter the text, however impossible to be reconciled to principles established in his own practice of astronomy. On such occasions, the usual apology for their sacred books is, that "such things may have been so formerly, and may be so still; but that for astronomical purposes, astronomical rules must be followed *." The great duties of morality have been prescribed in every religious code; and they are not overlooked in that of the Hindoos, though the highest merit that a Bramin can have consists in voluntary acts of abstinence and mortification, and in contempt of death.

* *Davis's Memoir, Asiatic Researches*, vol. ii.

12 Philosophy of the Arabians and Chinese.

Of the ancient philosophy of the Arabians and Chinese nothing certain can be said; and the narrow limits of such an abstract as this, do not admit of our mentioning the conjectures of the learned, which contradict each other, and are all equally groundless.

There is indeed sufficient evidence that both nations were at a very early period observers of the stars; and that the Chinese had even a theory by which they foretold eclipses (see ASTRONOMY, n° 2, 3.); but there is reason to believe that the Arabians, like other people in their circumstances, were nothing more than judicial astrologers, who possessed not the smallest portion of astronomical science.

History of Philosophy.

Pliny makes mention of their magi, whilst later writers tell us, that they were famous for their ingenuity in solving enigmatical questions, and for their skill in the arts of divination: but the authors of Greece are silent concerning their philosophy; and there is not an Arabian book of greater antiquity than the Koran extant. (See PHILOLOGY, Section II.)

13 Early science of the Phœnicians.

Leaving therefore regions so barren of information, let us pass to the Phœnicians, whose commercial celebrity has induced many learned men to allow them great credit for early science. If it be true, as seems highly probable, that the ships of this nation had doubled the Cape and almost encompassed the peninsula of Africa long before the era of Solomon (See OPHIR, n° 10), we cannot doubt but that the Phœnicians had made great proficiency in the art of navigation, and in the science of astronomy, at a period of very remote antiquity. Nor were these the only sciences cultivated by that ancient people: the learned Cudworth has, in our opinion, sufficiently proved that *Moschus* or *Mochus* a Phœnician, who, according to Strabo, flourished before the Trojan war, was the author of the atomic philosophy afterwards adopted by Leucippus, Democritus, and others among the Greeks; and that it was with some of the successors of this sage that Pythagoras, as Jamblichus tells us, conversed at Sidon, and from them received his doctrine of *Monads* (See PYTHAGORAS). Another proof of the early progress of the Phœnicians in philosophy may be found in the fragments of their historian Sanchoniatho which have been preserved by Eusebius†. We are indeed aware that men of great celebrity have called in question the authenticity of those fragments, and even the very existence of such a writer as Sanchoniatho; but for this scepticism we can discover no foundation (See SANCHONIATHO). His history may have been interpolated in some places by the translater Philo-Byblius; but Porphyry, Eusebius, and Theodoret, speak of it as a work of undoubted credit, and affirm that its author flourished before the Trojan war. Now this ancient writer teaches that, according to the *wise men* of his country, all things arose at first from the necessary agency of an active principle upon a passive chaotic mass which he calls *mot*. This chaos Cudworth thinks was the same with the elementary *water* of Thales, who was also of Phœnician extraction; but Mosheim justly observes that it was rather *dark air*, since Philo translates it ἀέρα ζοφώδη. Be this as it may, nothing can be more evident than that the Phœnicians must have made some progress in what must surely be considered as philosophy, however false, so early as the era of Sanchoniatho; for speculations about the origin of the world never occur to untaught barbarians. Besides Mochus and Sanchoniatho, Cadmus, who introduced letters into Greece, may undoubtedly be reckoned among the Phœnician philosophers; for though it is not pretended that the alphabet was of his invention, and

† *Prep. Ev.*

History of Philosophy.

though it is by no means certain that the Greeks, at the time of his arrival among them, were wholly deſtitute of alphabetic characters (See PHILOLOGY, n° 130.); yet the man who could prevail with illiterate ſavages to adopt the uſe of ſtrange characters, muſt have been a great maſter of the ſcience of human nature. Several other Phœnician philoſophers are mentioned by Strabo; but as they flouriſhed at a later period, and philoſophiſed after the ſyſtematic mode of the Greeks, they fall not properly under our notice. We paſs on therefore to the philoſophy of Egypt.

14 Egyptian philoſophy

It has been already obſerved that the Egyptians boaſted of being the firſt of nations, and the authors of all the ſcience which in ſeparate rays illuminated the reſt of the world. But though this claim was undoubtedly ill-founded, their high antiquity and early progreſs in the arts of civil life cannot be controverted. The Greeks with one voice confeſs that all their learning and wiſdom came from Egypt, either imported immediately by their own philoſophers, or brought through Phœnicia by the ſages of the eaſt; and we know from higher authority than the hiſtories of Greece, that at a period ſo remote as the birth of Moſes, the wiſdom of the Egyptians was proverbially famous. Yet the hiſtory of Egyptian learning and philoſophy, though men of the firſt eminence both ancient and modern have beſtowed much pains in attempts to elucidate it, ſtill remains involved in clouds of uncertainty. That they had ſome knowledge of phyſiology, arithmetic, geometry, and aſtronomy, are facts which cannot be queſtioned; but there is reaſon to believe that even theſe ſciences were in Egypt puſhed no farther than to the uſes of life. That they believed in the exiſtence of incorporeal ſubſtances is certain; becauſe Herodotus aſſures us that they were the firſt aſſerters of the immortality, pre-exiſtence, and tranſmigration of human ſouls, which they could not have been without holding thoſe ſouls to be at leaſt *incorporeal*, if not *immaterial*.

The author of Egyptian learning is generally acknowledged to have been *Thoth*, *Theut*, or *Taaut*, called by the Greeks *Hermes*, and by the Romans *Mercury*; but of this perſonage very little is known. Diodorus Siculus ſays that he was chief miniſter to Oſiris, and that he improved language, invented letters, inſtituted religious rites, and taught aſtronomy, muſic, and other arts. The ſame thing is affirmed by *Sanchoniatho*, whoſe antiquity has been already mentioned; by *Manetho* an Egyptian prieſt, who flouriſhed during the reign of Ptolemy Philadelphus; and by Plato, whoſe authority, as he reſided long in Egypt, and was himſelf an eminent philoſopher, is perhaps more to be depended upon than that of the other two. In the Philebus we are told that Thoth was the inventor of letters; and leſt we ſhould ſuppoſe that by thoſe letters nothing more is meant than picture writing or ſymbolical hieroglyphics, it is added, that he diſtinguiſhed between *vowels* and *conſonants*, determining the number of each. The ſame philoſopher, in his Phædrus, attributes to Thoth the invention of *arithmetic*, *geometry*, *aſtronomy*, and *hieroglyphic* learning; and ſubjoins a diſputation ſaid to have been held between him and *Thamus* then king of Egypt, concerning the advantage and diſadvantage of his newly invented letters. Thoth boaſted that the invention, by aiding memory, would greatly contribute to the progreſs of ſcience; whilſt the monarch contended, that it would enervate mens natural faculties by making them truſt to written characters without exerting the powers of their own minds.

History of Philoſophy.

All this, if real, muſt have happened before the era of Moſes; and ſince it is almoſt certain that alphabetical characters were in uſe prior to the *exod* of the Iſraelites from Egypt (See PHILOLOGY, n° 24, 25.) we may as well allow the invention to Thoth, as give it to an earlier author of unknown name. That arithmetic, geometry, and aſtronomy, were cultivated in Egypt from the moſt remote antiquity, is affirmed by all the ancients, and made in the higheſt degree probable by the ſituation of the country. The firſt elements of aſtronomy have certainly been diſcovered by various nations, whoſe habits of life led them to the frequent obſervation of the heavens; and it is obſerved by Cicero, that the Egyptians and Babylonians, dwelling in open plains where nothing intercepted the view of the heavenly bodies, naturally devoted themſelves to the ſtudy of that ſcience. The annual overflowing of the Nile, which broke up the boundaries of their lands, would lay the Egyptians under the neceſſity of adopting ſome method of ſettling thoſe boundaries anew; and neceſſity we know to be the parent of invention. Hence their early acquaintance with practical geometry cannot well be doubted. Their cuſtom of embalming their dead, and the perfection to which they carried that art (G), ſhows infallibly their knowledge of the properties of natural ſubſtances, and gives ſome reaſon to believe that they were not altogether ſtrangers to anatomy: but if we allow them to have been at this early period anatomiſts acquainted with the powers of drugs, we can hardly refuſe them ſome ſkill in the art of phyſic, which they themſelves traced up to their gods and demigods, to *Serapis*, *Iſis*, and her ſon *Horus* or *Apollo*.

The art of alchymy has been ſaid to have been known by the ancient Egyptians; and from the author of the Egyptian philoſophy it has been called the *Hermetic art*. But though this is unqueſtionably a fiction, there is evidence that they were poſſeſſed of one art which is even yet a *deſideratum* in the practice of chemiſtry. "Moſes (we are told*) took the golden calf, which his brother had made for idolatrous purpoſes, and *burnt it in the fire*, and *ground it to powder*, and ſtrowed it on the water, and made the children of Iſrael drink of it." Had this fact been related by Herodotus or Diodorus Siculus, it would

* *Exod.* xxii. 20.

(G) It is true that the diſſection of ſome mummies has leſſened the high opinion long entertained of the ſkill of the ancient Egyptians in the art of embalming; yet it muſt be granted that their knowledge of antiſeptic drugs was great, ſince it is now certainly known even from theſe diſſections, that by means of ſuch drugs they contrived to preſerve rags of cloth from corruption for upwards of 3000 years.

History of Philosophy.

have been deemed sufficient evidence that the Egyptians were even at that early period no strangers to the art of chemistry: and surely the evidence should not be the worse for coming from the pen of the Hebrew lawgiver, who was himself educated in the court of Egypt.

15 Not carried to high perfection.

But though it is thus evident that the rudiments of almost every useful science were known in Egypt from the remotest antiquity, it does not appear that any of them was carried to a great degree of perfection, unless perhaps chemistry alone must be excepted. One would think that no science could have been more indispensably requisite to them than geometry. And yet though Pythagoras is said to have spent 22 years in Egypt studying that science and astronomy, he himself discovered (H) the famous 47th Prop. of Euclid's first book after his return to Samos. This, though a very useful, is yet a simple theorem; and since it was not reached by the Egyptian geometry, we cannot suppose that those people had then advanced far in such speculations. The same conclusion must be drawn with respect to astronomy; for Thales is said to have been the first that calculated an eclipse of the sun; and we nowhere read that the *Egyptians* pretended to dispute that honour with him. To this it may be replied, that Pythagoras was in Egypt undoubtedly taught the true constitution of the solar system, and what is more extraordinary, the doctrine of comets in particular, and of their revolutions, like the other planets, round the sun (I). We grant that he was taught all this; but it was not scientifically, but dogmatically, as facts which the priests had received by tradition from their early ancestors, and of which they had never questioned the truth nor enquired into the reasons. Of this we need no better proof than that the Pythagorean system of the sun was totally neglected by the Greeks as soon as they began to frame hypotheses and to speculate in philosophy (K).

16 Their knowledge of the solar system.

History of Philosophy.

But it may seem strange, and certainly is so, that the Egyptian priests, in the days of Pythagoras, should have preserved so great a discovery of their ancestors, and at the same time have totally forgotten the principles and reasoning which led to a conclusion apparently contrary to the evidence of sense. This is a difficulty which we pretend not to remove, though the fact which involves it seems to be beyond the reach of controversy. Perhaps the following observations may throw upon it a feeble light. According to Manetho, the written monuments of the first Thoth were lost or neglected in certain civil revolutions or natural calamities which befel the kingdom of Egypt. After many ages great part of them were recovered by an ingenious interpretation of the symbols which he had inscribed upon ancient columns; and the man who made this interpretation was called the second *Thoth* or *Hermes Trismegistus*. But *thrice illustrious* as this personage was, it is at least possible that he may have been much inferior to the former Hermes, and have read his writings and transcribed his conclusions without being able to comprehend the principles or reasoning which led to those conclusions. Any man who understands Latin might translate into his own tongue the conclusions of Newton; but much more would be requisite to make him comprehend the demonstrations of his sublime geometry. By what mode of reasoning the first Hermes (L) was led to the true idea of the solar system, or whether it was by reasoning at all, cannot now be known; but it seems very evident, that when the intercourse between the Egyptians and Greeks first commenced, the wisdom of the former people consisted chiefly in the science of legislation and civil policy, and that the philoso-

pher,

(H) This discovery he claimed; and his claim was admitted by the Greek writers without having been *directly* controverted since. An excellent mathematician, however, has lately shown that the equality between the square of the hypothenuse of a right angled triangle, and the sum of the squares on the other two sides, was known to the astronomers of India at a period long prior to that of Pythagoras. Notwithstanding this, it is certainly possible that the sage of Samos may have made the discovery himself, though we think the contrary much more probable; for we agree with the able writer already mentioned, that Pythagoras, who is generally believed to have conversed with Indian brachmans as well as Egyptian priests, may have derived from them "some of the solid as well as the visionary speculations with which he delighted to instruct or amuse his disciples." See *Transactions of the Royal Society of Edinburgh*, vol. ii. Memoir xiii. Physic Class.

(I) This is recorded by Aristotle and Plutarch; and thus expressed by Ammianus Marcellinus.—"Stellas quasdam, *ceteris similes*, quarum *ortus orbitusque*, quibus sint temporibus *præstituti* humanis mentibus ignorari. Lib. xxv. cap. 10.

(K) *Fixas* in supremis mundi partibus immotas persistere, et planetas his inferiores circa solem revolvi, terram pariter moveri cursu annuo, diurno vero circa axem propriam, et solem ceu focum universi in omnium centro quiescere, antiquissima fuit philosophantium sententia. Ab Ægyptiis autem astrorum antiquissimis observationibus propagatam esse hanc sententiam verisimile est. Et etiam ab illis et a gentibus conterminis ad Græcos, gentem magis philologicam quam philosophicam, philosophia omnis antiquior juxta et senior manasse videtur. Subinde docuerunt Anaxagoras, Democritus, et alii nonnulli, terram in centro mundi immotam stare, et astra omnia in occasum, aliqua celerius, alia tardius moveri, idque in spatiis liberrimis. Namque orbis solidi postea ab Eudoxo, Calippo, Aristotele, introducti sunt; declinante indies philosophia primitus introducta, et novis Græcorum commentis paulatim prævalentibus. Quibus *vinculis* ANTIQUI planetas in spatiis liberis retineri, deque cursu rectilineo perpetuo retractas in orbem regulariter agi docere, non constat. *Newton de Mundi Systemate.*

(L) Some authors, deeply skilled in the Hebrew language, have thought that the true system of the sun and planets may be perceived in the Scriptures of the Old Testament, and that it is only from the ignorance or carelessness of the translators that it does not appear in the English bible and other versions. The writer of this article confesses

History of Philosophy.

pher, the divine, the legiſlator, and the poet, were all united in the ſame perſon. Their coſmogony (for all the ancients who pretended to ſcience framed coſmogonies) differed little from that of the Phœnicians already mentioned. They held that the world was produced from chaos by the energy of an intelligent principle; and they likewiſe conceived that there is in nature a continual tendency towards diſſolution. In Plato's Timæus, an Egyptian prieſt is introduced deſcribing the deſtruction of the world, and aſſerting that it will be effected by means of water and fire. They conceived that the univerſe undergoes a periodical conflagration; after which all things are reſtored to their original form, to paſs again through a ſimilar ſucceſſion of changes.

17 Their moral ſcience Enfield's Hiſt. of Philoſophy.

"Of preceptive doctrine the Egyptians had two kinds, the one ſacred, the other vulgar. The former, which reſpected the ceremonies of religion and the duties of the prieſts, was doubtleſs written in the ſacred books of Hermes, but was too carefully concealed to paſs down to poſterity. The latter conſiſted of maxims and rules of virtue, prudence, or policy. Diodorus Siculus relates many particulars concerning the laws, cuſtoms, and manners of the Egyptians; whence it appears that ſuperſtition mingled with and corrupted their notions of morals. It is in vain to look for accurate principles of ethics among an ignorant and ſuperſtitious people. And that the ancient Egyptians merited this character is ſufficiently evident from this ſingle circumſtance, that they ſuffered themſelves to be deceived by impoſtors, particularly by the profeſſors of the fanciful art of aſtrology; concerning whom Sextus Empiricus juſtly remarks, that they have done much miſchief in the world, by enſlaving men to ſuperſtition, which will not ſuffer them to follow the dictates of right reaſon." See EGYPT, MYSTERIES, MYTHOLOGY, &c.

18 Grecian Philoſophy.

From Egypt and Phœnicia philoſophy paſſed into Greece; where it was long taught without ſyſtem, as in the countries from which it was derived. Phoroneus, Cecrops, Cadmus, and Orpheus, were among the earlieſt inſtructors of the Greeks; and they inculcated Egyptian and Phœnician doctrines in detached maxims, and enforced them, not by ſtrength of argument, but by the authority of tradition. Their coſmogonies were wholly Phœnician or Egyptian diſguiſed under Grecian names; and they taught a future ſtate of rewards and puniſhments. The planets and the moon Orpheus conceived to be habitable worlds, and the ſtars to be fiery bodies like the ſun: but he taught that they are all animated by divinities; an opinion which prevailed both in Egypt and the eaſt: and it does not appear that he gave any other proof of his doctrines than a confident aſſertion that they were derived from ſome god. See ORPHEUS.

Hitherto we have ſeen philoſophy in its ſtate of infancy and childhood, conſiſting only of a collection of ſententious maxims and traditionary opinions; but among the Greeks, an ingenious and penetrating people, it ſoon aſſumed the form of profound ſpeculation and ſyſtematic reaſoning. Two eminent philoſophers aroſe nearly at the ſame period, who may be conſidered as the parents not only of Grecian ſcience, but of almoſt all the ſcience which was cultivated in Europe prior to the era of the great Lord Bacon: Theſe were Thales and Pythagoras; of whom the former founded the Ionic ſchool and the latter the Italic: from which two ſprung the various ſects into which the Greek philoſophers were afterwards divided. A bare enumeration of theſe ſects is all that our limits will admit of; and we ſhall give it in the perſpicuous language and juſt arrangement of Dr Enfield, referring our readers for a fuller account than we can give of their reſpective merits to his abridged tranſlation of Brucker's hiſtory.

History of Philoſophy.

19 The Ionic ſchool.

Of the IONIC SCHOOL were, 1. The Ionic ſect proper, whoſe founder Thales had as his ſucceſſors Anaximenes, Anaxagoras, Diogenes Apolloniates, and Archelaus. 2. The Socratic ſchool, founded by Socrates, the principal of whoſe diſciples were Xenophon, Æſchines, Simon, Cebes, Ariſtippus, Phædo, Euclid, Plato, Antiſthenes, Critias, and Alcibiades. 3. The Cyrenaic ſect, of which Ariſtippus was the author: his followers were, his daughter Arete, Hegeſias, Anicerris, Theodorus, and Bion. 4. The Megaric or Eriſtic ſect, formed by Euclid of Megara; to whom ſucceeded Eubulides, Diodorus, and Stilpo, famous for their logical ſubtlety. 5. The Eliac or Eretriac ſchool, raiſed by Phædo of Elis, who, though he cloſely adhered to the doctrine of Socrates, gave name to his ſchool. His ſucceſſors were Pliſtanus and Menedemus; the latter of whom, being a native of Eretria, transferred the ſchool and name to his own country. 6. The Academic ſect, of which Plato was the founder. After his death, many of his diſciples deviating from his doctrine, the ſchool was divided into the old, new, and middle academies. 7. The Peripatetic ſect, founded by Ariſtotle, whoſe ſucceſſors in the Lyceum were Theophraſtus, Strato, Lycon, Ariſto, Critolaus, and Diodorus. Among the Peripatetics, beſides thoſe who occupied the chair, were alſo Dicæarchus, Eudemus, and Demetrius Phalereus. 8. The Cynic ſect, of which the author was Antiſthenes, whom Diogenes, Oneſicritus, Crates, Metrocles, Menipus, and Menedemus, ſucceeded. In the liſt of Cynic philoſophers muſt alſo be reckoned Hipparchia, the wife of Crates. 9. The Stoic ſect, of which Zeno was the founder. His ſucceſſors in the porch were Perſæus, Ariſto of Chios, Herillus, Sphærus, Cleanthes,

---

ſeſſes that his knowledge of the Hebrew is very limited, which is probably the reaſon that to him the arguments of theſe men appear weak and their criticiſms fanciful. No man, however, has a higher veneration than he for the ſacred volume, which he believes to have been given for nobler purpoſes than to teach its readers the ſcience of aſtronomy; but could the principles of that ſcience be found in it, he ſhould be ſtrongly inclined to think that the firſt Thoth was Joſeph, and that the monarch to whom he was miniſter was the far-famed Oſiris. Were there any ſolid foundation for this ſuppoſition, it would be eaſy to conceive how Thoth acquired his ſcience, and how the Egyptian prieſts might retain juſt notions of the ſolar ſyſtem in general, long after they had forgotten the evidence upon which he communicated thoſe notions to their anceſtors.

History of Philosophy.

Chrysippus, Zeno of Tarsus, Diogenes the Babylonian, Antipater, Panætius, and Posidonius.

20 The Italic School.

Of the ITALIC SCHOOL were, 1. The Italic sect proper: it was founded by Pythagoras, a disciple of Pherecydes. The followers of Pythagoras were Aristæus, Mnesarchus, Alemæon, Ecphantus, Hippo, Empedocles, Epicharmus, Ocellus, Timæus, Archytas, Hippasus, Philolaus, and Eudoxus. 2. The Eleatic sect, of which Xenophanes was the author: his successors, Parmenides, Melissus, Zeno, belonged to the metaphysical class of this sect; Leucippus, Democritus, Protagoras, Diagoras, and Anaxarchus, to the physical. 3. The Heraclitean sect, which was founded by Heraclitus, and soon afterwards expired: Zeno and Hippocrates philosophised after the manner of Heraclitus, and other philosophers borrowed freely from his system. 4. The Epicurean sect, a branch of the Eleatic, had Epicurus for its author; among whose followers were Metrodorus, Polyænus, Hermachus, Polystratus, Basilides, and Protarchus. 5. The Pyrrhonic or Sceptic sect, the parent of which was Pyrrho: his doctrine was taught by Timon the Phliasian; and after some interval was continued by Ptolemy a Cyrenean, and at Alexandria by Ænesidemus.

Of the peculiar doctrines of these sects, the reader will in this work find a short account either in the lives of their respective founders, or under the names of the sects themselves. We shall only observe at present, that tho' many of them were undoubtedly absurd, and many wicked, it would yet perhaps be going too far to say with some, that the philosophy of Greece became impious under Diagoras, vicious under Epicurus, HYPOCRITICAL UNDER ZENO, impudent under Diogenes, covetous under Demochares, voluptuous under Metrodorus, fantastical under Crates, scurrilous under Menippus, licentious under Pyrrho, and quarrelsome under Cleanthes. Of the truth of this heavy charge every reader must judge for himself. We are strongly inclined to think, that there were virtues and vices peculiar to each sect; "and that the sects themselves had an affinity more or less direct with the different temperaments of man; whence the choice of sectators often depended on physical influence, or a peculiar disposition of their organs. Nothing appears more natural than that those men who were born with great force of mind and strong nerves should discover a predilection for stoicism; while mortals, endowed by nature with more delicacy of fibres and keener sensibility, fled for refuge to the myrtles of Epicurus. People whose temperaments partook of no extremes, were always inclined either for the Lyceum or the academy. Such as possessed solidity of understanding ranged themselves with Aristotle; and those who had only genius, or even pretensions to that endowment, went to augment the crowd of Platonists."

Pauw's Philosophical Dissertations, &c.

21 Grecian mode of philosophizing.

All the systematical philosophers, however, pursued their inquiries into nature by nearly the same method. Of their philosophy as well as of ours, the universe, with all that it contains, was the vast object: but the individual things which compose the universe are infinite in number and ever changing; and therefore, according to an established maxim of theirs, incapable of being the subjects of human science *. To reduce this infinitude, and to fix those fleeting beings, they established certain definite arrangements or classes, to some of which every thing past, present, or to come, might be referred; and having ascertained, as they thought, all that could be affirmed or denied of these classes, they proved, by a very short process of syllogistic reasoning, that what is true of the class must be true of every individual comprehended under it. The most celebrated of these arrangements is that which is known by the name of *categories*; which Mr Harris thinks at least as old as the era of Pythagoras, and to the forming of which mankind would, in his opinion, be necessarily led by the following considerations:

History of Philosophy.

22 The categories

Every subject of human thought is either *substance* or *attribute*; but *substance* and *attribute* may each of them be modified under the different characters of *universal* or *particular*. Hence there arises a quadruple arrangement of things into *substance universal* and *substance particular*; into *attribute universal* and *attribute particular*; to some one of *which four* not only our words and ideas, but every individual of that immense multitude of things which compose the universe, may be reduced. This arrangement, however, the learned author thinks too limited; and he is of opinion, that, by attending to the substances with which they were surrounded, the Grecian schools must soon have distinguished between the attributes *essential* to all substances and those which are only *circumstantial*; between the attributes proper to *natural* substances or bodies and those which are peculiar to *intelligible* substances or minds. He likewise thinks, that the *time* and *place* of the existence of substances not present, must soon have attracted their attention; and that in considering the place of this or that substance, they could hardly avoid thinking of its *position* or *situation*. He is of opinion, that the superinduction of one substance upon another would inevitably suggest the idea of *cloathing* or *habit*, and that the variety of *co-existing substances* and *attributes* would discover to them another attribute, viz. that of *relation*. Instead therefore of confining themselves to the simple division of *substance* and *attribute*, they divided *attribute* itself into nine distinct sorts, some *essential* and others *circumstantial*; and thus by setting substance at their head, made ten *comprehensive* and *universal genera*, called, with reference to their Greek name, *categories*, and with reference to their Latin name, *predicaments*. These categories are, SUBSTANCE, QUALITY, QUANTITY, RELATION, ACTION, PASSION, WHEN, WHERE, POSITION, and HABIT; which, according to the systematic philosophy of the Greeks, comprehend every human science and every subject of human thought. *History*, natural and civil, springs, says Mr Harris, out of SUBSTANCE; *mathematics* out of QUANTITY; *optics* out of QUALITY and QUANTITY; *medicine* out of the *same*; *astronomy* out of QUANTITY and MOTION; *music* and *mechanics* out of the *same*; *painting* out of QUALITY and SITE; *ethics* out of RELATION; *chronology* out of WHEN; *geography* out of WHERE; *electricity*, *magnetism*, and *attraction*, out of ACTION and PASSION; and so in other instances.

To these categories, considered as a mere arrangement of science, we are not inclined to make many objections. The arrangement is certainly not complete: but this is a matter of comparatively small importance; for a complete arrangement of science cannot, we believe, be formed. The greatest objection to the categories arises from the use that was made of them by

* *Boeth. in Predic. et Arist. Phys. lib. 1.*

History of Philosophy.

almost every philosopher of the Grecian schools; for those sages having reduced the objects of all human science to ten general heads or general terms, instead of setting themselves to inquire by a painful induction into the nature and properties of the real objects before them, employed their time in conceiving what could be predicated of *substance* in general, of this or that *quality*, *quantity*, *relation*, &c. in the abstract: and they soon found, that of such general conceptions as the *categories* there are but five *predicables* or classes of *predicates* in nature. The first class is that in which the *predicate* is the *genus* of the *subject*; the second, that in which it is the *species* of the *subject*; the third, is when the *predicate* is the *specific difference* of the *subject*; the fourth, when it is a *property* of the *subject*; and the fifth, when it is something *accidental* to the *subject* (see Logic, Part II. chap ii. and iii.) Having proceeded thus far in their system, they had nothing to do with individuals but to arrange them under their proper categories, which was commonly done in a very arbitrary manner; and then, with the formality of a syllogism, to predicate of each the predicable of the genus or species to which it belonged. But by this method of proceeding, it is obvious that no progress whatever could be made in physical, metaphysical, or ethical science; for if the individual truly belongs to the category under which it is arranged, we add nothing to our stock of knowledge by affirming or denying of it what we had before affirmed or denied of the whole genus: and if it belong not to the category under which we arrange it, our syllogising will only give the appearance of proof to what must, from the nature of things, be an absolute falsehood. It is only by experiments made on various substances apparently of the same kind that they can be certainly known to belong to the same category; and when this is done, all syllogistic reasoning from the genus to the species, and from the species to the individual, is but solemn trifling, as every proposition in this retrograde course takes for granted the thing to be proved.

23 And predicables

24 Are no instruments of science.

25 Thisphilosophy disseminated through the whole world;

Yet this mode of philosophizing spread from Greece almost over the whole world. It was carried by Alexander into Asia, by his successors into Egypt; and it found its way to Rome after Greece became a province of the empire. It was adopted by the Jews, by the fathers of the Christian church, by the Mohammedan Arabs during the caliphate, and continued to be cultivated by the schoolmen through all Europe, till its futility was exposed by Lord Bacon (M). The professors of this philosophy often displayed great acuteness; but their systems were built on mere hypotheses, and supported by syllogistic wrangling. Now and then indeed a superior genius, such as Alhazen and our countryman Roger Bacon, broke through the trammels of the schools, and, regardless of the authority of the Stagyrite and his *categories*, made real discoveries in physical science by experiments judiciously conducted on individual substances (see Bacon (*Roger*); and Optics, n° 6.); but the science in repute still continued to be that of *Generals*.

History of Philosophy.

It was indeed a combination of absurd metaphysics with more absurd theology; and that which is properly called *physics*, had in Europe no place in a liberal education from the end of the eighth century to the end of the fourteenth. Towards the beginning of this period of darkness, the whole circle of instruction, or the liberal arts as they were called, consisted of two branches, the *trivium* and the *quadrivium*; of which the former comprehended *grammar*, *rhetoric*, and *dialectics*; the latter *music*, *arithmetic*, *geometry*, and *astronomy*, to which was added about the end of the eleventh century the study of a number of *metaphysical subtleties* equally useless and unintelligible.

Hitherto the works of the ancient Greek philosophers had been read only in imperfect Latin translations; and before the scholastic system was completely established. Plato and Aristotle had been alternately looked up to as the oracle in science. The rigid schoolmen, however, universally gave the preference to the Stagyrite; because his analysis of body into matter and form is peculiarly calculated to keep in countenance the most incredible doctrine of the Romish church (see Transubstantiation): and upon the revival of Greek learning, this preference was continued after the school philosophy had begun to fall into contempt, on account of much useful information contained in some of his writings on subjects of natural history, and his supposed merit as a natural philosopher. At last the intrepid spirit of Luther and his associates set the minds of men free from the tyranny of ancient names, as well in human science as in theology; and many philosophers sprung up in different countries of Europe, who professed either to be *eclectics*, or to study nature, regardless of every authority but that of reason. Of these the most eminent beyond all comparison was Francis Bacon Lord Verulam.

26 Exposed as futile by Lord Bacon,

This illustrious man having read with attention the writings of the most celebrated ancients, and made himself master of the sciences which were then cultivated, soon discovered the absurdity of pretending to account for the phenomena of nature by syllogistic reasoning from hypothetical principles; and with a boldness becoming a genius of the first order, undertook to give a new chart of human knowledge. This he did in his two admirable works, intitled, 1. *De dignitate et augmentis scientiarum*; and, 2. *Novum organum scientiarum*, sive *Judicia vera de interpretatione Naturæ*. In the former of these works, he takes a very minute survey of the whole circle of human science, which he divides into three great branches, *history*, *poetry*, and *philosophy*, corresponding to the three faculties of the mind, *memory*, *imagination*, and *reason*. Each of these general heads is subdivided into minuter branches, and reflections are made upon the whole, which, though we can neither copy nor abridge them, will amply reward

(M) Scientiæ, quas habemus, fere a Græcis fluxerunt. Quæ enim scriptores Romani, aut Arabes, aut recentiores addiderunt, non multa, aut magni momenti sunt: et qualiacunque sint, fundata sunt super basin eorum quæ inventa sunt a Græcis. *Bacon.*

View of Bacon's Philosophy.

ward the perusal of the attentive reader. The purpose of the *Novum Organum* is to point out the proper method of interpreting nature; which the author shows can never be done by the logic which was then in fashion, but only by a painful and fair induction. "Homo naturæ minister (says he) et interpres tantum facit et intelligit, quantum de naturæ ordine re, vel mente observaverit; nec amplius scit aut potest. Syllogismus ad principia scientiarum non adhibetur, ad media axiomata frustra adhibetur, cum sit subtilitati naturæ longe impar. Assensum itaque constringit, non res. Syllogismus ex propositionibus constat, propositiones ex verbis, verba notionum tesseræ sunt. Itaque si notiones ipsæ (id quod basis rei est) confusæ sint et temere a rebus abstractæ, nihil in iis quæ superstruuntur, est firmitudinis. Itaque spes est una in *inductione vera*."

27 Who establishes a better method of inquiry.

To hypotheses and preconceived opinions, which he calls *idola theatri*, this great man was not less inimical than to syllogisms; and since his days almost every philosopher of eminence, except Descartes and his followers (see DESCARTES and CARTESIANS), has professed to study nature according to the method of induction so accurately laid down in the *Novum Organum*. On this method a few improvements have perhaps been made; but notwithstanding these, Lord Bacon must undoubtedly be considered as the author of that philosophy which is now cultivated in Europe, and which will continue to be cultivated as long as men shall have more regard for matters of fact than for hypothetical opinions. Of this mode of philosophizing we shall now give a short, though we hope not inaccurate, view, by stating its objects, comparing it with that which it superseded, explaining its rules, and pointing out its uses; and from this view it will appear, that its author shares with Aristotle the empire of science.

28 View of his philosophy

THE universe, that unbounded object of the contemplation, the curiosity and the researches of man, may be considered in two different points of view.

In the first place, it may be considered merely as a collection of existences, related to each other by means of resemblances and distinction, situation, succession, and derivation, as making parts of a whole. In this view it is the subject of pure description.

To acquire an acquaintance with, or a knowledge of, the universe in this point of view, we must enumerate all the beings in it, mention all their sensible qualities, and mark all these relations for each. But this would be labour immense; and when done, an undistinguishable chaos. A book containing every word of a language would only give us the materials, so to speak, of this language. To make it comprehensible, it must be put into some form, which will comprehend the whole in a small compass, and enable the mind to pass easily from one word to another related to it. Of all relations among words, the most obvious are those of resemblance and derivation. An etymological dictionary, therefore, in which words are classed in consequence of their resemblances, and arranged by means of their derivative distinctions, will greatly facilitate the acquisition of the language.

Just so in nature: The objects around us may be grouped by means of their resemblance, and then arranged in those groups by means of their distinctions and other relations. In this classification we are enabled to proceed by means of our faculty of abstracting our attention from the circumstances in which things differ, and turning it to those only in which they agree. By the judicious employment of this faculty we are able not only to distribute the individuals into classes, but also to distribute those classes into others still more comprehensive, by discovering circumstances of resemblance among them: for the fewer the circumstances are which concur to form that resemblance which has engaged our attention, the greater is the number of dissimilar circumstances which are neglected; and the more extensive will be the class of individuals in which the resemblance is observed. Thus a number of individuals resembling each other in the single circumstance of life, composes the most extensive KINGDOM of ANIMALS. If it be required, that they shall further resemble in the circumstance of having feathers, a prodigious number of animals are excluded, and we form the inferior *class* of BIRDS. We exclude a great number of birds, by requiring a further similarity of web feet, and have the *order* of ANSERES. If we add lingua citiata, we confine the attention to the *genus* of ANATES. In this manner may the whole objects of the universe be grouped, and arranged into kingdoms, classes, orders, genera, and species.

View of Bacon's Philosophy

29 Natural history

Such a classification and arrangement is called NATURAL HISTORY; and must be considered as the only foundation of any extensive knowledge of nature. To the natural historian, therefore, the world is a collection of existences, the subject of descriptive arrangement. His aim is threefold.

1. To observe with care, and describe with accuracy, the various objects of the universe.

2. To determine and enumerate all the great classes of objects; to distribute and arrange them into all their subordinate classes, through all degrees of subordination, till he arrive at what are only accidental varieties, which are susceptible of no farther distribution; and to mark with precision the principles of this distribution and arrangement, and the characteristics of the various assemblages.

3. To determine with certainty the particular group to which any proposed INDIVIDUAL belongs.

DESCRIPTION therefore, ARRANGEMENT, and REFERENCE, constitute the whole of his employment; and in this consists all his science.

30 Distinguished from philosophy.

Did the universe continue unchanged, this would constitute the whole of our knowledge of nature: but we are witnesses of an uninterrupted succession of changes, and our attention is continually called to the EVENTS which are incessantly happening around us. These form a set of objects vastly more interesting to us than the former; being the sources of almost all the pleasures or pains we receive from external objects.

We are therefore much interested in the study of the events which happen around us, and strongly incited to prosecute it: but they are so numerous and so multifarious, that the study would be immense, without some contrivance for abbreviating and facilitating the task. The same help offers itself here as in the study of what may be called *quiescent nature*. Events, like existences, are susceptible of classification, in consequence of resemblances and distinction; and

View of Bacon's Philosophy.

by attention to these, we can acquire a very extensive acquaintance with active nature. Our attention must be chiefly directed to those circumstances in which many events resemble each other, while they differ perhaps in a thousand others. Then we must attend to their most general distinctions; then to distinctions of smaller extent, and so on.

It is in this way accordingly that we have advanced in our knowledge of active nature, and are gradually, and by no means slowly, forming assemblages of events more and more extensive, and distributing these with greater and greater precision into their different classes.

In the zealous and attentive prosecution of this task a very remarkable and interesting observation occurs: In describing those circumstances of similarity among events, and particularly in distributing them according to those similarities, it is impossible for us to overlook that constancy which is observed in the changes of nature in the events which are the objects of our contemplation. Events which have once been observed to accompany each other are observed always to do so. The rising of the sun is always accompanied by the light of day, and his setting by the darkness of night. Sound argument is accompanied by conviction, impulse by motion, kindness by a feeling of gratitude, and the perception of good by desire. The unexcepted experience of mankind informs us, that the events of nature go on in certain regular trains; and if sometimes exceptions seem to contradict this general affirmation, more attentive observation never fails to remove the exception. Most of the spontaneous events of nature are very complicated; and it frequently requires great attention and penetration to discover the simple event amidst a croud of uneffential circumstances which are at once exhibited to our view. But when we succeed in this discovery, we never fail to acknowledge the perfect uniformity of the event to what has been formerly observed.

31 Constancy in the changes of nature

32 Universally expected.

But this is not all: We firmly *believe* that this uniformity will *still continue*; that fire will melt wax, will burn paper, will harden clay, as we have formerly observed it to do; and whenever we have undoubted proofs that the circumstance of situation are precisely the same as in some former case, though but once observed, we expect with irresistible and unshaken confidence that the event will also be the same.

It is not surely necessary to adduce many proofs of the universality of this law of human thought. The whole language and actions of men are instances of the fact. In all languages there is a mode of construction which is used to express this relation as distinct from all others, and the conversation of the most illiterate never confounds them, except when the conceptions themselves are confounded. The general employment of the active and passive verb is regulated by it. *Turris eversa est a militibus; turris eversa est terræ motu*, express two relations, and no schoolboy will confound them. The distinction therefore is perceived or felt by all who can speak grammatically. Nor is any language without general terms to express this relation, cause—effect—to occasion. Nay, it is a fact in the mind of brutes, who hourly show that they expect the same uses of every subject which they formerly made of it; and without this, animals would be incapable of subsistence, and man incapable of all improvement. From this alone memory derives all its value; and even the constancy of natural operation would be useless if not matched or adapted to our purposes by this expectation of and confidence in that constancy.

View of Bacon's Philosophy.

After all the labours of ingenious men to discover the foundation of this irresistible expectation, we must be contented with saying that such is the constitution of the human mind. It is an *universal fact* in human thought; and for any thing that has been yet discovered, it is an *ultimate* fact, not included in any other still more general. We shall soon see that this is sufficient for making it the foundation of true human knowledge; all of which must in like manner be reduced to ultimate facts in human thought.

We must consider this undoubted feeling, this persuasion of the constancy of nature, as an *instinctive* anticipation of events similar to those which we have already experienced. The general analogy of nature should have disposed philosophers to acquiesce in this, however unwelcome to their vanity. In no instance of essential consequence to our safety or well being are we left to the guidance of our boasted reason; God has given us the surer conduct of natural instincts. No case is so important as this: In none do we so much stand in need of a guide which shall be powerful, infallible, and rapid in its decisions. Without it we must remain incapable of all instruction from experience, and therefore of all improvement.

Our sensations are undoubtedly feelings of our mind. But all those feelings are accompanied by an instinctive reference of them to something distinct from the feelings themselves. Hence arises our perception of external objects, and our very notions of this externity (pardon the term). In like manner, this anticipation of events, this irresistible connection of the idea of fire with the idea of burning, is also a feeling of the mind: and this feeling is by a law of human nature referred, without reasoning, to something external as its cause; and, like our sensation, it is considered as a *sign* of that external something. It is like the conviction of the truth of a mathematical proposition. This is referred by us to something existing in nature, to a necessary and eternal relation subsisting between the ideas which are the subjects of the proposition. The conviction is the sign or indication of this relation by which it is brought to our view. In precisely the same manner, the irresistible connection of ideas is interpreted as the sensation or sign of a *necessary connection* of external things or events. These are supposed to include something in their nature which renders them inseparable companions. To this bond of connection between external things we give the name of CAUSATION. All our knowledge of this relation of cause and effect, is the knowledge or consciousness of what passes in our own minds during the contemplation of the phenomena of nature. If we adhere to this view of it, and put this branch of knowledge on the same footing with those called the *abstract sciences*, considering only the *relations* of ideas, we shall acquire *demonstrative science*. If we take any other view of the matter, we shall be led into inextricable mazes of uncertainty and error.

33 Our knowledge of causation.

We see then that the natural procedure of our faculty of abstraction and arrangement, in order to acquire

View of Bacon's Philosophy.

quire a more speedy and comprehensive knowledge of natural events, presents them to our view in another form. We not only see them as *similar* events, but as events naturally and necessarily *conjoined*. And the expression of *resemblance* among events is also an expression of *concomitancy*; and this arrangement of events in consequence of their resemblance is in fact the *discovery* of those accompaniments. The trains of natural appearance being considered as the appointments of the Author of Nature, has occasioned them to be considered also as consequences of *laws* imposed on his works by their great author, and every thing is said to be regulated by fixed laws. But this is the language of analogy. When a sovereign determines on certain trains of conduct for his subjects, he issues his orders. These orders are laws. He inforces the observance of them by his authority; and thus a certain regularity and constancy of conduct is produced. But should a stranger, ignorant of the promulgation of these laws, and of the exerted authority of the magistrate, observe this uniformity of conduct, he would ascribe it to the genius and disposition of the people; and his observation would be as useful to him for directing the tenor of his own conduct, as the knowledge of the subject himself of the real source of this constancy is for directing his.

34 Laws of nature explained.

Just so in nature, while the theologian pretends, from his discoveries concerning the existence and superintendance of God, to know that the constant accompaniment of events is the consequence of laws which the great Author and Governor of the universe has imposed on his works, the ordinary philosopher, a stranger to this scene, and to the unsearchable operations of the SUPREME MIND, must ascribe this constancy to the nature of the things. There is a great resemblance between the expression *natural law* and *grammatical rule*. Rule in strict language implies command; but in grammar it expresses merely a generality of *fact*, whether of flexion or construction. In like manner, a LAW OF NATURE is to the philosopher nothing but the expression of a generality of fact. A natural or physical law is a generally observed fact; and whenever we treat any subject as a generally observed fact, we treat it physically. It is a physical law of the understanding that argument is accompanied by conviction; it is a physical law of the affection that distress is accompanied by pity; it is a physical law of the material world that impulse is accompanied by motion.

And thus we see that the arrangement of events, or the discovery of those general points of resemblance, is in fact the discovery of the laws of nature; and one of the greatest and most important is, that the laws of nature are constant.

There is no question that this view of the universe is incomparably more interesting and important than that which is taken by the natural historian; contemplating every thing that is of value to us, and, in short, the whole life and movement of the universe. This study, therefore, has been dignified with the name of PHILOSOPHY and of SCIENCE; and natural history has been considered as of importance only in so far as it was conducive to the successful prosecution of philosophy.

35 Object of philosophy.

But the philosopher claims a superiority on another account: he considers himself as employed in the discovery of causes, saying that philosophy is the study of the objects of the universe as related by causation, and that it is by the discovery of these relations that he communicates to the world such important knowledge. Philosophy, he says, is the science of causes. The vulgar are contented to consider the prior of two inseparably conjoined events as the cause of the other; the stroke on a bell, for instance, as the cause of sound. But it has been clearly shown by the philosopher, that between the blow on the bell and the sensation of sound there are interposed a long train of events. The blow sets the bell a trembling; this agitates the air in contact with the bell; this agitates the air immediately beyond it; and thus between the bell and the ear may be interposed a numberless series of events, and as many more between the first impression on the ear and that last impression on the nerve by which the mind is affected. He can no longer therefore follow the nomenclature of the vulgar. Which of the events of this train therefore is the cause of the sensation? None of them: It is that *something* which inseparably connects any two of them, and constitutes their bond of union. These bonds of union or causes he considers as residing in one or both of the connected objects: diversities in this respect must therefore constitute the most important distinctions between them. They are therefore with great propriety called the *qualities*, the *properties*, of these respective subjects.

View of Bacon's Philosophy.

36 Cause

As the events from which we infer the existence of these qualities of things resemble in many respects such events as are the consequences of the exertion of our own powers, these qualities are frequently denominated POWERS, forces, energies. Thus, in the instance just now given of the sound of a bell, we infer the powers of impulse, elasticity, nervous irritability, and animal sensibility.

In consequence of this inference of a necessary connection between the objects around us, we not only infer the posterior event from the prior, or, in common language, the effect from the cause, but we also infer the prior from the posterior, the cause from the effect. We not only expect that the presence of a magnet will be followed by certain motions in iron-filings, but when we observe such motions, we infer the presence and agency of a magnet. Joy is inferred from merryment, poison from death, fire from smoke, and impulse from motion. And thus the appearances of the universe are the indications of the powers of the objects in it. Appearances are the language of nature, informing us of their causes. And as all our knowledge of the sentiments of others is derived from our confidence in their veracity; so all our knowledge of nature is derived from our confidence in the constancy of natural operations. A veracity and credulity necessarily resulting from that law of our mental constitution by which we are capable of speech, conduct us in the one case; and the constancy of nature, and the principle of induction, by which we infer general laws from particular facts, conduct us in the other. As human sentiment is inferred from language, and the existence of external things from sensation; so are the laws of nature, and the powers

37 Inferred from effects.

of

View of Bacon's Philosophy.

of natural objects inferred from the phenomena. It is by the successful study of this language of nature that we derive useful knowledge. The knowledge of the influence of motives on the mind of man enables the statesman to govern kingdoms, and the knowledge of the powers of magnetism enables the mariner to pilot a ship through the pathless ocean.

Such are the lofty pretensions of philosophy. It is to be wished that they be well founded; for we may be persuaded that a mistake in this particular will be fatal to the advancement of knowledge. An author of great reputation † gives us an opportunity of deciding this question in the way of experiment. He says that the ancients were philosophers, employed in the discovery of causes, and that the moderns are only natural historians, contenting themselves with observing the laws of nature, but paying no attention to the causes of things. If he speaks of their *professed* aim, we apprehend that the assertion is pretty just in general. With very few exceptions indeed it may be affirmed of his favourite Aristotle, the philosopher κατ' ἐξοχην, and of Sir Isaac Newton. We select these two instances, both because they are set in continual opposition by this author, and because it will be allowed that they were the most eminent students of nature (for we must not yet call them philosophers) in ancient and modern times. Aristotle's professed aim, in his most celebrated writings, is the investigation of causes; and in the opinion of this author, he has been so successful that he has hardly left any employment for his successors beside that of commenting upon his works. We must on the other hand acknowledge that Newton makes no such pretensions, at least in that work which has immortalised his name, and that his professed aim is merely to investigate the *general* laws of the planetary motions, and to apply these to the explanation of particular phenomena. Nor will we say that he has left no employment for succeeding inquirers; but, on the contrary, confess that he has only begun the study, has discovered but one law, and has enabled us to explain only the phenomena comprehended in it alone. But he has not been unsuccessful; his investigation has been complete; and he has discovered beyond all possibility of contradiction a *fact* which is observed through the whole extent of the solar system; namely, that every body, nay that every particle in it, is continually DEFLECTED toward every other body; and that this deflection is, in every instance, proportional to the quantity of matter in that body toward which the deflection is directed, and to the reciprocal of the square of the distance from it. He has therefore discovered a physical law of immense extent. Nor has he been less successful in the explanation of particular phenomena. Of this there cannot be given a better instance than the explanation of the lunar motions from the theory of gravity begun by Newton "Mathesi sua facem præferente;" and now brought to such a degree of perfection, that if the moon's place be computed from it for any moment within the period of two thousand years back, it will not be found to differ from the place on which she was actually observed by one hundredth part of her own breadth.

† *Ancient Metaphysics.*

38 Discoveries of Aristotle and Newton compared.

Discimus hinc tandem qua causa argentea Phœbe
Passibus haud æquis eat, et cur, subdita nulli
Hactenus astronomo, numerorum frena recusat.
Quæ toties animos veterum torsere sophorum,
Quæque scholas hodie rauco certamine vexant,
Obvia conspicimus, nube pellente mathesi;
Qua superos penetrare domos, et ardua cœli
Newtoni auspiciis jam dat contingere templa.

View of Bacon's Philosophy.

We may now desire the champions of the science of causes to name any one cause which has really been discovered by their great master, whether in the operations of mind or of body. But they must not on this occasion adduce the investigation of any natural law in which he has sometimes succeeded. With still greater confidence may we challenge them to produce any remarkable instance of the explanation of natural phenomena either of mind or body. By explanation, we mean an account of the production, and an appreciation of all the circumstances, susceptible of a scrupulous comparison with fact, and perfectly consistent with it. It is here that the weakness of this philosopher's pretensions is most conspicuous; and his followers candidly acknowledge, that in the enquiries which proceed by experiment, we have not derived great assistance from Aristotle's philosophy. But this, say they, does not derogate from the pre-eminence of his philosophy, because he has shown that the *particular* fields of observation are to be cultivated only by means of experiment. But surely every field of *observation* is particular. There is no *abstract* object of philosophical research, the study of which shall terminate in the philosophy of universals. In every kind of inquiry, that cause alone must be supposed to act which we understand so far as to be able to appreciate its effects in particular circumstances, and compare them with fact, and see their perfect coincidence. If we have discovered causes, they are *known* as far as they are discovered. Their genuine effects are known, and therefore the phenomena which result from their agency are understood. When therefore it is acknowledged, as it must be acknowledged, that mankind have made but little advances in the knowledge of nature, notwithstanding the pretended discovery of causes by Aristotle, and the conducting clue of his philosophy, till of late years; and when it is also allowed that *now*, while we are every day making great additions to this subordinate knowledge, the causes which Aristotle has discovered are forgotten, and his philosophy is neglected; there is great room for suspecting (to say the least), that either the causes which philosophy pretends to have discovered are not real, or that Aristotle and his followers have not aimed at the discovery of causes, but only at the discovery of natural laws, and have failed in the attempt.

There seems here to be a previous question: *Is it possible to discover a philosophical cause*, that something which is neither the prior nor the posterior of the two *immediately* adjoining events, but their bond of union, and this distinct from the union itself? It is evident that this is an enquiry purely experimental. It is of *human knowledge* we speak. This must depend on the nature of the human mind. This is a matter of contingency, known to us only by experiment and observation. By observing all the feelings and operations of the mind, and classing and arranging them like any other object of science, we discover the general laws of human thought and human reasoning; and this is all

39 Philosophical causes discovered only

View of Bacon's Philosophy.

all the knowledge we can ever acquire of it, or of any thing else.

Much has been written on this subject. The most acute observation and sound judgment have been employed in the study; and we may venture to say, that considerable progress has been made in pneumatology. Many laws of human thought have been observed, and very distinctly marked; and philosophers are busily employed, some of them with considerable success, in the distribution of them into subordinate classes, so as to know their comparative extent, and to mark their distinguishing characters with a precision similar to what has been attained in botany and other parts of natural history; sothat we may hope that this study will advance like others. But in all these researches, no phenomena have occurred which look like the perception or contemplation of these separate objects of thought, these philosophical causes, this POWER in abstracto. No philosopher has ever pretended to state such an object of the mind's observation, or attempted to group them into classes.

40 In the events.

We may say at once, without entering into any detail, that those causes, those bonds of necessary union between the naturally conjoined events or objects, are not only perceived *by means* of the events alone, but are perceived solely *in* the events, and cannot be distinguished from the conjunctions themselves. They are neither the objects of separate observation, nor the productions of memory, nor inferences drawn from reflection on the laws by which the operation of our own minds are regulated; nor can they be derived from other perceptions in the way of argumentative inference. We cannot infer the paroxysm of terror from the appearance of impending destruction, nor the fall of a stone when not supported, as we infer the incommensurability of the diagonal and side of a square. This last is *implied* in the very conception or notion of a square; not as a consequence of its other properties, but as one of its essential attributes: and the contrary proposition is not only false, but incapable of being distinctly conceived. This is not the case with the other phenomenon, or any matter of fact. The proofs which are brought of a mathematical proposition, are not the reason of its being true, but the steps by which this truth is brought into our view; and frequently, as in the instance now given, this truth is perceived, not directly, but consequentially, by the inconceivableness of the contrary proposition.

41 Mr Hume's theory a *petitio principii*.

Mr Hume derives this irresistible expectation of events from the known effect of custom, the association of ideas. The corelated event is brought into the mind by this well known power of custom, with that vivacity of conception which constitutes belief or expectation. But without insisting on the futility of his theory of belief, it is sufficient to observe, that this explanation begs the very thing to be proved, when it ascribes to custom a *power* of any kind. It is the origin of this very power which is the subject in dispute. Besides, on the genuine principles of scepticism, this custom involves an acknowledgement of past events, of a something different from prefent impressions, which, in this doctrine (if doctrine it can be called), are the only certain existences in nature: and, lastly, it is known that *one* clear experience is a sufficient foundation for this unshaken confidence and anticipation. General custom can never, on Mr Hume's principles, give superior vivacity to any particular idea.

View of Bacon's Philosophy.

This certain nonentity of it as a separate object of observation, and this impossibility to derive this notion of necessary and causal connection between the events of the universe from any source, have induced two of the most acute philosophers of Europe, Mr Leibnitz and Father Malebranche, to deny that there is any such connection, and to assert that the events of the universe go on in corresponding trains, but without any causal connection, just as a well-regulated clock will keep time with the motions of the heavens without any kind of dependence on them. This harmony of events was pre-established by the Author of the Universe, in subserviency to the purposes he had in view in its formation.

42 Another hypothesis respecting causal connection.

All those purposes which are cognisable by us, may certainly be accomplished by this perfect adjustment. But without insisting on the fantastic wildness of this ingenious whim, it is quite enough to observe, that it also is a begging of the question, because it supposes causation when it ascribes all to the agency of the Deity.

Thus have we searched every quarter, without being able to find a source from which to derive this perception of a necessary connection among the events of the universe, or of this confident expectation of the continuance of physical laws; and yet we are certain of the feeling, and of the persuasion, be its origin what it may: for we speak intelligibly on this subject, we speak familiarly of cause, effect, power, energy, necessary connection, motives and their influence, argument and conviction, reasons and persuasion, allurements and emotions, of gravity, magnetism, irritability, &c.; and we carry on conversations on these subjects with much entertainment and seeming instruction. Language is the expression of thought, and every word expresses some notion or conception of the mind; therefore it must be allowed, that we have such notions as are expressed by cause, power, energy. But it is here, as in many cases, we perceive a distinction without being able to express it by a definition; and that we do perceive the relation of causation as distinct from all others, and in particular as distinct from the relation of contiguity in time and place; or the relation of agent, action, and patient, must be concluded from the uniformity of language, which never confounds them except on purpose, and when it is perceived. But even here we shall find, that none of the terms used for expressing those powers of substance which are conceived as the causes of their characteristic phenomena, really express any thing different from the phenomena themselves. Let any person try to define the terms gravity, elasticity, sensibility, and the like, and he will find that the definition is nothing but a description of the phenomenon itself. The words are all derivatives, most of them verbal derivatives, implying action, gravitation, &c. As the general resemblances in shape, colour, &c. are expressed by the natural historian by generic terms, so the general resemblances in event are expressed by the philosopher in generic propositions, which, in the progress of cultivation, are also abbreviated into generic terms.

This abundantly explains the consistency of our language on this subject, both with itself and with the

View of Bacon's Philosophy.

the operations of nature, without however affording any argument for the truth of the assumption, that causes are the objects of philosophic research as separate existences; or that this supposed necessary connection is a *necessary truth*, whether supreme or subordinate. But since the perception of it has its foundation in the constitution of the human mind, it seems intitled to the name of a *first principle*. We are hardly allowed to doubt of this, when we consider the importance of it, and the care of nature to secure us in all things essential to our safety and well-being, from all danger, from inattention, ignorance, or indolence, by an instinct infallible in its information, and instantaneous in its decisions. "It would not be like her usual care (says Hume), if this operation of the mind, by which we infer like effects from like causes, and *vice versa*, were entrusted to the fallacious deduction of our reason, which is slow in its operations, appears not in any degree during the first years of infancy, and in every age and period of human life is extremely liable to error. It is more conformable to her *ordinary caution* (mark the acknowledgment) to secure so necessary an act of the mind by some instinct, or blind tendency, which may be infallible and rapid in all its operations, may discover itself at the first appearance of life, and may be independent of all the laboured deductions of reason. As she has taught us the use of our limbs, without giving us any knowledge of the nerves and muscles by which they are actuated; so she has implanted in us an instinct, which carries forward the thought in a course conformable to that established among external objects, though we be ignorant of the powers and forces on which this regularity depends."

43 The perception of this connection a first principle.

Such a knowledge is quite unnecessary, and therefore causes are no more cognoscible by our intellectual powers than colours by a man born blind: nay, whoever will be at the pains to consider this matter agreeably to the received rules and maxims of logic, will find that necessary connection, or the bond of causation, can no more be the subject of philosophical discussion by man, than the ultimate nature of truth. It is precisely the same absurdity or incongruity, as to propose to examine light with a microscope. Other rational creatures may perceive them as easily as we hear sounds. All that we can say is, that their existence is probable, but by no means certain. Nay, it may be (and we may never know it) that we are not the efficient causes of our own actions, which may be effected by the Deity or by ministering spirits; and this may even be true in the material world. But all this is indifferent to the real occupation of the philosopher, and does not affect either the certainty, the extent, or the utility of the knowledge which he may acquire.

We are now able to appreciate the high pretensions of the philosopher, and his claim to scientific superiority. We now see that this can neither be founded on any scientific superiority of his object, nor of his employment. His object is not causes; and his discoveries are nothing but the discovery of general facts, the discovery of physical laws: and his employment is the same with that of the descriptive historian. He observes and describes with care and accuracy the events of nature; and then he groups them into classes, in consequence of resembling circumstances, detected in the midst of many others which are dissimilar and occasional. By gradually throwing out more circumstances of resemblance, he renders his classes more extensive; and, by carefully marking those circumstances in which the resemblance is observed, he characterises all the different classes: and, by a comparison of these with each other, in respect to the number of resembling circumstances, he distributes his classes according to their generality and subordination; thus exhausting the whole assemblage, and leaving nothing unarranged but accidental varieties. In this procedure it is to be remarked, that every grouping of similar events is, *ipso facto*, discovering a general fact, a physical law; and the expression of this assemblage is the expression of the physical law. And as every observation of this constancy of fact affords an opportunity for exerting the instinctive inference of natural connection between the related subjects, every such observation is the discovery of a power, property, or quality, of natural substance. And from what has been said, this observation of event is all we know of the connection, all we know of the natural power. And when the philosopher proceeds farther to the arrangement of events, according to their various degrees of complication, he is, *ipso facto*, making an arrangement of all natural powers according to their various degrees of subordinate influence. And thus his occupation is perfectly similar to that of the descriptive historian, classification and arrangement; and this constitutes all the science attainable by both.

View of Bacon's Philosophy.

44 The object of the philosopher the discovery of physical laws.

45 Philosophy defined.

PHILOSOPHY may therefore be defined, the study of the phenomena of the universe, with a view to discover the general laws which indicate the powers of natural substances, to explain subordinate phenomena, and to improve art: Or, in compliance with that natural instinct so much spoken of, Philosophy is the study of the phenomena of the universe, with a view to discover their causes, to explain subordinate phenomena, and to improve art.

The task is undoubtedly difficult, and will exercise our noblest powers. The employment is manly in itself, and the result of it important. It therefore justly merits the appellation of *philosophy*, although its objects are nowise different from what occupy the attention of other men.

46 The employment of the philosopher.

The employment of the philosopher, like that of the natural historian, is threefold; DESCRIPTION, ARRANGEMENT, and REFERENCE; while the objects are not *things* but *events*.

The description, when employed about events, may be more properly termed *history*. A philosophical history of nature consists in a complete or copious enumeration and narration of facts, properly selected, cleared of all unnecessary or extraneous circumstances, and accurately narrated. This constitutes the materials of philosophy. We cannot give a better example of this branch of philosophical occupation than astronomy.

From the beginning of the Alexandrian school to this day, astronomers have been at immense pains in observing the heavenly bodies, in order to detect their true motions. This has been a work of prodigious difficulty: for the appearances are such as might have been exhibited although the real motions had been extremely different. Not that our senses give

View of Bacon's Philosophy.

us false information; but we form hasty, and frequently false judgments, from these informations; and call those things deceptions of sense, which are in fact errors of judgment. But the true motions have at last been discovered, and have been described with such accuracy, that the history may be considered as nearly complete. This is to be found in the usual systems of astronomy, where the tables contain a most accurate and synoptical account of the motion; so that we can

47 Phenomenology.

tell with precision in what point of the heavens a planet *has been* seen at any instant that can be named.

Sir Isaac Newton's Optics is such another perfect model of philosophical history, as far as it goes. This part of philosophy may be called PHENOMENOLOGY.

Having in this manner obtained the materials of philosophical description, we must put them into a compendious and perspicuous form, so that a general knowledge of the universe may be easily acquired and firmly retained. This is to be done by classification and arrangement, and this classification must proceed on resemblances *observed* in the events; and the subsequent arrangement must be regulated by the distinctions of which those resemblances are still susceptible. This assemblage of events into groups must be expressed. They are facts; therefore the expression must be propositions. These propositions must be what the logicians call *general* or *abstract propositions*; for they express, not any individual fact of the assemblage, but that circumstance in which they all resemble. Such propositions are the following: Proof is accompanied by belief; kindness is accompanied by gratitude; impulse is accompanied by motion. These

48 Investigation.

are usually called *general facts*; but there are none such; every fact is individual. This language, however inaccurate, is very safe from misconstruction, and we may use it without scruple. These propositions are NATURAL OR PHYSICAL LAWS; and then the detecting and marking those resemblances in event, is the investigation of physical laws; and we may denominate this employment of the philosopher INVESTIGATION.

In the prosecution of this task, it will be found that the similarities of fact are of various extent: and thus we shall form physical laws of various extent; and we shall also find that some are subordinate to others; for the resemblance of a number of facts in one circumstance does not hinder a part of them from also resembling in another circumstance: and thus we shall find subordinations of fact in the same way as of quiescent qualities. And it is found here, as in natural history, that our assemblage of resembling events will be the more extensive as the number of resembling circumstances is smaller; and thus we shall have kingdoms, classes, orders, genera, and species of phenomena, which are expressed by physical laws of all those different ranks.

It has been already observed, that this observation of physical laws is always accompanied by a reference of that uniformity of event to a natural bond of union between the concomitant facts which is conceived by us as the *cause* of this concomitancy; and therefore this procedure of the philosopher is considered as the discovery of those causes, that is, the discovery of those powers of natural substances which constitute their physical relations, and may justly be called their distinguishing *qualities* or *properties*. This view of the matter gives rise to a new nomenclature and language. We give to those powers generic names, such as *sensibility*, *intelligence*, *irritability*, *gravity*, *elasticity*, *fluidity*, *magnetism*, &c. These terms, without exception, mark resembling circumstances of event; and no other definition can be given of them but a description of these circumstances. In a few cases which have been the subjects of more painful or refined discussion, we have proceeded farther in this abbreviation of language.

View of Bacon's Philosophy.

We have framed the verb "to gravitate," and the verbal noun "gravitation," which purely expresses the fact, the phenomenon; but is conceived to express the *operation* or energy of the cause or natural power. It is of importance to keep in mind this metaphysical remark on these terms; for a want of attention to the pure meaning of the words has frequently occasioned very great mistakes in philosophical science.

49 Aitiology.

We may with propriety call this part of the philosopher's employment AITIOLOGY.

We shall give an instance of its most successful application to the class of events already adduced as an example of philosophic history or phenomenology.

Kepler, a celebrated Prussian astronomer, having maturely considered the phenomena recorded in the tables and observations of his predecessors, discovered, amidst all the varieties of the planetary motions, three circumstances of resemblance, which are now known by the name of *Kepler's laws*.

50 Kepler's laws an instance.

1. All the planets describe ellipses, having the sun in one focus.

2. The elliptic areas described by a planet in the different parts of its orbit, are proportional to the times of description.

3. The squares of the periodic times are proportional to the cubes of the mean distances from the sun.

By this observation or discovery, the study of the planetary motions was greatly promoted, and the calculation of their appearances was now made with a facility and an accuracy which surpassed all hopes: for the calculation of the place of a planet at any proposed instant was reduced to the geometrical problem of cutting off an area from an ellipse of known dimensions, which should bear the same proportion to the whole area, as the time for whose duration the motion is required, has to the known time of a complete revolution.

Long after this discovery of Kepler, Sir Isaac Newton found that these laws of Kepler were only particular cases of a fact or law still more general. He found that the deflections of the planets from uniform rectilineal motion were all directed to the sun; and that the simultaneous deflections were inversely proportional to the squares of the distances from him.

51 Comprehended under one more general law,

Thus was established a physical law of vast extent: but further observation showed him, that the motion of every body of the solar system was compounded of an original motion of projection, combined with a deflection towards every other body; and that the simultaneous deflections were proportional to the quantity of matter in the body towards which they were directed,

View of Bacon's Philosophy.

directed, and to the reciprocal of the square of the distance from it. Thus was the law made still more general. He did not stop here. He compared the deflection of the moon in her orbit with the simultaneous deflection of a stone thrown from the hand, and describing a parabola; and he found that they followed the same law, that is, that the deflection of the moon in a second, was to that of the stone in the same time, as the square of the stone's distance from the centre of the earth, to the square of the moon's distance from it. Hence he concluded, that the deflection of a stone from a straight line was just a particular instance of the deflections which took place through the whole solar system.

52 Called *gravitation.*

The deflection of a stone is one of the indications it gives of its being *gravis* or heavy; whence he calls it *gravitation.* He therefore expresses the physical law which obtains through the whole solar system, by saying that "every body *gravitates* to every other body; and the gravitations are proportional to the quantity of matter in that other body, and inversely proportional to the square of the distance from it."

Thus we see how the arrangement of the celestial phenomena terminated in the discovery of physical laws; and that the expression of this arrangement is the law itself.

Since the fall of a heavy body is one instance of the physical law, and since this fall is considered by all as the effect of its *weight*, and this weight is considered as the cause of the fall, the same cause is assigned for all the deflections observed in the solar system; and all the matter in it is found to be under the influence of this cause, or to be heavy; and thus his doctrine has been denominated the *system of universal gravitation.*

Philosophers have gone farther, and have supposed that gravity is a power, property, or quality, residing in all the bodies of the solar system. Sir Isaac Newton does not expressly say so, at least in that work where he gives an account of these discoveries. He contents himself with the immediate consequence of the first axiom in natural philosophy, viz. that every body remains in a state of rest, or of uniform rectilineal motion, unless affected by some moving force. Since the bodies of the solar system are neither in a state of rest, nor of uniform rectilineal motion, they must be considered as so affected; that is, that there operates on every one of them a moving force, directed towards all the others, and having the proportions observed in the deflection.

53 Attempts to include this law under impulse,

Other philosophers have endeavoured to show, that this general fact, detected by Sir Isaac Newton, is included in another still more general, viz. that every body moves which is impelled by another body in motion. They assert, that all the bodies of the solar system are continually impelled by a fluid which they call *ether*, which is moving in all places, and in all directions, or in circular vortices, and hurries along with it the planets and all heavy bodies. It would seem that the familiarity of motion produced by impulse, at least in those instances in which our own exertions are most employed, has induced philosophers to adopt such notions; perhaps, too, they are influenced by an obscure and indistinct notion affixed to the term action, as applied to changes in the material world, and which has given rise to an axiom, "that a body cannot act at a distance, or where it is not;" and thus have thought themselves obliged to look out for an immediate and contiguous agent in all those phenomena.

View of Bacon's Philosophy.

But the philosophers who profess to be most scrupulous in their adherence to the rules of philosophic discussion, deny the legitimacy of this pretended investigation of causes, saying that this doctrine is in direct opposition to the procedure of the mind in acquiring the knowledge of causes. Since the *fact* of impulse is not really *observed* in the celestial deflections, nor in the motions of heavy bodies, the law cannot be *inferred.* They say that it is not even necessary to show that the phenomena of the celestial motions are unlike the phenomena of impulse, although this can be done in the completest manner. It is enough that neither the fluid nor the impulse are observed; and therefore they are in the right when they assert, that there is inherent in, or accompanies all the bodies of the system, a power by which they deflect to one another. (See Optics, n° 66, 67.)

54 Whilst impulse itself is never observed.

The debate is foreign to our present purpose, which is only to show how the observation and arrangement of phenomena terminates in the discovery of their causes, or the discovery of the powers or properties of natural substances.

This is a task of great difficulty, as it is of great importance. There are two chief causes of this difficulty.

1. In most of the spontaneous phenomena of nature there is a complication of many events, and some of them escape our observation. Attending only to the most obvious or remarkable, we conjoin these only in our imagination, and are apt to think these the concomitant events in nature, the proper indication of the cause, and the subjects of this philosophical relation, and to suppose that they are always conjoined by nature. Thus it was thought that there resided in a vibrating chord a power by which the sensation of sound was excited, or that a chord had a sounding quality. But late observations have shown clearly that there is an inconceivable number of events interposed between the vibration of the chord and the sensitive affection of our ear; and therefore, that sound is not the effect of the vibration of the chord, but of the very last event of this series: and this is completely demonstrated by showing that the vibration and the sound are *not necessarily* connected, because they are not *always* connected, but require the interposition of air or of some other elastic body.

55 Causes of the difficulty of philosophical investigation.

These observations show the necessity of the most accurate and minute observation of the phenomena, that none of those intermediate events may escape us, and we be thus exposed to the chance of imaginary connections between events which are really far asunder in the procedure of nature. As the study has improved, mistakes of this kind have been corrected; and philosophers are careful to make their trains of events under one name as short as possible. Thus, in medicine, a drug is no longer considered as a *specific* remedy for the disease which is sometimes cured when it has been used, but is denominated by its most immediate operation on the animal frame: it is no longer called a *febrifuge*, but a *sudorific.*

2. When

View of Bacon's Philosophy.

50 Means of insuring success.

2. When many natural powers combine their influence in a spontaneous phenomenon of nature, it is frequently very difficult to discover what part of the complicated effect is the effect of each; and to state those circumstances of similarity which are the foundation of a physical law, or intitle us to infer the agency of any natural power. The most likely method for insuring success in such cases is to get rid of this complication of event, by putting the subject into such a situation that the operation of all the known powers of nature shall be suspended, or so modified as we may perfectly understand *their* effects. We can thus appreciate the effects of such as we could neither modify nor suspend, or we can discover the existence of a new law, the operation of a new power.

This is called *making an experiment*; and is, of all, the most effectual way of advancing in the knowledge of nature, and has been called EXPERIMENTAL PHILOSOPHY.

It seems, however, at first sight, in direct opposition to the procedure of nature in forming general laws. These are formed by induction from multitudes of individual facts, and must be affirmed to no greater extent than the induction on which they are founded.

57 A seeming anomaly explained.

Yet it is a matter of fact, a physical law of human thought, that one simple, clear, and unequivocal experiment, gives us the most complete confidence in the truth of a general conclusion from it to every similar case. Whence this anomaly? It is not an anomaly or contradiction of the general maxim of philosophical investigation, but the most refined application of it. There is no law more general than this, that "Nature is constant in all her operations." The judicious and simple form of our experiment insures us (we imagine) in the complete knowledge of all the circumstances of the event. Upon this supposition, and this alone, we consider the experiment as the faithful representative of every possible case of the conjunction. This will be more minutely considered afterwards.

58 Theory or explanation of subordinate phenomena.

The last branch of philosophic occupation is the explanation of subordinate phenomena. This is nothing more than the referring any particular phenomenon to that class in which it is included; or, in the language of philosophy, it is the pointing out the general law, or that general fact of which the phenomenon is a particular instance. Thus the feeling of the obligations of virtue is thought to be explained, when it is shown to be a particular case of that regard which every person has for his dearest interests. The rise of water in pumps is explained, when we show it to be a particular case of the pressure of fluids, or of the air. The general law under which we show it to be properly arranged is called the PRINCIPLE of the explanation, and the explanation itself is called the THEORY of the phenomenon. Thus Euler's explanation of the lunar irregularities is called a theory of the lunar motions on the principle of gravitation.

This may be done either in order to advance our own knowledge of nature, or to communicate it to others. If done with the first view, we must examine the phenomenon minutely, and endeavour to detect every circumstance in it, and thus discover all the known laws of nature which concur in its production; we then appreciate the operation of each according to the circumstances of its exertion; we then combine all these, and compare the result with the phenomenon. If they are similar, we have explained the phenomenon. We cannot give a better example than Franklin's explanation of the phenomena of thunder and lightning. See LIGHTNING, and ELECTRICITY *Index*.

View of Bacon's Philosophy.

If we explain a phenomenon from known principles, we proceed synthetically from the general law already established and *known* to exert its influence in the present instance. We state this influence both in kind and degree according to the circumstances of the case; and having combined them, we compare the result with the phenomenon, and show their agreement, and thus it is explained. Thus, because all the bodies of the solar system mutually gravitate, the moon gravitates to the sun as well as to the earth, and is continually, and in a certain determinate manner, deflected from that path which she would describe did she gravitate only to the earth. Her motion round the earth will be retarded during the first and third quarters of her orbit, and accelerated during the second and fourth. Her orbit and her period will be increased during our winter, and diminished during our summer. Her apogee will advance, and her nodes will recede; and the inclination of her orbit will be greatest when the nodes are in syzigee, and least when they are in quadrature. And all these variations will be in certain precise degrees. Then we show that all these things actually obtain in the lunar motions, and they are considered as explained.

This summary account of the object and employment in all philosophical discussion is sufficient for pointing out its place in the circle of the sciences, and will serve to direct us to the proper methods of prosecuting it with success. Events are its object; and they are considered as connected with each other by causation, which may therefore be called the philosophical relation of things. The following may be adopted as the fundamental proposition on which all philosophical discussion proceeds, and under which every philosophical discussion or discovery may be arranged:

59 Fundamental proposition of philosophical discussion

"*Every change that we observe in the state or condition of things* IS CONSIDERED BY US *as an effect, indicating the agency, characterising the kind, and determining the degree of its* INFERRED *cause.*"

As thus enounced, this proposition is evidently a physical law of human thought. It may be enounced as a necessary and independent truth, by saying, *every change in the state and condition of things* IS AN EFFECT, &c. And accordingly it has been so enounced by Dr Reid*; and its title to this denomination has been abundantly supported by him. But we have no occasion to consider it as possessing this quality. We are speaking of philosophy, which is something contingent, depending on the existence and constitution of an intellectual being such as man; and, in conformity to the view which we have endeavoured to give of human knowledge in the subjects of philosophical relation, it is quite sufficient for our purpose that we maintain its title to the rank of an universal law of human thought. This will make it a first principle, even although it may not be a necessary truth.

* *Essays on the Intellectual Powers of Man.*

All the proof necessary for this purpose is universality of fact; and we believe this to be without exception. We are not to expect that all mankind have made,

View of Bacon's Philosophy

or will ever make, a formal declaration of their opinion; but we may venture to say that all have made it, and continually do make it, virtually. What have the philosophers of all ages been employed about but the discovery of the causes of those changes that are incessantly going on? *Nil turpius physico* (says Cicero) *quam fieri sine causâ quidquam dicere.* Human curiosity has been directed to nothing so powerfully and so constantly as to this. Many absurd causes have been assigned for the phenomena of the universe; but no set of men have ever said that they happened without a cause. This is so repugnant to all our propensities and instincts, that even the atheistical sect, who, of all others, would have profited most by the doctrine, have never thought of advancing it. To avoid so shocking an absurdity, they have rather allowed that chance, that the concourse of atoms, are the causes of the beautiful arrangements of nature. The thoughtless vulgar are no less solicitous than the philosophers to discover the cause of things: and the poet expresses the natural and instinctive passion of all men, when he says,

Felix qui potuit rerum cognoscere causas.

And this anxiety is not to nourish, but to get rid of superstitious fears: for thus

—— metus omnes, et inexorabile fatum
Subjecit pedibus, strepitumque Acherontis avari.

Had men never speculated, their conduct alone gives sufficient evidence of the universality of the opinion. The whole conduct of man is regulated by it, nay almost wholly proceeds upon it, in the most important matters, and where experience seems to leave us in doubt: and to act otherwise, as if any thing whatever happened without a cause, would be a declaration of insanity. Dr Reid has beautifully illustrated this truth, by observing, that even a child will laugh at you if you try to persuade him that the top, which he misses from the place where he left it, was taken away by nobody. You may persuade him that it was taken away by a fairy or a spirit; but he believes no more about this nobody, than the master of the house when *he* is told that nobody was the author of any piece of theft or mischief. What opinion would be formed, says Dr Reid, of the intellects of the juryman, on a trial for murder by persons unknown, who should say that the fractured skull, the watch and money gone, and other like circumstances, might possibly have no cause? he would be pronounced insane or corrupted.

60 Controverted by Mr Hume

We believe that Mr Hume is the first author who has ventured to call the truth of this opinion in question; and even *he* does it only in the way of mere possibility. He acknowledges the *generality* of the opinion; and he only objects to the foundation of this generality: and he objects to it merely because it does not quadrate with his theory of belief; and therefore it *may* happen that some men may have no such opinion. But it must be observed on this occasion, that the opinion of a philosopher is of no greater weight in a case like this than that of a ploughboy. If it be a first principle, directing the opinions and actions of all, it must operate on the minds of all. The philosopher is the only person who may chance to be without it: for it requires much labour, and long habits resolutely maintained, to warp our natural sentiments; and experience shows us that they may be warped if we are at sufficient pains. It is also worthy of remark, that this philosopher seems as much under the influence of this law as ordinary mortals. It is only when he is aware of its not tallying with his other doctrines that his scruples appear. Observe how he speaks when off his guard: "As to those impressions which arise from the senses, their ultimate cause is, in my opinion, perfectly inexplicable by human reason; and it will always be impossible to decide with certainty whether they arise immediately from the object, are produced by the creative power of the mind, or are derived from the Author of our being."

View of Bacon's Philosophy.

61 Wit great inconsistency.

Among these alternatives he never thought of their not being derived from any cause.

But it is not enough to show that this is a physical law of the human mind: we have assumed it as a first principle, the foundation of a whole science; therefore not included in or derived from any thing more general. Mr Hume's endeavours to show that it is not a necessary truth, show with sufficient evidence that most attempts to derive it in the way of argument are *petitiones principii;* a thing very commonly met with in all attempts to prove first principles. It cannot be proved by induction of facts that every event has a cause, because induction always supposes an *observed fact* or event. Now in by far the greatest number of events the causes are unknown. Perhaps in no event whatever do we know the real cause, or that power or energy which, without any intervention, produces the effect. No man can say, that in the simplest event which he ever observed, he was fully apprised of every circumstance which concurred to its production. We suppose that no event in nature can be adduced more simple than the motion of a suspended glass ball when gently struck by another glass ball; and we imagine that most of our readers will say that he perfectly sees every thing which happens in this phenomenon. We believe, too, that most of our readers are of opinion that a body is never put in motion but by the impulse of another, except in the cases of animal motion; and that they are disposed to imagine that magnets put iron in motion, and that an electrified body moves another by means of an interposed though invisible fluid somehow circulating round them. Now we must inform such readers, that unless the stroke has been very smart, so smart indeed as to shatter the glass balls, the motion of the suspended ball was produced without impulse: that is, the two balls were not in contact during the stroke; and the distance between them was not less than the 900th part of an inch, and probably much greater. We must say farther, that it is not certain that even the most violent stroke, such as would shatter them to pieces, is enough to bring them into real contact. The proofs of this singular position are too long for this place; but the evidence will be sufficiently seen by consulting the article Optics, nº 66, 67.

62 This proposition a first principle incapable of proof.

Unless, therefore, our readers are willing to allow that the suspended ball was put in motion by a repulsive force inherent in one or both balls, they must acknowledge that they *do not* fully know all the circumstances of this so simple phenomenon, or all the train of events which happen in it; and therefore they are reduced to the necessity of *supposing*, although they do not

View of Bacon's Philosophy.

not see it, an intervening fluid or matter, by the immediate action of whose *adjoining* particles the motion is produced.

This being the case in the simplest phenomenon that we can pitch upon, what shall we say of the numberless multitudes which are incomparably more complex? Must we not acknowledge that the efficient causes, even in the vulgar sense of the word, the immediately preceding events, are unknown, because the conjunctions are not observed? and therefore it cannot be said that it is from experimental induction that this truth gains universal belief. Experience, so far from supporting it as a direct proof, seems rather the strongest argument against it; for we have no experiment of unquestionable authority but the narrow circle of our own power exerted on our thoughts and actions. And even here there are perhaps cases of change where we cannot say with certainty that we perceive the efficient cause.

Nothing seems to remain, therefore, but to allow that this physical law of human judgment is instinctive, a constituent of the human soul, a first principle; and incapable of any other proof than the appeal to the feelings of every man.

63 Causes not observed but inferred from the phenomena which are the language of nature.

Simply to say, that every change is considered as an effect, is not giving the whole characters of this physical law. The cause is not always, perhaps never, *observed*, but is *inferred* from the phenomena. The inference is therefore in every instance dependant on the phenomenon. The phenomenon is to us the language of nature: It is therefore the sole indication of the cause and of its agency: It is therefore the indication of the very cause, and of no other. The observed change therefore characterises the cause, and marks its kind. This is confirmed by every word of philosophical language, where, as has already been observed, the names of the inferred powers of nature are nothing but either abbreviated descriptions of the phenomena, or terms which are defined solely by such descriptions. In like manner, the phenomenon determines the cause in a *particular degree*, and in no other; and we have no immediate measure of the degree of the cause but the phenomenon itself. We take many measures of the cause, it is true; but on examination they will be found not to be immediate measures of the cause, but of the effect. Assuming gravitation as the cause of the planetary deviations from uniform rectilineal motion, we say that the gravitation of the moon is but $\frac{1}{3600}$th part of the gravitation of a stone thrown from the hand: but we say this only from observing that the deflection of the stone is 3600 times greater than the simultaneous deflection of the moon. In short, our whole knowledge of the cause is not only *founded* on our knowledge of the phenomenon, but *it is the same*. This will be found a remark of immense consequence in the prosecution of philosophical researches; and a strict attention to it will not only guard us against a thousand mistakes into which the reasoning pride of man would continually lead us, but will also enable us fully to detect many egregious and fatal blunders made in consequence of this philosophical vanity. Nothing can be more evident than that whenever we are puzzled, it would be folly to continue groping among those obscure beings called *causes*, when we have their prototypes, the phenomena themselves, in our hands.

View of Bacon's Philosophy.

Such is the account which may be given of philosophy, the study of the works of God, as related by causation. It is of vast extent, reaching from an atom to the glorious Author of the Universe, and contemplating the whole connected chain of intelligent, sensitive, and inanimate beings. The philosopher makes use of the descriptions and arrangements of the natural historian as of mighty use to himself in the beginning of his career; confiding in the uniformity of nature, and expecting that similarity in the quiescent properties of things will be accompanied by some resemblances in those more important properties which constitute their mutual dependences, linking them together in a great and endlessly ramified chain of events.

We have endeavoured to ascertain with precision the peculiar province of philosophy, both by means of its object and its mode of procedure. After this it will not require many words to point out the methods for prosecuting the study with expedition and with success. The rules of philosophizing, which Newton premises to his account of the planetary motions, which he so scrupulously followed, and with a success which gives them great authority, are all in strict conformity to the view we have now given of the subject.

64 The chief rule of philosophizing explained.

The chief rule is, that similar causes are to be assigned to similar phenomena. This is indeed the source of all our knowledge of connected nature; and without it the universe would only present to us an incomprehensible chaos. It is by no means, however, necessary to enjoin this as a maxim for our procedure: it is an instinctive propensity of the human mind. It is absolutely necessary, on the contrary, to caution us in the application of this propensity. We must be extremely confident in the certainty of the resemblance before we venture to make any inference. We are prone to reason from analogy: the very employment is agreeable; and we are ever disposed to embrace opportunities of engaging in it. For this reason we are satisfied with very slight resemblances, and eagerly run over the consequences, as if the resemblances were complete; and our researches frequently terminate in falsehood.

This propensity to analogical reasoning is aided by another equally strong, and equally useful, when properly directed; we mean the propensity to form general laws: it is in fact a propensity to discover *causes*, which is equivalent to the establishing of general laws. It appears in another form, and is called a love of or taste for simplicity; and this is encouraged or justified as agreeable to the uniformity and simplicity of nature. "Natura semper sibi similis et consona," says Newton; "Frustra fit per plura, quod fieri potest per pauciora," says another. The beautiful, the wise economy of nature, are phrases in every body's mouth; and Newton enjoins us to adopt no more causes than are sufficient to explain the phenomena. All this is very well, and is true in its own degree; but it is too frequently the subterfuge of human vanity and self-love. This inordinate admiration of the economy and simplicity of nature is generally conjoined with a manifest love of system, and with the actual production of some new system, where from one general principle some extensive theory or explanation is deduced and offered to the world. The author sees *a sort* of resemblance

View of Bacon's Philosophy.

blance between a certain series of phenomena and the consequences of some principle, and thinks the principle adequate to their explanation. Then, on the authority of the acknowledged simplicity of nature, he roundly excludes all other principles of explanation; because, says he, this principle is sufficient "et frustra fit per plura," &c. We could point out many instances of this kind in the writings of perhaps the first mathematician and the poorest philosopher of this century; where extensive theories are thus cavalierly exhibited, which a few years examination have shown to be nothing but analogies, indistinctly observed, and, what is worse, inaccurately applied.

To regulate these hazardous propensities, and keep philosophers in the right path, Newton inculcates another rule, or rather gives a modification of this injunction of simplicity. He enjoins, that no cause shall be admitted but what is real. His words are, that *no causes shall be admitted but such as are true, and sufficient to account for the phenomena.* We apprehend that the meaning of this rule has been mistaken by many philosophers, who imagine that by *true* he means causes which really exist in nature, and are not mere creatures of the imagination. We have met with some who would boggle at the doctrines of Aristotle respecting the planetary motions, *viz.* that they are carried along by conducting intelligent minds, because we know of *none such* in the universe; and who would nevertheless think the doctrine of the Cartesian vortices deserving of at least an examination, because we see such vortices exist, and produce effects which have some resemblance to the planetary motions, and have justly rejected them, *solely* because this resemblance has been very imperfect. We apprehend Newton's meaning by these words is, that no cause of any event shall be admitted, or even considered, which we *do not know* to be actually concurring or exerting some influence *in that very event.* If this be his meaning, he would reject the Cartesian vortices, and the conducting spirits of Aristotle for one and the same reason; not because they were not adequate to the explanation, nor because such causes did not exist in nature, but because we did not *see them* anyhow concerned in the phenomenon under consideration. We neither see a spirit nor a vortex, and therefore need not trouble ourselves with enquiring what effects they would produce. Now we know that this was his very conduct, and what has distinguished him from all philosophers who preceded him, though many, by following his example, have also been rewarded by similar success. This has procured to Newton the character of the *modest* philosopher; and modest his procedure may, for distinction's sake, be called, because the contrary procedure of others did not originate so much from ignorance as from vanity. Newton's conductor in this was not modesty, but sagacity, prudence, caution, and to say it purely, it was sound judgment.

65 A true cause explained.

For the bonds of nature, the supposed philosophical causes are not *observed*; they are *inferred* from the phenomena. When two substances are observed, and only when they are observed, to be connected in any series of events, we *infer* that they are connected by a natural power: but when one of the substances is not seen, but fancied, no law of human thought produces any inference whatever. For this reason alone Newton stopped short at the last FACT which he could discover in the solar system, that all bodies were deflected to all other bodies, according to certain regulations of distance and quantity of matter. When told that he had done nothing in philosophy, that he had discovered no cause, and that to merit any praise he must show how this deflection was produced;—he said, that he knew no more than he had told them; that he saw nothing causing this deflection; and was contented with having described it so exactly, that a good mathematician could now make tables of the planetary motions as accurate as he pleased, and with hoping in a few years to have every purpose of navigation and of philosophical curiosity completely answered; and he was not disappointed. And when philosophers on all sides were contriving hypothetical fluids and vortices which would produce these deflections, he contented himself with showing the total inconsistency of these explanations with the mechanical principles acknowledged by their authors; showing that they had transgressed both parts of his rule, their causes neither being real nor sufficient for explaining the phenomena. A cause is sufficient for explaining a phenomenon only when its legitimate consequences are perfectly agreeable to these phenomena.

Newton's discoveries remain without any diminution or change: no philosopher has yet advanced a step further.

66 This doctrine founded in reason.

But let not the authority, or even the success, of Newton be our guide. Is his rule founded in reason? It surely is. For if philosophy be only the interpretation of nature's language, the inference of causes from the phenomena, a fancied or hypothetical phenomenon can produce nothing but a fanciful cause, and can make no addition to our knowledge of real nature.

All hypotheses therefore must be banished from philosophical discussion as frivolous and useless, administering to vanity alone. As the explanation of any appearance is nothing but the pointing out the general fact, of which this is a particular instance, a hypothesis can give no explanation: knowing nothing of cause and effect but the conjunction of two events, we see nothing of causation where one of the events is hypothetical. Although all the legitimate consequences of a hypothetical principle should be perfectly similar to the phenomenon, it is extremely dangerous to assume this principle as the real cause. It is illogical to make use of the economy of nature as an argument for the truth of any hypothesis: for if true, it is a physical truth, a matter of fact, and true only to the extent in which it is observed, and we are not intitled to say that it is so one step farther; therefore not in *this* case *till it be observed.* But the proposition that nature is so economical is false; and it is astonishing that it has been so lazily acquiesced in by the *readers* of hypotheses: for it is not the *authors* who are deceived by it, they are generally led by their own vanity. Nothing is more observable than the prodigious variety of nature. That the same phenomena may be produced by different means is well known to the astronomers, who must all grant, that the appearances of motion will be precisely the same whether the earth moves round the sun like the other planets, or whether the sun with his attendant planets moves round the earth; and that the

67 Dangers of hypotheses.

View of Bacon's Philosophy.

the demonstration of the first opinion is had from a fact totally unconnected with all the deflections or even with their causes: for it may be asserted, that Dr Bradley's discovery of the aberration of the fixed stars, in consequence of the progressive motion of light, was the first thing which put the Copernican system beyond question; and even this is still capable of being explained in another way. The Author of Nature seems to delight in variety; and there cannot be named a single purpose in which the most inconceivable fertility in resource is not observed. It is the most delightful occupation of the curious mind and the sensible heart to contemplate the various contrivances of nature in accomplishing similar ends.

As a principle therefore on which to found any maxim of philosophical procedure, this is not only injudicious, because imprudent and *apt* to mislead, but as false, and almost sure to mislead. In conformity to this observation, it must be added, that nothing has done so much harm in philosophy as the introduction of hypotheses.

Authors have commonly been satisfied with very slight resemblances, and readers are easily misled by the appearances of reasoning which these resemblances have countenanced. The ancients, and above all Aristotle, were much given to this mode of explanation, and have filled philosophy with absurdities. The slightest resemblances were with them sufficient foundations of theories. It has been by very slow degrees that men have learned caution in this respect; and we are sorry to say that we are not yet cured of the disease of hypothetical systematizing, and to see attempts made by ingenious men to bring the frivolous theories of antiquity again into credit. Nay, modern philosophers even of the greatest name are by no means exempted from the reproach of hypothetical theories. Their writings abound in ethers, nervous fluids, animal spirits, vortices, vibrations, and other invisible agents. We may affirm that all these attempts may be shown to be either unintelligible, fruitless, or false. Either the hypothesis has been such that no consequence can be distinctly drawn from it, on account of its obscurity and total want of resemblance to any thing we know; or the just and legitimate consequences of the hypothesis are inconsistent with the phenomena (N). This is remarkably the case in the hypotheses which have been introduced for the explanation of the mechanical phenomena of the universe. These can be examined by accurate science, and the consequences compared without any mistake; and nothing else but a perfect agreement should induce us even to listen to any hypothesis whatever.

View of Bacon's Philosophy.

It may here be asked, Whether, in the case of the most perfect agreement, after the most extensive comparison, the hypothesis should be admitted? We believe that this must be left to the feelings of the mind. When the belief is irresistible, we can reason no more. But as there is no impossibility of as perfect an agreement with some other hypothesis, it is evident that it does not convey an irrefragable title to our hypothesis. It is said, that such an agreement authorises the reception of the hypothetical theory in the same manner as we *must* admit that to be the *true* cypher of a letter which will make perfect sense of it. But this is not true: in decyphering a letter we know the sounds which *must* be represented by the characters, and that they are really the constituents of speech: but in hypothetical explanations the first principle is not known to exist; nay, it is possible to make two cyphers, each of which shall give a meaning to the letter. Instances of this are to be seen in treatises on the art of decyphering; and there has been lately discovered a national character (the *ogam* discovered in Ireland) which has this property.

We conclude our criticism on hypothetical explanations with this observation, that it is *impossible* that they can give any addition of knowledge. In every hypothesis we thrust in an intermediate event between the phenomenon and some general law; and this event is not seen, but supposed. Therefore, according to the true maxims of philosophical investigation, we give no explanation; for we are not by this means enabled to assign the general law in which this particular phenomenon is included: nay, the hypothesis makes no addition to our list of general laws; for our hypotheses must be *selected*, in order to tally with all the phenomena. The hypothesis therefore is understood only *by* and *in* the phenomena; and it must not be made more general than the phenomena themselves. The hypothesis gives no generalisation of facts. Its very application is founded on a great coincidence of facts; and the hypothetical fact is thrust in between two which we really observe to be united by nature. The applicability therefore of the hypothesis is not more

(N) It has often been matter of amusement to us to examine the hypothetical theories of ingenious men, and to observe the power of nature even when we are transgressing her commands, *Naturam expellat furca, tamen usque revertitur*. The hypothesis of an ingenious man is framed in perfect conformity to nature's dictates: for you will find that the hypothetical cause is touched and retouched, like the first sitting of a picture, till it is made to resemble the phenomena, and the cause is still inferred, nay explained, in spite of all his ingenuity, from the phenomenon; and then, instead of desiring the spectators to pay him his due praise, by saying that the picture is like the man, he insists that they shall say, what gives him no credit, that the man is like the picture. But, alas! this is seldom the case: The picture is generally an anamorphosis, unlike any thing extant in nature, and having parts totally incongruous. We have seen such pictures, where a wood is standing on the sea, and an eye is on the end of an elephant's trunk; and yet when this was viewed through a proper glass, the wood became an eyebrow to the eye, and the proboscis was a very pretty ringlet of hair. We beg indulgence for this piece of levity, because it is a most apposite illustration of a hypothetical theory. The resemblance between the principle and phenomenon is true only in detached unconnected scraps, and the principle itself is an incongruous patchwork. But by a perversion of the rules of logic, all these inconsistencies are put out of view, and the explanation is something like the phenomenon.

View of Bacon's Philosophy.

extensive than the similarity of facts which we observe, and the hypothetical law is not more general than the observed law. Let us then throw away entirely the hypothetical law, and insert the observed one in our list of general laws: it will be in different language from the hypothetical law, but it will express the same facts in nature.

68 On what occasions they may be useful.

It is in experimental philosophy alone that hypotheses can have any just claim to admission; and here they are not admitted as explanations, but as conjectures serving to direct our line of experiments.

Effects only appear; and by their appearance, and the previous information of experience, causes are immediately ascertained by the perfect similarity of the whole train of events to other trains formerly observed: Or they are suggested by more imperfect resemblances of the phenomena; and these suggestions are made with stronger or fainter evidence, according as the resemblance is more or less perfect. These suggestions do not amount to a confidential inference, and only raise a conjecture. Wishing to verify or overturn this conjecture, we have recourse to experiment; and we put the subject under consideration in such a situation, that we can say what will be the effect of the conjectural cause if real. If this tallies with the appearance, our conjecture has more probability of truth, and we vary the situation, which will produce a new set of effects of the conjectured cause, and so on. It is evident that the probability of our conjecture will increase with the increase of the conformity of the legitimate effects of the supposed cause with the phenomena, and that it will be entirely destroyed by *one* disagreement. In this way conjectures have their great use, and are the ordinary means by which experimental philosophy is improved. But conjectural systems are worse than nonsense, filling the mind with false notions of nature, and generally leading us into a course of improper conduct when they become principles of action. This is acknowledged even by the abettors of hypothetical systems themselves, when employed in overturning those of their predecessors, and establishing their own: witness the successive maintainers of the many hypothetical systems in medicine, which have had their short-lived course within these two last centuries.

Let every person therefore who calls himself a philosopher resolutely determine to reject all temptations to this kind of system-making, and let him never consider any composition of this kind as any thing better than the amusement of an idle hour.

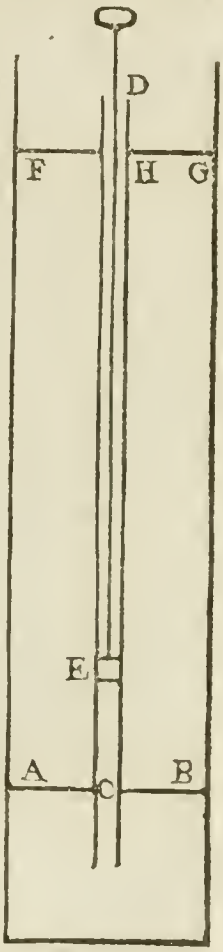
69 True mode of philosophical procedure.

After these observations, it cannot require much dissension to mark the mode of procedure which will insure progress in all philosophical investigations.

The sphere of our intuitive knowledge is very limited; and we must be indebted for the greatest part of our intellectual attainments to our rational powers, and it must be deductive. In the spontaneous phenomena of nature, whether of mind or body, it seldom happens that the energy of that natural power, which is the principle of explanation, is so immediately connected with the phenomenon that we see the connection at once. Its exertions are frequently concealed, and in all cases modified, by the joint exertions of other natural powers: the particular exertion of each must be considered apart, and their mutual connection traced out. It is only in this way that we can discover the perhaps long train of intermediate operations, and also see in what manner and degree the real principle of explanation concurs in the ostensible process of nature.

View of Bacon's Philosophy.

In all such cases it is evident that our investigation (and investigation it most strictly is) must proceed by steps, conducted by the sure hand of logical method. To take an instance from the material world, let us listen to Galileo while he is teaching his friends the cause of the rise of water in a pump. He says that it is owing to the pressure of the air. This is his principle; and he announces it in all its extent. All matter, says he, is heavy, and in particular air is heavy. He then points out the connection of this general principle with the phenomenon. Air being heavy, it must be supported: it must lie and press on what supports it: it must press on the surface AB of the water in the cistern surrounding the pipe CD of the pump; and also on the water C within this pipe. He then takes notice of another general principle which exerts its subordinate influence in this process. Water is a fluid; a fluid is a body whose parts yield to the smallest impression; and, by yielding, are easily moved among themselves: and no little parcel of the fluid can remain at rest unless it be equally pressed in every direction, but will recede from that side where it sustains the greatest pressure. In consequence of this fluidity, *known* to be a property of water, if any part of it is pressed, the pressure is propagated thro' the whole; and if not resisted on every side, the water will move to that side where the propagated pressure is not resisted. All these subordinate or collateral propositions are supposed to be previously demonstrated or allowed. Water therefore must yield to the pressure of the air unless pressed by it on every side, and must move to that side where it is not withheld by some opposite pressure. He then proceeds to show, from the structure of the pump, that there is no opposing pressure on the water in the inside of the pump. "For (says he) suppose the piston thrust down till it touches the surface of the water in the pipe; suppose the piston now drawn up by a power sufficient to lift it, and all the air incumbent on it; and suppose it drawn up a foot or a fathom—there remains nothing now (says he) that I know of, to press on the surface of the water. In short (says he), gentlemen, it appears to me, that the water in the pump is in the same situation that it would be in were there no air at all, but water poured into the cistern to a height AF; such, that the column of water FABG



View of Bacon's Philosophy.

preſſes on the ſurface AB as much as the air does. Now in this caſe we know that the water at C is preſſed upwards with a force equal to the weight of a column of water, having the ſection of the pipe for its baſe and CH for its height. The water below C therefore will be preſſed up into the pipe CD, and will riſe to G, ſo that it is on a level with the external water FG; that is, it will riſe to H. This is a neceſſary conſequence of the weight and preſſure of the incumbent column FABG, and the fluidity of the water in the ciſtern. Conſequences perfectly ſimilar muſt neceſſarily follow from the weight and preſſure of the air; and therefore on drawing up the piſton from the ſurface C of the water, with which it was in contact, the water muſt follow it till it attain that height which will make its own weight a balance for the preſſure of the circumambient air. Accordingly, gentlemen, the Italian plumbers inform me, that a pump will not raiſe water quite fifty palms; and from their information I conclude, that a pillar of water fifty palms high is ſomewhat heavier than a pillar of air of the ſame baſe, and reaching to the top of the atmoſphere."

To the ſynthetic method.

Thus is the phenomenon explained. The riſe of the water in the pump is ſhown to be a particular caſe of the general fact in hydroſtatics, that fluids in communicating veſſels will ſtand at heights which are inverſely as their denſities, or that columns of equal weights are in equilibrio.

This way of proceeding is called arguing *à priori*, the ſynthetic method. It is founded on juſt principles; and the great progreſs which we have made in the mathematical ſciences by this mode of reaſoning ſhows to what length it may be carried with irreſiſtible evidence. It has long been conſidered as the only inlet to true knowledge; and nothing was allowed to be known with certainty which could not be demonſtrated in this way to be true. Accordingly logic, or the art of reaſoning, which was alſo called the art of diſcovering truth, was nothing but a ſet of rules for ſucceſsfully conducting this mode of argument.

Under the direction of this infallible guide, it is not ſurely unreaſonable to expect that philoſophy has made ſure progreſs towards perfection; and as we know that the brighteſt geniuſes of Athens and of Rome were for ages ſolely occupied in philoſophical reſearches in every path of human knowledge, it is equally reaſonable to ſuppoſe that the progreſs has not only been ſure but great. We have ſeen that the explanation of an appearance in nature is nothing but the arrangement of it into that general claſs in which it is comprehended. The claſs has its diſtinguiſhing mark, which, when it is found in the phenomenon under conſideration, fixes it in its claſs, there to remain for ever an addition to our ſtock of knowledge. Nothing can be loſt any other way but by forgetting it; and the doctrines of philoſophers muſt be ſtable like the laws of nature.

We have ſeen, however, that the very reverſe of all this is the caſe; that philoſophy has but very lately emerged from worſe than total darkneſs and ignorance; that what paſſed under the name of philoſophy was nothing but ſyſtems of errors (if ſyſtems they could be called), which were termed doctrines, delivered with the moſt impoſing apparatus of logical demonſtration, but belied in almoſt every inſtance by experience, and affording us no aſſiſtance in the application of the powers of nature to the purpoſes of life. Nor will this excite much wonder in the mind of the enlightened reader of the preſent day, who reflects on the uſe that in this dialectic proceſs was made of the *categories*, and the method in which thoſe categories were formed. From firſt principles ſo vague in themſelves, and ſo gratuitouſly aſſumed, ingenious men might deduce many different concluſions all equally erroneous: and that this was actually done, no ſurer evidence can be given, than that hardly a lifetime elapſed in which the whole ſyſtem of doctrines which had captivated the minds of the moſt penetrating, have been oftener than once exploded and overturned by another ſyſtem, which flouriſhed for a while, and then was ſupplanted by a third which ſhared the ſame fate. Here was an infallible proof of their error, for inſtability is incompatible with truth.

View of Bacon's Philoſophy.

It is allowed by all that this has been the caſe in thoſe branches of ſtudy at leaſt which contemplate the philoſophical relations of the material world, in aſtronomy, in mechanical philoſophy, in chemiſtry, in phyſiology, in medicine, in agriculture. It is alſo acknowledged, that in the courſe of leſs than two centuries back we have acquired much knowledge on theſe very ſubjects, call it philoſophy, or by what name you will, ſo much more conformable to the natural courſe of things, that the deductions made from it by the ſame rules of the ſynthetic method are more conformable to fact, and therefore better fitted to direct our conduct and improve our powers. It is alſo certain that theſe bodies of doctrine which go by the name of philoſophical ſyſtems, have much more ſtability than in ancient times; and though ſometimes in part ſuperſeded, are ſeldom or never wholly exploded.

This cannot perhaps be affirmed with equal confidence with reſpect to thoſe ſpeculations which have our intellect or propenſities for their object: and we have not perhaps attained ſuch a repreſentation of human nature as will bear compariſon with the original; nor will the legitimate deductions from ſuch doctrines be of much more ſervice to us for directing our conduct than thoſe of ancient times: and while we obſerve this difference between theſe two general claſſes of ſpeculations, we may remark, that it is conjoined with a difference in the manner of conducting the ſtudy. We have proceeded in the old Ariſtotelian method when inveſtigating the nature of mind; but we ſee the material philoſophers running about, paſſing much of their time away from books in the ſhop of the artiſan, or in the open fields engaged in obſervation, labouring with their hands, and buſy with experiments. But the ſpeculatiſt on the intellect and the active powers of the human ſoul ſeems unwilling to be indebted to any thing but his own ingenuity, and his labours are confined to the cloſet. In the firſt claſs, we have met with ſomething like ſucceſs, and we have improved many arts: in the other, it is to be feared that we are not much wiſer, or better, or happier, for all our philoſophic attainments.

No inlet to truth.

Here, therefore, muſt ſurely have been ſome great, ſome fatal miſtake. There has indeed been a material defect in our mode of procedure, in the employment of this method of reaſoning as an inlet to truth. The

View of Bacon's Philosophy.

fact is, that philosophers have totally mistaken the road of discovery, and have pretended to set out in their investigation from the very point where this journey should have terminated.

The Aristotelian logic, the syllogistic art, that art so much boasted of as the only inlet to true knowledge, the only means of discovery, is in direct opposition to the ordinary procedure of nature, by which we every day, and in every action of our lives, acquire knowledge and discover truth. It is not the art of discovering truth, it is the art of communicating knowledge, and of detecting error: it is nothing more than the application of this maxim, "whatever is true of a whole class of objects, is true of each individual of that class." This is not a just account of the art of discovering truth, nor is it a complete account of the art of reasoning. Reasoning is the producing belief; and whatever mode of argumentation invariably and irresistibly produces belief, is reasoning. The ancient logic supposes that all the first principles are already known, and that nothing is wanted but the application of them to particular facts. But were this true, the application of them, as we have already observed, can hardly be called a discovery: but it is not true; and the fact is, that the first principles are generally the chief objects of our research, and that they have come into view only now and then as it were by accident, and never by the labour of the logician. He indeed can tell us whether we have been mistaken; for if our general principle be true, it must influence *every* particular case. If, therefore, it be false in any one of these, it is not a true principle. And it is here that we discover the source of that fluctuation which is so much complained of in philosophy. The authors of systems give a set of consecutive propositions logically deduced from a first principle, which has been hastily adopted, and has no foundation in nature. This does not hinder the amusement of framing a system from it, nor this system from pleasing by its symmetry; and it takes a run: but when some officious follower thinks of making some use of it, which requires the comparison with experience and observation, they are found totally unlike, and the whole fabric must be abandoned as unsound: and thus the successive systems were continually pushing out their predecessors, and presently met with the same treatment.

72 But the art of communicating knowledge

How was this to be remedied? The ratiocination was seldom egregiously wrong; the syllogistic art had ere now attained a degree of perfection which left little room for improvement, and was so familiarly understood by the philosophical practitioners, that they seldom committed any great blunders. Must we examine the first principles? This was a task quite new in science; and there were hardly any rules in the received systems of logic to direct us to the successful performance of it. Aristotle, the sagacious inventor of those rules, had not totally omitted it; but in the fervour of philosophic speculation he had made little use of them. His fertile genius never was at a loss for first principles, which answered the purpose of verbal disquisition without much risk of being belied on account of its dissimilitude to nature; for there was frequently no prototype with which his systematic doctrine could be compared. His enthusiastic followers found abundant amusement in following his example; and philosophy, no longer in the hands of men acquainted with the world, conversant in the great book of nature, was now confined almost entirely to recluse monks, equally ignorant of men and of things. But curiosity was awakened, and the men of genius were fretted as well as disgusted with the disquisitions of the schools, which one moment raised expectations by the symmetry of composition, and the next moment blasted them by their inconsistency with experience.

View of Bacon's Philosophy.

They saw that the best way was to begin *de novo*, to throw away the first principles altogether, without exception or examination, and endeavour to find out new ones, which should stand the test of logic; that is, should in every case be agreeable to fact.

73 The method of induction pointed out by nature.

Philosophers began to reflect, that under the unnoticed tuition of kind nature we have acquired much useful knowledge. It is therefore highly probable, that her method is the most proper for acquiring knowledge, and that by imitating her manner we shall have the like success. We are too apt to slight the occupations of children, whom we may observe continually busy turning every thing over and over, putting them into every situation, and at every distance. We excuse it, saying that it is an innocent amusement; but we should say with an ingenious philosopher (Dr Reid), that they are most seriously and rationally employed: they are acquiring the habits of observation; and by merely indulging an undetermined curiosity, they are making themselves acquainted with surrounding objects: they are struck by similitudes, and amused with mere classification. If some new effect occurs from any of their little plays, they are eager to repeat it. When a child has for the first time tumbled a spoon from the table, and is pleased with its jingling noise on the floor, if another lies within its reach, it is sure to share the same fate. If the child is indulged in this diversion, it will repeat it with a greediness that deserves our attention. The very first eager repetition shows a confidence in the constancy of natural operations, which we can hardly ascribe wholly to experience; and its keenness to repeat the experiment, shows the interest which it takes in the exercise of this most useful propensity. It is beginning the study of nature; and its occupation is the same with that of a Newton computing the motions of the moon by his sublime theory, and comparing his calculus with observation. The child and the philosopher are equally employed in the contemplation of a similarity of event, and are anxious that this similarity shall return. The child, it is true, thinks not of this abstract object of contemplation but throws down the spoon again to have the pleasure of hearing it jingle. The philosopher suspects that the conjunction of events is the consequence of a general law of nature, and tries an experiment where this conjunction recurs. The child is happy, and eager to enjoy a pleasure which to us appears highly frivolous; but it has the same foundation with the pleasure of the philosopher, who rejoices in the success of his experiment: and the fact, formerly a trifle to both, now acquires importance. Both go on repeating the experiment, till the fact ceases to be a novelty to either: the child is satisfied,

and

View of Bacon's Philosophy.

and the philosopher has now established a new law of nature.

Such (says this amiable philosopher) is the education of kind nature, who from the beginning to the end of our lives makes the play of her scholars their most instructive lessons, and has implanted in our mind the curiosity and the inductive propensity by which we are enabled and disposed to learn them. The exercise of this inductive principle, by which nature prompts us to infer general laws from the observation of particular facts, gives us a species of logic new in the schools, but old as human nature. It is certainly a method of discovery; for by these means general principles, formerly unknown, have come into view.

74 Is a just logic.

It is a just and rational logic; for it is founded on, and indeed is only the habitual application of, this maxim, "That whatever is true with respect to every individual of a class of events, is true of the whole class." This is just the inverse of the maxim on which the Aristotelian logic wholly proceeds, and is of equal authority in the court of reason. Indeed the expression of the general law is only the abbreviated expression of every particular instance.

This new logic, therefore, or the logic of induction, must not be considered as subordinate to the old, or founded on it. See Logic, Part III. chap. 5. In fact, the use and legitimacy of the Aristotelian logic is founded on the inductive,

All animals are mortal;
All men are animals: therefore
All men are mortal

This is no argument to any person who chooses to deny the mortality of man: even although he acknowledges his animal nature, he will deny the major proposition.

It is beside our purpose to show, how a point so general, so congenial to man, and so familiar, remained so long unnoticed, although the disquisition is curious and satisfactory. It was not till within these two centuries that the increasing demand for practical knowledge, particularly in the arts, made inquisitive men see how useless and insufficient was the learning of the schools in any road of investigation which was connected with life and business; and observe, that society had received useful information chiefly from persons actually engaged in the arts which the speculatists were endeavouring to illustrate; and that this knowledge consisted chiefly of experiments and observations, the only contributions which their authors could make to science.

The *Novum Organum* of Bacon, which points out the true method of forming a body of real and useful knowledge, namely, the study of nature in the way of description, observation, and experiment, is undoubtedly the noblest present that science ever received. It may be considered as the grammar of nature's language, and is a counter-part to the logic of Aristotle; not exploding it, but making it effectual.

75 Its chief rule

As the logic of Aristotle had its rules, so has the Baconian or inductive; and this work, the *Novum Organum Scientiarum*, contains them all. The chief rule, and indeed the rule from which all the rest are but derivations, is, that "the induction of particulars must be carried as far as the general affirmation which is deduced from them." If this be not attended to, the mind of man, which from his earliest years shows great eagerness in searching for first principles, will frequently ascribe to the operation of a general principle events which are merely accidental. Hence the popular belief in omens, palmistry, and all kinds of fortune-telling.

View of Bacon's Philosophy.

76 For discovering general principles,

This rule must evidently give a new turn to the whole track of philosophical investigation. In order to discover first principles, we must make extensive and accurate observations, so as to have copious inductions of facts, that we may not be deceived as to the extent of the principle inferred from them. We must extend our acquaintance with the phenomena, paying a minute attention to what is going on all around us; and we must study nature, not shut up in our closet drawing the picture from our own fancy, but in the world, copying our lines from her own features.

To delineate human nature, we must see how men act. To give the philosophy of the material world, we must notice its phenomena.

This method of studying nature has been prosecuted during these two last centuries with great eagerness and success. Philosophers have been busy in making accurate observations of facts, and copious collections of them. Men of genius have discovered points of resemblance, from which they have been able to infer many general powers both of mind and body; and resemblances among these have suggested powers still more general.

By these efforts investigation became familiar; philosophers studied the rules of the art, and became more expert; hypotheses were banished, and nothing was admitted as a principle which was not inferred from the most copious induction. Conclusions from such principles became every day more conformable to experience. Mistakes sometimes happened; but recourse being had to more accurate observation or more copious induction, the mistakes were corrected. In the present study of nature, our steps are more slow, and hesitating and painful; our conclusions are more limited and modest, but our discoveries are more certain and progressive, and the results are more applicable to the purposes of life. This pre-eminence of modern philosophy over the ancient is seen in every path of inquiry. It was first remarkable in the study of the material world; and there it still continues to be most conspicuous. But it is no less to be seen in the later performances of philosophers in metaphysics, pneumatology, and ethics, where the mode of investigation by analysis and experiment has been greatly adopted; and we may add, that it is this juster view of the employment which has restored philosophers to the world, to society. They are no longer to be found only in the academies of the sophists and the cloisters of a convent, but in the discharge of public and private duty. A philosophic genius is a genius for observation as well as reflection, and he says, *Homo sum, humani a me nihil alienum puto.*

77 And rectifying mistakes.

78 Estimate of the philosophic character.

After saying so much on the nature of the employment, and the mode of procedure, it requires no deep penetration to perceive the value of the philosophical character. If there is a propensity in the human mind which

View of Bacon's Philosophy.

which distinguishes us from the inferior orders of sentient beings, without the least circumstance of interference, a propensity which alone may be taken for the characteristic of the species, and of which no trace is to be found in any other, it is disinterested intellectual curiosity, a love of discovery for its own sake, independent of all its advantages.

We think highly (and with great justice do we think so) of our rational powers; but we may carry this too far, as we do every ground of self-estimation. To every man who enjoys the cheering thought of living under the care of a wise Creator, this boasted prerogative will be viewed with more modesty and diffidence; and He has given us evident marks of the rank in which He esteems the rational powers of man. In no case that is of essential importance, of indispensable necessity, not only to our well being but to our very existence, has He left man to the care of his reason alone; for in the first instance, He has given us reason

79 We should think modestly of our rational powers.

To guide the helm, while passion blows the gale.

God has not trusted either the preservation of the individual or the continuance of the race to man's notions of the importance of the task, but has committed them to the surer guards of hunger and of sexual desire. In like manner, He has not left the improvement of his noblest work, the intellectual powers of the soul of man, to his own notions how important it is to his comfort that he be thoroughly acquainted with the objects around him. No: He has committed this also to the sure hand of curiosity: and He has made this so strong in a few superior souls, whom He has appointed to give light and knowledge to the whole species, as to abstract them from all other pursuits, and to engage them in intellectual research with an ardour which no attainment can ever quench, but, on the contrary, inflames it the more by every draught of knowledge.

80 Importance of our instinctive principles.

——————— But what need words
To paint its power? For this the daring youth
Breaks from his weeping mother's fondling arms
In foreign climes to rove. The pensive sage,
Heedless of sleep, or midnight's hurtful vapour,
Hangs o'er the sickly taper.—Hence the scorn
Of all familiar prospects, though beheld
With transport once. Hence th' attentive gaze
Of young astonishment.
Such is the bounteous providence of Heaven,
In every breast implanting the desire
Of objects new and strange, to urge us on
With unremitting labour to attain
The sacred stores that wait the rip'ning soul
In Truth's exhaustless bosom. *Aikenside.*

But human life is not a situation of continual necessity; this would ill suit the plans of its Beneficent Author: and it is from induction of phenomena totally opposite to this, and from such induction alone, that we have ever thought of a wise Creator. His wisdom appears only in His beneficence. Human life is a scene filled with enjoyment; and the soul of man is stored with propensities and powers which have *pleasure, in direct terms*, for their object. Another striking distinction of our nature is a continual disposition to refinement, of which few traces are to be found in the actions of other animals. There is hardly a gift of nature so grateful in itself as to please the freakish mind of man till he has moulded it to his fancy. Not contented with food, with raiment, and with shelter, he must have nice cookery, ornamental dress, and elegant houses. He hunts when he is not hungry, and he refines sexual appetite into a most elegant passion. In like manner he has improved this anxious desire of the knowledge of the objects around him, so as to derive from them the means of subsistence and comfort, into the most elegant and pleasing of all gratifications, the accumulation of intellectual knowledge, independent of all consideration of its advantages. And as every man has a title to the enjoyment of such pleasures as he can attain without injuring his neighbour; so it is allowable to such as have got the means of intellectual improvement, without relinquishing the indispensible social duties, to push this advantage as far as it will go: and, in all ages and countries, it has been considered as forming the greatest distinction between men of easy fortune and the poor, who must earn their subsistence by the sweat of their brow. The plebeian must learn to work, the gentleman must learn to think; and nothing can be a surer mark of a groveling soul than for a man of fortune to have an uncultivated mind.

View of Bacon's Philosophy, 81 Our disposition to refinement

82 Ought to be cherished as far as it is subservient to the duties of life.

Let us then cherish to the utmost this distinguishing propensity of the human soul: but let us do even this like philosophers. Let us cultivate it as it is; as the handmaid to the arts and duties of life; as the guide to something yet more excellent. A character is not to be estimated from what the person knows, but from what he can perform. The accumulation of intellectual knowledge is too apt to create an inordinate appetite for it; and the man habituated to speculation is, like the miser, too apt to place that pleasure in the mere *possession*, which he ought to look for only or chiefly in the *judicious use* of his favourite object. Like the miser, too, his habits of hoarding up generally unfit him for the very enjoyment which at setting out he proposed to himself. Seldom do we find the man, who has devoted his life to scientific pursuits for their own sake, possessed of that superiority of mind which the active employ to good purpose in times of perplexity; and much seldomer do we find him possessed of that promptitude of apprehension, and that decision of purpose, which are necessary for passing through the difficult scenes of human life.

But we may use the good things of this life without abusing them; and by moderation here, as in all other pursuits, derive those solid advantages which philosophy is able to bestow. And these advantages are great. To enumerate and describe them would be to write a great volume. We may just take notice of one, which is an obvious consequence of that strict and simple view which we have given of the subject; and this is, a modest opinion of our attainments. Appearances are all that we know; causes are for ever hid from our view; the powers of our nature do not lead us so far. Let us therefore, without hesitation, relinquish all pursuits which have such things as ultimate principles for *objects of examination*. Let us attend to the subordinations of things which it is our great business to explore.

83 Limits of our knowledge.

View of Bacon's Philosophy

explore. Among these there is such a subordination as that of means to ends, and of instruments to an operation. All will acknowledge the absurdity of the project of viewing light with a microscope. It is equally absurd for us to examine the nature of knowledge, of truth, of infinite wisdom, by our intellectual powers. We have a wide field of accessible knowledge in the works of God; and one of the greatest advantages, and of the most sublime pleasures, which we can derive from the contemplation, is the view which a judicious philosophical research will most infallibly give us of a world, not consisting of a number of detached objects, connected only by the fleeting tie of coexistence, but an *universe*, a *system* of beings, all connected together by causation, with innumerable degrees of subordination and subserviency, and all cooperating in the production of one great and glorious purpose. The heart which has but a spark of sensibility must be warmed by such a prospect, must be pleased to find itself an important part of this stupendous machine; and cannot but adore the incomprehensible Artist who contrived, created, and directs the whole. Let us not listen, then, to the timid admonitions of theological ignorance, which shrinks with superstitious horror from the thoughts of accounting for every thing by the powers of nature, and considers these attempts as an approach to atheism. Philosophical disquisition will, on the contrary, exhibit these general laws of the universe, that wonderful concatenation and adjustment of every thing both material and intellectual, as the most striking instance of incomprehensible wisdom; which, by means so few and so simple, can produce effects which by their grandeur dazzle our imagination, and by their multiplicity elude all possibility of enumeration. Of all the obstacles which the weakness, the folly, or the sinful vanity of men, have thrown in the way of the theologian, there is none so fatal, so hostile to all his endeavours, as a cold and comfortless system of materialism, which the reasoning pride of man first engendered, which made a figure among a few speculatists in the last century, but was soon forgotten by the philosophers really busy with the observation of nature and of nature's God. It has of late reared up its head, being now cherished by all who wish to get rid of the stings of remorse, as the only opinion compatible with the peace of the licentious and the sensual: for we may say to them as Henry IV. said to the Prince of Wales, "Thy wish was, father Harry, to that thought." In vain will the divine attempt to lay this devil with the metaphysical exorcisms of the schools; it is philosophy alone that can detect the cheat. Philosophy singles out the characteristic phenomena which distinguish every substance; and philosophy never will hesitate in saying that there is a set of phenomena which characterise mind and another which characterise body, and that these are *toto cœlo* different. Continually appealing to fact, to the phenomena, for our knowledge of every cause, we shall have no difficulty in deciding that thought, memory, volition, joy, hope, are not compatible attributes with bulk, weight, elasticity, fluidity. *Tuta sub ægide Pallas*; philosophy will maintain the dignity of human nature, will detect the sophisms of the materialists, confute their arguments; and she alone will restore to the countenance of nature that ineffable beauty of which those would deprive her, who would take away the supreme Mind which shines from within, and gives life and expression to every feature.

84 Philosophical disquisition gives just notions of God and of our own souls.

View of Bacon's Philosophy

PHI

Philosophy || Philostratus.

Natural PHILOSOPHY. See *NATURAL Philosophy*, PHILOSOPHY, and PHYSICS.

Experimental PHILOSOPHY. See *EXPERIMENTAL Philosophy*.

Moral PHILOSOPHY. See *MORAL Philosophy*.

PHILOSTORGIUS, an ecclesiastical historian of the 4th century, was born in Cappadocia, and wrote an abridgment of ecclesiastical history, in which he treats Athanasius with some severity. This work contains many curious and interesting particulars. The best edition is that of Henry de Valois in Greek and Latin. There is also attributed to him a book against Porphyry.

PHILOSTRATUS (Flavius), was an ancient Greek author. He wrote the Life of Apollonius Tyanensis, and some other things which have come down to our time. Eusebius against Hierocles calls him an Athenian, because he taught at Athens; but Eunapius and Suidas always speak of him as a Lemnian: and he hints, in his Life of Apollonius, that he used to be at Lemnos when he was young. He frequented the schools of the sophists; and he mentions his having heard Damianus of Ephesus, Proclus Naucratitas, and Hippodromus of Larissa. This seems to prove that he lived in the reign of the emperor Severus, from 193 to 212, when those sophists flourished. He became known afterwards to Severus's wife Julia Augusta, and was one of those learned men whom this philosophic empress had continually about her. It was by her command that he wrote the Life of Apollonius Tyanensis, as he relates himself in the same place where he informs us of his connections with that learned lady. Suidas and Hesychius say that he was a teacher of rhetoric, first at Athens and then at Rome, from the reign of Severus to that of Philippus, who obtained the empire in 244.

Philostratus

Philostratus's celebrated work is his Life of Apollonius; which has erroneously been attributed to Lucian, because it has been printed with some of that author's pieces. Philostratus endeavours, as Cyril observes, to represent Apollonius as a wonderful and extraordinary person; rather to be admired and adored as a god than to be considered as a mere man. Hence Eunapius, in the preface to his Lives of the Sophists, says that the proper title of that work would have been, *The Coming of a God to Men*; and Hierocles, in his book against the Christians which was called *Philalethes*, and which was refuted by Eusebius in a work still extant, among other things drew a comparison between Apollonius and Jesus Christ. It has always been supposed that Philostratus composed his work with a view to discredit the miracles and doctrines of our Lord, by

Philoſtratus.

by ſetting up other miracles and other doctrines againſt them, and this ſuppoſition may be true; but that Apollonius was really an impoſtor and magician may not be ſo certain. He may, for what we know, have been a wiſe and excellent perſon; and it is remarkable, that Euſebius, though he had the worſt opinion of Philoſtratus's hiſtory, ſays nothing ill of Apollonius. He concluded that that hiſtory was written to oppoſe the hiſtory of Jeſus; and the uſe which the ancient infidels made of it juſtifies his opinion; but he draws no information from it with regard to Apollonius. It would have been improper to have done ſo; ſince the ſophiſtical and affected ſtyle of Philoſtratus, the ſources from whence he owns his materials to have been drawn, and, above all, the abſurdities and contradictions with which he abounds, plainly ſhow his hiſtory to be nothing but a collection of fables, either invented or at leaſt embelliſhed by himſelf.

The works of Philoſtratus, however, have engaged the attention of critics of the firſt claſs. Grævius had intended to have given a correct edition of them, as appears from the preface of Meric Caſaubon to a diſſertation upon an intended edition of Homer, printed at London in 1658, 8vo. So had Bentley, who deſigned to add a new Latin verſion of his notes; and Fabricius ſays that he ſaw the firſt ſheet of Bentley's edition printed at Leipſic in 1691. Both theſe deſigns were dropped. A very exact and beautiful edition was publiſhed at length at Leipſic, 1709, in folio, by Olearius, profeſſor of the Greek and Latin tongues in that univerſity; who has proved himſelf perfectly qualified for the work he undertook, and ſhown all the judgment, learning, and induſtry, that are required in an excellent editor.

See Apollonius, p. 127 col. 1. and Blount (Charles).

At the end of Apollonius's Life there are 95 Letters which go under his name. They are not, however, believed to be his; the ſtyle of them being very affected, and like that of a ſophiſt, while they bear in other reſpects all the marks of a forgery. Philoſtratus ſays that he ſaw a collection of Apollonius's Letters in Hadrian's library at Antium, but had not inſerted them all among theſe. They are ſhort, and have in them little elſe than moral ſentences. The Lives of the Sophiſts contain many things which are to be met with nowhere elſe. The Heroics of Philoſtratus are only a dialogue between a vintner of Thracian Cherſoneſus and a Phœnician, in which the former draws characters of Homer's heroes, and repreſents ſeveral things differently from that poet; and this upon the faith of Protelilaus's ghoſt, who had lately viſited his farm, which was not far from the tomb of this hero. Olearius conjectures, with much probability, that Philoſtratus's deſign in this dialogue was ſecretly to criticiſe ſome things in Homer, which he durſt not do openly on account of the great veneration then paid to him, and for fear of the odium which Zoilus and others had incurred by cenſuring him too freely. The images are elegant deſcriptions and illuſtrations of ſome ancient paintings and other particulars relating to the fine arts: to which Olearius has ſubjoined the deſcription of ſome ſtatues by Calliſtratus; for the ſame reaſon that he ſubjoined Euſebius's book againſt Hierocles to the Life and Letters of Apollonius, namely, becauſe the ſubjects of theſe reſpective works are related to each other. The laſt piece is a collection of Philoſtratus's Letters; but ſome of theſe, though it is not eaſy to determine which, were written by a nephew to our Philoſtratus, of the ſame name, as were alſo the laſt eighteen in the book of images. This is the reaſon why the title runs not *Philoſtrati*, but *Philoſtratorum quæ ſuperſunt omnia.*

Philotis & Philter.

There were many perſons of the name of Philoſtratus among the ancients; and there were many other works of the Philoſtratus here recorded, but no others are extant beſides thoſe we have mentioned.

PHILOTIS, a ſervant maid at Rome, ſaved her countrymen from deſtruction. After the ſiege of Rome by the Gauls, the Fidenates aſſembled an army, and marched againſt the capital, demanding all the wives and daughters in the city as the only conditions of peace. This demand aſtoniſhed the ſenators; and when they refuſed to comply, Philotis adviſed them to ſend all their female ſlaves diſguiſed in matron's clothes, and ſhe offered to march herſelf at the head. Her advice was followed; and when the Fidenates had feaſted late in the evening, and were quite intoxicated and fallen aſleep, Philotis lighted a torch as a ſignal for her countrymen to attack the enemy. The whole was ſucceſsful; the Fidenates were conquered; and the ſenate, to reward the fidelity of the female ſlaves, permitted them to appear in the dreſs of the Roman matrons.

PHILOXENUS, an officer of Alexander, who received Cilicia at the general diviſion of the provinces. ——A ſon of Ptolemy, who was given to Pelopidas as an hoſtage.——A dythyrambic poet of Cythera. He enjoyed the favour of Dionyſius tyrant of Sicily for ſome time, till he offended him by ſeducing one of his female ſingers. During his confinement Philoxenus compoſed an allegorical poem called *Cyclops*; in which he had delineated the character of the tyrant under the name of Polyphemus, and repreſented his miſtreſs under the name of Galatæa, and himſelf under that of Ulyſſes. The tyrant, who was fond of writing poetry, and of being applauded, removed Philoxenus from his dungeon; but the poet refuſed to purchaſe his liberty by ſaying things unworthy of himſelf, and applauding the wretched verſes of Dionyſius, and therefore he was ſent to the quarries. Being ſet at liberty, he ſome time after was aſked his opinion at a feaſt about ſome verſes which Dionyſius had juſt repeated, and which the courtiers had received with the greateſt applauſe. Philoxenus gave no anſwer, but he ordered the guards that ſurrounded the tyrant's table to take him back to the quarries. Dionyſius was pleaſed with his pleaſantry and with his firmneſs, and immediately forgave him. Philoxenus died at Epheſus about 380 years before Chriſt.

PHILTER, or Philtre, *(Philtrum)*, in pharmacy, &c. a ſtrainer.

Philter, is alſo uſed for a drug or preparation, which it is pretended will excite love.—The word is formed from the Greek φιλέω, "I love," or φίλος, "lover."

Philters are diſtinguiſhed into *true* and *ſpurious*, and were given by the Greeks and Romans to excite love. (See Love in medicine.) The ſpurious are ſpells or charms, ſuppoſed to have an effect beyond the ordinary laws of nature by ſome magic virtue; ſuch are thoſe ſaid to be given by old women, witches, &c.—The true

Philyca || Phinehas.

philters are thoſe ſuppoſed to work their effect by ſome natural and magnetical power. There are many grave authors who believe the reality of theſe philters, and allege matter of fact in confirmation of their ſentiments: among the reſt, Van Helmont, who ſays, that upon holding a certain herb in his hand for ſome time, and taking afterwards a little dog by the foot with the ſame hand, the dog followed him wherever he went, and quite deſerted his former maſter; which he pretends to account for thus: The heat communicated to the herb, not coming alone, but animated by the emanations of the natural ſpirits, determines the herb towards the man, and identifies it to him: having then received this ferment, it attracts the ſpirit of the other object magnetically, and gives it an amorous motion.—But this is mere cant; and all philters, whatever facts may be alleged, are mere chimeras.

PHILYCA, in botany. See PHYLICA.

PHILYRA (fab. hiſt.), was one of the Oceanides, whom Saturn met in Thrace. The god, to eſcape from the vigilance of Rhea, changed himſelf into a horſe, to enjoy the company of Philyra, by whom he had a ſon half a man and half a horſe, called *Chiron*. Philyra was ſo aſhamed of giving birth to ſuch a monſter, that ſhe entreated the gods to change her nature. She was accordingly metamorphoſed into a tree, called by her name among the Greeks.

PHIMOSIS, in medicine, a diſorder of the penis, in which the prepuce is ſo ſtrict or tenſe, that it cannot be drawn back over the glans. See SURGERY.

PHINEHAS, or, as the Jews pronounce it, PINCHAS, was the ſon of Eleazar, and grandſon of Aaron. He was the third high prieſt of the Jews, and diſcharged this office from the year of the world 2571, till towards the year 2590. He is particularly commended in Scripture for the zeal he ſhowed in vindicating the glory of God, when the Midianites had ſent their daughters into the camp of Iſrael, to tempt the Hebrews to fornication and idolatry. For Zimri having publicly entered into the tent of a Midianitiſh woman named *Cozbi*, Phinehas aroſe up from among the people (Numb. xxv. 7, &c.), took a javelin in his hand, entered after Zimri into that infamous place, and ſtabbed both man and woman at one blow, in thoſe parts that were chiefly concerned in this criminal commerce. Upon which the plague or diſtemper ceaſed with which the Lord had already begun to puniſh the Iſraelites. This happened in the year of the world 2553.

Then the Lord ſaid to Moſes, Phinehas the ſon of Eleazar the high-prieſt has turned away my wrath from the children of Iſrael, becauſe he has been zealous in my cauſe, and has hindered me from deſtroying them: wherefore acquaint him, that I give him my covenant of peace, and the prieſthood ſhall be given to his poſterity by a perpetual covenant, becauſe he has been zealous for his God, and has made atonement for the crime of the children of Iſrael. This promiſe that the Lord made to Phinehas, to give him the prieſthood by a perpetual covenant, interpreters obſerve, evidently included this tacit condition, that his children ſhould continue faithful and obedient; ſince we know that the prieſthood paſſed out of the family of Eleazar and Phinehas to that of Ithamar, and that it returned not to the poſterity of Eleazar till after about 150 years.

This is what we find concerning the tranſlation of the high-prieſthood from one family to the other. This dignity continued in the race of Phinehas, from Aaron down to the high-prieſt Eli, for about 335 years. See AARON. Phinehas, Phineus.

The manner and cauſes of this change are unknown. It re-entered again into the family of Eleazar under the reign of Saul, when this prince having put to death Abimelech, and the other prieſts of Nob, he gave the high-prieſthood to Zadok, who was of the race of Phinehas. At the ſame time, David had Abiathar with him, of the race of Eli, who performed the functions of high-prieſt. So that after the death of Saul, David continued the prieſthood to Zadok and Abiathar conjointly. But towards the end of David's reign, Abiathar having eſpouſed the intereſt of Adonijah, to the prejudice of Solomon, he was in diſgrace, and Zadok only was acknowledged as high-prieſt. The prieſthood continued in his family till after the captivity of Babylon, and even to the deſtruction of the temple. But from the beginning of Zadok's prieſthood alone, and the excluſion of Abiathar, to the ruin of the temple, is 1084 years.

We read of another memorable action of Phinehas, in which he ſtill ſhowed his zeal for the Lord. This was when the Iſraelites that were beyond Jordan had raiſed upon the banks of this river a vaſt heap of earth (Joſh. xxii. 30, 31.). Thoſe on the other ſide fearing they were going to forſake the Lord, and ſet up another religion, deputed Phinehas and other chief men among them, to go and inform themſelves of the reaſon of erecting this monument. But when they had found that it was in commemoration of their union and common original, Phinehas took occaſion from thence to praiſe the Lord, ſaying, "We know that the Lord is with us, ſince you are not guilty of that prevarication we ſuſpected you were."

We do not exactly know the time of the death of Phinehas. But as he lived after the death of Joſhua, and before the firſt ſervitude under Chuſhan-riſhathaim, during the time that there were neither kings nor judges in the land, and every one did what was right in his own eyes (Judges xvii. 6. xviii. 1. xxi. 24.); his death is put about the year of the world 2590. It was under his pontificate that the ſtory of Micah happened, as alſo that of the tribe of Dan, when they made a conqueſt of Laiſh; and the enormity that was committed upon the wife of the Levite of the mountain of Ephraim (Judges xx. 28.). Phinehas's ſucceſſor in the high-prieſthood was Abiezer, or Abiſhuah.

The Rabbins allow a very long life to Phinehas. There are ſome who believe he lived to the time of the high-prieſt Eli, or even to the time of Samſon. Others will have it, that he was the ſame as Eli, or rather as the prophet Elias, which would ſtill prolong his life for ſeveral ages.

PHINEUS (fab. hiſt.), was a ſon of Agenor, king of Phœnicia, or according to ſome of Neptune. He became king of Thrace, or, according to the greater part of mythologiſts, of Bithynia. He married Cleopatra the daughter of Boreas, called by ſome *Cleobula*, by whom he had Plexippus and Pandion. After her death, he married Idæa the daughter of Dardanus. Idæa, jealous of his former wife's children, accuſed them of attempts upon their father's life and crown, or, as others aſſert, of attempts upon her virtue; on which they were condemned by

Phlebotomy || Phlegon.

Phineus to be deprived of their eyes. This cruelty was soon after punished by the gods; for Phineus suddenly became blind, and the Harpies were sent by Jupiter to keep him in continual alarm, and to spoil the meats which were placed on his table. He was afterwards delivered from these dangerous monsters by his brothers-in-law Zetes and Calais, who pursued them as far as the Strophades. He likewise recovered his sight by means of the Argonauts, whom he had received with great hospitality, and whom he instructed in the easiest and speediest way of arriving in Colchis. The causes of the blindness of Phineus are a matter of dispute among the ancients; some supposing that this was inflicted by Boreas for his cruelty to his grandson; while others attribute it to the anger of Neptune, because he had directed the sons of Phryxus how to escape from Colchis to Greece. Many, however, imagine that it proceeded from his having rashly attempted to develope futurity; while others assert that Zetes and Calais put out his eyes on account of his cruelty to their nephews. The second wife of Phineus is called by some *Dia*, *Eurytia*, *Danae*, and *Idothea*.—He was killed by Hercules.

PHLEBOTOMY, the opening of a vein with a proper sharp-edged and pointed instrument, in order to let out a certain quantity of blood either for the preservation or recovery of a person's health. See SURGERY.

PHLEGM, in the animal economy, one of the four humours whereof the ancients supposed the blood to be composed. The chemists make phlegm or water an elementary body; the characters of which are fluidity, insipidity, and volatility.

PHLEGMAGOGUES, in medicine, a term anciently made use of for such medicines as were supposed to be endowed with the property of purging off phlegm; such as hermodactyls, agaric, turbith, jalap, &c.

PHLEGMATIC, among physicians, an appellation given to that habit or temperament of body wherein phlegm is predominant; which gives rise to catarrhs, coughs, &c.

PHLEGMON, denotes an external inflammation and tumor, attended with a burning heat.

PHLEGON, who was surnamed *Trallianus*, was born in Trallis a city of Lydia. He was the emperor Hadrian's freed man, and lived to the 18th year of Antoninus Pius; as is evident from his mentioning the consuls of that year. He wrote several works of great erudition, of which we have nothing left but fragments. Among these was a History of the Olympiads, A Treatise of Long-lived Persons, and another of Wonderful Things; the short and broken remains of which Xylander translated into Latin, and published at Basil in 1568, with the Greek and with notes. Meursius published a new edition of them with his notes at Leyden, in 1622. The titles of part of the rest of Phlegon's writings are preserved by Suidas. It is supposed that the History of Hadrian, published under Phlegon's name, was written by Hadrian himself, from this passage of Spartianus: "Hadrian thirsted so much after fame (says he), that he gave the books of his own life, drawn up by himself, to his freedmen, commanding them to publish those books under their own names; for we are told that Hadrian wrote Phlegon's books."

Phlegon's name has been more familiar among the moderns, and his fragments have had a greater degree of regard paid to them than perhaps they deserve, merely because he has been supposed to speak of the darkness which prevailed during our Lord's passion. The book in which the words are contained is lost; but Eusebius has preserved them in his *Chronicon*. They are these: "In the 4th year of the 202d Olympiad, there was a greater and more remarkable eclipse of the sun than any that had ever happened before: for at the sixth hour the day was so turned into the darkness of night, that the very stars in the firmament were visible; and there was an earthquake in Bithynia which threw down many houses in the city of Nicæa." Eusebius thinks that these words of Phlegon related to the prodigies which accompanied Christ's crucifixion; and many other fathers of the church have thought the same: but this opinion is liable to many difficulties; for no man had ever a stronger desire than Phlegon to compile marvellous events, and to observe the supernatural circumstances in them. How was it then possible that a man of this turn of mind should not have taken notice of the most surprising circumstance in the eclipse which it is imagined he hints at, viz. its happening on the day when the moon was at the full? But had Phlegon done this, Eusebius would not have omitted it; and Origen would not have said that Phlegon had omitted this particular.

Phlegon, Phlogiston.

It was a matter of controversy some time ago, whether Phlegon really spoke of the darkness at the time of our Lord's passion; and many dissertations were written on both sides of the question. This dispute was occasioned by the above passage from Phlegon being left out in an edition of Clarke's Boyle's Lectures, published after his death, at the instance of Sykes, who had suggested to Clarke, that an undue stress had been laid upon it. Whiston, who informs us of this affair, expresses great displeasure against Sykes, and calls "the suggestion groundless." Upon this, Sykes published "A Dissertation on the Eclipse mentioned by Phlegon: or, "An Inquiry whether that Eclipse had any relation to the darkness which happened at our Saviour's Passion, 1732," 8vo. Sykes concludes it to be most probable that Phlegon had in view a natural eclipse which happened November 24. in the 1st year of the 202d Olympiad, and not in the 4th year of the Olympiad in which Christ was crucified. Many pieces were written against him, and to some of them he replied; but perhaps it is a controversy which concerns the learned world merely, since the cause of religion is but little affected by it.

Photius blames Phlegon for expatiating too much on trifles, and for collecting too great a number of answers pronounced by the oracles. "His style (he tells us) is not altogether flat and mean, nor does it everywhere imitate the Attic manner of writing. But otherwise, the over nice accuracy and care with which he computes the Olympiads, and relates the names of the contests, the transactions, and even oracles, is not only very tiresome to the reader, whereby a cloud is thrown over all other particulars in that book, but the diction is thereby rendered unpleasant and ungrateful; and indeed he is every moment bringing in the answers pronounced by all kinds of deities."

PHLOGISTON, a term used by chemists to express a principle which was supposed to enter the composition of various bodies.

Phlogiſton. The bodies which were thought to contain it in the largeſt quantity are the inflammable ſubſtances; and the property which theſe ſubſtances poſſeſs of being ſuſceptible of inflammation was thought to depend on this principle; and hence it was ſometimes called the *Principle of Inflammability*. Inflammation, according to this doctrine, was the ſeparation of *this principle* or *phlogiſton* from the other matter which compoſed the combuſtible body. As its ſeparation was always attended with the emiſſion of light and heat, ſome of the chemiſts concluded that it was light and heat combined with other matter in a peculiar manner, or that it was ſome highly elaſtic and very ſubtile matter, on certain modifications of which heat and light depended.

Another claſs of bodies which were ſuppoſed to contain phlogiſton are the metals; and the chemiſts ſuppoſed that the peculiar luſtre of the metals depended on this principle. Of this they thought themſelves convinced by the evidence of their ſenſes in two ways; viz. firſt, becauſe by expoſing a metal to the action of a long continued heat, it loſt its metallic luſtre, and was converted into an earthy-like ſubſtance called *calx metallicus*; and ſecondly, becauſe by mixing this calx with any inflammable ſubſtance whatever, and ſubjecting the mixture to certain operations, the inflammable matter diſappeared, and the metal was reſtored to its former ſtate and luſtre, without ſuffering much diminution in quantity, eſpecially if the proceſſes had been conducted with care and attention.

This fact relative to the metals was thought to be a full demonſtration of itſelf, independent of other proofs which were brought to ſupport the doctrine. Theſe were, that a combuſtible body, by the act of inflammation (*i.e.* by the diſſipation of its phlogiſton in the form of heat and light), was converted into a body that was no longer combuſtible, but which might have its property of combuſtibility reſtored to it again by mixing the incombuſtible remains with any kind of inflammable matter, and ſubmitting the mixture to certain proceſſes. In this way the body was reſtored to its former ſtate of inflammability.

They were alſo at ſome pains to prove that the *phlogiſton* or the *principle of inflammability* was the ſame in all inflammable bodies and in the metals. This identity of phlogiſton they thought to be evident from the fact, that the calx of a metal might be reſtored to its metallic ſtate, or that the remains after the combuſtion of a combuſtible body might be again reſtored to its original ſtate of combuſtibility by the addition of any inflammable body whatever, taken either from the animal, vegetable, or mineral kingdoms.

Theſe and ſeveral other facts were brought to prove, not only the exiſtence of phlogiſton, but its effects in mixture with other ſubſtances; and the objections which were made againſt the doctrine were removed with wonderful ingenuity. The chief objection againſt it was, that if the inflammation of a combuſtible body, or the converſion of a metal into calx, depends on the diſſipation or extrication of phlogiſton; then it muſt follow, that the remains of a combuſtible body after inflammation, and the calx of the metal, muſt be leſs than the matter from which they were produced: but this is contrary to fact; for when we collect with care all the vapour into which the pureſt inflammable bodies are converted by combuſtion, theſe incombuſtible remains are much heavier than the inflammable body from which they were produced, and the calx into which a metal is converted by long expoſure to the action of heat is heavier than the metal from which it was produced. This conſideration made ſeveral people doubt of the truth of the doctrine; but the objection was removed by ſaying, that phlogiſton was ſo ſubtile, as not only to have no weight, but to poſſeſs an abſolute levity; and that when it was taken from an abſolutely heavy body, that body muſt, by loſing ſo much abſolute levity, become heavier, in the ſame manner as the algebraiſts ſay, that a poſitive quantity is augmented by the ſubſtraction of a negative quantity. This ſophiſm ſatisfied the minds of moſt of the chemiſts, eſpecially thoſe who were algebraiſts. Phlogiſton.

The opinion that phlogiſton was heat and light ſomehow combined with other matter, was proved, not only by the fact, that heat and light were emitted from a combuſtible body during its combuſtion, but from the reduction of certain metallic calces to their original metallic ſtate again, at leaſt in ſome degree, by ſimple expoſure to heat and light. The white calx of ſilver for inſtance, when expoſed in cloſe ſealed glaſs veſſels to the light and heat of the ſun, reſumes a black tinge, and is in part reſtored to its metallic luſtre without any addition whatever; but then this reſtoration, like the others above mentioned, is attended with a loſs of weight.

Beſides conſtituting the principal part of inflammable bodies and metals, phlogiſton was thought to be the cauſe of colour in all vegetable and animal ſubſtances. This was concluded from the fact of plants growing white when defended from the action of the ſun's rays, and in having their green colour reſtored by expoſure to his rays again; and ſo far did the chemiſts ſuffer themſelves to be deceived, that they actually thought the green colouring matter, which they extracted from freſh plants by certain chemical proceſſes, to be an inflammable ſubſtance. A very material objection was made to this argument, viz. if plants owe their colour to phlogiſton imparted by the ſun's rays, why do the ſun's rays deſtroy vegetable colours that are expoſed to them? for we know that the ſun's rays are very effectual in diminiſhing the luſtre of cloth dyed with vegetable colours, and in bleaching or taking out various ſtains from linen and other ſubſtances. All this was removed by ſaying, that the ſun's rays poſſeſſed different powers on living and on dead vegetable matter, and that the living vegetables had the power of abſorbing phlogiſton from the ſun's rays, which dead vegetable matter had not.

Since the exiſtence of phlogiſton, as a chemical principle in the compoſition of certain bodies, is now fully proved to be falſe, we ſhall not trouble our readers with any farther obſervations on it, except adding, that although the chemiſts were ſatisfied with the proofs they gave of its reality, they were never able to exhibit it in a ſeparate ſtate, or ſhow it in a pure form, unmixed with other matter.

Phlogiſton ſeems to have been admitted as a principle in the compoſition of certain bodies, and to have been ſuppoſed the cauſe of certain modifications of matter, merely with a view to explain ſome of thoſe natural phenomena which the authors of it were unable to explain on other principles. Subſequent diſcoveries in natural philoſophy and in chemiſtry have repre-

Phlogiſton. repreſented things in a very different light from that in which the old chemiſts viewed them. The old chemiſts knew nothing but chemiſtry; they ſeldom extended their views to the obſervation of objects beyond their laboratories, and it was not till philoſophers became chemiſts, and chemiſts philoſophers, that chemiſtry began to wear the garb of ſcience. The epoch in which this change began was in the time of Lord Verulam, who firſt removed the dimneſs from the chemiſt's eyes, and to him ſucceeded the Honourable Mr Boyle. Sir Iſaac Newton, with the little aſſiſtance which his predeceſſors in this branch of ſcience afforded him, is in reality the firſt who eſtabliſhed chemiſtry on ſcientific ground. It muſt, however, be acknowledged, that although he made a great progreſs, he left much undone; and ſubſequent chemiſts, who were leſs accurate obſervers of nature, admitted principles unwarrantably. From the time of Sir Iſaac Newton till the middle of the 18th century, no real improvement was made in ſcientific chemiſtry; and the progreſs this ſcience has made ſince that period is owing to the important diſcovery of the exiſtence of heat in a ſtate of compoſition with other matter. Heat thus combined loſes its activity or becomes inſenſible, juſt in the ſame way as any other active ſubſtance loſes its apparent qualities in compoſition. Acids, for example, when combined in a certain proportion with ſubſtances for which they have ſtrong attraction, as alkalis or abſorbent earths, loſe all their obvious acid qualities, and the compound turns out mild, and totally conceals the acid which it contains. In a ſimilar manner, heat, when combined in certain proportions with other matter, loſes its ſenſible qualities, and the compound conceals the heat which it contains. Heat, in this combined ſtate, was called by its ingenious diſcoverer, Dr Black, *latent heat*, and it was found to be very abundant in the atmoſphere, which owes its exiſtence as an elaſtic fluid to the quantity of latent heat that it contains. After this diſcovery was made, Dr Crawford, conſidering that air was abſorbed by a burning body, concluded that the heat which appears in the combuſtion of a combuſtible body, is the heat that had before exiſted in the air which was conſumed by the burning body. Mr Lavoiſier and others, proſecuting this inquiry, found that the combuſtible body, while it is burning, unites with the baſis of the air, and that the heat which the air contained, and which was the cauſe of the air exiſting in the ſtate of air, is expelled. This abſorption of the baſis of the air by the burning body, and the reduction of this baſis to a ſolid form, accounts for the increaſe of weight which a body acquires by burning; or, in other words, gives a reaſon why the matter into which a combuſtible body is converted by combuſtion, is heavier than the body from which it was produced. The ſame abſorption of air is obſervable, when a metal is converted into a calx, and the additional weight of the calx is found to be preciſely equal to the weight of the air abſorbed during the calcination. On theſe principles, therefore, we now explain the phenomena in a much more ſatisfactory manner than by the ſuppoſition of phlogiſton, or a principle of inflammability.

This theory is more fully elucidated in ſeveral articles in the former part of this work; we ſhall not, therefore, in this place, repeat what the reader may find under the words HEAT, INFLAMMATION, FLAME, CHEMISTRY, CALCINATION *of Metals*, OXYGEN, &c.

Phlogoniæ, Phlomis.

PHLOGONIÆ, a claſs of compound, inflammable, and metallic foſſils, found in ſmall maſſes of determinately angular figures; comprehending the pyrieubia, pyroctogonia, and pyripolygonia.

PHLOMIS, the SAGE-TREE, or *Jeruſalem Sage*; a genus of the gymnoſpermia order, belonging to the didynamia claſs of plants. There are 14 ſpecies, all of which have perennial roots, and of many the ſtalks alſo are perennial. The latter riſe from two to five or ſix feet high; and are adorned with yellow, blue, or purple flowers in whorls. They are all ornamental plants; and deſerve a place in gardens, as they are ſufficiently hardy to endure the ordinary winters in this climate: they require, however, a pretty warm ſituation.

Planting and Ornamental Gardening.

There are two ſpecies of this plant, which are peculiarly adapted to the ſhrubbery, viz. the *Phlomis fruticoſa*, a native of Spain and Sicily, and the *Phlomis purpurea*. Of the firſt ſpecies there are three varieties, 1. The *broad-leaved Jeruſalem Sage-tree*, is now very common in our gardens. Its beauty is great, and its culture very eaſy. It grows to be about five feet high, and ſpreads its branches without order all around. The older branches are covered with a dirty, greeniſh, dead, falling, ill-looking bark; and this is the worſt property of this ſhrub: but the younger ſhoots are white and beautiful; they are four-cornered, woolly, and ſoft to the touch. The leaves are roundiſh and oblong, and moderately large; and theſe grow oppoſite at the joints of the ſhrub on long footſtalks. They are hoary to a degree of whiteneſs, and their footſtalks alſo are woolly, white, tough, and ſtrong. The flowers are produced in June, July, and Auguſt, at the top joints of the young ſhoots, in large whorled bunches. They are of the labiated kind, each conſiſting of two lips, the upper end of which is forked, and bends over the other. A finer yellow can hardly be conceived than the colour of which they are poſſeſſed; and being large, they exhibit their golden flowers at a great diſtance, cauſing thereby a handſome ſhow. 2. The *narrow leaved Jeruſalem Sage tree*, is of lower growth than the other, ſeldom riſing higher than a yard or four feet. This ſhrub is in every reſpect like the other; only the ſhoots ſeem to have a more upright tendency of growth. The leaves alſo, which are narrower, are more inclined to a lanceolate form: They are numerous in both the ſorts, and hide the deformity of the bark on the older ſtems, which renders them leſs exceptionable on that account. In ſhort, theſe ſorts are qualified for ſhrubberies of all kinds, or to be ſet in borders of flower-gardens, where they will flower, and be exceeded even in that reſpect by very few ſhrubs. 3. *Cretan Sage-tree*, is ſtill of lower growth than either of the former, ſeldom ariſing to a yard in height. The leaves are of the ſame white hoary nature; they are very broad, and ſtand on long footſtalks. The flowers are alſo of a delightful yellow colour, very large, and grow in large whorls, which give the plant great beauty.

The ſecond ſpecies, which is *Purple Phlomis* or *Portugal Sage*, is four feet high; the ſtalks are woody, and ſend forth ſeveral angular branches, which are covered with a white bark. The leaves are ſpear-ſhaped,

Phlomis || Phoca.

ped, oblong, woolly underneath, crenated, and grow on ſhort footſtalks. The flowers are produced in whorls from the joints of the branches. They are of a deep purple colour, and have narrow involucra. They appear in June and July, but are not ſucceeded by ripe ſeeds in England. There is a variety of this ſpecies with iron-coloured flowers, and another with flowers of a bright purple.

There are ſome other ſhrubby ſorts of phlomis, of great beauty; but theſe not only often loſe their leaves, and even branches, from the firſt froſt, but are frequently wholly deſtroyed, if it happens to be ſevere. They are low ſhrubs, very beautiful, and look well among perennial flowers, where they will not only claſs as to ſize with many of that ſort, but, being rather tender, may with them have ſuch extraordinary care as the owner may think proper to allow them.

The propagation of the above ſorts is, as we have already hinted, very eaſy, and is accompliſhed either by layers or cuttings. 1. If a little earth be thrown upon the branches any time in the winter, they will ſtrike root and be good plants by the autumn following, fit for any place. Thus eaſy is the culture by that method. 2. The cuttings will alſo grow, if planted any time of the year. Thoſe planted in winter ſhould be the woody ſhoots of the former ſummer: Theſe may be ſet cloſe in a ſhady border; and being watered in dry weather, will often grow. This ſhrub may be propagated by young ſlips alſo, in any of the ſummer months. Theſe ſhould be planted in a ſhady border, like ſage, and well watered. If the border is not naturally ſhady, the beds muſt be hooped, and covered with matting in hot weather. Watering muſt be conſtantly afforded them; and with this care and management many of them will grow.

PHLOX, Lychnidea, or *Baſtard Lychnis;* a genus of the monogynia order, belonging to the pentandria claſs of plants. There are ſeven ſpecies, all of them natives of North America. They have perennial roots, from which ariſe herbaceous ſtalks from nine inches to two feet in height, adorned with tubulated flowers of a purple colour. They are propagated by offsets, and will bear the winters in this country. They require a moiſt rich ſoil, in which they thrive better and grow taller than in any other.

PHLYCTENÆ, in medicine, ſmall eruptions on the ſkin.

PHOCA, in zoology, a genus of quadrupeds of the order of feræ. There are ſix parallel fore-teeth in the upper jaw, the outermoſt being larger; and four blunt, parallel, diſtinct, equal fore-teeth in the under jaw. There is but one dog-tooth, and five or ſix three-pointed grinders; and the hind feet are united ſo as to reſemble a ſheep's tail. There are a variety of ſpecies, the principal of which are,

1. The urſina, ſea bear, or urſine ſeal, has external ears. The male is greatly ſuperior in ſize to the female. The bodies of each are of a conic form, very thick before, and taper to the tail. The length of a large one is eight feet; the greateſt circumference, five feet; near the tail, 20 inches; and the weight is about 800 lb. The noſe projects like that of a pug-dog, but the head riſes ſuddenly; the teeth lock into one another when the mouth is ſhut: the tongue is large; the eyes are large and prominent, and may be covered at pleaſure by a fleſhy membrane. The length of the fore-legs is 24 inches; they are like thoſe of other quadrupeds, not immerſed in the body like thoſe of ſeals; the feet are formed with toes like thoſe of other animals, but are covered with a naked ſkin, ſo that externally they ſeem to be a ſhapeleſs maſs; the hind-legs are fixed to the body quite behind, like thoſe of common ſeals; but are capable of being brought forward, ſo that the animal makes uſe of them to ſcratch its head. Phoca.

Theſe animals are found in the northern ſeas. They are found in amazing quantities between Kamtſchatka and America; but are ſcarcely known to land on the Aſiatic ſhore: nor are they ever taken except in the three Kurilian iſlands, and from thence in the Bobrowoie More, or Beaver Sea, as far as the Kronoſki headland, off the river Kamtſchatka, which comprehends only from 50 to 56 north latitude. It is obſervable that they never double the ſouthern cape of the peninſula, or are found on the weſtern ſide in the Penſchinſka ſea: but their great reſort has been obſerved to be to Bering's iſlands. They are as regularly migratory as birds of paſſage. They firſt appear off the three Kurili iſlands and Kamtſchatka in the earlieſt ſpring. There is not one female which does not come pregnant. Such as are then taken are opened, the young taken out and ſkinned. They are found in Bering's iſland only on the weſtern ſhore, being the part oppoſite to Aſia, where they firſt appear on their migration from the ſouth. *Pennant's Arctic Zoology.*

Urſine ſeals are alſo found in the ſouthern hemiſphere, even from under the line, in the iſle of Gallipagos (A), to New Georgia, in ſouth latitude 54. 15. and weſt longitude 37. 15. In the intermediate parts, they are met with in New Zealand, in the iſle of Juan Fernandez, and its neighbour Maſſa Fuera, and probably along the coaſts of Chili to Terra del Fuego and Staten Land. In Juan Fernandez, Staten Land, and New Georgia, they ſwarm; as they do at the northern extremity of this vaſt ocean. Thoſe of the ſouthern hemiſphere have alſo their ſeaſons of migration.—Alexander Selkirk, who paſſed three lonely years on the iſle of Juan Fernandez, remarks that they come aſhore in June, and ſtay till September. Captain Cook found them again in their place of remigration in equal abundance, on Staten Land and New Georgia in the months of December and January; and Don Pernety found them on the Falkland iſlands in the month of February. According to the Greenlanders, this ſpecies inhabits the ſouthern parts of their country. They call it *Auvekajak.* That it is very fierce, and tears to pieces whatſoever it meets; that it lives on land as well as in water, and is greatly dreaded by the hunters.

During the three months of ſummer they lead a moſt indolent

(A) *Woodes Roger's Voy.* 265. He ſays that they are neither ſo numerous there, nor is their fur ſo fine, as thoſe on Juan Fernandez, which is ſaid to be extremely ſoft and delicate.

Phoca. indolent life: they arrive at the iſlands vaſtly fat; but during that time they are ſcarce ever in motion, confine themſelves for whole weeks to one ſpot, ſleep a great part of the time, eat nothing, and, except the employment the females have in ſuckling their young, are totally inactive. They live in families: each male has from 8 to 50 females, whom he guards with the jealouſy of an eaſtern monarch; and though they lie by thouſands on the ſhores, each family keeps itſelf ſeparate from the reſt, and ſometimes, with the young and unmarried ones, amount to 120. The old animals, which are deſtitute of females, or deſerted by them, live apart, and are exceſſively ſplenetick, peeviſh, and quarrelſome: are exceeding fierce, and ſo attached to their old haunts, that they would die ſooner than quit them. They are monſtrouſly fat, and have a moſt hircine ſmell. If another approaches their ſtation, they are rouſed from their indolence, and inſtantly ſnap at it, and a battle enſues; in the conflict, they perhaps intrude on the ſeat of another: this gives new cauſe of offence, ſo in the end the diſcord becomes univerſal, and is ſpread through the whole ſhore.

The other males are alſo very irafcible: the cauſes of their diſputes are generally theſe. The firſt and moſt terrible is, when an attempt is made by another to ſeduce one of their miſtreſſes or a young female of the family. This inſult produces a combat; and the conqueror is immediately followed by the whole ſeraglio, who are ſure of deſerting the unhappy vanquiſhed. The ſecond reaſon of a quarrel is, when one invades the ſeat of another: the third ariſes from their interfering in the diſputes of others. Theſe battles are very violent; the wounds they receive are very deep, and reſemble the cuts of a ſabre. At the end of a fight they fling themſelves into the ſea, to waſh away the blood.

The males are very fond of their young, but very tyrannical towards the females; if any body attempts to take their cub, the male ſtands on the defenſive, while the female makes off with the young in her mouth; ſhould ſhe drop it, the former inſtantly quits his enemy, falls on her, and beats her againſt the ſtones, till he leaves her for dead. As ſoon as ſhe recovers, ſhe comes in the moſt ſuppliant manner to the male, crawls to his feet, and waſhes them with her tears: he, in the mean time, ſtalks about in the moſt inſulting manner; but in caſe the young one is carried off, he melts into the deepeſt affliction, and ſhows all ſigns of extreme concern. It is probable that he feels his misfortunes the more ſenſibly, as the female generally brings but one at a time, never more than two.

They ſwim very ſwiftly, at the rate of ſeven miles an hour. If wounded, they will ſeize on the boat, and carry it along with vaſt impetuoſity, and oftentimes ſink it. They can continue a long time under water. When they want to climb the rocks, they faſten with the fore-paws, and ſo draw themſelves up. They are very tenacious of life, and will live for a fortnight after receiving ſuch wounds as would immediately deſtroy any other animal.

Pennant, ibid. The Kamtſchatkans take them by harpooning, for they never land on their ſhore. To the harpoon is faſtened a long line, by which they draw the animal to the boat after it is ſpent with fatigue; but in the chaſe, the hunters are very fearful of too near an approach, leaſt the animal ſhould faſten on, and ſink their veſſel. Phoca.

The uſes of them are not great. The fleſh of the old males is rank and nauſeous; that of the females is ſaid to reſemble lamb; of the young ones roaſted, a ſucking pig. The ſkins of the young, cut out of the bellies of the dams, are eſteemed for clothing, and are ſold for about three ſhillings and fourpence each; thoſe of the old for only four ſhillings.

Their remigration is in the month of September, when they depart exceſſively lean, and take their young with them. On their return, they again paſs near the ſame parts of Kamtſchatka which they did in the ſpring. Their winter retreats are quite unknown; it is probable that they are the iſlands between Kurili and Japan, of which we have ſome brief accounts, under the name of *Compagnie Land*, *States Land*, and *Jeſo Gaſima*, which were diſcovered by Martin Uriel in 1642. It is certain, that by his account the natives employed themſelves in the capture of ſeals. Sailors do not give themſelves the trouble of obſerving the nice diſtinction of ſpecific marks; we are therefore at liberty to conjecture thoſe which he ſaw to be our animals, eſpecially as we can fix on no more convenient place for their winter quarters. They arrive along the ſhores of the Kurili iſlands, and part of thoſe of Kamtſchatka, from the ſouth. They land and inhabit only the weſtern ſide of Bering's iſle which faces Kamtſchatka; and when they return in September, their route is due ſouth, pointing towards the diſcoveries of Uriel. Had they migrated from the ſouth-eaſt as well as the ſouth-weſt, every iſle, and every ſide of every iſle, would have been filled with them; nor ſhould we have found (as we do) ſuch a conſtant and local reſidence.

2. The leonina, ſea-lion, or bottlenoſe, is found near the ſouth pole. One variety of this ſpecies is deſcribed at ſome length by the publiſher of Anſon's voyage. However, according to others who have written on this ſubject, the name of *ſea-lion* belongs not ſo properly to this as to another, which has a mane like a true lion. Of theſe we have the following account from Pernety's Hiſtorical Journal. "The hair that covers the back part of the head, neck, and ſhoulders, is at leaſt as long as the hair of a goat. It gives this amphibious animal an air of reſemblance to the common lion of the foreſt, excepting the difference of ſize. The ſea-lions of the kind I ſpeak of are 25 feet in length, and from 19 to 20 in their greateſt circumference. In other reſpects they reſemble the common ſea-lions. Thoſe of the ſmall kind have a head reſembling a maſtiff's, with cloſe cropt ears.

"The teeth of the ſea-lions which have manes, are much larger and more ſolid than thoſe of the reſt. In theſe, all the teeth which are inſerted into the jaw-bone are hollow. They have only four large ones, two in the lower and two in the upper jaw. The reſt are not even ſo large as thoſe of a horſe. I brought home one belonging to the true ſea-lion, which is at leaſt three inches in diameter, and ſeven in length, though not one of the largeſt. We counted 22 of the ſame ſort in the jaw-bone of one of theſe lions, where five or ſix were wanting. They were entirely ſolid, and projected ſcarce more than an inch, or an inch and

Phoca. a half beyond their ſockets. They are nearly equal in ſolidity to flint, and are of a dazzling white. Several of our ſeamen took them for white flints when they found them upon the ſhore. I could not even perſuade them that they were not real flints, except by rubbing them againſt each other, or breaking ſome pieces off, to make them ſenſible that they exhaled the ſame ſmell as bones and ivory do when they are rubbed or ſcraped. Phoca.

"Theſe ſea-lions that have manes are not more miſchievous or formidable than the others. They are equally unwieldy and heavy in their motions; and are rather diſpoſed to avoid than to fall upon thoſe who attack them. Both kinds live upon fiſh and water-fowl, which they catch by ſurpriſe. They bring forth and ſuckle their young ones among the corn flags, where they retire at night, and continue to give them ſuck till they are large enough to go to ſea. In the evening you ſee them aſſembling in herds upon the ſhore, and calling their dams in cries ſo much like lambs, calves, and goats, that, unleſs appriſed of it, you would eaſily be deceived. The tongue of theſe animals is very good eating: we preferred it to that of an ox or calf. For a trial we cut off the tip of the tongue hanging out of the mouth of one of theſe lions which was juſt killed. About 16 or 18 of us eat each a pretty large piece, and we all thought it ſo good, that we regretted we could not eat more of it.

"It is ſaid that their fleſh is not abſolutely diſagreeable. I have not taſted it: but the oil which is extracted from their greaſe is of great uſe. This oil is extracted two ways; either by cutting the fat in pieces, and melting it in large cauldrons upon the fire; or by cutting it in the ſame manner upon hurdles, or pieces of board, and expoſing them to the ſun, or only to the air: this greaſe diſſolves of itſelf, and runs into veſſels placed underneath to receive it.—Some of our ſeamen pretended, that this laſt ſort of oil, when it is freſh, is very good for kitchen uſes: this, as well as the other, is commonly uſed for dreſſing leather for veſſels, and for lamps. It is preferred to that of the whale: it is always clear, and leaves no ſediment.

"The ſkins of the ſea-lions are uſed chiefly in making portmanteaus, and in covering trunks. When they are tanned, they have a grain almoſt like Morocco. They are not ſo fine, but are leſs liable to tear, and keep freſh a longer time. They make good ſhoes and boots, which, when well ſeaſoned, are water-proof.

"One day Mr Guyot and ſome others brought on board five ſea lioneſſes. They were about ſeven feet long, and three and a half in circumference, tho' their inteſtines were drawn. Theſe gentlemen had landed on a ſmall iſland, where they found a prodigious number of theſe animals, and killed eight or nine hundred of them with ſticks. No other weapon is neceſſary on theſe occaſions. A ſingle blow with a bludgeon, three feet or three feet and a half long, almoſt full at the noſe of theſe animals, knocks them down, and kills them on the ſpot.

"This is not altogether the caſe with the males: their ſize is prodigious. Our gentlemen encountered two of them for a long time, with the ſame weapons, without being able to overcome them. They lodged three balls in the throat of one while he opened his mouth to defend himſelf, and three muſket-ſhot in his body. The blood guſhed from his wounds like wine from a tap. However, he crawled into the water and diſappeared. A ſailor attacked the other, and engaged him for a long time, ſtriking him on the head with a bludgeon, without being able to knock him down: the ſailor fell down very near his antagoniſt, but had the dexterity to recover himſelf at the inſtant the lion was going to gorge him. Had he once ſeized him, the man would infallibly have been loſt: the animal would have carried him into the water as they uſually do their prey, and there feaſted upon him. In his retreat to the ſea this animal ſeized a pinguin, and devoured him inſtantaneouſly."

Mr Pennant deſcribes three ſeals of different ſpecies, which are called *ſea-lions*, viz. the *phoca leonina*, or hooded ſeal; the *phoca leonina*, or bottlenoſe; and the *beſtia marina*, or leonine ſeal. He differs in ſome particulars from the author juſt quoted; and ſuch of our readers as deſire to know theſe differences, we refer to his works.

3. The vitulina, ſea-calf, or common ſeal, inhabits the European ocean. It has a ſmooth head without external ears; and the common length is from five to ſix feet. The fore-legs are deeply immerſed in the ſkin of the body: the hind-legs are placed in ſuch a manner as to point directly backwards: every foot is divided into five toes; and each of thoſe connected by a ſtrong and broad web, covered on both ſides with ſhort hair. The toes are furniſhed with ſtrong claws, well adapted to aſſiſt the animal in climbing the rocks it baſks on: the claws on the hind-feet are ſlender and ſtraight; except at the ends, which are a little incurvated. The head and noſe are broad and flat, like thoſe of the otter; the neck ſhort and thick; the eyes large and black; in lieu of external ears, it has two ſmall orifices: the noſtrils are oblong: on each ſide the noſe are ſeveral long ſtiff hairs: and above each eye are a few of the ſame kind. The form of the tongue is ſo ſingular, that were other notes wanting, that alone would diſtinguiſh it from all other quadrupeds; being forked, or ſlit at the end. The cutting teeth are ſingular in reſpect to their number, being ſix in the upper jaw, and only four in the lower. It has two canine teeth above and below, and on each ſide of the jaw five grinders; the total 34. The whole animal is covered with ſhort hair, very cloſely ſet together: the colour of that on the body is generally duſky, ſpotted irregularly with white; on the belly white: but ſeals vary greatly in their marks and colours, and ſome have been found entirely white.

The ſeal is common on moſt of the rocky ſhores of Great Britain and Ireland, eſpecially on the northern coaſts: in Wales, it frequents the coaſts of Caernarvonſhire and Angleſey. They inhabit all the European ſeas, even to the extreme north; are found far within the arctic circle, in the ſeas both of Europe and Aſia, and are even continued to thoſe of Kamtſchatka*. It preys entirely on fiſh, and never moleſts the ſea-fowl: for numbers of each are often ſeen floating on the waves, as if in company. Seals eat their prey beneath the water; and in caſe they are devouring any very oily fiſh, the place is known by a certain ſmoothneſs of the waves immediately above. The

* *Stellar. in Nov. Com. Petrop.* ii. 290.

Phoca. power of oil in ſtilling the waves excited by a ſtorm is mentioned by Pliny: the moderns have made the experiment with ſucceſs; and thereby made one advance towards eradicating the vulgar prejudices againſt that great and elegant writer.

Seals are excellent ſwimmers, and ready divers; and are very bold when in the ſea, ſwimming careleſsly enough about boats: their dens or lodgments are in hollow rocks or caverns near the ſea, but out of the reach of the tide: in the ſummer they will come out of the water, to baſk or ſleep in the ſun on the top of large ſtones or ſhivers of rocks; and that is the opportunity our countrymen take of ſhooting them: if they chance to eſcape, they haſten towards their proper element, ſlinging ſtones and dirt behind them as they ſcramble along; at the ſame time expreſſing their fears by piteous moans: but if they happen to be overtaken, they will make a vigorous defence with their feet and teeth till they are killed. They are taken for the ſake of their ſkins, and for the oil their fat yields: the former ſell for 4s. or 4s. 6d. a-piece; which, when dreſſed, are very uſeful in covering trunks, making waiſtcoats, ſhot-pouches, and ſeveral other conveniences. We remember ſome years ago to have ſeen a young ſeal in ſome degree domeſticated. It was taken at a little diſtance from the ſea, and was generally kept in a veſſel full of ſalt water; but ſometimes it was allowed to crawl about the houſe, and even to approach the fire. Its natural food was regularly procured for it, and it was taken to the ſea every day and thrown in from a boat. It uſed to ſwim after the boat, and always allowed itſelf to be taken back. It lived thus for ſeveral weeks; and we doubt not would have lived much longer had it not been ſometimes too roughly uſed by the boys who took it to and from the ſea.

The fleſh of theſe animals, and even of porpoiſes, formerly found a place at the tables of the great; as appears from the bill of fare of that vaſt feaſt that Archbiſhop Nevill gave in the reign of Edward IV. in which is ſeen that ſeveral were provided on the occaſion. They couple about April, on large rocks or ſmall iſlands not remote from the ſhore; and bring forth in thoſe vaſt caverns that are frequent on our coaſts: they commonly bring two at a time, which in their infant ſtate are covered with a whitiſh down or woolly ſubſtance. The ſeal hunters in Caithneſs ſay, that their growth is ſo ſudden, that in nine tides from their birth (108 hours) they will become as active as their parents. On the coaſt of that country are immenſe caverns opening into the ſea, and running ſome hundreds of yards beneath the land. Theſe are the reſort of ſeals in the breeding time, where they continue till their young are old enough to go to ſea, which is in about ſix or ſeven weeks. The firſt of theſe caves is near the Ord, the laſt near Thrumſter: their entrance is ſo narrow as only to admit a boat; their inſide very ſpacious and lofty. In the mouth of October, or the beginning of November, the ſeal-hunters enter the mouth of the caverns about midnight, and rowing up as far as they can, they land; each of them being provided with a bludgeon, and properly ſtationed, they light their torches, and make a great noiſe, which brings down the ſeals from the farther end in a confuſed body with fearful ſhrieks and cries: at firſt the men are obliged to give way for fear of being overborne; but when the firſt crowd is paſt, they kill as many as ſtraggle behind, chiefly the young, by ſtriking them on the noſe; a very ſlight blow on that part diſpatches them. When the work is over, they drag the ſeals to the boat, which two men are left to guard. This is a moſt hazardous employment; for ſhould their torches go out, or the wind blow hard from ſea during their continuance in the cave, their lives are loſt. The young ſeals of ſix weeks age yield more oil than their emaciated dams: above eight gallons have been got from a ſingle whelp, which ſells from 6d. to 9d. per gallon; the ſkins from 6d. to 1s. each. Phoca.

The natural hiſtory of this animal may be further elucidated by the following extracts from a letter of the reverend Dr William Borlaſe, dated October the 24th 1763. "The ſeals are ſeen in the greateſt plenty on the ſhores of Cornwall in the months of May, June, and July. They are of different ſizes; ſome as large as a cow, and from that downwards to a ſmall calf. They feed on moſt ſorts of fiſh which they can maſter; and are ſeen ſearching for their prey near ſhore, where the whilling fiſh, wraws, and polacks, reſort. They are very ſwift in their proper depth of water, dive like a ſhot, and in a trice riſe at 50 yards diſtance; ſo that weaker fiſhes cannot avoid their tyranny except in ſhallow water. A perſon of the pariſh of Sennan ſaw not long ſince a ſeal in purſuit of a mullet (that ſtrong and ſwift fiſh); the ſeal turned it to and fro in deep water, as a gre-hound does a hare: the mullet at laſt found it had no way to eſcape, but by running into ſhoal water: the ſeal purſued; and the former, to get more ſurely out of danger, threw itſelf on its ſide, by which means it darted into ſhoaler water than it could have ſwam in with the depth of its paunch and fins, and ſo eſcaped. The ſeal brings her young about the beginning of autumn: our fiſhermen have ſeen two ſucking their dam at the ſame time, as ſhe ſtood in the ſea in a perpendicular poſition. Their head in ſwimming is always above water, more ſo than that of a dog. They ſleep on rocks ſurrounded by the ſea, or on the leſs acceſſible parts of our cliffs left dry by the ebb of the tide; and if diſturbed by any thing, take care to tumble over the rocks into the ſea. They are extremely watchful, and never ſleep long without moving; ſeldom longer than a minute; then raiſe their heads, and if they hear or ſee nothing more than ordinary, lie down again, and ſo on, raiſing their heads a little and reclining them alternately in about a minute's time. Nature ſeems to have given them this precaution, as being unprovided with auricles or external ears; and conſequently not hearing very quick, nor from any great diſtance." Pennant's British Zoology.

Theſe animals are ſo very uſeful to the inhabitants of Greenland and other arctic people, that they may be called their flocks. We cannot give a better account of theſe uſes than in the words of Mr Crantz, who was long reſident in thoſe northern regions.

"Seals (ſays he) are more needful to them than ſheep are to us, though they furniſh us with food and raiment; or than the cocoa-tree is to the Indians, although that preſents them not only with meat to eat, and covering for their bodies, but alſo houſes to dwell in, and boats to ſail in, ſo that in caſe of neceſſity they could live ſolely from it. The ſeals fleſh (together with the rein-deer, which is already grown pretty ſcarce)

Phoca. scarce) supplies the natives with their most palatable and substantial food. Their fat furnishes them with oil for lamp-light, chamber and kitchen fire; and whoever sees their habitations, presently finds, that if they even had a superfluity of wood, it would not do, they can use nothing but train in them. They also mollify their dry food, mollly fish, in the train; and finally, they barter it for all kinds of necessaries with the factor. They can sew better with fibres of the seals sinews than with thread or silk. Of the skins of the entrails they make their windows, curtains for their tents, shirts, and part of the bladders they use at their harpoons; and they make train bottles of the maw. Formerly, for want of iron, they made all manner of instruments and working tools of their bones. Neither is the blood wasted, but boiled with other ingredients, and eaten as soup. Of the skin of the seal they stand in the greatest need; for, supposing the skins of rein-deer and birds would furnish them with competent clothing for their bodies, and coverings for their beds; and their flesh, together with fish, with sufficient food; and provided they could dress their meat with wood, and also new-model their house keeping, so as to have light, and keep themselves warm with it too; yet without the seals-skins they would not be in a capacity of acquiring these same rein deer, fowls, fishes, and wood; because they must cover over with seal-skin both their large and small boats in which they travel and seek their provision. They must also cut their thongs or straps out of them, make the bladders for their harpoons, and cover their tents with them; without which they could not subsist in summer.

"Therefore no man can pass for a right Greenlander who cannot catch seals. This is the ultimate end they aspire at, in all their device and labour from their childhood up. It is the only art (and in truth a difficult and dangerous one it is) to which they are trained from their infancy; by which they maintain themselves, make themselves agreeable to others, and become beneficial members of the community *.

* *Hist. Greenl.* i. 130.

"The Greenlanders have three ways of catching seals: either singly, with the bladder; or in company, by the clapper-hunt; or in the winter on the ice: whereto may be added the shooting them with a gun.

"The principal and most common way is the taking them with the bladder. When the Greenlander sets out equipped, and spies a seal, he tries to surprise it unawares, with the wind and sun in his back, that he may not be heard or seen by it. He tries to conceal himself behind a wave, and makes hastily but softly up to it, till he comes within four, five, or six fathom of it; meanwhile he takes the utmost care that the harpoon, line, and bladder, lie in proper order. Then he takes hold of the oar with his left hand, and the harpoon with his right by the hand-board, and so away he throws it at the seal, in such a manner that the whole dart flies from the hand-board and leaves that in his hand. If the harpoon hits the mark, and buries itself deeper than the barbs, it will directly disengage itself from the bone joint, and that from the shaft; and also unwind the string from its lodge on the kajak. The moment the seal is pierced, the Greenlander must throw the bladder, tied to the end of the string, into the water, on the same side as the seal runs and dives; for that he does instantly like a dart. Then the Greenlander goes and takes up the shaft swimming on the water, and lays it in its place. The seal often drags the bladder with it under water, tho' it is a considerable impediment, on account of its great bigness; but it so wearies itself out with it, that it must come up again in about a quarter of an hour to take breath. The Greenlander hastens to the spot where he sees the bladder rise up, and smites the seal as soon as it appears with a great lance. This lance always comes out of its body again; but he throws it at the creature afresh every time it comes up till it is quite spent. Then he runs the little lance into it, and kills it outright, but stops up the wound directly to preserve the blood; and lastly, he blows it up, like a bladder, betwixt skin and flesh, to put it into a better capacity of swimming after him; for which purpose he fastens it to the left side of his kajak or boat. Phoca.

"In this exercise the Greenlander is exposed to the most and greatest danger of his life; which is probably the reason that they call this hunt or fishery *kamavock*, i. e. "the extinction," *viz.* of life. For if the line should entangle itself, as it easily may, in its sudden and violent motion; or if it should catch hold of the kajak, or should wind itself round the oar, or the hand, or even the neck, as it sometimes does in windy weather; or if the seal should turn suddenly to the other side of the boat, it cannot be otherwise than that the kajak must be overturned by the string, and drawn down under water. On such desperate occasions the poor Greenlander stands in need of every possible art to disentangle himself from the string, and to raise himself up from under the water several times successively; for he will continually be overturning till he has quite disengaged himself from the line. Nay, when he imagines himself to be out of all danger, and comes too near the dying seal, it may still bite him in the face or hand; and a female seal that has young, instead of flying the field, will sometimes fly at the Greenlander in the most vehement rage, and do him a mischief, or bite a hole in his kajak that he must sink.

"In this way, singly, they can kill none but the careless stupid seal called *attarsoak*. Several in company must pursue the cautious kassigiak by the clapper-hunt. In the same manner they also surround and kill the attarsoit in great numbers at certain seasons of the year; for in autumn they retire into the creeks or inlets in stormy weather, as in the Nepiset sound in Ball's river, between the main land and the island Kangek, which is full two leagues long, but very narrow. There the Greenlanders cut off their retreat, and frighten them under water by shouting, clapping, and throwing stones; but as they must come up again continually to draw breath, then they persecute them again till they are tired, and at last are obliged to stay so long above water that they surround them, and kill them with a kind of dart for the purpose. During this hunt we have a fine opportunity to see the agility of the Greenlanders, or, if I may call it so, their hussar-like manœuvres. When the seal rises out of the water, they all fly upon it as if they had wings, with a desperate noise; the poor creature is forced to dive again directly; and the moment he does they disperse

Phoca. perſe again as faſt as they came, and every one gives heed to his poſt to ſee where it will ſtart up again; which is an uncertain thing, and is commonly three quarters of a mile from the former ſpot. If a ſeal has a good broad water, three or four leagues each way, it can keep the ſportſmen in play for a couple of hours before it is ſo ſpent that they can ſurround and kill it. If the ſeal in its fright betakes itſelf to the land for a retreat, it is welcomed with ſticks and ſtones by the women and children, and preſently pierced by the men in the rear. This is a very lively and a very profitable diverſion for the Greenlanders, for many times one man will have eight or ten ſeals for his ſhare.

"The third method of killing ſeals upon the ice is moſtly practiſed in Diſko, where the bays are frozen over in the winter. There are ſeveral ways of proceeding. The ſeals themſelves make ſometimes holes in the ice, where they come and draw breath; near ſuch a hole a Greenlander ſeats himſelf on a ſtool, putting his feet on a lower one to keep them from the cold. Now when the ſeal comes and puts its noſe to the hole, he pierces it inſtantly with his harpoon; then breaks the hole larger, and draws it out and kills it quite. Or a Greenlander lays himſelf upon his belly on a kind of a ſledge, near other holes, where the ſeals come out upon the ice to baſk themſelves in the ſun. Near this great hole they make a little one, and another Greenlander puts a harpoon into it with a very long ſhaft or pole. He that lies upon the ice looks into the great hole, till he ſees a ſeal coming under the harpoon; then he gives the other the ſignal, who runs the ſeal through with all his might.

"If the Greenlander ſees a ſeal lying near its hole upon the ice, he ſlides along upon his belly towards it, wags his head, and grunts like a ſeal; and the poor ſeal, thinking it is one of its innocent companions, lets him come near enough to pierce it with his long dart. When the current wears a great hole in the ice in the ſpring, the Greenlanders plant themſelves all round it, till the ſeals come in droves to the brim to fetch breath, and then they kill them with their harpoons. Many alſo are killed on the ice while they lie ſleeping and ſnoring in the ſun."

To this long quotation, which we think both curious and intereſting, we ſhall ſubjoin the following obſervations of Mr Pennant, which are not leſs worthy of attention.

Arctic Zoology, v. 1.

"Nature (ſays this intelligent writer) has been ſo niggardly in providing variety of proviſion for the Greenlanders, that they are neceſſitated to have recourſe to ſuch which is offered to them with a liberal hand. The Kamtſchatkan nations, which enjoy ſeveral animals, as well as a great and abundant choice of fiſh, are ſo enamoured with the taſte of the fat of ſeals, that they can make no feaſt without making it one of the diſhes. Of that both Ruſſians and Kamtſchatkans make their candles. The latter eat the fleſh boiled, or elſe dried in the ſun. If they have a great quantity, they preſerve it in the following manner:

"They dig a pit of a requiſite depth, and pave it with ſtones; then fill it with wood, and ſet it on fire ſo as to heat the pit to the warmth of a ſtove. They then collect all the cinders into a heap. They ſtrew the bottom with the green wood of alder, on which they place ſeparately the fleſh and the fat, and put between every layer branches of the ſame tree; when the pit is filled they cover it with ſods, ſo that the vapour cannot eſcape. After ſome hours they take out both fat and fleſh, and keep it for winter's proviſions, and they may be preſerved a whole year without ſpoiling. Phoca.

"The Kamtſchatkans have a moſt ſingular ceremony. After they take the fleſh from the heads of the ſeals, they bring a veſſel in form of a canoe, and fling into it all the ſkulls, crowned with certain herbs, and place them on the ground. A certain perſon enters the habitation with a ſack filled with *tonchitche*, ſweet herbs, and a little of the bark of willow. Two of the natives then roll a great ſtone towards the door, and cover it with pebbles; two others take the ſweet herbs and diſpoſe them, tied in little packets. The great ſtone is to ſignify the ſea ſhore, the pebbles the waves, and the packets ſeals. They then bring three diſhes of a haſh called *tolkoucha*: of this they make little balls, in the middle of which they ſtick the packets of herbs: of the willow-bark they make a little canoe, and fill it with tolkoucha, and cover it with the ſack. After ſome time the two Kamtſchatkans, who had put the mimic ſeals into the tolkoucha, take the balls, and a veſſel reſembling a canoe, and draw it along the ſand as if it was on the ſea, to convince the real ſeals how agreeable it would be to them to come among the Kamtſchatkans, who have a ſea in their very jurts or dwellings. And this they imagine will induce the ſeals to ſuffer themſelves to be taken in great numbers. Various other ceremonies, equally ridiculous, are practiſed; in one of which they invoke the winds, which drive the ſeals on their ſhores, to be propitious.

"Beſides the uſes which are made of the fleſh and fat of ſeals, the ſkins of the largeſt are cut into ſoles for ſhoes. The women make their ſummer boots of the undreſſed ſkins, and wear them with the hair outmoſt. In a country which abounds ſo greatly in furs, very little more uſe is made of the ſkins of ſeals in the article of dreſs than what has been mentioned. But the Koriaks, the Oloutores, and Tchutſchi, form with the ſkins canoes and veſſels of different ſizes, ſome large enough to carry thirty people.

"Seals ſwarm on all the coaſts of Kamtſchatka, and will go up the rivers eighty verſts in purſuit of fiſh. The Tunguſi give the milk of theſe animals to their children inſtead of phyſic. The navigators obſerved abundance of ſeals about Bering's iſland, but that they decreaſed in numbers as they advanced towards the ſtraits; for where the walruſes abounded, the ſeals grew more and more ſcarce.

"I did not obſerve any ſeal-ſkin garments among thoſe brought over by the navigators, ſuch as one might have expected among the Eſquimaux of the high latitudes they viſited, and which are ſo much in uſe with thoſe of Hudſon's Bay and Labrador. That ſpecies of dreſs doubtleſsly was worn in the earlieſt times. Theſe people wanted their hiſtorians; but we are aſſured that the Maſſagetæ clothed themſelves in the ſkins of ſeals. They, according to D'Anville, inhabited the country to the eaſt of the Caſpian ſea, and the lake Aral, both of which waters abound with ſeals.

"Seals are now become a great article of commerce. The oil from the vaſt whales is no longer equal to the demand for ſupplying the magnificent profuſion of

Phoca. lamps in and round our capital. The chafe of thefe animals is redoubled for that purpofe; and the fkins, properly tanned, are in confiderable ufe in the manufactory of boots and fhoes."

4. The phoca barbata, or great feal, has long white whifkers with curled points. The back is arched; hair black, very deciduous, and very thinly difperfed over a thick fkin, which is almoft naked in fummer. The teeth of this fpecies are like thofe of the common feal; the fore-feet are like the human hand, the middle toe being the longeft and the thumb fhort. They are upwards of 12 feet long.

The inhabitants of Greenland cut out of the fkin of this fpecies thongs and lines, a finger-thick, for the feal fifhery. Its flefh is as white as veal, and is efteemed the moft delicate of any. They produce plenty of lard, but very little oil. The fkins of the young are fometimes ufed to lie on.—It inhabits the high fea about Greenland, is very timid, and commonly refts on the floating ice. It breeds about the month of March, and brings forth a fingle young on the ice, generally among the iflands; for then it approaches a little nearer to the land. The great old ones fwim very flowly.

On the northern coaft of Scotland is found a feal twelve feet long. A young one, feven feet and a half long, was fhown in London fome years ago, which was fo far from maturity as to have fcarcely any teeth *: yet the common feals have them complete before they attain the fize of fix feet, their utmoft growth.

A fpecies larger than an ox was found in the Kamtfchatkan feas from 56 to 64 north latitude, called by the natives *lachtak* †. They weighed 800 pounds, and were eaten by Bering's crew; but their flefh was very loathfome ‡. The cubs are entirely black.

Steller has given accounts of other feals found in thofe wild feas; but his defcriptions are fo very imperfect as to render it impoffible to afcertain the fpecies. He fpeaks in his MSS. of a middle fized kind, wholly and moft elegantly fpotted; of another which is black with brown fpots, having the belly of a yellowifh white, and as large as a yearling ox. He mentions a third fpecies, black, and with a particular formation of the hinder legs; and a fourth of a yellowifh colour, with a great circle on it of the colour of cherries ||.

5. The phoca fœtida, or rough feal, is diftinguifhed by a fhort nofe and fhort round head; a body almoft elliptical, covered with lard almoft to the hind feet. This fpecies feldom if ever exceeds four feet in length. Their hairs are clofely fet together, foft, long, and fomewhat erect, intermixed with curled. They are of a dufky colour, mixed with white, which fometimes varies to white, with a dufky dorfal line.

This fpecies never frequents the high feas, but keeps on the fixed ice in the remote bays near the frozen land; and when old never forfakes its haunts. They couple in June, and bring forth in January on the fixed ice, its proper element. In that cold fituation they have a hole for the benefit of fifhing; near which they generally remain folitary, being rarely found in pairs. They are very incautious, and often fleep on the furface of the water, by which means they become an eafy prey to the eagle. They feed on fmall fifh, fhrimps, &c. The fkin, tendons, and lard, are ufed in the fame way with thofe of other feals. The flefh is red and fœtid, efpecially in males, which is naufeated even by the inhabitants of Greenland. Phoca Phocæa.

The feal-hunters in Newfoundland have a larger kind, which they call the *fquare phipper*, and which weighs 500 pounds. Its coat is like that of a water-dog; fo that it appears by the length of its hair to be allied to this fpecies; but the vaft difference in fize admits not of certainty in this refpect.

6. The phoca leporina, or leporine feal, has hair of a dirty white colour, tinged with yellow, but never fpotted. The hairs are erect, interwoven, and foft like thofe of a hare, efpecially in the young. The head is long; the upper lip fwelling and thick; the whifkers very ftrong and very thick, ranged in 15 rows, covering the whole front of the lip, fo that it appears bearded; the eyes are blue, and the pupil of them black; the teeth are ftrong; the fore-feet are fhort; the membranes of the hind feet are even and not waved; the tail is fhort and thick, it being four inches two lines in length; the cubs are of a milk white colour. The length of the fpecies is about fix feet fix inches, and the circumference where greateft five feet two.

This fpecies inhabits the White Sea in the fummer time, and afcends and defcends the mouths of rivers with the tide in queft of prey. It is likewife found on the coafts of Iceland, and within the polar circle from Spitzbergen to Tchutki Nofs, and from thence fouthward about Kamtfchatka.

There are feveral other fpecies of this genus, and a variety of curious particulars refpecting them, which our limits permit us not to give. Such of our readers, however, as wifh for further information on this fubject, will find themfelves amply gratified by a careful perufal of what Mr Pennant has written on the fubject, from whofe labours we have extracted much of our article. See his *Hiftory of Quadrupeds*, Vol. II. p. 518——536. his *Arctic Zoology*, Vol. I. p. 151——177. and his *Britifh Zoology*, as alfo the feveral authors whofe works he quotes.

PHOCÆA, the laft town of Ionia, (Mela, Pliny); of Æolis, (Ptolemy), becaufe fituated on the right or north fide of the river Hermus, which he makes the boundary of Æolis to the fouth. It ftood far in the land, on a bay or arm of the fea; had two very fafe harbours, the one called *Lampter* the other *Nauftathmos*, (Livy). It was a colony of Ionians, fituated in the territory of Æolis, (Herodotus). Maffilia in Gaul was again a colony from it. *Phocæenfes*, the people, (Livy); *Phocaicus*, the epithet, (Lucan); applied to *Marfeilles*. It was one of the 12 cities which aflembled in the panionium or general council of Ionia.

Some writers tell us, that while the foundations of this city were laying, there appeared near the fhore a great fhoal of fea-calves; whence it was called *Phocæa*, the word *phoca* fignifying in Greek a *fea-calf*. Ptolemy, who makes the river Hermus the boundary between Æolia and Ionia, places Phocæa in Æolis; but all other geographers reckon it among the cities of Ionia. It ftood on the fea-coaft, between Cuma to the north, and Smyrna to the fouth, not far from the Hermus; and was, in former times, one of the moft wealthy and powerful cities of all Afia; but is now a poor

Ancient Univ. Hift. vol. vi.

Phocæa. poor beggarly village, though the ſee of a biſhop. The Phocæans were expert mariners, and the firſt among the Greeks that undertook long voyages; which they performed in galleys of fifty oars. As they applied themſelves to trade and navigation, they became acquainted pretty early with the coaſts and iſlands of Europe, where they are ſaid to have founded ſeveral cities, namely, Velia in Italy: Alalia, or rather Aleria, in Corſica; and Marſeilles in Gaul. Neither were they unacquainted with Spain; for Herodotus tells us, that, in the time of Cyrus the Great, the Phocæans arriving at Sarteſſus, a city in the Bay of Cadiz, were treated with extraordinary kindneſs by Arganthonius king of that country; who, hearing that they were under no ſmall apprehenſion of the growing power of Cyrus, invited them to leave Ionia, and ſettle in what part of his kingdom they pleaſed. The Phocæans could not be prevailed upon to forſake their country; but accepted a large ſum of money, which that prince generouſly preſented them with, to defray the expence of building a ſtrong wall round their city. The wall they built on their return; but it was unable to reſiſt the mighty power of Cyrus, whoſe general Harpagus, inveſting the city with a numerous army, ſoon reduced it to the utmoſt extremities. The Phocæans, having no hopes of any ſuccour, offered to capitulate; but the conditions offered by Harpagus ſeeming ſevere, they begged he would allow them three days to deliberate; and, in the mean time, withdraw his forces. Harpagus, though not ignorant of their deſign, complied with their requeſt. The Phocæans, taking advantage of this condeſcenſion, put their wives, children, and all their moſt valuable effects, on board ſeveral veſſels which they had ready equipped, and conveyed them ſafe to the iſland of Chios, leaving the Perſians in poſſeſſion of empty houſes. Their deſign was to purchaſe the Œneſſian iſlands, which belonged to the Chians, and ſettle there. But the Chians not caring to have them ſo near, leſt they ſhould engroſs all the trade to themſelves, as they were a ſea-faring people, they put to ſea again; and, having taken Phocæa, their native country, by ſurpriſe, put all the Perſians they found in it to the ſword. They went to Corſica; great part of them however returned very ſoon, as did the reſt alſo in a few years. They then lived in ſubjection either to the Perſians, or tyrants of their own. Among the latter we find mention made of Laodamus, who attended Darius Hyſtaſpis in his expedition againſt the Scythians; and of Dionyſius, who, joining Ariſtagoras, tyrant of Miletus, and chief author of the Ionian rebellion, retired, after the defeat of his countrymen, to Phœnicia, where he made an immenſe booty, ſeizing on all the ſhips he met with trading to that country. From Phœnicia he ſailed to Sicily, where he committed great depredations on the Carthaginians and Tuſcans; but is ſaid never to have moleſted the Greeks.

In the Roman times the city of Phocæa ſided with Antiochus the Great; whereupon it was beſieged, taken, and plundered, by the Roman general; but allowed to be governed by its own laws. In the war which Ariſtonicus brother to Attalus, king of Pergamus, raiſed againſt the Romans, they aſſiſted the former to the utmoſt of their power; a circumſtance which ſo diſpleaſed the ſenate, that they commanded the town to be demoliſhed, and the whole race of the Phocæans to be utterly rooted out. This ſevere ſentence would Phocas. have been put in execution, had not the Maſſilienſes, a Phocæan colony, interpoſed, and, with much difficulty, aſſuaged the anger of the ſenate. Pompey declared Phocæa a free city, and reſtored the inhabitants to all the privileges they had ever enjoyed; whence, under the firſt emperors, it was reckoned one of the moſt flouriſhing cities of all Aſia Minor. This is all we have been able to collect from the ancients touching the particular hiſtory of Phocæa.

PHOCAS, a Roman centurion, was raiſed to the dignity of emperor by the army, and was crowned at Conſtantinople about the year 603. The emperor Mauritius, who was thus deſerted both by the army and the people, fled to Chalcedon with his five children, whom Phocas cauſed to be inhumanly murdered before his eyes, and then he murdered Mauritius himſelf, his brother, and ſeveral other perſons who were attached to that family.

Phocas, thus proclaimed and acknowledged at Conſtantinople, ſent, according to cuſtom, his own image and that of his wife Leontia to Rome, where they were received with loud acclamations, the people there being incenſed againſt Mauritius on account of the cruel exactions of the exarchs, and his other miniſters in Italy. Gregory, ſurnamed the Great, then biſhop of Rome, cauſed the images to be lodged in the oratory of the martyr Cæſarius, and wrote letters to the new emperor, congratulating him upon his advancement to the throne, which he ſaid was effected by a particular providence, to deliver the people from the innumerable calamities and heavy oppreſſions under which they had long groaned. Had we no other character of Phocas and Leontia but that which has been conveyed to us in Gregory's letters, we ſhould rank him amongſt the beſt princes mentioned in hiſtory; but all other writers paint him in quite different colours; and his actions, tranſmitted to us by ſeveral hiſtorians, evidently ſpeak him a moſt cruel and blood-thirſty tyrant. He was of middling ſtature, ſays Cedrenus, deformed, and of a terrible aſpect: his hair was red, his eye-brows met, and one of his cheeks was marked with a ſcar, which, when he was in a paſſion, grew black and frightful: he was greatly addicted to wine and women, blood-thirſty, inexorable, bold in ſpeech, a ſtranger to compaſſion, in his principles a heretic. He endeavoured, in the beginning of his reign, to gain the affections of the people by celebrating the Circenſian games with extraordinary pomp, and diſtributing on that occaſion large ſums amongſt the people; but finding that inſtead of applauding they reviled him as a drunkard, he ordered his guards to fall upon them. Some were killed, many wounded, and great numbers were dragged to priſons but the populace riſing, ſet them at liberty, and thenceforth conceived an irreconcileable averſion to the tyrant. *Ancient Univ. Hiſt.* v. 15.

As ſoon as the death of Mauritius was known, Narſes, who then commanded the troops quartered on the frontiers of Perſia, revolted. Phocas, however, managed matters ſo as to gain him over to his intereſt, and then treacherouſly and cruelly burnt him alive. He endeavoured to ſtrengthen his cauſe by reſpectable alliances; but his cruelty was ſuch as to render him generally hated, for he ſpared neither ſex nor age, and amongſt others he murdered Conſtantina the widow of Mauritius,

Phocas & Phocion.

Mauritius, and her daughters. Theſe cruelties were at length the cauſe of his downfall. He became univerſally hateful; and perſons in great authority near his perſon conſpired againſt him. This conſpiracy, however, was diſcovered, and the perſons concerned in it were all put to death. The following year, however, 610, he was overtaken by the fate he had ſo long deſerved.

Heraclius, the ſon of the governor of Africa, who bore the ſame name, taking upon him the title of emperor, and being acknowledged as ſuch by the people of Africa, ſailed from thence with a formidable fleet, and a powerful army on board, for Conſtantinople, while Nicetas marched thither by way of Alexandria and the Pentapolis. Heraclius ſteered his courſe to Abydus, where he was received with great demonſtrations of joy by ſeveral perſons of rank, who had been baniſhed by Phocas. From Abydus he ſailed to Conſtantinople, where he engaged and utterly defeated the tyrant's fleet. Phocas took refuge in the palace; but one Photinus, whoſe wife he had formerly debauched, purſuing him with a party of ſoldiers, forced the gates, dragged the cowardly emperor from the throne, and having ſtripped him of the imperial robes, and clothed him with a black veſt, carried him in chains to Heraclius, who commanded firſt his hands and feet, then his arms, and at laſt his head, to be cut off: the remaining part of his body was delivered up to the ſoldiers, who burnt it in the forum. We are told, that Heraclius having reproached him with his evil adminiſtration, he anſwered, with great calmneſs, "It is incumbent upon you to govern better." Such was the end of this cruel tyrant, after he had reigned ſeven years and ſome months.

PHOCILIDES, a Greek poet and philoſopher of Miletus, flouriſhed about 540 years before the Chriſtian era. The poetical piece now extant, attributed to him, is not of his compoſition, but of another poet who lived in the reign of Adrian

PHOCION was a diſtinguiſhed Athenian general and orator in the time of Philip II. of Macedon. His character is thus deſcribed in the Ancient Univerſal Hiſtory. "He was too moderate to ſolicit command, nor did he promote wars that he might raiſe his authority by them; though, taken either as a ſoldier, orator, ſtateſman, or general, he was by far the moſt eminent Athenian of his time. As he was a moſt diſintereſted patriot, he could entertain no great affection for Philip: but as he perfectly well knew the diſpoſition of his countrymen, and how unlikely they were long to ſupport ſuch meaſures as were neceſſary to humble the Macedonian power, he did not expreſs himſelf vehemently, but choſe rather to cultivate the eſteem which on all occaſions Philip ſhowed for the ſtate of Athens, as a mean of preſerving her, when ſhe ſhould be reduced to that ſituation which he conceived they wanted virtue to prevent. From this character the reader will eaſily diſcern that Demoſthenes and he could not well agree. The former was always warm, his language copious, and his deſigns extenſive: and Phocion, on the other hand, was of a mild temper, delivered his opinion in very few words, and propoſed ſchemes at once neceſſary and eaſy to be effected. Yet he ſeldom or never concurred with the people, but ſpoke as poignantly againſt their vices as Demoſthenes himſelf; inſomuch that this orator once told him, 'The Athenians, Phocion, in ſome of their mad fits, will murder thee.' 'The ſame (anſwered he) may fall to thee, Demoſthenes, if ever they come to be ſober."

Ancient Univ. Hiſt. v. 5.

Phocion.

He was afterwards appointed to command the army which was ſent to aſſiſt the Byzantines againſt Philip, whom he obliged to return to his own dominions. This truly great man, whom (though extremely poor) no ſum could bribe to betray his country, and who at every riſk on all occaſions gave them ſound advice, was at length accuſed by his ungrateful countrymen. This event happened in the year before Chriſt 318. He was ſent to Athens by Polyperchon head of a faction in Macedonia, together with his friends, chained in carts, with this meſſage, "That though he was convinced they were traitors, yet he left them to be judged by the Athenians as a free people." Phocion demanded whether they intended to proceed againſt him by form of law; and ſome crying out that they would, Phocion demanded how that could be if they were not allowed a fair hearing? but perceiving, by the clamour of the people, that no ſuch thing was to be expected, he exclaimed, "As for myſelf, I confeſs the crime objected to me, and ſubmit to the judgment of the law; but conſider, O ye Athenians, what have theſe poor innocent men done that they ſhould be involved in the ſame calamity with me?" The people replied with great vociferation, "They are your accomplices, and that is enough." Then the decree was read, adjudging them all to death, viz. Phocion, Nicocles, Aheudippus, Agamon, and Pythocles; theſe were preſent: Demetrius, Phalereus, Callimedon, Charicles, and others, were condemned in their abſence. Some moved that Phocion might be tortured before he was put to death; nay, they were for bringing the rack into the aſſembly, and torturing him there. The majority, however, thought it enough if he was put to death, for which the decree was carried unanimouſly; ſome putting on garlands of flowers when they gave their votes. As he was going to execution, a perſon who was his intimate friend aſked him if he had any meſſage for his ſon? "Yes," replied Phocion; "tell him it is my laſt command that he forget how ill the Athenians treated his father."

The ſpleen of his enemies was not extinguiſhed with his life: they paſſed a decree whereby his corpſe was baniſhed the Athenian territories; they likewiſe forbad any Athenians to furniſh fire for his funeral pile. One Conopian took up the corpſe, and carried it beyond Eleuſina, where he borrowed ſome fire of a Megarian woman and burned it. A Megarian matron, who attended with her maid, raiſed on the place an honorary monument; and having gathered up the bones, carried them home, and buried them under her own hearth; praying at the ſame time thus to the Penates: "To you, O ye gods, guardians of this place, I commit the precious remains of the moſt excellent Phocion. Protect them, I beſeech you, from all inſults; and deliver them one day to be repoſited in the ſepulchre of his anceſtors, when the Athenians ſhall become wiſer." It was not long before this opportunity occurred. When the Athenians began to cool a little, and remember the

Phoc's

the many ſervices they had received from Phocion, they decreed him a ſtatue of braſs; ordered his bones to be brought back at the public expence; and decreed that his accuſers ſhould be put to death. Agnonides, who was principally concerned in that tragedy, ſuffered; but Epicurus and Demophilus, who were alſo accomplices in it, fled. However, Phocion's ſon met with them, and executed his revenge upon them; which was almoſt the only good action he ever performed, as he had a very ſmall ſhare of his father's abilities, and not any of his virtues. Such is the fickleneſs and ſuch the injuſtice of popular governments; failings which, if we are to judge from univerſal experience, are abſolutely inſeparable from them.

PHOCIS, (Demoſthenes, Strabo, Pauſanias); a country of Greece, contained between Bœotia to the eaſt and Locris to the weſt, but extending formerly from the Sinus Corinthiacus on the ſouth to the ſea of Eubœa on the north, and, according to Dionyſius, as far as Thermopylæ; but reduced afterwards to narrower bounds. *Phocenſes*, the people; *Phocicus*, the epithet, (Juſtin); *Bellum Phocicum*, the ſacred war which the Thebans and Philip of Macedon carried on againſt them for plundering the temple at Delphi; and by which Philip paved the way to the ſovereignty of all Greece, (Juſtin.) Its greateſt length was from north to ſouth, that is, from 38° 45′ to 39° 20′, or about 35 miles; but very narrow from eaſt to weſt, not extending to 30 miles, that is, from 23° 10′ to 23° 40′ at the wideſt, but about 23 miles towards the Corinthian bay, and much narrower ſtill towards the north. This country is generally allowed to have taken its name from Phocus the ſon of Ornytion, a native of Corinth; but having been ſoon after invaded by the Eginetæ, under the conduct of another Phocus, who was the ſon of Eacus king of Enopia, the memory of the firſt inſenſibly gave way to that of the ſecond.

Tacitus Univ. Hiſt. v. 5.

In Phocis there were many celebrated mountains, ſuch as Cythæron, Helicon, and Parnassus. The laſt two we have already noticed in the order of the alphabet. Cythæron was conſecrated to the muſes as well as the other two, and was conſequently much celebrated by the poets. Both it and Helicon contend with mount Parnaſſus for height and magnitude. There were no remarkable rivers in Phocis except Cephiſus, which runs from the foot of Parnaſſus northward, and empties itſelf in the Pindus, which was near the boundary of that kingdom. It had ſeveral very conſiderable cities; ſuch as Cyrra, Criſſa, and Antecyra, which, according to Ptolemy, were on the ſea coaſts; and Pythia, Delphi, Daulis, Elatia, Ergoſthenia, and Baulia, which were inland towns. Elatia was the largeſt and richeſt after Delphi.

Deucalion was king of that part of Phocis which lies about Parnaſſus, at the time that the Cecrops flouriſhed in Attica; but the Phocians afterwards formed themſelves into a commonwealth, to be governed by their general aſſemblies, the members of which were choſen from among themſelves, and were changed as often as occaſion required. Of the hiſtory of the Phocians but little is known till the time of the holy war, of which we have the following account in the Ancient Univerſal Hiſtory.

"The Phocians having preſumed to plough the territories of the city of Cyrra, conſecrated to the Delphic god, were ſummoned by the other Grecian ſtates before the court of the Amphictyons, where a conſiderable fine was impoſed upon them for their ſacrilege. They refuſed to pay it, on pretence that it was too large; and at the next aſſembly their dominions were adjudged confiſcated to the uſe of the temple. This ſecond ſentence exaſperated the Phocians ſtill more; who, at the inſtigation of one Philomelus, or, as he is called by Plutarch, Philomedes, ſeized upon the temple, plundered it of its treaſure, and held the ſacred depoſitum for a conſiderable time. This ſecond crime occaſioned another aſſembly of the Amphictyons, the reſult of which was a formal declaration of war againſt the Phocians. The quarrel being become more general, the ſeveral ſtates took part in it according to their inclinations or intereſt. Athens, Sparta, and ſome others of the Peloponneſians, declared for the Phocians; and the Thebans, Theſſalians, Locrians, and other neighbouring ſtates, againſt them. A war was commenced with great fury on both ſides, and ſtyled *the holy war*, which laſted ten years; during which the Phocians, having hired a number of foreign troops, made an obſtinate defence, and would in all probability have held out much longer had not Philip of Macedon given the finiſhing ſtroke to their total defeat and puniſhment. The war being ended, the grand council aſſembled again, and impoſed an annual fine of 60 talents upon the Phocians, to be paid to the temple, and continued till they had fully repaired the damage it had ſuſtained from them; and, till this reparation ſhould be made, they were excluded from dwelling in walled towns, and from having any vote in the grand aſſembly. They did not, however, continue long under this heavy ſentence: their known bravery made their aſſiſtance ſo neceſſary to the reſt, that they were glad to remit it; after which remiſſion they continued to behave with their uſual courage and reſolution, and ſoon obliterated their former guilt."

Phœnicia II.

We cannot finiſh this article without mentioning more particularly Daulis, rendered famous, not ſo much for its extent or richneſs, as for the ſtature and proweſs of its inhabitants; but ſtill more for the inhuman repaſt which was ſerved up to Tereus king of Thrace by the women of this city, by whom he was ſoon after murdered for the double injury he had done to his ſiſter-in-law Philomela, daughter of Pandion king of Athens. See Philomela.

PHŒBUS, one of the names given by ancient mythologiſts to the Sun, Sol, or Apollo. See Apollo.

PHŒNICIA, or more properly Phœnice, the ancient name of a country lying between the 34th and 36th degrees of north latitude; bounded by Syria on the north and eaſt, by Judæa on the ſouth, and by the Mediterranean on the weſt. Whence it borrowed its name is not abſolutely certain. Some derive it from one Phœnix; others from the Greek word *phœnix*, ſignifying a *palm* or *date*, as that tree remarkably abounded in this country. Some again ſuppoſe that Phœnice is originally a tranſlation of the Hebrew word *Edom*, from the Edomites who fled thither in the days of David. By the contraction of Canaan it was alſo called.

Antiq. Univ. Hiſt. v. ii.

Phœnicia. called *Chna*, and anciently *Rhabbothin* and *Colpitis* (A). The Jews commonly named it *Canaan*; though fome part of it, at leaft, they knew by the name of *Syrophœnice* (B). Bochart tells us that the moft probable etymology is *Phene Anak*, i. e. "the defcendants of Anak." Such were the names peculiar to this fmall country; though Phœnice was fometimes extended to all the maritime countries of Syria and Judæa, and Canaan to the Philiftines, and even to the Amalekites. On the contrary, thefe two names, and the reft, were moft generally fwallowed up by thofe of Paleftine and Syria (C).

There is fome difagreement among authors with refpect to the northern limits of this country. Ptolemy makes the river Eleutherus the boundary of Phœnice to the north; but Pliny, Mela, and Stephanus, place it in the ifland of Aradus, lying north of that river. Strabo obferves, that fome will have the river Eleutherus to be the boundary of Seleucis, on the fide of Phœnice and Cœlefyria. On the coaft of Phœnice, and fouth of the river Eleutherus, ftood the following cities: SIMYRA, Orthofia, TRIPOLIS, Botrys, Byblus, Palæbyblus, Berytus, SIDON, SAREPTA, TYRUS, Palætyrus.

Phœnice extended, according to Ptolemy, even beyond mount Carmelus; for that geographer places in Phœnice not only Ecdippa and Ptolemais, but Sycaminum and Dæra, which ftand fouth of that mountain. Thefe, however, properly fpeaking, belonged to Paleftine. We will not take upon us to mark out the bounds of the midland Phœnice. Ptolemy reckons in it the following towns: Arca, Palæbyblus (Old Byblus), Gabala, and Cæfaria Paniæ. This province was confiderably extended in the times of Chriftianity; when, being confidered as a province of Syria, it included not only Damafcus but Palmyra alfo.

The foil of this country is good, and productive of many neceffaries for food and clothing. The air is wholefome, and the climate agreeable. It is plentifully watered by fmall rivers; which, running down from mount Libanus, fometimes fwell to an immoderate degree, either increafed by the melting of the fnows on that mountain, or by heavy rains. Upon thefe occafions they overflow, to the great danger and hinderance of the traveller and damage of the country. Among thefe rivers is that of ADONIS.

It is univerfally allowed that the Phœnicians were Canaanites (D) by defcent: nothing is plainer or lefs contefted, and therefore it were time loft to prove it. We fhall only add, that their blood muft have been mixed with that of foreigners in procefs of time, as it happens in all trading places; and that many ftrange families muft have fettled among them, who could confequently lay no claim to this remote origin, how much foever they may have been called Phœnicians, and reckoned of the fame defcent with the ancient proprietors. Phœnicia.

The Phœnicians were governed by kings; and their territory, as fmall a flip as it was, included feveral kingdoms; namely, thofe of Sidon, Tyre, Aradus, Berytus, and Byblus. In this particular they imitated and adhered to the primitive government of their forefathers; who, like the other Canaanitea, were under many petty princes, to whom they allowed the fovereign dignity, referving to themfelves the natural rights and liberties of mankind. Of their civil laws we have no particular fyftem.

With regard to religion, the Phœnicians were the moft grofs and abominable idolaters. The Baal-berith, Baalzebub, Baalfamen, &c. mentioned in Scripture, were fome of the Phœnician gods; as were alfo the Moloch, Aftaroth, and Thammuz, mentioned in the facred writings.—The word *Baal*, in itfelf an appellative, was no doubt applied to the true God, until he rejected it on account of its being fo much profaned by the idolaters. The name was not appropriated to any particular deity among the idolatrous nations, but was common to many; however, it was generally imagined that one great God prefided over all the reft. Among the Phœnicians this deity was named *Baal-famen*; whom the Hebrews would have called *Baal fhemim*, or the God of heaven. In all probability this was alfo the principal Carthaginian deity, though his Punic name is unknown. We have many religious rites of the Carthaginians handed down to us by the Greek and Roman writers; but they all beftowed names of their own gods upon thofe of the Carthaginians, which leads us to a knowledge of the correfpondence between the characters of the Phœnician and European deities. The principal deity of Carthage, according to Diodorus Siculus, was Chronus or Saturn. The facrifices offered up to him were children of the beft families. Our author alfo tells us, that the Carthaginians had a brazen ftatue or coloffus of this god, the hands of which were extended in act to receive, and bent downwards in fuch a manner, that the child laid thereon

(A) This laft name is a tranflation of the firft. *Rabbotfen* is in Hebrew a *great gulph* or *bay*. From *rabbotfen*, by changing the Hebrew *tf* into the Greek *t*, comes *rabboten*; and, with a little variation, *rhabbothin*. Κολπος, *colpos*, is Greek alfo for a *bay* or *gulph*; whence it appears that *colpitis* or *colpites* is a tranflation of *rabbothin*.

(B) Bochart fuppofes that the borderers, both upon the Phœnician and Syrian fide, were called by the common name of Syrophœnicians, as partaking equally of both nations.

(C) Or rather Phœnice, Paleftine, and Syria, were promifcuoufly ufed for each other, and particularly the two former. Phœnice and Paleftine, fays Stephanus Byzantinus, were the fame. As for Syria, we have already obferved, that in its largeft extent it fometimes comprehended Phœnice and Cœlefyria. Herodotus plainly confounds thefe three names; we mean, ufes one for the other indifferently.

(D) Bochart infinuates that the Canaanites were afhamed of their name, on account of the curfe denounced on their progenitor, and terrified by the wars fo vigorouſly and fucceſsfully waged on them by the Iſraelites, purely becauſe they were Canaanites; and that therefore, to avoid the ignominy of the one and the danger of the other, they abjured their old name, and changed it for Phœnicians, Syrians, Syrophœnicians, and Aſſyrians. Heidegger conjectures alſo that they were aſhamed of their anceſtor Canaan.

Phœnicia. thereon immediately fell down into a hollow where there was a fiery furnace. He adds alſo, that this inhuman practice ſeemed to confirm a tradition, handed down to the Greeks from very early antiquity, viz. that Saturn devoured his own children.

The goddeſs Cœleſtis, or Urania, was held in the higheſt veneration by the Carthaginians. She is thought to have been the ſame with the queen of heaven mentioned in Jeremiah, the Juno Olympia of the Greeks. According to Heſychius, the ſame word applied in the Punic language both to Juno and Venus: Nay, the ancient Greeks frequently confound Juno, Venus, and Diana or the moon, all together; which is to be attributed to the Egyptians and Phœnicians, from whom they received their ſyſtem of religion; who ſeem in the moſt ancient times to have had but one name for them all. Beſides theſe there were ſeveral other deities of later date, who were worſhipped among the Phœnicians, particularly thoſe of Tyre, and conſequently among the Carthaginians alſo. Theſe were Jupiter, Apollo, Mars, and Bacchus. Jupiter was worſhipped under the name of *Belus* or *Baal*. To him they addreſſed their oaths; and placed him for the moſt part, as there is reaſon to believe, at the head of their treaties. The ſame name was alſo given to the other two, whence they were frequently miſtaken for one another. Apollo or the ſun went either by this name ſimply, or by others of which this made a part.

The Carthaginian ſuperſtition, however, was not confined to theſe deities alone. They worſhipped alſo the fire, air, and other elements; and had gods of rivers, meads, &c. Nay, they paid divine honours to the ſpirits of their heroes, and even to men and women themſelves while yet in life; and in this adoration Hannibal the Great had for ſome time a ſhare, notwithſtanding the infamous conduct of his countrymen towards him at laſt. In order to worſhip thoſe gods with more conveniency on all occaſions, the Carthaginians had a kind of portable temples. Theſe were only covered chariots, in which were ſome ſmall images repreſenting their favourite deities; and which were drawn by oxen. They were alſo a kind of oracle; and their reſponſes were underſtood by the motion impreſſed upon the vehicle. This was likewiſe an Egyptian or Libyan cuſtom; and Tacitus informs us that the ancient Germans had ſomething of the ſame kind. The tabernacle of Moloch is thought to have been a machine of this kind; and it is not improbable that the whole was derived from the tabernacle of the Jews in the wilderneſs.

Beſides all the deities above-mentioned, we ſtill find another, named the *Dæmon* or *Genius* of Carthage, mentioned in the treaty made by Philip of Macedon and Hannibal. What this deity might be, we know not; however, it may be obſerved, that the pagan world in general believed in the exiſtence of demons, or intelligences who had a kind of middle nature between gods and men, and to whom the adminiſtration of the world was in a great meaſure committed. Hence it is no wonder that they ſhould have received religious honours. For when once mankind were poſſeſſed with the opinion that they were the miniſters of the gods, and truſted with the diſpenſation of their favours, as well as the infliction of their puniſhments, it is natural to ſuppoſe that they would be deſirous of making their addreſſes to them. See Astarte and Polytheism. Phœnicia.

Herodotus ſuppoſes the Phœnicians to have been circumciſed; but Joſephus aſſerts, that none of the nations included under the vague name of Paleſtine and Syria uſed that rite, the Jews excepted; ſo that if the Phœnicians had anciently that cuſtom, they came in time to neglect it, and at length wholly laid it aſide. They abſtained however from the fleſh of ſwine.

Much is ſaid of their arts, ſciences, and manufactures; but as what we find concerning them is couched in general terms only, we cannot deſcant on particulars. The Sidonians, under which denomination we comprehend the Phœnicians in general, were of a moſt happy genius. They were from the beginning addicted to philoſophical exerciſes of the mind; inſomuch that a Sidonian, by name Moſchus, taught the doctrine of atoms before the Trojan war: and Abomenus of Tyre puzzled Solomon by the ſubtilty of his queſtions. Phœnice continued to be one of the ſeats of learning, and both Tyre and Sidon produced their philoſophers of later ages; namely, Boethus and Diodatus of Sidon, Antipater of Tyre, and Appollonius of the ſame place; who gave an account of the writings and diſciples of Zeno. For their language, ſee Philology, n° 61. As to their manufactures, the glaſs of Sidon, the purple of Tyre, and the exceeding fine linen they wove, were the product of their own country, and their own invention; and for their extraordinary ſkill in working metals, in hewing timber and ſtone; in a word, for their perfect knowledge of what was ſolid, great, and ornamental in architecture—we need only put the reader in mind of the large ſhare they had in erecting and decorating the temple at Jeruſalem under their king Hiram. Their fame for taſte, deſign, and ingenious invention, was ſuch, that whatever was elegant, great, or pleaſing, whether in apparel, veſſels, or toys, was diſtinguiſhed by way of excellence with the epithet of Sidonian.

The Phœnicians were likewiſe celebrated as merchants, navigators, and planters of colonies in foreign parts. As merchants, they may be ſaid to have engroſſed all the commerce of the weſtern world: as navigators, they were the boldeſt, the moſt experienced, and greateſt diſcoverers, of the ancient times: they had for many ages no rivals. In planting colonies they exerted themſelves ſo much, that, conſidering their habitation was little more than the ſlip of ground between mount Libanus and the ſea, it is ſurpriſing how they could furniſh ſuch ſupplies of people, and not wholly depopulate their native country.

It is generally ſuppoſed that the Phœnicians were induced to deal in foreign commodities by their neighbourhood with the Syrians, who were perhaps the moſt ancient of thoſe who carried on a conſiderable and regular trade with the more eaſtern regions: and this conjecture appears probable at leaſt; for their own territory was but ſmall, and little able to afford any conſiderable exports, if we except manufactures: but that their manufactures were anyways conſiderable till they began to turn all the channels of trade into their own country, it is hard to believe. In Syria, which was a large country, they found ſtore of productions of the natural growth of that ſoil, and many choice and uſeful commodities brought from the eaſt. Thus, having

Phœnicia. a safe coast, with convenient harbours, on one side, and excellent materials for ship-building on the other; perceiving how acceptable many commodities that Syria furnished would be in foreign parts, and being at the same time, perhaps, shown the way by the Syrians themselves, who may have navigated the Mediterranean—they turned all their thoughts to trade and navigation, and by an uncommon application soon eclipsed their masters in that art.

It were in vain to talk of the Edomites, who fled hither in David's time; or to inquire why Herodotus supposes the Phœnicians came from the Red Sea: their origin we have already seen. That some of the Edomites fled into this country in the days of David, and that they were a trading people, is very evident: what improvements they brought with them into Phœnice, it is hard to say; and by the way, it is as difficult to ascertain their numbers. In all probability they brought with them a knowledge of the Red Sea, and of the south parts of Arabia, Egypt, and Ethiopia; and by their information made the Phœnicians acquainted with those coasts; by which means they were enabled to undertake voyages to those parts, for Solomon, and Pharoah Necho, king of Egypt.

Their whole thoughts were employed on schemes to advance their commerce. They affected no empire but that of the sea; and seemed to aim at nothing but the peaceable enjoyment of their trade. This they extended to all the known parts they could reach; to the British isles, commonly understood by the Cassiterides; to Spain, and other places in the ocean, both within and without the Straits of Gibraltar; and, in general, to all the ports of the Mediterranean, the Black Sea, and the Lake Mæotis. In all these parts they had settlements and correspondents, from which they drew what was useful to themselves, or might be so to others; and thus they exercised the three great branches of trade, as it is commonly divided into importation, exportation, and transportation, in full latitude. Such was their sea-trade; and for that which they carried on by land in Syria, Mesopotamia, Assyria, Babylonia, Persia, Arabia, and even in India, it was of no less extent, and may give us an idea of what this people once was, how rich and how deservedly their merchants are mentioned in Scripture as equal to princes. Their country was, at that time, the great warehouse, where every thing that might either administer to the necessities or luxury of mankind was to be found; which they distributed as they judged would be best for their own interest. The purple of Tyre, the glass of Sidon, and the exceeding fine linen made in this country, together with other curious pieces of art in metals and wood, already mentioned, appear to have been the chief and almost only commodities of Phœnice itself. Indeed their territory was so small, that it is not to be imagined they could afford to export any of their own growth; it is more likely that they rather wanted than abounded with the fruits of the earth.

Having thus spoken in general terms of their trade, we shall now touch upon their shipping and some things remarkable in their navigation. Their larger embarkations were of two sorts; they divided them into round ships or gauli; and long ships, galleys, or triremes. When they drew up in line of battle, the gauli were disposed at a small distance from each other in the wings, or in the van and the rear: their triremes were contracted together in the centre. If, at any time, they observed that a stranger kept them company in their voyage, or followed in their track, they were sure to get rid of him if they could, or deceive him if possible; in which policy they went so far, as to venture the loss of their ships, and even their lives; so jealous were they of foreigners, and so tenaciously bent on keeping the whole trade to themselves. In order to discourage other nations from engaging in commerce, they practised piracy, or pretended to be at war with such as they met when they thought themselves strongest. This was but a natural stroke of policy in people who grasped at the whole commerce of the then known world. We must not forget here the famous fishery of Tyre, which so remarkably enriched that city in particular. See Astronomy, n° 7. Ophir, and Tyre. Phœnicopterus.

PHOENICOPTERUS, or Flamingo, in ornithology, a genus of birds belonging to the order of grallæ. The beak is naked, teethed, and bent as if it was broken; the nostrils are linear; the feet are palmated, and four-toed. There is but one species; viz. the Bahamensis of Catesby, a native of Africa and America. Plate CCCXCII.

This bird resembles the heron in shape, excepting the bill, which is of a very singular form. It is two years old before it arrives at its perfect colour; and then it is entirely red, excepting the quill-feathers, which are black. A full-grown one is of equal weight with a wild duck; and when it stands erect, it is five feet high. The feet are webbed. The flesh is delicate; and most resembles that of a partridge in taste. The tongue, above any other part, was in the highest esteem with the luxurious Romans. These birds make their nests on hillocks in shallow water; on which they sit with their legs extended down, like a man sitting on a stool. They breed on the coasts of Cuba and the Bahama islands in the West Indies; and frequent salt-water only. By reason of the particular shape of its bill, this bird, in eating, twists its neck from side to side, and makes the upper mandible touch the ground. They are very stupid, and will not rise at the report of a gun; nor is it any warning to those who survive, that they see others killed by their side; so that, by keeping himself out of sight, a fowler may kill as many as he pleases.

These birds prefer a warm climate. In the old continent they are not often met with beyond 40 degrees north or south. They are met with everywhere on the African coast and adjacent isles, to the Cape of Good Hope; and sometimes on the coasts of Spain, Italy, and those of France lying in the Mediterranean Sea; being at times found at Marseilles, and for some way up the Rhone. In some seasons they frequent Aleppo and the parts adjacent. They are seen also on the Persian side of the Caspian Sea, and from thence along the western coast as far as the Wolga; tho' this is at uncertain times, and chiefly in considerable flocks coming from the north-east, mostly in October and November; but so soon as the wind changes they totally disappear. They breed in the Cape Verd isles, particularly in that of Sal. They go for the most part together in flocks, except in breeding time. Dampier says, that, with two more in company, he killed 14 at once, which was effected by secreting themselves; *Latham's Synopsis.*

Phœnicopterus, Phœnix.

for they are so very shy, that they will by no means suffer any one to approach openly near enough to shoot them. Kolben tells us, that they are very numerous at the Cape; keeping in the day on the borders of the lakes and rivers, and lodging themselves at night in the long grass on the hills. They are also common to various places in the warmer parts of America, frequenting the same latitudes as in other quarters of the world; being found at Peru, Chili, Cayenne, and the coast of Brasil, as well as the various islands of the West Indies. Sloane found them in Jamaica; but particularly at the Bahama Islands and at Cuba, where they breed. When seen at a distance, they appear as a regiment of soldiers, being ranged along-side one another, on the borders of the rivers, searching for food; which chiefly consists of small fish or the eggs of them; and of water-insects, which they search after by plunging in the bill and part of the head, from time to time trampling with their feet to muddy the water, that their prey may be raised from the bottom. Whilst they are feeding, one of them is said to stand centinel, and the moment he sounds the alarm the whole flock takes wing. This bird, when at rest, stands on one leg, the other being drawn up close to the body, with the head placed under the wing on that side of the body it stands on.

They are sometimes caught young, and are brought up tame; but are always impatient of cold: and in this state will seldom live a great while, gradually losing their colour, flesh, and appetite, and dying for want of that food which in a state of nature at large they were abundantly supplied with.

PHOENIX, in astronomy. See there, n° 406.

Phœnix, the *Great Palm*, or *Date-tree*; a genus of plants belonging to the order of palmæ. There is only one species, viz. the dactylifera, or common date-tree, a native of Africa and the eastern countries, where it grows to 50, 60, and 100 feet high. The trunk is round, upright, and studded with protuberances, which are the vestiges of the decayed leaves. From the top issues forth a cluster of leaves or branches eight or nine feet long, extending all round like an umbrella, and bending a little towards the earth. The bottom part produces a number of stalks like those of the middle, but seldom shooting so high as four or five feet. These stalks, says Adanson, diffuse the tree very considerably; so that, wherever it naturally grows in forests, it is extremely difficult to open a passage through its prickly leaves. The date-tree was introduced into Jamaica soon after the conquest of the island by the Spaniards. There are, however, but few of them in Jamaica at this time. The fruit is somewhat in the shape of an acorn. It is composed of a thin, light, and glossy membrane, somewhat pellucid and yellowish; which contains a fine, soft, and pulpy fruit, which is firm, sweet, and somewhat vinous to the taste, oleulent, and wholesome; and within this is inclosed a solid, tough, and hard kernel, of a pale grey colour on the outside, and finely marbled within like the nutmeg. For medicinal use dates are to be chosen large, full, fresh, yellow on the surface, soft and tender, not too much wrinkled; such as have a vinous taste, and do not rattle when shaken. They are produced in many parts of Europe, but never ripen perfectly there. The best are brought from Tunis; they are also very fine and good in Egypt and in many parts of the east. Those of Spain and France look well; but are never perfectly ripe, and very subject to decay. They are preserved three different ways; some pressed and dry; others pressed more moderately, and again moistened with their own juice; and others not pressed at all, but moistened with the juice of other dates, as they are packed up, which is done in baskets or skins. Those preserved in this last way are much the best. Dates have always been esteemed moderately strengthening and astringent. Phœnix.

Though the date-tree grows everywhere indiscriminately on the northern coasts of Africa, it is not cultivated with care, except beyond Mount Atlas; because the heat is not sufficiently powerful along the coasts to bring the fruits to proper maturity. We shall here extract some observations from Mr Des Fontaines respecting the manner of cultivating it in Barbary, and on the different uses to which it is applied. All that part of the Zaara which is near Mount Atlas, and the only part of this vast desert which is inhabited, produces very little corn; the soil being sandy, and burnt up by the sun, is almost entirely unfit for the cultivation of grain, its only productions of that kind being a little barley, maize, and sorgo. The date-tree, however, supplies the deficiency of corn to the inhabitants of these countries, and furnishes them with almost the whole of their subsistence. They have flocks of sheep; but as they are not numerous, they preserve them for the sake of their wool; besides, the flesh of these animals is very unwholesome food in countries that are excessively warm; and these people, though ignorant, have probably been enabled by experience to know that it was salutary for them to abstain from it. The date trees are planted without any order, at the distance of 12 feet one from the other, in the neighbourhood of rivulets and streams which issue from the sand. Forests of them may be seen here and there, some of which are several leagues in circumference. The extent of these plantations depends upon the quantity of water which can be procured to water them; for they require much moisture. All these forests are intermixed with orange, almond, and pomegranate trees, and with vines which twist round the trunks of the date trees; and the heat is strong enough to ripen the fruit, though they are never exposed to the sun.

Along the rivulets and streams, dykes are erected to stop the course of their waters, in order that they may be distributed amongst the date trees by means of small canals. The number of canals is fixed for each individual; and in several cantons, to have a right to them, the proprietors are obliged to pay an annual sum proportionable to the number and extent of their plantations. Care is taken to till the earth well, and to raise a circular border around the root of each tree, that the water may remain longer and in larger quantity. The date trees are watered in every season, but more particularly during the great heats of summer.

It is generally in winter that new plantations of this tree are formed. For this purpose those who cultivate them take shoots of those which produce the best dates, and plant them at a small distance one from the other. At the end of three or four years these shoots, if they have been properly taken care of, begin to bear fruit; but this fruit is as yet dry, without sweetness,

Phœnix. and even without kernels; they never reach the higheſt degree of perfection of which they are ſuſceptible till they are about 15 or 20 years old. Phœnix.

Theſe plants are however produced from the ſeeds taken out of the fruit, provided they are freſh. They ſhould be ſown in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, which ſhould be kept in a moderate temperature of heat, and the earth frequently refreſhed with water. When the plants are come up to a proper ſize, they ſhould be each planted in a ſeparate ſmall pot, filled with the ſame light earth, and plunged into a hot-bed again, obſerving to refreſh them with water, as alſo to let them have air in proportion to the warmth of the ſeaſon and the bed in which they are placed. During the ſummer time they ſhould remain in the ſame hot bed; but in the beginning of Auguſt, they ſhould have a great ſhare of air to harden them againſt the approach of winter; for if they are too much forced, they will be ſo tender as not to be preſerved through the winter without much difficulty, eſpecially if you have not the conveniency of a bark-ſtove to keep them in. The ſoil in which theſe plants ſhould be placed, muſt be compoſed in the following manner, viz. half of light freſh earth taken from a paſture-ground, the other half ſea-ſand and rotten dung or tanners bark in equal proportion; theſe ſhould be carefully mixed, and laid in a heap three or four months at leaſt before it is uſed, but ſhould be often turned over to prevent the growth of weeds, and to ſweeten the earth.

The trees, however, which ſpring from ſeed never produce ſo good dates as thoſe that are raiſed from ſhoots; they being always poor and ill taſted. It is undoubtedly by force of cultivation, and after ſeveral generations, that they acquire a good quality.

The date trees which have been originally ſown, grow rapidly, and we have been aſſured that they bear fruit in the fourth or fifth year. Care is taken to cut the inferior branches of the date tree in proportion as they riſe; and a piece of the root is always left of ſome inches in length, which affords the eaſy means of climbing to the ſummit. Theſe trees live a long time, according to the account of the Arabs; and in order to prove it, they ſay that when they have attained to their full growth, no change is obſerved in them for the ſpace of three generations.

The number of females which are cultivated is much ſuperior to that of the males, becauſe they are much more profitable. The ſexual organs of the date tree grow, as is well known, upon different ſtalks, and theſe trees flower in the months of April and May, at which time the Arabs cut the male branches to impregnate the female. For this purpoſe, they make an inciſion in the trunk of each branch which they wiſh to produce fruit, and place in it a ſtalk of male flowers; without this precaution the date tree would produce only abortive fruit (A). In ſome cantons the male branches are only ſhaken over the female. The practice of impregnating the date tree in this manner is very ancient. Pliny deſcribes it very accurately in that part of his work where he treats of the palm tree.

There is ſcarcely any part of the date tree which is not uſeful. The wood, though of a ſpongy texture, laſts ſuch a number of years, that the inhabitants of the country ſay it is incorruptible. They employ it for making beams and inſtruments of huſbandry; it burns ſlowly, but the coals which reſult from its combuſtion are very ſtrong, and produce a great heat.

The Arabs ſtrip the bark and fibrous parts from the young date trees, and eat the ſubſtance, which is in the centre; it is very nouriſhing, and has a ſweet taſte: it is known by the name of the marrow of the date tree. They eat alſo the leaves, when they are young and tender, with lemon juice; the old ones are laid out to dry, and are employed for making mats and other works of the ſame kind, which are much uſed, and with which they carry on a conſiderable trade in the interior parts of the country. From the ſides of the ſtumps of the branches which have been left ariſe a great number of delicate filaments, of which they make ropes, and which might ſerve to fabricate cloth.

Of the freſh dates and ſugar, ſays Haſſelquiſt, the Egyptians make a conſerve, which has a very pleaſant taſte. In Egypt they uſe the leaves as fly flaps, for driving away the numerous inſects which prove ſo troubleſome in hot countries. The hard boughs are uſed for fences and other purpoſes of huſbandry; the principal ſtem for building. The fruit, before it is ripe, is ſomewhat aſtringent; but when thoroughly mature, is of the nature of the fig. The Senegal dates are ſhorter than thoſe of Egypt, but much thicker in the pulp, which is ſaid to have a ſugary agreeable taſte, ſuperior to that of the beſt dates of the Levant.

A white liquor, known by the name of *milk*, is drawn alſo from the date tree. To obtain it, all the branches are cut from the ſummit of one of theſe trees, and after ſeveral inciſions have been made in it, they are covered with leaves, in order that the heat of the ſun may not dry it.

The ſap drops down into a veſſel placed to receive it, at the bottom of a circular groove, made below the

(A) The celebrated Linnæus, in his Diſſertation on the Sexes of Plants, ſpeaking of the date tree, ſays, "A female date-bearing palm flowered many years at Berlin without producing any ſeeds; but the Berlin people taking care to have ſome of the bloſſoms of the male tree, which was then flowering at Leipſic, ſent to them by the poſt, they obtained fruit by theſe means; and ſome dates, the offſpring of this impregnation, being planted in my garden, ſprung up, and to this day continue to grow vigorouſly. Kœmpfer formerly told us, how neceſſary it was found by the oriental people, who live upon the produce of palm-trees, and are the true *Lotophagi*, to plant ſome male trees among the females, if they hoped for any fruit: hence it is the practice of thoſe who make war in that part of the world to cut down all the male palms, that a famine may afflict their proprietors; ſometimes even the inhabitants themſelves deſtroy the male trees when they dread an invaſion, that their enemies may find no ſuſtenance in the country."

Phœnix. the inciſions. The milk of the date tree has a ſweet and agreeable taſte when it is new; it is very refreſhing, and it is even given to ſick people to drink, but it generally turns ſour at the end of 24 hours. Old trees are choſen for this operation, becauſe the cutting of the branches, and the large quantity of ſap which flows from them, greatly exhauſt them, and often cauſe them to decay.

The male flowers of the date tree are alſo uſeful. They are eaten when ſtill tender, mixed up with a little lemon juice. They are reckoned to be very provocative: the odour which they exhale is probably the cauſe of this property being aſcribed to them.

Theſe date trees are very lucrative to the inhabitants of the deſert. Some of them produce 20 bunches of dates; but care is always taken to lop off a part of them, that thoſe which remain may become larger; 10 or 12 bunches only are left on the moſt vigorous trees.

It is reckoned that a good tree produces, one year with another, about the value of 10 or 12 ſhillings to the proprietor. A pretty conſiderable trade is carried on with dates in the interior part of the country, and large quantities of them are exported to France and Italy. The crop is gathered towards the end of November. When the bunches are taken from the tree, they are hung up in ſome very dry place where they may be ſheltered and ſecure from inſects.

Dates afford wholeſome nouriſhment, and have a very agreeable taſte when they are freſh. The Arabs eat them without ſeaſoning. They dry and harden them in the ſun, to reduce them to a kind of meal, which they lay up in ſtore to ſupply themſelves with food during the long journeys which they often undertake acroſs their deſerts. This ſimple food is ſufficient to nouriſh them for a long time.—The inhabitants of the Zaara procure alſo from their dates a kind of honey which is exceedingly ſweet. For this purpoſe they chooſe thoſe which have the ſofteſt pulp; and having put them into a large jar with a hole in the bottom, they ſqueeze them by placing over them a weight of eight or ten pounds.—The moſt fluid part of the ſubſtance, which drops through the hole, is what they call the *honey* of the date.

Even the ſtones, though very hard, are not thrown away. They give them to their camels and ſheep as food, after they have bruiſed them or laid them to ſoften in water.

The date, as well as other trees which are cultivated, exhibits great variety in its fruit, with reſpect to ſhape, ſize, quality, and even colour. There are reckoned to be at leaſt twenty different kinds. Dates are very liable to be pierced by worms, and they ſoon corrupt in moiſt or rainy weather.

From what has been ſaid, it may eaſily be perceived, that there is, perhaps, no tree whatever uſed for ſo many and ſo valuable purpoſes as the date tree.

Phœnix, in ornithology, a bird famous in antiquity, but generally looked upon by the moderns as fabulous. The ancients ſpeak of this bird as ſingle, or the only one of its kind; they deſcribe it as of the ſize of an eagle; its head finely creſted with a beautiful plumage, its neck covered with feathers of a gold colour, and the reſt of its body purple, only the tail white, and the eyes ſparkling like ſtars: they hold, that it lives 500 or 600 years in the wilderneſs; that when thus advanced in age, it builds itſelf a pile of ſweet wood and aromatic gums, and fires it with the waſting of its wings, and thus burns itſelf; and that from its aſhes ariſes a worm, which in time grows up to be a phœnix. Hence the Phœnicians gave the name of *phœnix* to the palm-tree; becauſe when burnt down to the root it riſes again fairer than ever. Phœnix.

In the ſixth book of the Annals of Tacitus, ſect. 28. it is obſerved that, in the year of Rome 787, the phœnix reviſited Egypt; which occaſioned among the learned much ſpeculation. This being is ſacred to the ſun. Of its longevity the accounts are various. The common perſuaſion is, as we have mentioned above, that it lives 500 years; though by ſome the date is extended to 1461. The ſeveral eras when the phœnix has been ſeen are fixed by tradition. The firſt, we are told, was in the reign of Seſoſtris; the ſecond in that of Amaſis; and, in the period when Ptolemy the third of the Macedonian race was ſeated on the throne of Egypt, another phœnix directed its flight towards Heliopolis. When to theſe circumſtances are added the brilliant appearance of the phœnix, and the tale that it makes frequent excurſions with a load on its back, and that when, by having made the experiment through a long tract of air, it gains ſufficient confidence in its own vigour, it takes up the body of its father and flies with it to the altar of the ſun to be there conſumed; it cannot but appear probable, that the learned of Egypt had enveloped under this allegory the philoſophy of comets.

Phœnix, ſon of Amyntor king of Argos by Cleobule or Hippodamia, was preceptor to young Achilles. His father having proved faithleſs to his wife, through fondneſs for a concubine called *Clytia*, Cleobule, who was jealous of him, perſuaded her ſon Phœnix to ingratiate himſelf with his father's miſtreſs. Phœnix eaſily ſucceeded; but Amyntor diſcovering his intrigues, he drew a curſe upon him, and the ſon was ſoon after deprived of his ſight by divine vengeance. Some ſay that Amyntor himſelf put out his ſon's eyes, which ſo cruelly provoked him that he meditated the death of his father. Reaſon and piety, however, prevailed over paſſion; and that he might not become a parricide, Phœnix fled from Argos to the court of Peleus king of Phthia. Here he was treated with tenderneſs; Peleus carried him to Chiron, who reſtored him to his eye ſight; ſoon after which he was made preceptor to Achilles, his benefactor's ſon. He was alſo preſented with the government of many cities, and made king of the Dolopes. He went with his pupil to the Trojan war; and Achilles was ever grateful for the inſtructions and precepts which he had received from him. After the death of Achilles, Phœnix, with others, was commiſſioned by the Greeks to return into Greece, to bring to the war young Pyrrhus. This commiſſion he ſucceſsfully performed; and after the fall of Troy, he returned with Pyrrhus, and died in Thrace. He was buried, according to Strabo, near Trachinia, where a ſmall river in the neighbourhood received the name of *Phœnix*. There was another Phœnix, ſon of Agenor, by a nymph who was called *Telephaſſa*, according to Apollodorus and Muſchus, or, according to others, *Epimeduſa*, *Perimede*, or *Argiope*. He was, like his brother Cadmus, and Cilix, ſent by his

Pholas. his father in purſuit of his ſiſter Europa, whom Jupiter had carried away under the form of a bull; and when his inquiries proved unſucceſsful, he ſettled in a country, which, according to ſome, was from him called *Phœnicia*. From him, as ſome ſuppoſe, the Carthaginians were called *Pœni*.

Plate CCCXCII. PHOLAS, a genus of inſects, belonging to the order of vermes teſtacea. The ſhell is double-valved and divaricated; the cardo is turned backwards, and connected by a cartilage. There are ſix ſpecies, diſtinguiſhed by the figure of their ſhells.

The word *pholas* is derived from the Greek, and ſignifies ſomething which lies hid. This name they derive from their property of making themſelves holes in the earth, ſand, wood, or ſtone, and living in them. The means of their getting there, however, are as yet entirely unknown. All that we can know with certainty is, that they muſt have penetrated theſe ſubſtances when very ſmall; becauſe the entrance of the hole in which the pholas lodges is always much leſs than the inner part of it, and indeed than the ſhell of the pholas itſelf. Hence ſome have ſuppoſed that they were hatched in holes accidentally formed in ſtones, and that they naturally grew of ſuch a ſhape as was neceſſary to fill the cavity.

The holes in which the pholades lodge are uſually twice as deep, at leaſt, as the ſhells themſelves are long; the figure of the holes is that of a truncated cone, excepting that they are terminated at the bottom by a rounded cavity, and their poſition is uſually ſomewhat oblique to the horizon. The openings of theſe holes are what betray the pholas being in the ſtone; but they are always very ſmall in proportion to the ſize of the fiſh. There ſeems to be no progreſſive motion of any animal in nature ſo ſlow as that of the pholas; it is immerſed in the hole, and has no movement except a ſmall one towards the centre of the earth; and this is only proportioned to the growth of the animal. Its work is very difficult in its motion; but it has great time to perform it in, as it only moves downward, ſinking itſelf deeper in the ſtone as it increaſes itſelf in bulk. That part by means of which it performs this, is a fleſhy ſubſtance placed near the lower extremity of the ſhell; it is of the ſhape of a lozenge, and is conſiderably large in proportion to the ſize of the animal; and though it be of a ſoft ſubſtance, it is not to be wondered at that in ſo long a time it is able, by conſtant work, to burrow into a hard ſtone. The manner of their performing this may be ſeen by taking one of them out of the ſtone, and placing it upon ſome ſoft clay; for they will immediately get to work in bending and extending that part allotted to dig for them, and in a few hours they will bury themſelves in the mud in as large a hole as they had taken many years to make in the ſtone. They find little reſiſtance in ſo ſoft a ſubſtance; and the neceſſity of their hiding themſelves evidently makes them haſten their work. The animal is lodged in the lower half of the hole in the ſtone, and the upper half is filled up by a pipe of a fleſhy ſubſtance and conic figure, truncated at the end: this they uſually extend to the orifice of the hole, and place on a level with the ſurface of the ſtone; but they ſeldom extend it any farther than this. The pipe, though it appears ſingle, is in reality compoſed of two pipes, or at leaſt it is compoſed of two parts ſeparated by a membrane. The uſe of this pipe or proboſcis is the ſame with that of the proboſcis of other ſhell-fiſh, to take in ſea-water into their bodies, and afterwards to throw it out again. In the middle of their bodies they have a ſmall green veſſel, the uſe of which has not yet been diſcovered. This, when plunged in ſpirit-of-wine, becomes of a purple colour: but its colour on linen will not become purple in the ſun like that of the murex; and even if it would, its quantity is too ſmall to make it worth preſerving. Pholas.

The pholas is remarkable for its luminous quality. That this fiſh is luminous was noticed by Pliny, who obſerves that it ſhines in the mouth of the perſon who eats it; and if it touch his hands or clothes, it makes them luminous. He alſo ſays that the light depends upon its moiſture. The light of this fiſh has furniſhed matter for various obſervations and experiments to M. Reaumur and the Bolognian academicians, eſpecially Beccarius, who took ſo much pains with the ſubject of phoſphoreal light.

M. Reaumur obſerves, that whereas other fiſhes give light when they tend to putreſcence, this is more luminous in proportion to its being freſh; that when they are dried, their light will revive if they be moiſtened either with freſh or ſalt water, but that brandy immediately extinguiſhes it. He endeavoured to make this light permanent, but none of his ſchemes ſucceeded.

The attention of the Bolognian academicians was engaged to this ſubject by M. F. Marſilius in 1724, who brought a number of theſe fiſhes, and the ſtones in which they were incloſed, to Bologna, on purpoſe for their examination.

Beccarius obſerved, that though this fiſh ceaſed to ſhine when it became putrid, yet that in its moſt putrid ſtate it would ſhine, and make the water in which it was immerſed luminous when it was agitated. Galeatius and Montius found that wine or vinegar extinguiſhed this light; that in common oil it continued ſome days, but in rectified ſpirit of wine or urine hardly a minute.

In order to obſerve in what manner this light was affected by different degrees of heat, they made uſe of a Reaumur's thermometer, and found that water rendered luminous by theſe fiſhes increaſed in light till the heat arrived to 45°, but that it then became ſuddenly extinct, and could not be revived again.

In the experiments of Beccarius, a ſolution of ſea-ſalt increaſed the light of the luminous water; a ſolution of nitre did not increaſe it quite ſo much. Sal ammoniac diminiſhed it a little, oil of tartar *per deliquium* nearly extinguiſhed it, and the acids entirely. This water poured upon freſh calcined gypſum, rock cryſtal, ceruſe, or ſugar, became more luminous. He alſo tried the effects of it when poured upon various other ſubſtances, but there was nothing very remarkable in them. Afterwards, uſing luminous milk, he found that oil of vitriol extinguiſhed the light, but that of tartar increaſed it.

This gentleman had the curioſity to try how differently coloured ſubſtances were affected by this kind of light; and having, for this purpoſe, dipped ſeveral ribbons in it, the white came out the brighteſt, next to this was the yellow, and then the green; the other colours could hardly be perceived. It was not, however,

Pholas, Pholeys.

however, any particular colour, but only light, that was perceived in this caſe. He then dipped boards painted with the different colours, and alſo glaſs tubes filled with ſubſtances of different colours, in water rendered luminous by the fiſhes. In both theſe caſes, the red was hardly viſible, the yellow was the brighteſt, and the violet the dulleſt. But on the boards, the blue was nearly equal to the yellow, and the green more languid; whereas in the glaſſes, the blue was inferior to the green.

Of all the liquors to which he put the pholades, milk was rendered the moſt luminous. A ſingle pholas made ſeven ounces of milk ſo luminous, that the faces of perſons might be diſtinguiſhed by it, and it looked as if it was tranſparent.

Air appeared to be neceſſary to this light; for when Beccarius put the luminous milk into glaſs tubes, no agitation would make it ſhine unleſs bubbles of air were mixed with it. Alſo Montius and Galeatius found, that, in an exhauſted receiver, the pholas loſt its light, but the water was ſometimes made more luminous; which they aſcribed to the riſing of bubbles of air through it.

Beccarius, as well as Reaumur, had many ſchemes to render the light of theſe pholades permanent. For this purpoſe he kneaded the juice into a kind of paſte with flour, and found that it would give light when it was immerſed in warm water; but it anſwered beſt to preſerve the fiſh in honey. In any other method of preſervation, the property of becoming luminous would not continue longer than ſix months, but in honey it had laſted above a year; and then it would, when plunged in warm water, give as much light as ever it had done. See Barbut's *Genera Verminum*, p. 14. &c.

PHOLEYS, or Foulies, are a people of Africa, of very peculiar manners. Some authors tell us, that the kingdom of Pholey, from whence they derive their name, is divided from that of Jaloff by a lake called in the language of the Mundingoes *Cayor*; and that it ſtretches from eaſt to weſt about 180 miles; but that, though it extends a great way ſouth, its limits in that direction are not exactly aſcertained.

Payne's Geography, Vol I. p. 442.

Mr Moore, however, gives a very different account, and ſays, that the Pholeys live in clans, build towns, and are in every kingdom and country on each ſide the river; yet are not ſubject to any of the kings of the country, though they live in their territories; for if they are uſed ill in one nation, they break up their towns, and remove to another. They have chiefs of their own, who rule with ſuch moderation, that every act of government ſeems rather an act of the people than of one man. This form of government is eaſily adminiſtered, becauſe the people are of a good and quiet diſpoſition, and ſo well inſtructed in what is juſt and right, that a man who does ill expoſes himſelf to univerſal contempt.

The natives of all theſe countries, not being avaricious of land, deſire no more than they can uſe; and as they do not plough with horſes or other cattle, they can uſe but very little; and hence the kings willingly allow the Pholeys to live in their dominions, and cultivate the earth.

The Pholeys have in general a tawney complexion, though many of them are of as deep a black as the Mundingoes; and it is ſuppoſed that their alliances with the Moors have given them the mixed colour between the true olive and the black. They are rather of a low ſtature, but have a genteel and eaſy ſhape, with an air peculiarly delicate and agreeable. Pholeys.

Though they are ſtrangers in the country, they are the greateſt planters in it. They are extremely induſtrious and frugal, and raiſe much more corn and cotton than they conſume, which they ſell at reaſonable rates; and are ſo remarkable for their hoſpitality, that the natives eſteem it a bleſſing to have a Pholey town in their neighbourhood; and their behaviour has gained them ſuch reputation, that it is eſteemed infamous for any one to treat them in an unhoſpitable manner. Their humanity extends to all, but they are doubly kind to people of their race; and if they know of any one of their body being made a ſlave, they will readily redeem him. As they have plenty of food, they never ſuffer any of their own people to want; but ſupport the old, the blind, and the lame, equally with the others.

Theſe people are ſeldom angry; and Mr Moore obſerves that he never heard them abuſe each other; yet this mildneſs is far from proceeding from want of courage, they being as brave as any people of Africa, and very expert in the uſe of their arms, which are javelins, cutlaſſes, bows and arrows, and upon occaſion guns. They uſually ſettle near ſome Mundingo town, there being ſcarce any of note up the river that has not a Pholey town near it. Moſt of them ſpeak Arabic, which is taught in their ſchools; and they are able to read the Koran in that language, though they have a vulgar tongue called *Pholey*. They are ſtrict Mahometans, and ſcarce any of them will drink brandy, or any thing ſtronger than ſugar and water.

They are ſo ſkilful in the management of cattle, that the Mundingoes leave theirs to their care. The whole herd belonging to a town feed all day in the ſavannahs, and after the crop is off, in the rice-grounds. They have a place without each town for their cattle, ſurrounded by a circular hedge, and within this incloſure they raiſe a ſtage about eight feet high, and eight or ten feet wide, covered with a thatched roof; all the ſides are open, and they aſcend to it by a ladder. Round this ſtage they fix a number of ſtakes, and when the cattle are brought up at night, each beaſt is tied to a ſeparate ſtake with a ſtrong rope made of the bark of trees. The cows are then milked, and four or five men ſtay upon the ſtage all night with their arms to guard them from the lions, tygers, and other wild beaſts. Their houſes are built in a very regular manner, they being round ſtructures, placed in rows at a diſtance from each other to avoid fire, and each of them has a thatched roof ſomewhat reſembling a high-crowned hat.

They are alſo great huntſmen, and not only kill lions, tygers, and other wild beaſts, but frequently go 20 or 30 in a company to hunt elephants; whoſe teeth they ſell, and whoſe fleſh they ſmoke-dry and eat, keeping it for ſeveral months together. As the elephants here generally go in droves of 100 or 200, they do great miſchief by pulling up the trees by the roots, and trampling down the corn; to prevent which, when the natives have any ſuſpicion of their coming, they make fires round their corn to keep them out.

They

Pholis
||
Phormium.

They are almoſt the only people who make butter, and ſell cattle at ſome diſtance up the river. They are very particular in their dreſs, and never wear any other clothes but long robes of white cotton, which they make themſelves. They are always very clean, eſpecially the women, who keep their houſes exceedingly neat. They are, however, in ſome particulars very ſuperſtitious; for if they chance to know that any perſon who buys milk of them boils it, they will from thenceforth on no conſideration ſell that perſon any more, from their imagining that boiling the milk makes the cows dry.

PHOLIS, in natural hiſtory, is the name of a genus of foſſils of the claſs of gypſums or plaſter-ſtones. Its diſtinguiſhing characters are, that the bodies of it are tolerably hard, compoſed of particles ſomewhat broad, and of a bright cryſtalline luſtre. The name is derived from φολις, a *ſcale* or *ſmall flake*, becauſe they are compoſed of particles of that form.

The ſpecies of this genus are very valuable, and perhaps the moſt ſo of all the gypſums, becauſe they burn to the beſt and fineſt plaſter, but ſo far as is yet known, there are but two of them: the fine plaſter-ſtone of Montmartre in France, called by us *plaſter of Paris ſtone* and *parget*; and the other, the coarſer and ſomewhat reddiſh kind, common in many parts of England, and called *hall plaſter*. See PLASTER *of Paris*.

PHOLIS, in ichthyology, is the name of a ſmall anguilliform fiſh. The back is brown, the belly is white, the whole back and ſides are ſpotted, and the ſkin is ſoft, free of ſcales, but with a tough mucilaginous matter like the eel. This ſpecies moſt of all approaches to the *alauda*; and tho' uſually larger, yet Mr Ray doubts whether it really differs from it in any thing eſſential; the diſtinction is its colour, which though a very obvious is certainly a very precarious one.

PHONICS, the doctrine or ſcience of ſounds, otherwiſe called ACOUSTICS. See that article.

PHORMIUM, FLAX-PLANT, (*Phormium tenax*, Forſt.) is a name which we may give to a plant that ſerves the inhabitants of New Zealand inſtead of hemp and flax. Of this plant there are two ſorts; the leaves of both reſemble thoſe of flags, but the flowers are ſmaller, and their cluſters more numerous; in one kind they are yellow, and in the other a deep red. Of the leaves of theſe plants, with very little preparation, they make all their common apparel, and alſo their ſtrings, lines, and cordage, for every purpoſe; which are ſo much ſtronger than any thing we can make with hemp, that they will not bear a compariſon.—From the ſame plant, by another preparation, they draw long ſlender fibres, which ſhine like ſilk, and are as white as ſnow: of theſe, which are very ſtrong, they make their fineſt cloths; and of the leaves, without any other preparation than ſplitting them into proper breadths, and tying the ſtrips together, they make their fiſhing-nets, ſome of which are of an enormous ſize.

The ſeeds of this valuable plant have been brought over into England; but, upon trial, appeared to have loſt their vegetating power.

The filamentous parts of different vegetables have been employed in different countries for the ſame mechanic uſes as hemp and flax among us. Putrefaction, and in ſome degree alkaline lixivia, deſtroy the pulpy or fleſhy matter, and leave the tough filaments entire. By curiouſly putrefying the leaf of a plant in water, we obtain the fine flexible fibres which conſtituted the baſis of the ribs and minute veins, and which form as it were a ſkeleton of the leaf. In Madagaſcar, different kinds of cloth are prepared from the filaments of the bark of certain trees boiled in ſtrong ley; and ſome of theſe cloths are very fine, and approach to the ſoftneſs of ſilk, but in durability come ſhort of cotton: others are coarſer and ſtronger, and laſt thrice as long as cotton; and of theſe filaments they make ſails and cordage to their veſſels. The ſtalks of nettles are ſometimes uſed for like purpoſes, even in France; and Sir Hans Sloane relates, in one of his letters to Mr Ray, that he has been informed by ſeveral, that muſlin and callico, and moſt of the Indian linens, are made of nettles. A ſtrong kind of cloth is ſaid to be prepared in ſome of the provinces of Sweden of hop-ſtalks; and in the Tranſactions of the Swediſh Academy for 1750, we have an account of an experiment relating to this ſubject: A quantity of the ſtalks was gathered in autumn, which was equal in bulk to a quantity of flax ſufficient to yield a pound after preparation. The ſtalks were put into water, and kept covered with it during the winter. In March they were taken out, dried in a ſtove, and dreſſed as flax. The prepared filaments weighed nearly a pound, and proved fine, ſoft, and white; they were ſpun and wove into ſix ells of fine ſtrong cloth. Unleſs the ſtalks are fully rotted, which will take much longer time than flax, the woody part will not ſeparate, and the cloth will prove neither white nor fine.

Phormium
Phoſphat.

PHOSPHAT, is a mineral found in Eſtremadura, It is of a whitiſh colour, and of great ſolidity, though not ſufficiently hard to ſtrike fire with ſteel. If triturated in an iron mortar in the dark, or even if two pieces of it be rubbed together, it becomes luminous; but when it has once loſt this property, it does not, like ſome natural phoſphori, receive it again by being expoſed to the rays of the ſun. If reduced to a very fine powder, and laid on coals, it does not decrepitate, but burns with a beautiful green light; though, if the coals be very hot, and the powder coarſe, decrepitation will take place.

According to the analyſis made by theſe chemiſts, 100 grains of the calcareous phoſphat is reſolvable into the following elements:

Carbonic acid	1 grain
Muriatic acid	½
Iron	1
Quartzous earth	2
Pure calcareous earth	59
Phoſphoric acid	34
Fluoric acid	2½
	100 grains.

We have the following account of an analyſis of a native phoſphat of lime (earth of bones) by Mr Haſſenfratz in the *Annals of Chemiſtry*. "The phoſphat of lime of Eſtremadura, found by Mr Prouſt, determined me to examine on the coals a phoſphorefcent powder which I collected at Kobala-Polyana near Sigeth,

Phof. hat. phofphorus

Sigeth, in the county of Marmarofch, during the metallurgic tour I made through Hungary by command of government. Though this powder gives abfolutely the fame appearance when treated on the coals as the fluat of lime (*fpath-fluor*), yet no fluoric acid is diſengaged from it when heated with ſulphuric acid. It diſſolves in nitric acid (dephlogiſticated nitrous acid); and ſulphuric (vitriolic) acid precipitates from this ſolution a conſiderable quantity of ſulfat of lime (gypſum): the liquor filtered, and concentrated by evaporation, gives a new precipitate ſimilar to the former. The liquor again filtered, and evaporated to dryneſs, left a ſlight reſiduum. This reſiduum, after having been expoſed to a fire ſufficiently ſtrong to make the veſſel containing it red-hot, and diſengage the nitric and ſulphuric acids which might have remained united with it, was ſoluble in diſtilled water, which it acidified. This acid did not precipitate barytic muriat; it cauſed a white precipitate from the ſolutions of ſulfat of iron (green vitriol), and nitrat of mercury (mercurial nitre), and formed a thick and copious one in lime water: hence it is evident, that this acid was the phoſphoric, and the powder was phoſphat of lime."

The phoſphat of ſoda is obtained by combining the phoſphoric acid with the mineral alkali. It has, we are told, been given with ſucceſs as a purge; and M. Pelletier thinks it may be applied to the ſoldering of metals inſtead of borax: and indeed it reſembles this ſubſtance ſo much in many of its properties, that it has been ſuppoſed that phoſphoric acid is one of the conſtituent principles of borax. See CHEMISTRY, n° 904.

1 Phoſphorus defined and diſtinguiſhed.
