Fluid. Notwithstanding the fabulous accounts of salamanders, it is now well known, that no animal, large or small, can bear the force of fire for any considerable time; and, by parity of reason; we are not to believe, that any insect, or embryo insect, in any state, can bear the heat of boiling water for many minutes. To proceed to enquiries on this foundation: If several tubes filled with water, with a small quantity of vegetable matter, such as pepper, oak-bark, truffles, &c. in which, after a time, insects will be discovered by the microscope; and other like tubes be filled with simple water boiled, with water and pepper boiled together, and with water with the two other ingredients, all separately boiled in it; when all these liquors come to a proper time for the observation of the microscope, all, as well those which have been boiled as those which have not, will be found equally to abound with insects; and those of the same kind, in infusions of the same kind, whether boiled or not boiled. Those in the infusions which had sustained a heat capable of destroying animal life, must therefore not have subsisted either in the water or in the matters put into it, but must have been brought thither after the boiling; and it seems by no way so probably, as by means of some little winged inhabitants of the air depositing their eggs or worms in these fluids.

On this it is natural to ask, how it comes to pass, that while we see myriads of the progeny of these winged insects in water, we never see themselves? The answer is equally easy, viz. because we can always place a drop of this water immediately before the focus of the microscope, and keep it there while we are at leisure to examine its contents; but that is not the case with regard to the air inhabited by the parent flies of these worms, which is an immense extent in proportion to the water proper for nourishing these worms; and consequently, while the latter are clustered together in heaps, the former may be dispersed and scattered. Nor do we want instances of this, even in insects of a larger kind. In many of our gardens, we frequently find vessels of water filled with worms of the gnat kind, as plentifully, in proportion to their size, as those of other fluids are with animalcules. Every cubic inch of water in these vessels contains many hundreds of animals; yet we see many cubic inches of air in the garden not affording one of the parent flies.

But neither are we positively to declare that the parent flies of these animalcules are in all states wholly invisible to us; if not singly to be seen, there are some strong reasons to imagine that they may in great clusters. Every one has seen in a clear day, when looking stedfastly at the sky, that the air is in many places disturbed by motions and convolutions in certain spots. These cannot be the effects of imagination, or of faults in our eyes, because they appear the same to all; and if we consider what would be the case to an eye formed in such a manner as to see nothing smaller than an ox, on viewing the air on a marsh fully peopled with gnats, we must be sensible, that the clouds of these insects, though to us distinctly enough visible, would appear to such an eye merely as the moving parcels of air in the former instance do to us: and surely it is thence no rash conclusion to infer, that the case may be the same, and that myriads of flying in-

Fluid
Fluidity. sects, too small to be singly the objects of our view, yet are to us what the clouds of gnats would be in the former case.

Nervous FLUID. See ANATOMY, p. 761. col. 2.

Elastic FLUIDS. See AEROLOGY, AIR, *FIXED Air*, GAS, VAPOUR, &c.

FLUIDITY, is by Sir Isaac Newton defined to be, that property of bodies by which they yield to any force impressed, and which have their parts very easily moved among one another.

To this definition some have added, that the parts of a fluid are in a continual motion. This opinion is supported by the solution of salts, and the formation of tinctures. If a small bit of saffron is thrown into a phial full of water, a yellow tincture will soon be communicated to the water to a considerable height, though the phial is allowed to remain at rest; which indicates a motion in those parts of the fluid which touch the saffron, by which its colouring matter is carried up.

With regard to water, this can scarce be denied; the constant exhalations from its surface show, that there must be a perpetual motion in its parts from the ascent of the steam through it. In mercury, where insensible evaporation does not take place, it might be doubted; and accordingly the Newtonian philosophers in general have been of opinion, that there are some substances essentially fluid, from the spherical figure of their constituent particles. The congelation of mercury, however, by an extreme degree of cold*, demonstrates that fluidity is not essentially inherent in mercury more than in other bodies.

*See Congelation.

That fluids have vacuities in their substance is evident, because they may be made to dissolve certain bodies without sensibly increasing their bulk. For example, water will dissolve a certain quantity of salt; after which it will receive a little sugar, and after that a little allum, without increasing its first dimensions. Here we can scarce suppose any thing else than that the saline particles were interposed between those of the fluid; and, as by the mixture of salt and water, a considerable degree of cold is produced, we may thence easily see why the fluid receives these substances without any increase of bulk. All substances are expanded by heat, and reduced into less dimensions by cold; therefore, if any substance is added to a fluid, which tends to make it cold, the expansion by the bulk of the substance added, will not be so much perceived as if this effect had not happened; and if the quantity added be small, the fluid will contract as much, perhaps more, from the cold produced by the mixture, than it will be expanded from the bulk of the salt. This also may let us know with what these interstices between the particles of the fluid were filled up; namely, the element of fire or heat. The saline particles, upon their solution in the fluid, have occupied these spaces; and now the liquor, being deprived of a quantity of this element equal in bulk to the salt added, feels sensibly colder.

As, therefore, there is scarce any body to be found, but what may become solid by a sufficient degree of cold, and none but what a certain degree of heat will render fluid; the opinion naturally arises, that fire is the cause of fluidity in all bodies, and that this element is the only essentially fluid substance in nature.

Hence we may conclude, that those substances which we call *fluids* are not essentially so, but only assume that appearance in consequence of an intimate union with the element of fire; just as gums assume a fluid appearance on being dissolved in spirit of wine, or salts in water.

Fluidity
||
Flummery.

Upon these principles Dr Black mentions fluidity as an effect of heat*. The different degrees of heat which are required to bring different bodies into a state of fluidity, he supposes to depend on some particulars in the mixture and composition of the bodies themselves: which becomes extremely probable, from considering that we change the natural state of bodies in this respect, by certain mixtures; thus, if two metals are compounded, the mixture is usually more fusible than either of them separately. See CHEMISTRY, n° 542.

*See Chemistry, n° 115, 117, 119.

It is certain, however, that water becomes warmer by being converted into ice†; which may seem contradictory to this opinion. To this, however, the Doctor replies, that fluidity does not consist in the degree of sensible heat contained in bodies, which will affect the hand or a thermometer; but in a certain quantity which remains in a latent state‡. This opinion he supports from the great length of time required to melt ice; and to ascertain the degree of heat requisite to keep water in a fluid state, he put five ounces of water into a Florence flask, and converted it into ice by means of a freezing mixture put round the flask. Into another flask of the same kind he put an equal quantity of water cooled down nearly to the freezing point, by mixing it with snow, and then pouring it off. In this he placed a very delicate thermometer; and found that it acquired heat from the air of the room in which it was placed: seven degrees of heat were gained the first half hour. The ice being exposed to the same degree of heat, namely, the air of a large room without fire, it cannot be doubted that it received heat from the air as fast as the water which was not frozen: but, to prevent all possibility of deception, he put his hand under the flask containing the ice, and found a stream of cold air very sensibly descending from it, even at a considerable distance from the flask; which undeniably proved, that the ice was all that time absorbing heat from the air. Nevertheless, it was not till 11 hours that the ice was half-melted, though in that time it had absorbed so much heat as ought to have raised the thermometer to 140°; and even after it was melted, the temperature of the water was found scarce above the freezing point: so that, as the heat which entered could not be found in the melted ice, he concluded that it remained concealed in the water, as an essential ingredient of its composition. See CONGELATION.

FLUKE, or FLOUNDER, in ichthyology. See PLEURONECTES.

FLUKE-Worm. See FASCIOLA.

FLUKE of an Anchor, that part of it which fastens in the ground. See ANCHOR.

FLUMMERY, a wholesome sort of jelly made of oat-meal.

The manner of preparing it is as follows. Put three large handfuls of finely ground oat-meal to steep, for 24 hours, in two quarts of fair water: then pour off the clear water, and put two quarts of fresh water to it:

it:

Flour.

it : strain it through a fine hair-sieve, putting in two spoonfuls of orange-flower water and a spoonful of sugar : boil it till it is as thick as a haasty-pudding, stirring it continually while it is boiling, that it may be very smooth.

FLUOR, in physics, a fluid ; or, more properly, the state of a body that was before hard or solid, but is now reduced by fusion or fire into a state of fluidity.

FLOUR Acid. See CHEMISTRY-Index

FLOUR Albus. See MEDICINE-Index.

FLOUR-Spar, or *Blue-John,* called also fluxing spars, vitrescent or glass spars, are a genus of fossils composed of calcareous earth united with an acid of a peculiar kind, of which an account is given under CHEMISTRY ; see that article, per Index at *Fluor acid.*

They are little harder than common calcareous spars, and do not strike fire with steel ; nor do they effervesce with acids either before or after calcination. When exposed to a strong fire, they crack and split in pieces, but do not melt without a violent heat. Engenstroom informs us, that all of them which he tried melted pretty easily before the blow-pipe ; but he was obliged to take great care to prevent them from flying away before they were thoroughly heated. Their specific gravity is from 3144 to 3175. Notwithstanding the difficulty with which they are fused by themselves however, they melt very readily in conjunction with other earths ; running into a corrosive glass which dissolves the strongest crucibles, unless some quartz or fire-clay be mixed in their composition. When gradually heated, they give a phosphorescent light ; but lose this property when made red-hot. Those which are coloured, particularly the green ones, give the strongest light. They melt easily with borax, and next to that with the microcosmic salt, neither of them making any effervescence. They dissolve in acids when boiling, particularly aqua-regia ; and the solutions are precipitated by an alkali even though cold, but not so completely. M. Magellan informs us, that he has frequently dissolved them in boiling vitriolic acid in order to get that of fluor in an aerial state. There are three species.

1. The indurated fluor is solid, and of an indeterminate figure, of a dull texture, semitransparent, and full of cracks in the rock. It is of a white colour.

2. Sparry fluor. This has nearly the figure of spar ; though, on close observation, it is found less regular ; nothing but its glossy surface giving it the resemblance of spar. It is found of various colours, viz. white, blue, green, pale-green, violet, and yellow.

3. The crystallized fluor is of four kinds. 1. Having an irregular figure, of a white, blue, or red colour. 2. Crystallized in cubes, of a yellow or violet colour. 3. Of a polygonal spherical figure, white or blue coloured. 4. Of an octoedral figure, clear and colourless.

The principal use of fluors is for smelting ores, where they act as very powerful fluxes, and on this account are much valued. They are found in various countries, particularly Sweden, and some other northern countries of Europe. From this quality of melting easily in combination with other earthy matters, they have got the name of *fluors*. "The resemblance between the coloured fluors and the compositions made of coloured glass (says Cronstedt), has perhaps contributed not only to the fluors being

reckoned of the same value with the coloured quartz crystals, by such collectors as only mind colour and figure, but to their also obtaining a rank among the precious stones in the apothecaries and druggists shops."

M. Fabroni observes, that this combination of calcareous earth with the sparry acid is almost always transparent : it often crystallizes in regular cubes, sometimes single from one line to two inches in diameter, and sometimes of an indeterminate figure. They are sometimes of a blue colour ; others are purple like amethysts ; some are of a brown colour, others opaque. M. Magellan says, that fluors in general have this singular property, that on being melted by the flame of the blow-pipe, together with gypsum, the lead resulting from both is all formed with facets on the outside ; but if melted with terra ponderosa, its surface is quite round or spherical.

M. Margraaf has made experiments in order to discover the nature of these stones. He ascertained the abovementioned distinctions between them and the gypseous spars ; and therefore infers, that they are not compounded of vitriolic acid with calcareous earth. He observed singular appearances on mixing them with vitriolic and other acids, and subjecting the mixtures to distillation.

Eight ounces of the powder of a green fluor being mixed with an equal weight of pure oil of vitriol, and distilled together with a graduated heat, yielded, after the watery part of the acid had passed, a fine white sublimate, which arose and adhered to the neck of the retort, and even passed into the receiver. The first parts of this sublimate which arose appeared like butter of antimony ; and, like this butter, they melted by the heat of a live coal brought near the neck of the retort : but the parts which arose towards the end of the operation, with the greatest degree of heat, could not be melted by that heat. The retort being broken, a residuum was found weighing 12 oz. Hence 4 oz. of oil of vitriol remained united with the spar. The bottom of the retort was observed to be pierced with holes. Lastly, the liquor which had passed into the receiver and the white sublimate, had very sensibly a sulphureous smell. The sublimate, triturated a long time in a mortar with hot distilled water, dissolved, and passed thro' a filter. To the filtrated liquor some fixed alkali being added, a precipitate was formed ; which being well washed and dried, was readily melted by fire into a mass resembling porcelain. The same excellent and accurate chemist produced the same effects upon this stone, by substituting, instead of the vitriolic acid, the nitrous, marine, phosphoric, or the concentrated acetic acids.

FLUOR Albus or *Uterinus*, in medicine, a kind of flux incident to women, popularly called the *whites*. See MEDICINE-Index.

FLUSHING, an handsome, strong, and considerable town of the United Provinces, in Zealand, and in the island of Walcheren, with a very good harbour, and a great foreign trade. It was put into the hands of queen Elizabeth for a pledge of their fidelity, and as a security for the money she advanced. It is one of the three places which Charles V. advised Philip II. to preserve with care. E. Long. 3. 32. N. Lat. 51. 26.

FLUTE, an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it

Fluor

Fute

Flute.

it with the mouth; and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side.

This is a very ancient instrument. It was at first called the flute *à bec*, from *bec* an old Gaulish word signifying the beak of a bird or fowl, but more especially of a cock; the term *flute à bec* must therefore signify the *beaked flute*; which appears very proper, on comparing it with the traverse or German flute. The word *flute* is derived from *fluta*, the Latin for a lamprey or small eel taken in the Sicilian seas, having seven holes immediately below the gills on each side, the precise number of those in the front of the flute.

By Merfennus this instrument is called the *fistuladulcis, seu Anglica*; the lowest note, according to him, for the treble flute, is *C faut*, and the compass of the instrument 15 notes. There is, however a flute known by the name of the *concert flute*, the lowest note of which is F. Indeed, ever since the introduction of the flute into concerts, the lowest note of the instrument, of what size soever it is, has been called F; when in truth its pitch is determinable only by its correspondence in respect of acuteness or gravity with one or other of the chords in the *scala maxima* or great system.

Besides the true concert-flute, others of a less size were soon introduced into concerts of violins; in which case the method was to write the flute-part in a key correspondent to its pitch. This practice was introduced in 1710 by one Woodcock, a celebrated performer on this instrument, and William Babel organist of the church of All-hallows, Bread Street, London. They failed, however, in procuring for the flute a reception into concerts of various instruments; for which reason, one Thomas Stanesby, a very curious maker of flutes and other instruments of the like kind, about the year 1732, adverting to the scale of Merfennus, in which the lowest note was C, invented what he called the *new system*; in which, by making the flute of such a size as to be a fifth above concert pitch, the lowest note became *C sol fa ut*. By this contrivance the necessity of transposing the flute part was taken away; for a flute of this size, adjusted to the system abovementioned, became an octave to the violin. To further this invention of Stanesby, one Lewis Mercè, an excellent performer on the flute, published, about the year 1735, six solos for this instrument, three of which are said to be accommodated to Mr Stanesby's new system; but the German flute was now become a favourite instrument, and Stanesby's ingenuity failed of its effect.—One great objection indeed lies against this instrument, which, however, equally affects all perforated pipes; namely, that they are never perfectly in tune, or cannot be made to play all their notes with equal exactness. The utmost that the makers of them can do is to tune them to some one key; as the hautboy to C, the German flute to D, and the English flute to F; and to effect this truly is a matter of no small difficulty. The English flutes made by the younger Stanesby came the nearest of any to perfection; but those of Bressian, though excellent in their tone, are all too flat in the upper octave. For these reasons some are induced to think, that the utmost degree of proficiency on any of those instruments is not worth the labour of attaining it.

German FLUTE, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played; but the end is stopt with a stoppion or plug, and the lower lip is applied to a hole about two inches and a half or three inches distant from the end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, besides that for the mouth, the lowest or which is stopped and opened by the little finger's pressing on a brass or sometimes a silver key, like those in hautboys, bassoons, &c. Its sound is exceeding sweet and agreeable; and serves as a treble in a concert.

FLUTE, or FLUYT, is a kind of long vessel, with flat ribs or floor-timbers, round behind, and swelled in the middle; serving chiefly for the carrying of provisions in fleets or squadrons of ships; though it is often used in merchandize. The word *flute*, taken for a sort of boat or vessel, is derived, according to Borel, from the ancient *flotte*, a little boat. In the verbal process of the miracles of St Catherine of Sweden, in the 12th century, we read *Unus equum suum una cum mercibus magni ponderis introduxit super instrumentum lignis fabricatum, vulgarter dictum fluta*. Upon which the Bollandists observe, that in some copies it is read *flotta*, an instrument called by the Laints *ratis*; and that the word *flutta* or *flotta* arose from *flotten* or *plotten*, "to float."

FLUTES, or FLUTINGS, in architecture, are perpendicular channels or cavities cut along the shaft of a column or pilaster. They are supposed to have been first introduced in imitation of the plaits of womens robes; and are therefore called by the Latins *striges* and *rugæ*. The French call them *cannelures*, as being excavations; and we, *flutes* or *flutings*, as bearing some resemblance to the musical instrument so called. They are chiefly affected in the Ionic order, in which they had their first rise; though they are also used in all the richer orders, as the Corinthian and Composite; but rarely in the Doric, and scarce ever in the Tuscan.

FLUX, in medicine, an extraordinary issue or evacuation of some humour. Fluxes are various and variously denominated according to their seats or the humours thus voided; as a flux of the belly, uterine flux, hepatic flux, salival flux, &c. The flux of the belly is of four kinds, which have each their respective denominations, viz. the *lientry*, or *fluxus lientericus*; the *cæliac*, or *fluxus chylosus*; the *diarrhæa*; and the *dysentery*, or *bloody flux*;—all which are properly treated of in MEDICINE.

FLUX, in hydrography, a regular periodical motion of the sea, happening twice in 24 hours; wherein the water is raised and driven violently against the shores. The flux or flow is one of the motions of the tide; the other, whereby the water sinks and retires, is called the reflux or ebb. There is also a kind of rest or cessation of about half an hour between the flux and reflux; during which time the water is at its greatest height, called *high-water*. The flux is made by the motion of the water of the sea from the equator towards the poles; which, in its progress, striking against the coasts in its way, and meeting with opposition from them, swells, and where it can find passage, as in flats, rivers, &c rises up and runs into the land. This motion follows, in some measure, the course of the moon;

as

Flute
Flux.

Flux. as it looses or comes later every day by about three quarters of an hour, or more precisely, by 48 minutes; and by so much is the motion of the moon slower than that of the sun. It is always highest and greatest in full moons, particularly those of the equinoxes. In some parts, as at Mount St Michael, it rises 80 or 90 feet, though in the open sea it never rises above a foot or two; and in some places, as about the Morea, there is no flux at all. It runs up some rivers above 120 miles. Up the river Thames it only goes 80, viz. near to Kingston in Surry. Above London bridge the water flows four hours and ebbs eight; and below the bridge, flows five hours and ebbs seven.

FLUX, in metallurgy, is sometimes used synonymously with *fusion*. For instance, an ore, or other matter, is said to be in liquid flux, when it is completely fused.

But the word *flux* is generally used to signify certain saline matters, which facilitate the fusion of ores, and other matters which are difficultly fusible in essays and reductions of ores. Fixed alkalis, nitre, borax, tartar, and common salt, are the saline matters of which fluxes are generally composed. But the word *flux* is more particularly applied to mixtures of different proportions of only nitre and tartar; and these fluxes are called by particular names according to the proportion of these ingredients, as in the following articles.

White FLUX, is made with equal parts of nitre and of tartar detonated together, by which they are alkalis. The residuum of this detonation is an alkali composed of the alkalis of the nitre and of the tartar, both which are absolutely of the same nature. As the proportion of nitre in this mixture is more than is sufficient to consume entirely all the inflammable matter of the tartar, the alkali remaining after the detonation is perfectly white, and is therefore called *white flux*; and as this alkali is made very quickly, it is also called *extemporaneous alkali*. When a small quantity only of white flux is made, as a few ounces for instance, some nitre always remains undecomposed, and a little of the inflammable principle of the tartar, which gives a red or even a black colour to some part of the flux; but this does not happen when a large quantity of white flux is made; because then the heat is much greater. This small quantity of undecomposed nitre and tartar

which remains in white flux is not hurtful in most of the metallic fusions in which this flux is employed: but if the flux be required perfectly pure, it might easily be disengaged from those extraneous matters by a long and strong calcination, without fusion.

Crude FLUX. By crude flux is meant the mixture of nitre and tartar in any proportions, without detonation. Thus the mixture of equal parts of the two salts used in the preparation of the white flux, or the mixture of one part of nitre and two parts of tartar for the preparation of the black flux, are each of them a crude flux before detonation. It has also been called *white flux*, from its colour: but this might occasion it to be confined with the white flux above described. The name, therefore, of crude flux is more convenient.

Crude flux is detonated and alkalisied during the reductions and fusions in which it is employed, and is then changed into white or black flux according to the proportion of which it is composed. This detonation produces good effects in these fusions and reductions, if the swelling and extravasation of the detonating matters be guarded against. Accordingly, crude flux may be employed successfully in many operations; as, for instance, in the ordinary operation for procuring the regulus of antimony.

Black FLUX. Black flux is produced from the mixture of two parts of tartar and one part of nitre detonated together. As the quantity of nitre which enters into the composition of this flux is not sufficient to consume all the inflammable matter of the tartar, the alkali which remains after the detonation contains much black matter, of the nature of coal, and is therefore called *black flux*.

This flux is designedly so prepared, that it shall contain a certain quantity of inflammable matter; for it is thereby capable, not only of facilitating the fusion of metallic earths like the white flux, but also of reviving these metals by its phlogiston. From this property it is also called *reducing flux*; the black flux, therefore, or crude flux made with such proportions of the ingredients as to be convertible into black flux, ought always to be used when metallic matters are at once to be fused and reduced, or even when destructive metals are to be fused, as these require a continual supply of phlogiston to prevent their calcination.

F L U X I O N S;

A METHOD of calculation which greatly facilitates computations in the higher parts of mathematics. Sir Isaac Newton and Mr Leibnitz contended for the honour of inventing it. It is probable they had both made progress in the same discovery, unknown to each other, before there was any publication on the subject.

In this branch of mathematics, magnitudes of every kind are supposed generated by motion: a line by the motion of a point, a surface by the motion of a line, and a solid by the motion of a surface. And some part of a figure is supposed generated by an uniform motion; in consequence of which, the other parts may increase uniformly or with an accelerated or retarded motion, or may decrease in any of these ways; and

the computations are made by tracing the comparative velocities with which the parts flow.

Fig. 1. If the parallelogram ABCD be generated Plate by an uniform motion of the line AB toward CD while CXCXV it moves from EE towards fe, while the line BF receives the increment Ff, and the figure will be increased by the parallelogram Fe; the line FE in this case undergoes no variation.

The fluxion of any magnitude at any point is the increment that it would receive in any given time, supposing it to increase uniformly from that point: and as the measures will be the same, whatever the time be, we are at liberty to suppose it less than any assigned time.

The first letters in the alphabet are used to represent:

sent invariable quantities; the letters x, y, z , variable quantities; and the same letters with points over them $\dot{x}, \dot{y}, \dot{z}$, represent their fluxions.

Therefore if $AB=a$, and $BF=\dot{x}$; $E\dot{f}$, the fluxion of BF , will be $=\dot{x}$, and $F\dot{e}$, the fluxion of AF , $=a\dot{x}$.

If the rectangle be supposed generated by the uniform motion of FG towards CD , at the same time that HG moves uniformly towards AD , the point G keeping always on the diagonal, the lines FG, HG will flow uniformly; for while $B\dot{f}$ receives the increment $E\dot{f}$, and HB the increment HK , FG will receive the increment hg , and HG the increment Gh , and they will receive equal increments in equal successive times. But the parallelogram will flow with an accelerated motion; for while F flows to f , and H to K , it is increased by the gnomon KGf ; but while F and H flow through the equal spaces fm KL , it is increased by the gnomon Lgm greater than KGf ; consequently when fluxions of the sides of a parallelogram are uniform, the fluxion of the parallelogram increases continually.

The fluxion of the parallelogram $BHGF$ is the two parallelograms KG and Gf ; for though the parameter receives an increment of the gnomon KGf , while its sides flow to f and K , the part gG is owing to the additional velocity wherewith the parallelogram flows during that time; and therefore is no part of the measure of the fluxion, which must be computed by supposing the parameter to flow uniformly as it did at the beginning, without any acceleration.

Therefore if the sides of a parallelogram be x and y , their fluxions will be $\dot{x}\dot{y}$; and the fluxion of the parallelogram $\dot{x}y+y\dot{x}$; and if $x=y$, that is, if the figure be a square, the fluxion of x , will be $2x\dot{x}$.

Fig. 2. Let the triangle ABC be described by the uniform motion of DE from A towards B , the point E moving in the line DE , so as always to touch the lines AC, CB ; while D moves from A to F , DE is uniformly increased, and the increase of the triangle is uniformly accelerated. When DE is in the position FC , it is a maximum. As D moves from F to B , the line DE decreases, and the triangle increases, but with a motion uniformly retarded.

Fig. 3. If the semicircle AFB be generated by the uniform motion of CD from A towards B , while C moves from A to G , the line CD will increase, but with a retarded motion; the circumference also increases with a retarded motion, and the circular space increases with an accelerated motion, but not uniformly, the degrees of acceleration growing less as CD approaches to the position GF . When C moves from G to B , it decreases with a motion continually accelerated, the circumference increases with a motion continually accelerated, and the area increases with a motion continually retarded, and more quickly retarded as CD approaches to B .

The fluxion of a quantity which decreases is to be considered as negative.

When a quantity does not flow uniformly, its fluxion may be represented by a variable quantity, or a line of a variable length; the fluxion of such a line is called the *second fluxion of the quantity whose fluxion that line is*: and if it be variable, a third fluxion may be deduced from it, and higher orders from these in the same

manner: the second fluxion is represented by two points as \ddot{x}

The increment a quantity receives by flowing for any given time, contains measures of all the different orders of fluxions; for if it increases uniformly, the whole increment is the first fluxion; and it has no second fluxions. If it increases with a motion uniformly accelerated, the part of the increment occasioned by the first motion measures the first fluxion, and the parts occasioned by the acceleration measures the second fluxion. If the motion be not only accelerated, but the degree of acceleration continually increased, the two first fluxions are measured as before: and the part of the increment occasioned by the additional degree of acceleration measures the third; and so on. These measures require to be corrected, and are only mentioned here to illustrate the subject.

DIRECT METHOD.

Any flowing quantity being given to find its fluxion.

RULE I. To find the fluxion of any power of a quantity, multiply the fluxion of the root by the exponent of the power, and the product by a power of the same root less by unity than the given exponent.

The fluxion of x^n is $nx^{n-1}\dot{x}$; for the root of x^n is x , whose fluxion is \dot{x} ; which multiplied by the exponent n , and by a power of x less by unity than n , gives the above fluxion.

If x receive the increment \dot{x} , it becomes $x+\dot{x}$; raise both to the power of n , and x^n becomes $x^n+n\dot{x}x^{n-1}+\frac{n.n-1}{2}\dot{x}^2x^{n-2}+\dots$; but all the parts of the increment, except the first term, are owing to the accelerated increase of x^n , and form measures of the higher fluxions. The first term only measures the first fluxion. The

fluxion of a^2+z^2 is $2z\dot{z}$; for put $x=a^2+z^2$, we have $\dot{x}=2z\dot{z}$; and the fluxion of $x^{\frac{3}{2}}$, which is equal to the proposed fluent, is $\frac{3}{2}x^{\frac{1}{2}}\dot{x}$; for which substituting the values of z and x we have the above fluxion.

RULE II. To find the fluxion of the product of several variable quantities multiplied together, multiply the fluxion of each by the product of the rest of the quantities, and the sum of the products thus arising will be the fluxion sought.

Thus the fluxion of xy , is $x\dot{y}+y\dot{x}$; that of xyz , is $xy\dot{z}+xz\dot{y}+yz\dot{x}$; and that of $xyzu$, is $xyz\dot{u}+xyu\dot{z}+xzy\dot{u}+yzux$.

RULE III. To find the fluxion of a fraction—From the fluxion of the numerator multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator.

Thus, the fluxion of $\frac{x}{y}$ is $\frac{y\dot{x}-x\dot{y}}{y^2}$; that of $\frac{x}{x+y}$, is $\frac{\dot{x}x+y\dot{x}-x\dot{x}-y\dot{x}x}{(x+y)^2} = \frac{y\dot{x}-x\dot{y}}{(x+y)^2}$

RULE

RULE IV. In complex cases, let the particulars be collected from the simple rules, and combined together.

The fluxion of $\frac{x^2 y^2}{z}$ is $\frac{2x^2 \dot{y}y + 2y^2 x \dot{x}z - x^2 y^2 \dot{z}}{z^2}$; for

the fluxion of x^2 is $2x\dot{x}$, and of y^2 is $2y\dot{y}$, by Rule I. and therefore the fluxion of $x^2 y^2$ is (by Rule II.) $2x^2 \dot{y}y + 2y^2 x \dot{x}$; which multiplied by z , (by Rule III.) and subtracting from it the fluxion of the denominator z , multiplied by the numerator, and dividing the whole by the square of the denominator, gives the above fluxion.

RULE V. The second fluxion is derived from the first, in the same manner as the first from the flowing quantity.

Thus the fluxion of x^3 , $3x^2 \dot{x}$; its second, $6x\ddot{x} + 3x^2 \ddot{x}$ (by Rule II.); and so on; but if \dot{x} be invariable, $\ddot{x} = 0$, and the second fluxion of $x^3 = 6x\dot{x}$.

PROB. I. To determine maxima and minima.

WHEN a quantity increases, its fluxion is positive; when it decreases, it is negative; therefore when it is just betwixt increasing and decreasing, its fluxion is $= 0$.

RULE. Find the fluxion, make it $= 0$, whence an equation will result that will give an answer to the question.

EXAMP. To determine the dimensions of a cylindric measure ABCD, (fig. 4.) open at the top, which shall contain a given quantity (of liquor, grain, &c.) under the least internal superficies possible.

Let the diameter $AB = x$, and the altitude $BD = y$; moreover, let p . (3,14159, &c.) denote the periphery of the circle whose diameter is unity, and let c be the given content of the cylinder. Then it will be $r : p :: x : (px)$ the circumference of the base; which, multiplied by the altitude y , gives pxy for the concave superficies of the cylinder. In like manner, the area of the base, by multiplying the same expression into $\frac{1}{4}$

of the diameter x , will be found $= \frac{px^2}{4}$; which drawn

into the altitude y , gives $\frac{px^2 y}{4}$ for the solid content of

the cylinder; which being made $= c$, the concave surface pxy will be found $= \frac{4c}{x}$, and consequently the

whole surface $= \frac{4c}{x} + \frac{px^2}{4}$: Whereof the fluxion, which

is $-\frac{4cx}{x^2} + \frac{px\dot{x}}{2}$ being put $= 0$, we shall get $-8c \times px^3 = 0$;

and therefore $x = 2\sqrt{\frac{3c}{p}}$: further, because $px^2 = 8c$,

and $px^2 y = 4c$, it follows, that $x = 2y$; whence y is also known, and from which it appears that the diameter of the base must be just double of the altitude.

Fig. 7. To find the longest and shortest ordinates of any curve, GEF, whose equation or the relation which the ordinates bear to the abscissas is known.

Make AC the abscissa $= x$, and CE the ordinate $= y$; take a value of y in terms of x , and find its fluxion; which

VOL. VII.

making $= 0$, an equation will result whose roots give the value of x when y is a maximum or a minimum.

To determine when it is a maximum and when a minimum, take the value of y , when x is a little more than the root of the equation so found, and it may be perceived whether it increases or decreases.

If the equation has an even number of equal roots, y will be neither a maximum nor minimum when its fluxion is $= 0$.

PROB. II. To draw a tangent to any curve.

Fig. 5. When the abscissa CS of a curve moves uniformly from A to B, the motion of the curve will be retarded if it be concave, and accelerated if convex towards AB; for a straight line TC is described by an uniform motion, and the fluxion of the curve at any point is the same as the fluxion of the tangent, because it would describe the tangent if it continued to move equably from that point. Now if Ss or Ce be the fluxion of the base, Cd will be the fluxion of the tangent, and de of the ordinate. And because the triangles TSC, Ced, are equiangular, $de : Ce :: CS : ST$, wherefore,

RULE. Find a fourth proportional to the fluxion of the ordinate valued in terms of the abscissa, the fluxion of the abscissa, and the ordinate, and it determines the line ST, which is called the *subtangent*, and TC joined is a tangent to the curve.

EXAMP. To draw a right line CT, (fig. 6.) to touch a given circle BCA in a point C.

Let CS be perpendicular to the diameter AB, and put $AB = a$, $BS = x$, and $SC = y$: then, by the property of the circle, $y^2 (CS^2) = BS \times AS (= x \times a - x) = ax - x^2$; whereof the fluxion being taken, in order to determine the ratio of \dot{x} and \dot{y} , we get $2y\dot{y} = a\dot{x} - 2x\dot{x}$; consequently $\frac{\dot{x}}{\dot{y}} = \frac{2y}{a - 2x} = \frac{y}{\frac{1}{2}a - x}$; which multiplied by y , gives $\frac{y^2 \dot{x}}{y} = \frac{y^2}{\frac{1}{2}a - x} =$ the subtangent ST. Whence (O being supposed the centre) we have $OS (\frac{1}{2}a - x) : CS (y) :: CS (y) : ST$; which we also know from other principles.

PROB. III. To determine points of contrary flexure in curves.

FIG. 7. Supposing C to move uniformly from A to B, the curve GEF will be convex towards AB when the celerity of E increases, and concave when it decreases; therefore, at the point where it ceases to be convex and begins to be concave, or the opposite way, the celerity of E will be uniform, that is, CE will have no second fluxion. Therefore,

RULE. Find the second fluxion of the ordinate in terms of the abscissa, and make it $= 0$; and from the equation that arises you get a value of the abscissa, which determines the point of contrary flexure.

Ex. Let the nature of the curve AGE be defined by the equation $ay = a^{\frac{2}{3}} x^{\frac{1}{3}} + xx$, (the abscissa AF and the ordinate FG being, as usual, represented by x and y respectively). Then \dot{y} expressing the celerity of the

point G, in the line FH, will be equal to $\frac{\frac{1}{3} a^{\frac{2}{3}} x^{-\frac{2}{3}} + 2xx}{a}$

Whose fluxion, or that of $\frac{1}{3} a^{\frac{2}{3}} x^{-\frac{5}{3}} + 2x$ (because a and

R r

and

and \dot{x} are constant) must be equal to nothing; that is, $-\frac{1}{4}ax^{\frac{3}{2}} - \frac{3}{2}x + 2\dot{x} = 0$: Whence $a^{\frac{3}{2}}x - \frac{3}{2} = 8$, $a^{\frac{3}{2}} = 8x^{\frac{3}{2}}$
 $64x^3 = a^3$, and $x = \frac{1}{4}a = AF$; therefore $FG (= \frac{a^{\frac{3}{2}}x^{\frac{1}{2}} + xx}{a})$
 $= \frac{3}{4}a$: From which the position of the point G is given.

PROB. IV. To find the radii of curvature.

THE curvature of a circle is uniform in every point, that of every other curve continually varying: and it is measured at any point by that of a circle whose radius is of such a length as to coincide with it in curvature in that point.

All curves that have the same tangent have the same first fluxion, because the fluxion of a curve and its tangent are the same. If it moved uniformly on from the point of contact, it would describe the tangent. And the deflection from the tangent is owing to the acceleration or retardation of its motion, which is measured by its second fluxion: and consequently two curves which have not only the same tangent, but the same curvature at the point of contact, will have both their first and second fluxions equal. It is easily proved from thence, that the radius of curvature is

$\frac{\dot{z}^2}{-\dot{x}\dot{y}}$; x, y , and z , representing the abscissa, ordinate, and curve respectively.

EXAMP. Let the given curve be the common parabola, whose equation is $y = a^{\frac{1}{2}}x^{\frac{1}{2}}$: Then will $\dot{y} = \frac{1}{2}a^{\frac{1}{2}}x^{-\frac{1}{2}}$
 $= \frac{a^{\frac{1}{2}}\dot{x}}{2x^{\frac{1}{2}}}$, and (making \dot{x} constant) $\ddot{y} = \frac{1}{2} \times \frac{1}{2} a^{\frac{1}{2}} \dot{x}^2 x^{-\frac{3}{2}} =$
 $-\frac{a^{\frac{1}{2}}\dot{x}^2}{4x^{\frac{3}{2}}}$: Whence $\dot{z} (\sqrt{\dot{x}^2 + \dot{y}^2}) = \frac{\dot{x}}{2} \sqrt{\frac{4x+a}{x}}$, and

the radius of curvature $\left(\frac{z^3}{-\dot{x}\dot{y}}\right) = \frac{a+4}{2\sqrt{a}}$: Which at the vertex where $x=0$, will be $=\frac{1}{2}a$.

I N V E R S E M E T H O D.

From a given fluxion to find a fluent.

THIS is done by tracing back the steps of the direct method. The fluxion of x is \dot{x} ; and therefore the fluent of \dot{x} is x : but as there is no direct method of finding fluents, this branch of the art is imperfect. We can assign the fluxion of every fluent; but we cannot assign the fluent of a fluxion, unless it be such a one as may be produced by some rule in the direct method from a known fluent.

GENERAL RULE. Divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent so increased.

For dividing the fluxion $nx^{n-1}\dot{x}$ by x (the fluxion of the root x) it becomes nx^{n-1} ; and, adding 1 to the exponent ($n-1$), we have nx^n ; which divided by n , gives x^n , the true fluent of $nx^{n-1}\dot{x}$.

Hence (by the same rule) the
 Fluent of $3x^2\dot{x}$ will be $=x^3$;

That of $8x^{\frac{3}{2}}\dot{x} = \frac{8x^{\frac{3}{2}}}{\frac{3}{2}}$;

That of $2x^5\dot{x} = \frac{x^6}{3}$

That of $y^{\frac{1}{2}}\dot{y} = \frac{2}{3}y^{\frac{3}{2}}$.

Sometimes the fluent so found requires to be corrected. The fluxion of x is \dot{x} , and the fluxion of $a+x$ is also \dot{x} ; because a is invariable, and has therefore no fluxion.

Now when the fluent of \dot{x} is required, it must be determined, from the nature of the problem, whether any invariable part, as a , must be added to the variable part x .

When fluents cannot be exactly found, they can be approximated by infinite series.

Ex. Let it be required to approximate the fluent of

$$\frac{a^2 - x^2}{c^2 - x^2} \times x^n \dot{x}$$

in an infinite series.

The value of $\frac{a^2 - x^2}{c^2 - x^2}$, expressed in a series, is $\frac{a}{c} +$

$$\frac{a}{2c^3} - \frac{1}{2ac} \times x^2 + \frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times x^4 + \frac{5a}{16c} - \frac{3}{16ac}$$

$$\frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times x^6 + \&c.$$

Which value being therefore multiplied by $x^n \dot{x}$, and the fluent taken (by the common method) we get $\frac{ax^{n+1}}{n+1 \times c} + \frac{a}{2c^3} - \frac{1}{2ac} \times \frac{x^{n+3}}{n+3} +$

$$\frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times \frac{x^{n+5}}{n+5} +$$

$$\frac{5a}{16c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times \frac{x^{n+7}}{n+7} + \&c.$$

PROB. I. To find the area of any curve.

RULE. Multiply the ordinate by the fluxion of the abscissa, and the product gives the fluxion of the figure, whose fluent is the area of the figure.

EXAMP. I. Fig. 8. Let the curve ARMH, whose area you would find, be the common parabola. Let u represent the area, and \dot{u} its fluxion.

In which case the relation of AB. (x) and BR (y) being expressed by $y = ax$ (where a is the parameter) we thence get $y = a^{\frac{1}{2}}x^{\frac{1}{2}}$; and therefore $\dot{u} = RmHB (=y\dot{x}) = a^{\frac{1}{2}}x^{\frac{1}{2}}\dot{x}$: whence $u = \frac{2}{3} \times a^{\frac{1}{2}}x^{\frac{3}{2}} = \frac{2}{3}a^{\frac{1}{2}}x^{\frac{3}{2}} \times x = \frac{2}{3}yx$ (because $a^{\frac{1}{2}}x^{\frac{1}{2}} = y = \frac{2}{3} \times AB \times BR$: hence a parabola is $\frac{2}{3}$ of a rectangle of the same base and altitude.

EXAMP. 2. Let the proposed curve CSDR (fig. 9.) be of such a nature, that (supposing AB unity) the sum of the areas CSTBC and CDGBC answering to any two proposed abscissas AT and AG, shall be equal to the area CRNBC, whose corresponding abscissa AN is equal

equal to $AT \times AG$, the product of the measures of the two former abscissas.

First, in order to determine the equation of the curve (which must be known before the area can be found), let the ordinates GD and NR move parallel to themselves towards HF ; and then having put $GD=y$, $NR=z$, $AT=a$, $AG=s$, and $AN=u$, the fluxion of the area $CDGB$ will be represented by ys , and that of the area $CRNB$ by zu : which two expressions must, by the nature of the problem, be equal to each other; because the latter area $CRNB$ exceeds the former $CDGB$ by the area $CSTB$, which is here considered as a constant quantity: and it is evident, that two expressions, that differ only by a constant quantity, must always have equal fluxions.

Since, therefore, ys is zu , and $u=as$, by hypothesis, it follows, that $\dot{u}=a\dot{s}$, and that the first equation (by substituting for \dot{u}) will become $ys=azs$, or $y=az$, or lastly $ys=zas$, that is, $GD \times AG = NR \times AN$: therefore, $GD : NR :: AN : AG$; whence it appears, that every ordinate of the curve is reciprocally as its corresponding abscissa.

Now, to find the area of the curve so determined, put $AB=1$, $BC=b$, and $BG=x$: then, since $AG(1+x) : AB(1) :: EC(b) : GD(y)$ we have $y = \frac{bx}{1+x}$,

consequently $\dot{u} (=y\dot{x}) = \frac{bx\dot{x}}{1+x} = b \times \dot{x} - x\dot{x} + x^2\dot{x} - x^3\dot{x} + x^4\dot{x} - \&c.$ Whence $BGDC$, the area itself will be $=b \times x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5}$, &c. which was to be found.

Hence it appears, that as these areas have the same properties as logarithms, this series gives an easy method of computing logarithms; and the fluent may be found by means of a table of logarithms, without the trouble of an infinite series: and every fluxion whose fluent agrees with any known logarithmic expression, may be found the same way. Hence the fluents of fluxions of the following forms are deduced.

The fluent of $\frac{\dot{x}}{\sqrt{x^2 \pm a^2}} = \text{hyp. log. of } x + \sqrt{x^2 \pm a^2}$;

of $\frac{\dot{x}}{\sqrt{2ax \pm xx}} = \text{hyp. log. of } a \times x + \sqrt{2ax \pm xx}$;

of $\frac{2a\dot{x}}{a^2 - x^2} = \text{hyp. log. of } \frac{a+x}{a-x}$

and of $\frac{2a\dot{x}}{x\sqrt{a^2 \pm x^2}} = \text{hyp. log. of } \frac{a - \sqrt{a^2 \pm x^2}}{a + \sqrt{a^2 \pm x^2}}$

PROB. 2. To determine the length of curves.

Fig. 5. Because Cde is a right-angled triangle, $Cd^2 = Ce^2 + de^2$; wherefore the fluxions of the abscissa and ordinate being taken in the same terms and squared, their sum gives the square of the fluxion of the curve; whose root being extracted, and the fluent taken, gives the length of the curve.

EXAMP. To find the length of a circle from its tangent. Make the radius AO (fig. 5.) $=a$, the tangent of $\Lambda C = t$, and its secant $=s$, the curve $=z$, and its

fluxion $=\dot{z}$; because the triangles OTC , OCS , are similar, $OT : OC :: OC : OS$; whence $OS = \frac{a^2}{s}$, and $SA = a - \frac{a^2}{s} = a - \frac{a^2}{\sqrt{a^2 + t^2}}$; whose

fluxion is $\frac{a^2 \dot{t}}{a^2 + t^2}$; and because the triangles OTC , dCe are similar, $TC (=t) : TO (= \sqrt{a^2 + t^2}) :: Ce = \left(\frac{a^2 \dot{t}}{a^2 + t^2} \right) : Cd = \frac{a^2 \dot{t}}{a^2 + t^2} = \text{fluxion of the curve.}$

Now by converting this into an infinite series we have the fluxion of the curve $= \dot{t} - \frac{t^2 \dot{t}}{a^2} + \frac{t^4 \dot{t}}{a^4} - \frac{t^6 \dot{t}}{a^6}$, &c. and con-

sequently $z = t - \frac{t^3}{3a^2} + \frac{t^5}{5a^4} - \frac{t^7}{7a^6} + \frac{t^9}{9a^8}$, &c. $= AC$.

Where, if (for example's sake) AC be supposed an arch of 30 degrees, and AO (to render the operation more easy) be put $=$ unity, we shall have $t = \sqrt{\frac{3}{4}} = .5773502$ (because $OS (\sqrt{\frac{3}{4}}) : SC (\frac{1}{2}) :: OA (1) : CT (t) = \sqrt{\frac{3}{4}}$) Whence,

$$t^3 = (=t \times t^2 = t \times \frac{1}{3}) = .1924500$$

$$t^5 = (=t^3 \times t^2 = \frac{t^3}{3}) = .0641500$$

$$t^7 = (=t^5 \times t^2 = \frac{t^5}{3}) = .0213833$$

$$t^9 = (=t^7 \times t^2 = \frac{t^7}{3}) = .0071277$$

$$t^{11} = (=t^9 \times t^2 = \frac{t^9}{3}) = .0023759$$

$$t^{13} = (=t^{11} \times t^2 = \frac{t^{11}}{3}) = .0007919$$

$$t^{15} = (=t^{13} \times t^2 = \frac{t^{13}}{3}) = .0002639$$

&c.

And therefore $AC = .5773502 - \frac{.1924500}{3} +$

$$\frac{.0641500}{5} - \frac{.0213833}{7} + \frac{.0091277}{9} - \frac{.0023759}{11} +$$

$$\frac{.0007919}{13} - \frac{.0002639}{15} + \frac{.0000879}{17} - \frac{.0000293}{19} +$$

$$\frac{.0000097}{21} - \frac{.0000032}{23} + = .5235987: \text{ for the length of}$$

an arch of 30 degrees, which multiplied by 6 gives $3.141592 +$ for the length of the semi-periphery of the circle whose radius is unity.

Other series may be deduced from the versed sine and secant; and these are of use for finding fluents which cannot be expressed in finite terms.

the fluent of	{	$\frac{\dot{w}}{\sqrt{2aw - w^2}}$	} is equal to the arch whose	{	Versed sine	} is $\frac{w}{a}$, and Radius Unity.
		$\frac{\dot{w}}{\sqrt{a^2 - w^2}}$			Right sine	
		$\frac{a\dot{w}}{a^2 + w^2}$			Tangent	
		$\frac{a\dot{w}}{w\sqrt{w^2 - a^2}}$			Secant	
				R r 2		

F L U X I O N S.

PROB. III. To find the contents of a solid.

LET the surface of the generating plane be multiplied by the space it passes through in any time, the product will give a solid which is the fluxion of the solid required: the surface must therefore be computed in terms of x , which represents the line or axis on which it moves, and by its motion on which the fluxion is to be measured, and the fluent found will give the contents of the solid.

EXAMP. Let it be proposed to find the content of a cone ABC, fig. 10.

Put the given altitude (AD) of the cone $=a$, and the semidiameter (BD) of its base $=b$, the solid $=s$, its fluxion $=\dot{s}$, and the area of a circle whose radius is unity, $=p$: then the distance (AF) of the circle EG, from the vertex A, being denoted by x , we have, by similar triangles, as $a : b :: x : EF (y) = \frac{bx}{a}$. Whence in this case, $\dot{s} (=p y^2 \dot{x}) = \frac{pb^2 x \dot{x}}{a^2}$;

and consequently $s = \frac{pb^2 x^2}{3a^2}$; which, when $x=a (=AD)$

gives $\frac{pb^2 a}{3} (=p \times BD^2 \times \frac{1}{3} AD)$ for the content of the

whole cone ABC: which appears from hence to be just $\frac{1}{3}$ of a cylinder of the same base and altitude.

PROB. IV. To compute the surface of any solid body.

THE fluxion of the surface of the solid is equal to the periphery of the surface, by whose motion the so-

lid is generated, multiplied by its velocity on the edge of the solid, and the computation is made as in the foregoing.

EXAMP. Let it be proposed to determine the convex superficies of a cone ABC, fig. 11.

Then, the semidiameter of the base (BD or CD) being put $=b$, the slanting line or hypotenuse $AC=c$, and FH (parallel to DC) $=y$, AH $=z$, the surface $=w$, its fluxion $=\dot{w}$, and p the periphery of a circle whose diameter is unity, we shall, from the similarity of the triangles ADC and Hmb, have $b : c :: y : (mh) : z (Hb) = \frac{cy}{b}$: whence $\dot{w} (2py\dot{z}) = \frac{2pcy\dot{y}}{b}$; and

consequently $w = \frac{pcy^2}{b}$. This, when $y=b$, becomes $=pcb = p \times DC \times AC =$ the convex superficies of the whole cone ABC: which therefore is equal to a rectangle under half the circumference of the base and slanting line.

The method of fluxions is also applied to find the centres of gravities, and oscillation of different bodies; to determine the paths described by projectiles and bodies acted on by central forces, with the laws of centripetal force in different curves, the retardates given to motions performed in resisting medii, the attractions of bodies under different forms, the direction of wind which has the greatest effect on an engine, and to solve many other curious and useful problems.

F L Y

Fly. FLY, in zoology, a larger order of insects, the distinguishing characteristic of which is, that their wings are transparent. By this they are distinguished from beetles, butterflies, grasshoppers, &c.

Flies are subdivided into those which have four, and those which have two wings.

Of those with four wings there are several genera or kinds; as the ant, apis, ichneumon, &c. See APIS, FORMICA, &c.

Of those with two wings, there are likewise several kinds, as the gad-fly, gnat, &c. See GAD-FLY, &c.

Those who desire a more particular account of the anatomy, generation, structure, and manifold subdivisions of flies, may consult Reaumer's History of Insects, tom. 4. See also ENTOMOLOGY.

House-FLY. See MUSCA.

Pestilential-FLY. See ETHIOPIA, n^o II.

FLY, in mechanics, a cross with leaden weights at its ends; or rather, a heavy wheel at right angles, to the axis of a windlass, jack, or the like; by means of which, the force of the power, whatever it is, is not only preserved, but equally distributed in all parts of the revolution of the machine. See MECHANICS.

FLIES for Fishing. See FISHING-FLY.

Vegetable FLY, a very curious natural production chiefly found in the West Indies. "Excepting that it has no wings, it resembles the drone both in size and colour more than any other British insect. In the month of May it buries itself in the earth, and begins to vegetate. By the latter end of July, the tree

F L Y

is arrived at its full growth, and resembles a coral branch; and is about three inches high, and bears several little pods, which dropping off become worms, and from thence flies, like the British caterpillar."

Such was the account originally given of this extraordinary production. But several boxes of these flies having been sent to Dr Hill for examination, his report was this: "There is in Martinique a fungus of the clavaria kind, different in species from those hitherto known. It produces soboles from its sides; I call it therefore *clavaria sobolifera*. It grows on putrid animal bodies, as our fungus *ex pede equino* from the dead horse's hoof. The cicada is common in Martinique, and in its nymph state, in which the old authors call it *tettigometra*: it buries itself under dead leaves to wait its change; and when the season is unfavourable, many perish. The seeds of the clavaria find a proper bed on this dead insect, and grow. The *tettigometra* is among the cicadae in the British museum: the clavaria is just now known. This is the fact; and all the fact; though the untaught inhabitants suppose a fly to vegetate, and though there is a Spanish drawing of the plants growing into a trifoliate tree, and it has been figured with the creature flying with this tree upon its back."

The ingenious Mr Edwards has taken notice of this extraordinary production in his Gleanings of Natural History, from which the figures on Plate CXCVI. are taken,

FLY-Boat, or Flight, a large flat-bottomed Dutch vessel,

vessel, whose burden is generally from 600 to 1200 tons. It is distinguished by a stern remarkably high, resembling a Gothic turret, and by very broad buttocks below.

FLY-Catcher, in zoology. See *MUSCICAPA*.

FLY-Trap, in botany, a newly discovered sensitive plant. See *DIONÆA Muscipula*.

FLY-Tree, in natural history, a name given by some people of America to a tree, whose leaves, they say, at a certain time of the year produce flies. On examining these leaves about the middle of summer, the time at which the flies used to be produced, there are found on them a sort of bag of a tough matter, of about the size of a filbert, and of a dusky greenish colour. On opening one of these bags with a knife, there is usually found a single full-grown fly, of the gnat kind, and a number of small worms, which in a day or two more have wings, and flee away in the form of their parent. The tree is of the mulberry kind, and its leaves are usually very largely stocked with these insect-bags; and the generality of them are found to contain the insects in their worm-state; when they become winged, they soon make their way out. The bags begin to appear when the leaves are young, and afterwards grow with them; but they never rumple the leaf or injure its shape. They are of the kind of leaf-galls, and partake in all respects, except size, of a species we have frequent on the large maple, or, as it is called, the *Sycamore*.

FLYERS, in architecture, such stairs as go straight, and do not wind round, nor have the steps made tapering; but the fore and back part of each stair and the ends respectively parallel to one another: So that if one flight do not carry you to your designed height, there is a broad half space; and then you fly again, with steps every where of the same breadth and length as before.

FLYERS, the performers in a celebrated exhibition among the Mexicans, which was made on certain great festivals, and is thus described by Clavigero in his History of that people. "They sought in the woods for an extremely lofty tree, which after stripping it of its branches and bark, they brought to the city, and fixed in the centre of some large square. They cased the point of the tree in a wooden cylinder, which, on account of some resemblance in its shape, the Spaniards called a *mortar*. From this cylinder hung four strong ropes, which served to support a square frame. In the space between the cylinder and the frame, they fixed four other thick ropes, which they twisted as many times round the tree as there were revolutions to be made by the flyers. These ropes were drawn through four holes, made in the middle of the four planks of which the frame consisted. The four principal flyers disguised like eagles, herons, and other birds, mounted the tree with great agility, by means of a rope which was laced about it from the ground up to the frame; from the frame they mounted one at a time successively upon the cylinder, and after having danced there a little, they tied themselves round with the ends of the ropes, which were drawn through the holes of the frame, and launching with a spring from it, began their flight with their wings expanded. The action of their bodies put the frame and the cylinder in motion; the frame

by its revolutions gradually untwisted the cords by which the flyers swung; so that as the ropes lengthened, they made so much the greater circles in their flight. Whilst these four were flying, a fifth danced upon the cylinder, beating a little drum, or waving a flag, without the smallest apprehension of the danger he was in of being precipitated from such a height. The others who were upon the frame (there having been 10 or 12 persons generally who mounted), as soon as they saw the flyers in their last revolution, precipitated themselves by the same ropes, in order to reach the ground at the same time amidst the acclamations of the populace. Those who precipitated themselves in this manner by the ropes, that they might make a still greater display of their agility, frequently passed from one rope to another, at that part where, on account of the little distance between them, it was possible for them to do so. The most essential point of this performance consisted in proportioning so justly the height of the tree with the length of the ropes, that the flyers should reach the ground with 13 revolutions, to represent by such a number their century of 52 years, composed in the manner we have already mentioned. This celebrated diversion is still in use in that kingdom; but no particular attention is paid to the number of the revolutions or the flyers; as the frame is commonly hexagonal or octagonal, and the flyers 6 or 8 in number. In some places they put a rail round the frame, to prevent accidents which were frequent after the conquest; as the Indians became much given to drinking, and used to mount the tree when intoxicated with wine or brandy, and were unable to keep their station on so great a height, which was usually 60 feet." See Plate CXCVI.

FLYING, the progressive motion of a bird, or other winged animal, in the air.

The parts of birds chiefly concerned in flying are the wings and tail: by the first, the bird sustains and wafts himself along: and by the second, he is assisted in ascending and descending, to keep his body poised and upright, and to obviate the vacillations thereof.

It is by the largeness and strength of the pectoral muscles, that birds are so well disposed for quick, strong, and continued flying. These muscles, which in men are scarce a 70th part of the muscles of the body in birds, exceed and outweigh all the other muscles taken together; upon which Mr Willoughby makes this reflection, that if it be possible for man to fly, his wings must be so contrived and adapted, that he may make use of his legs, and not his arms, in managing them.

The tail, Messrs Willoughby, Ray, and many others, imagine to be principally employed in steering and turning the body in the air, as a rudder; but Borelli has put it beyond all doubt, that this is the least use of it, which is chiefly to assist the bird in its ascent and descent in the air, and to obviate the vacillations of the body and wings: for, as to turning to this or that side, it is performed by the wings and inclination of the body, and but very little by the help of the tail. The flying of a bird, in effect, is quite a different thing from the rowing of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern,

Flying.

Flying. stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is disposed horizontally, and preserves the same situation what way soever the bird turns. In effect, as a vessel is turned about on its centre of gravity to the right, by a brisk application of the oars to the left; so a bird, in beating the air with its right wing alone, towards the tail, will turn its fore-part to the left. Thus pigeons changing their course to the left, would labour it with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclination of their head and neck; which altering the course of gravity, the bird will proceed in a new direction.

The manner of FLYING is thus: The bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings, with all the feathers therein, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists those succussions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The resistance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the waft or stroke of the fan of the wing is longer: but as the force of the wing is continually diminished by this resistance, when the two forces continue to be in *equilibrium*, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes makes a resistance equal to the excess of the specific gravity of the bird above the air. If the air, therefore be so rare as to give way with the same velocity as it is struck withal, there will be no resistance, and consequently the bird can never mount. Birds never fly upwards in a perpendicular line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

Artificial FLYING, that attempted by men, by the assistance of mechanics.

The art of flying has been attempted by several persons in all ages. The Leucadians, out of superstition, are reported to have had a custom of precipitating a man from a high cliff into the sea, first fixing feathers, variously expanded, round his body, in order to break the fall.

Friar Bacon, who lived near 500 years ago, not only affirms the art of flying possible, but assures us, that he himself knew how to make an engine wherein a man sitting might be able to convey himself through the air like a bird; and further adds, that there was then one who had tried it with success. The secret consisted in a couple of large thin hollow copper-globes, exhausted of air; which being much lighter than air, would sustain a chair whereon a person might sit. Fa. Francisco Lana, in his *Prodr mo*, proposes the same thing, as his own thought. He computes, that a round vessel of plate-brass, 14 feet in diameter, weighing

three ounces the square foot, will only weigh 1848 ounces; whereas a quantity of air of the same bulk will weigh 2155 $\frac{1}{2}$ d ounces; so that the globe will not only be sustained in the air, but will carry with it a weight of 373 $\frac{2}{3}$ d ounces, and by increasing the bulk of the globe, without increasing the thickness of the metal, he adds, that a vessel might be made to carry a much greater weight.—But the fallacy is obvious: a globe of the dimensions he describes, Dr Hook shows, would not sustain the pressure of the air, but be crushed inwards. Besides, in whatever ratio the bulk of the globe were increased, in the same must be the thickness of the metal, and consequently the weight be increased: so that there would be no advantage in such augmentation. See AEROSTATION.

The same author describes an engine for flying, invented by the Sieur Besnier, a smith of Sable, in the county of Main. *Vid. Philosoph. Collect. N^o 1.*

The philosophers of king Charles the Second's reign were mightily busied about this art. The famous bishop Wilkins was so confident of success in it, that he says, he does not question but in future ages it will be as usual to hear a man call for his wings, when he is going a journey, as it is now to call for his boots.

FLYING-Bridge. See BRIDGE.

FLYING-Fish, a name given by the English writers to several species of fish, which by means of their long fins, have a method of keeping themselves out of water a considerable time. See EXOCOETUS.

FLYING-Pinion, is a part of a clock, having a fly or fan whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part.

FO, or FOE; an idol of the Chinese. He was originally worshipped in the Indies, and transported from thence into China, together with the fables with which the Indian books were filled. He is said to have performed most wonderful things, which the Chinese have described in several volumes, and represented by cuts.

Set of Fo. See CHINA, n^o 103.

Fo Kien. See FOKIEN.

FOAL, or COLT and FILLY; the young of the horse kind. The word *colt*, among dealers, is understood of the male, as *filly* is of the female. See COLT.

FOCUS, in geometry and conic sections, is applied to certain points in the parabola, ellipsis, and hyperbola, where the rays reflected from all parts of these curves concur and meet. See CONIC SECTIONS.

FOCUS, in optics; a point in which any number of rays, after being reflected or refracted, meet.

FODDER, any kind of meat for horses or other cattle. In some places hay and straw, mingled together, is peculiarly denominated *fodder*.

FODDER, in the civil law, is used for a prerogative that the prince has, to be provided of corn and other meats for his horses, by the subjects, in his warlike expeditions.

FODDER, in mining, a measure containing 22 hundred and an half weight, though in London but 20 hundred weight.

FOENUGREEK, in botany. See TRIGONELLA.

FOENUS NAUTICUM. Where money is lent to a merchant, to be employed in a beneficial trade with condition to be repaid, with extraordinary interest, in

Flying
||
Foenus.

||
Fog.

case such voyage was safely performed, the agreement was sometimes called *fœnus nauticum*, sometimes *usura maritima*. But as this gave an opening for usurious and gaming contracts, 19 Geo. II. c. 37. enacts, that all money lent on bottomry, or at *respondentia*, on vessels bound to or from the East-Indies, shall be expressly lent only upon the ship or merchandise: the lender to have the benefit of salvage, &c. *Blackst. Com. II. 459. Mol. de Jur. Mar. 361.*

FOESIUS (Annius), a very learned and celebrated physician of the faculty of Paris, born at Mentz in 1523. He translated into Latin the whole works of Hippocrates, judiciously correcting the Greek text as he went along; and composed a kind of dictionary to him, intitled, *Oeconomia Hippocratis*. He translated, beside, the Commentaries of Galen upon the second book of Hippocrates; and was the author of some other works. After practising physic a long time with great success and reputation, at Lorrain and other places, he died in 1596.

FOETOR, in medicine, stinking or fetid effluvia arising from the body or any part thereof.

FOETUS, the young of all viviparous animals whilst in the womb, and of oviparous animals before being hatched: the name is transferred by botanists to the *embryos of vegetables*.

Strictly, the name is applied to the young after it is perfectly formed: till which time it is more properly called EMBRYO. See ANATOMY, n° 109, 110.

In the human foetus are several peculiarities not to be found in the adult; some of them are as follows.

1. The arteries of the navel-string, which are continuations of the hypogastrics, are, after the birth, shrivelled up, and form the ligamenta umbilic. infer. 2. The veins of the navel-string are formed by the union of all the venous branches in the placenta, and passing into the abdomen become the falciform ligament of the liver. 3. The lungs, before being inflated with air, are compact and heavy, but after one inspiration they become light, and as it were spongy: and it may be noted here, that the notion of the lungs sinking in water before the child breathes, and of their swimming after the reception of air, are no certain proofs that the child had or had not breathed, much less that it was murdered: for the uninflated lungs become specifically lighter than water as soon as any degree of putrefaction takes place in them; and this soon happens after the death of the child; besides, where the utmost care hath been taken to preserve the child it hath breathed once or twice, and then died. 4. The thymus gland is very large in the foetus, but dwindles away in proportion as years advance. 5. The foramen ovale in the heart of a foetus, is generally closed in an adult.

FOG, or MIST, a meteor, consisting of gross vapours, floating near the surface of the earth.

Mists, according to lord Bacon, are imperfect condensations of the air consisting of a large proportion of the air, and a small one of the aqueous vapour: and these happen in the winter, about the change of the weather from frost to thaw, or from thaw to frost; but in the summer, and in the spring; from the expansion of the dew.

If the vapours, which are raised plentifully from the earth and waters, either by the solar or subterraneous

heat, do at their first entrance into the atmosphere meet with cold enough to condense them to a considerable degree, their specific gravity is by that means increased, and so they will be stopped from ascending; and either return back in form of dew or of drizzling rain, or remain suspended for some time in form of a fog. Vapours may be seen on the high grounds as well as the low, but more especially about marshy places. They are easily dissipated by the wind, as also by the heat of the sun. They continue longest in the lowest grounds, because these places contain most moisture, and are least exposed to the action of the wind.

Hence we may easily conceive, that fogs are only low clouds, or clouds in the lowest region of the air; as clouds are no other than fogs raised on high. See CLOUD.

When fogs stink, then the vapours are mixed with sulphureous exhalations, which smell so. Objects viewed through fogs appear larger and more remote than through the common air. Mr Boyle observes, that upon the coast of Coromandel, and most maritime parts of the East-Indies, there are, notwithstanding the heat of the climate, annual fogs so thick, as to occasion people of other nations who reside there, and even the more tender sort of the natives, to keep their houses close shut up.

Fogs are commonly pretty strongly electrified, as appears from Mr Cavallo's observations upon them. See ELECTRICITY, n° 76.

FOGAGE, in the forest law, is rank grass not eaten up in summer.

FOGLIETA, (Oberto or Hubert), a Genoese priest, and one of the most learned writers of the 16th century. He had a share in the disturbances that were raised at Genoa, for which he was banished; and died at Rome in 1581, aged 63. He wrote a history of Genoa in Italian, which is highly esteemed; and many works in Latin.

FOGO, or FUEGO. See FUEGO.

FOHI. See FE; and CHINA, n° 7.

FOIBLE, a French term, frequently used also in our language. It literally signifies *weak*; and in that sense is applied to the body of animals and the parts thereof, as *foible reins*, *foible sight*, &c. being derived from the Italian *fiavole*, of the Latin *febilis*, to be "lamented, pitied."

But it is chiefly used with us substantively, to denote a defect or flaw in any person or thing. Thus we say, every person has his foible; and the great secret consists in hiding it artfully: Princes are gained by flattery, that is their foible: The foible of young people is pleasure; the foible of old men is avarice; the foible of the great and learned is vanity; the foible of women and girls, coquetry, or an affectation of having gallants: You should know the forty and the foible of a man before you employ him: We should not let people perceive that we know their foible.

FOIL, in fencing, denotes a blunt sword, or one that has a button at the end covered with leather, used in learning the art of fencing.

FOIL, among glass-grinders, a sheet of tin, with quicksilver, or the like, laid on the backside of a looking-glass, to make it reflect. See FOLIATING.

FOIL, among jewellers, a thin leaf of metal placed under

Fogage
||
Foil.

Foil
↓
Folard.

under a precious stone, in order to make it look transparent, and give it an agreeable different colour, either deep or pale: thus, if you want a stone to be of a pale colour, put a foil of that colour under it; or if you would have it deep, lay a dark one under it.

These foils are made either of copper, gold, or gold and silver together. The copper foils are commonly known by the name of *Nuremberg* or *German foils*; and are prepared as follows: Procure the thinnest copper-plates you can get: beat these plates gently upon a well-polished anvil, with a polished hammer, as thin as possible; and placing them between two iron-plates as thin as writing-paper, heat them in the fire; then boil the foil in a pipkin, with equal quantities of tartar, and salt, constantly stirring them till by boiling they become white; after which, taking them out and drying them, give them another hammering, till they are made fit for your purpose: however care must be taken not to give the foils to much heat, for fear of melting; nor must they be too long boiled, for fear of attracting too much salt.

The manner of polishing these foils is as follows: Take a plate of the best copper, one foot long and about five or six inches wide, polished to the greatest perfection; bend this to a long convex, fasten it upon a half roll, and fix it to a bench or table; then take some chalk, washed as clean as possible, and filtered through a fine linen cloth, till it be as fine as you can make it; and having laid some thereof on the roll, and wetted the copper all over, lay your foils on it, and with a polishing stone and the chalk polish your foils till they are as bright as a looking-glass; after which they must be dried, and laid up secure from dust.

FOKIEN, a province of China in Asia, commodiously situated for navigation and commerce, part of it bordering on the sea, in which they catch large quantities of fish, which they send salted to other parts of the empire. Its shores are very uneven, by reason of the number and variety of its bays; and there are many forts built thereon to guard the coast. The air is hot, but pure and wholesome.

The mountains are almost every where disposed into a kind of amphitheatres, by the labour of the inhabitants, with terraces placed one above another. The fields are watered with rivers and springs, which issue out of the mountains, and which the husbandmen conduct in such a manner as to overflow the fields of rice when they please, because it thrives best in watery ground. They make use of pipes of bambo for this purpose.

They have all commodities in common with the rest of China; but more particularly musk, precious stones, quicksilver, silk, hempen cloth, calico, iron, and all sorts of utensils, wrought to the greatest perfection. From other countries they have cloves, cinnamon, pepper, sandal-wood, amber, coral, and many other things. The capital city is Foutcheou Fou; or, as others would have it written, Fucherofu. But as for Fokien, which most geographers make the capital, Grosier informs us there is no such place.

FOLARD (Charles), an eminent Frenchman, famous for his skill and knowledge in the art military, was born at Avignon in 1669, of a noble family, but not a rich one. He discovered an early turn for the

sciences, and a strong passion for arms; which last was so inflamed by reading Cæsar's Commentaries, that he enlisted at 16 years of age. His father got him off, and shut him in a monastery: but he made his escape in about two years after, and entered himself a second time in quality of cadet. His inclination for military affairs, and the great pains he took to accomplish himself in that way, recommended him to notice; and he was admitted into the friendship of the first-rate officers. M. de Vendome, who commanded in Italy in 1720, made him his aid-de-camp, having conceived the highest regard for him; and soon after sent him with part of his forces into Lombardy. He was entirely trusted by the commander of that army; and no measures were concerted, or steps taken, without consulting him. By pursuing his plans, many places were taken, and advantages gained; and such, in short, were his services, that he had a pension of 400 livres settled upon him, and was honoured with the cross of St Lewis. He distinguished himself greatly August 15, 1705, at the battle of Cassano; where he received a wound upon his left hand, which deprived him of the use of it ever after. It was at this battle that he conceived the first idea of that system of columns, which he afterwards prefixed to his Commentaries upon Polybius. The duke of Orleans sending de Vendome again into Italy in 1706, Folard had orders to throw himself into Modena to defend it against Eugene: where, tho' he acquitted himself with his usual skill, he was very near being assassinated. The description which he has given of the conduct and character of the governor of this town, may be found in his Treatise of the Defence of Places, and deserves to be read. He received a dangerous wound on the thigh at the battle of Malplaquet, and was some time after made prisoner by prince Eugene. Being exchanged in 1711, he was made governor of Bourbourg. In 1714 he went to Malta, to assist in defending that island against the Turks. Upon his return to France, he embarked for Sweden, having a passionate desire to see Charles XII. He acquired the esteem and confidence of that famous general, who sent him to France to negotiate the re-establishment of James II. upon the throne of England; but that project being dropped, he returned to Sweden, followed Charles XII. in his expedition to Norway, and served under him at the siege of Frederickshall, where that prince was killed, Dec. 11, 1718. Folard then returned to France; and made his last campaign in 1719, under the duke of Berwick, in quality of colonel. From that time he applied himself intently to the study of the art military as far as it could be studied at home; and built his theories upon the foundation of his experience and observations on facts. He contracted an intimacy with count Saxe, who, as he then declared, would one day prove a very great general. He was chosen a fellow of the Royal Society at London in 1749; and, in 1751, made a journey to Avignon, where he died in 1752, aged 83 years. He was the author of several works, the principal of which are, 1. Commentaries upon Polybius, in six volumes, 4to. 2. A Book of new Discoveries in War. 3. A Treatise concerning the Defence of Places, &c. in French. Those who would know more of this eminent soldier, may consult a French piece, intitled,

Folard.

Folc-lands titled, *Memoirs pour servir a l'Histoire de M. de Chevalier de Folard. Ratisbone, 1753, 12mo.*

FOLC-LANDS, (Sax.) copy-hold lands so called in the time of the Saxons, as charter-lands were called *boc-lands*, Kitch. 173. *Folkland* was *terra vulgi* or *popularis*; the land of the vulgar people, who had no certain estate therein, but held the same, under the rents and services accustomed or agreed, at the will only of their lord the thane; and it was therefore not put in writing, but accounted *prædium rusticum et ignobile*. Spelm. of Feuds, c. 5.

FOFLCMOTE, or FOLKMOTE, (Sax. *Folcgemot*, i. e. *conventus populi*), is compounded of *folk* *populus*, and *mote*, or *gemote convenire*; and signified originally, as Somaer in his Saxon Dictionary informs us, a general assembly of the people, to consider of and order matters of the commonwealth. And Sir Henry Spelman says, the *folcmote* was a sort of annual parliament, or convention of the bishops, thanes, aldermen, and freemen, upon every May-day yearly; where the laymen were sworn to defend one another and the king, and to preserve the laws of the kingdom; and then consulted of the common safety. But Dr Brady infers from the laws of the Saxon kings of England, that it was an inferior court, held before the king's reeve or steward, every month, to do *folk* right, or compose smaller differences, from whence there lay appeal to the superior courts; *Gloss.* p. 48. Squire seems to think the *folcmote* not distinct from the *shiremote*, or common general meeting of the county. See his *Angl. Sax. Gov.* 155. n.

Mauwood mentions *folcmote* as a court holden in London, wherein all the *folk* and people of the city did complain of the mayor and aldermen, for misgovernment within the said city; and this word is still in use among the Londoners, and denotes *celebrem ex tota civitate conventum*. *Stow's Survey*. According to Kennet, the *folcmote* was a common-council of all the inhabitants of a city, town, or borough, convened often by sound of bell, to the *Mote Hall*, or *House*; or it was applied to a larger congress of all the freemen within a county, called the *shire-mote*, where formerly all knights and military tenants did fealty to the king, and elected the annual sheriff on the 1st of October; till this popular election, to avoid tumults and riots, devolved to the king's nomination, anno 1315, 3 Edw. 1. After which the city *folcmote* was swallowed up in a select committee or common-council, and the country *folcmote* in the sheriff's tourn and assises.

The word *folcmote* was also used for any kind of popular or public meeting; as of all the tenants at the *court-leet*, or *court-baron*, in which signification it was of a less extent. *Paroch. Antiq.* 120.

FOLENGIO (Theophilus), of Mantua, known also by the title of *Merlin Coccaye*, an Italian poet, remarkable for giving to a poem a name which has been adopted ever since for all trifling performances of the same species, consisting of buffoonry, puns, anagrams, wit without wisdom, and humour without good-sense. His poem was called *The Macaroni*, from an Italian cake of the same name, which is sweet to the taste, but has not the least alimentary virtue, on the contrary palls the appetite and cloyes the stomach. These idle poems, however, became the reigning taste in Italy and in France: they gave birth to macaroni acad-

mies; and, reaching England, to macaroni clubs: till, in the end, every thing insipid, contemptible, and ridiculous, in the character, dress, or behaviour, of both men and women, is now fumed up in the despicable appellation of a *macaroni*. Folengio died in 1544.

FOLIA, among botanists, particularly signify the leaves of plants; those of flowers being expressed by the word *petals*. See LEAF.

FOLIAGE, a cluster or assemblage of flowers, leaves, branches, &c.

FOLIAGE, is particularly used for the representations of such flowers, leaves, branches, rinds, &c. whether natural or artificial, as are used for enrichments on capitals, friezes, pediments, &c.

FOLIATING of LOOKING-GLASSES, the spreading the plates over, after they are polished, with quicksilver, &c. in order to reflect the image. It is performed thus: A thin blotting paper is spread on the table, and sprinkled with fine chalk; and then a fine lamina or leaf of tin, called *foil*, is laid over the paper; upon this is poured mercury, which is to be distributed equally over the leaf with a hare's-foot or cotton: over this is laid a clean paper, and over that the glass-plate, which is pressed down with the right-hand, and the paper drawn gently out with the left: this being done, the plate is covered with a thicker paper, and loaded with a greater weight that the superfluous mercury may be driven out and the tin adhere more closely to the glass. When it is dried, the weight is removed, and looking-glass is complete.

Some add an ounce of marcasite, melted by the fire; and, lest the mercury should evaporate in smoke, they pour it into cold water; and when cooled, squeeze through a cloth, or through leather.

Some add a quarter of an ounce of tin and lead to the marcasite, that the glass may dry the sooner.

FOLIATING of *Globe Looking-glasses*, is done as follows: Take five ounces of quicksilver and one ounce of bismuth; of lead and tin, half an ounce each: first put the lead and tin into fusion, then put in the bismuth; and when you perceive that in fusion too, let it stand till it is almost cold, and pour the quicksilver into it: after this, take the glass-globe, which must be very clean, and the inside free from dust: make a paper-funnel, which put into the hole of the globe, as near the glass as you can, so that the amalgam, when you pour it in, may not splash, and cause the glass to be full of spots; pour it in gently, and move it about, so that the amalgam may touch every where: if you find the amalgam begin to be curdly and fixed, then hold it over a gentle fire, and it will easily flow again; and if you find the amalgam too thin, add a little more lead, tin, and bismuth to it. The finer and clearer your globe is, the better will the looking-glass be.

Dr Shaw observes, that this operation has considerable advantages, as being performable in the cold; and that it is not attended with the danger of poisonous fumes from arsenic, or other unwholesome matters, usually employed for this purpose: besides, how far it is applicable to the more commodious foliating of the common looking glasses, and other speculums, he thinks, may deserve to be considered.

FOLIO, in merchants books, denotes a page, or rather both the right and left hand pages, these being

Folia.

Folio.

Folio
||
Follis.

expressed by the same figure, and corresponding to each other. See BOOK-KEEPING.

FOLIO, among printers and booksellers, the largest form of books, when each sheet is so printed that it may be bound up in two leaves only.

FOLIS. See FOLLIS.

FOLIUM, or LEAF, in botany. See LEAF.

FOLKES (Martin), an English antiquary, mathematician, and philosopher, was born at Westminster about 1690; and was greatly distinguished as a member of the Royal Society in London, and of the Academy of Sciences at Paris. He was admitted into the former at 24 years of age; made one of their council two years after; named by Sir Isaac Newton himself as vice-president; and, after Sir Hans Sloane, became president. There are numerous Memoirs of his in the Philosophical Transactions. Coins, ancient and modern, were a great object with him; and his last production was a book upon the English Silver Coin, from the conquest to his own times. He died at London in 1754. Dr Birch had drawn up materials for a life of Mr Folkes, which are preserved at large in the Anecdotes of Bowyer, p. 562. *et seq.*

FOLKESTONE, a town of Kent, between Dover and Hythe, 72 miles from London, appears to have been a very ancient place, from the Roman coins and British bricks often found in it. Stillingfleet and Tanner take it for the *Lapis Tituli* of Nennius. It was burnt by Earl Godwin, and by the French in the reign of Edward III. It had five churches, now reduced to one. It is a member of the town and port of Dover; and has a weekly market and an annual fair. It is chiefly noted for the multitude of fishing-boats that belong to its harbour, which are employed in the season in catching mackerel for London; to which they are carried by the mackerel-boats of London and Barking. About Michaelmas, the Folkestone-barks, with others from Sussex, go away to the Suffolk and Norfolk coasts, to catch herrings for the merchants of Yarmouth and Lowestoff.—Folkestone gives title of *Viscount* to William Henry Bouverie, whose grandfather, Jacob, was so created in 1747. It has been observed of some hills in this neighbourhood, that they have visibly sunk and grown lower within memory.

FOLKLAND, and FOLKNOTE. See FOLCLAND.

FOLLICULUS, (from *follis*, "a bag,") a species of seed-vessel first mentioned by Linnæus in his *Delineatio plantæ*, generally consisting of one valve, which opens from bottom to top on one side, and has no suture for fastening or attaching the seeds within it.

FOLLICULI are likewise defined by the same author to be small glandular vessels distended with air, which appear on the surface of some plants; as at the root of water-milfoil, and on the leaves of aldrovanda. In the former, the vessels in question are roundish, and furnished with an appearance like two horns; in the latter, pot-shaped, and semicircular.

FOLLIS, or FOLIS, anciently signified a little bag or purse; whence it came to be used for a sum of money, and very different sums were called by that name: thus the scholiast on the Basilics, mentions a follis of copper which was worth but the 24th part of the miliarenis; the glossæ nomicæ, quoted by Gronovius and others, one of 125 miliarenis, and another of 250

denarii, which was the ancient sestertium; and three different sums of eight, four, and two pounds of gold; were each called *follis*. According to the account of the scholiast, the ounce of silver, which contained 5 miliarenis of 60 in the pound, was worth 120 follis of copper. The glossographer, describing a follis of 250 denarii, says it was equal to 312 pounds 6 ounces of copper; and as the denarius of that age was the 8th part of an ounce, an ounce of silver must have been worth 120 ounces of copper; and therefore the scholiast's follis was an ounce of copper, and equal to the glossographer's nummus. But as Constantine's copper money weighed a quarter of a Roman ounce, the scholiast's follis and the glossographer's nummus contained four of them, as the ancient nummus contained four asses.

FOLLY, according to Mr Locke, consists in the drawing of false conclusions from just principles; by which it is distinguished from madness, which draws just conclusions from false principles.

But this seems too confined a definition; *folly*, in its most general acceptation, denoting a weakness of intellect or apprehension, or some partial absurdity in sentiment or conduct.

FOMAHANT, in astronomy, a star of the first magnitude in the constellation AQUARIUS.

FOMENTATION, in medicine, is a fluid externally applied, usually as warm as the patient can bear it, and in the following manner. Two flannel cloths are dipped into the heated liquor, one of which is wrung as dry as the necessary speed will admit, then immediately applied to the part affected; it lies on until the heat begins to go off, and the other is in readiness to apply at the instant in which the first is removed: thus these flannels are alternately applied, so as to keep the affected part constantly supplied with them warm. This is continued 15 or 20 minutes, and repeated two or three times a-day.

Every intention of relaxing and soothing by fomentations may be answered as well by warm water alone as when the whole tribe of emollients are boiled in it; but when discutients or antiseptics are required, such ingredients must be called in as are adapted to that end.

The degree of heat should never exceed that of producing a pleasing sensation; great heat produces effects very opposite to that intended by the use of fomentations.

FONG-YANG, a city of China, in the province of KIANG-Nan. It is situated on a mountain, which hangs over the yellow river, and incloses with its walls several fertile little hills. Its jurisdiction is very extensive: for it comprehends 18 cities; 5 of which are of the second, and 13 of the third class. As this was the birth-place of the emperor Hong-vou, chief of the preceding dynasty, this prince formed a design of rendering it a famous and magnificent city, in order to make it the seat of empire. After having expelled the western Tartars, who had taken possession of China, he transferred his court hither, and named the city *Fong-yang*; that is to say, "The Place of the Eagle's Splendor." His intention, as we have said, was to beautify and enlarge it; but the inequality of the ground, the scarcity of fresh water, and above all the vicinity of his father's tomb, made him change his design. By
the

Folly
||
Fong-yang.

Fong-yang the unanimous advice of his principal officers, this prince established his court at NAN-KING, a more beautiful and commodious place. When he had formed this resolution, a stop was put to the intended works: the imperial palace which was to have been inclosed by a triple wall, the walls of the city to which a circumference of nine leagues were assigned, and the canals that were begun, all were abandoned; and nothing was finished but three monuments; which still remain. The extent and magnificence of these sufficiently show what the beauty of this city would have been had the emperor pursued his original design. The first is the tomb of the father of Hong-vou, to decorate which no expence was spared; it is called *Hoan-lin*, or the *Royal Tomb*. The second is a tower built in the middle of the city, which is of an oblong form, and 100 feet high. The third is a magnificent temple erected to the god Fo. At first it was only a pagod, to which Hong-vou retired after having lost his parents, and where he was admitted as an inferior domestic; but, having soon become weary of this kind of life, he enlisted with the chief of a band of banditti, who had revolted from the Tartars. As he was bold and enterprising, the general made choice of him for his son-in-law; soon after he was declared his successor by the unanimous voice of the troops. The new chief, seeing himself at the head of a large party, had the presumption to carry his views to the throne. The Tartars, informed of the progress of his arms, sent a numerous army into the field: but he surprised and attacked them with so much impetuosity, that they were obliged to fly; and though they several times returned to the charge, they were still defeated, and at length driven entirely out of China. As soon as he mounted the throne, he caused the superb temple which we have mentioned to be raised out of gratitude to the Bonzes, who had received him in his distress, and assigned them a revenue sufficient for the maintenance of 300 persons, under a chief of their own sect, whom he constituted a mandarin, with power of governing them, independent of the officers of the city. This pagod was supported as long as the preceding dynasty lasted; but that of the eastern Tartars, which succeeded, suffered it to fall to ruin.

FONG-Choui, the name of a ridiculous superstition among the Chinese. See CHINA, n^o 105.

FONT, among ecclesiastical writers, a large basin, in which water is kept for the baptizing of infants or other persons.

FONT, in the art of printing, denotes a complete assortment of letters, accents, &c. used in printing. See FOUNT.

FONTAINE (John), the celebrated French poet, and one of the first rate geniuses of his age, was born at Chateau Thierrri in Champagne, the 8th of July 1621, of a good extraction. At the age of 19 he entered amongst the Oratorians, but quitted that order 18 months after. He was 22 years of age before he knew his own talents for poetry; but hearing an ode of Malherbe read, upon the assassination of Henry IV. he was so taken with admiration of it, that the poetical fire, which had before lain dormant within him, seemed to be enkindled from that of the other great poet. He applied himself to read, to meditate, to repeat, in fine, to imitate, the works of Malherbe. The

first essays of his pen he confined to one of his relations, who made him read the best Latin authors, Horace, Virgil, Terence, Quintilian, &c. and then the best compositions in French and Italian. He applied himself likewise to the study of the Greek authors, particularly Plato and Plutarch. Some time afterwards his parents made him marry a daughter of a lieutenant-general, a relation of the great Racine. This young lady, besides her very great beauty, was remarkable for the delicacy of her wit, and Fontaine never composed any work without consulting her. But as her temper was none of the best, to avoid dissention, he separated himself from her company as often as he well could. The famous duchess of Bouillon, niece to cardinal Mazarine, being exiled to Chateau Thierrri, took particular notice of Fontaine. Upon her recal, he followed her to Paris; where, by the interest of one of his relations, he got a pension settled upon him. He met with great friends and protectors amongst the most distinguished persons of the court, but madam de la Sabliere was the most particular. She took him to live at her house; and it was then that Fontaine, divested of domestic concerns, led a life conformable to his disposition, and cultivated an acquaintance with all the great men of the age. It was his custom after he was fixed at Paris, to go every year, during the month of September, to his native place of Chateau-Thierrri, and pay a visit to his wife, carrying with him Racine, Despreaux, Chappelle, or some other celebrated writers. When he has sometimes gone thither alone by himself, he has come away without remembering even to call upon her; but seldom omitted selling some part of his lands, by which means he squandered away a considerable fortune. After the death of madame de la Sabliere he was invited into England, particularly by madame Marazin, and by St Evremond, who promised him all the sweets and comforts of life; but the difficulty of learning the English language, and the liberality of the duke of Burgundy, prevented his voyage.

About the end of the year 1692 he fell dangerously ill: and as it is customary upon these occasions in the Romish church, he made a general confession of his whole life to P. Pogue, an oratorian, and before he received the sacrament, he sent for the gentlemen of the French academy, and in their presence declared his sincere compunction for having composed his Tales; a work he could not reflect upon without the greatest repentance and detestation; promising, that if it should please God to restore his health, he would employ his talents only in writing upon matters of morality or piety. He survived this illness two years, living in the most exemplary and edifying manner, and died the 13th of March 1695, being 74 years of age. When they stripped his body, they found next his skin a hair shirt; which gave room for the following expression of the younger Racine:

*Et l'Auteur de *Jaconda* est orme d'un Cilice.*

Fontaine's character is remarkable for a simplicity, candour, and probity, seldom to be met with. He was of an obliging disposition; cultivating a real friendship with his brother poets and authors; and, what is very rare, beloved and esteemed by them all. His conversation was neither gay nor brilliant, especially when he was not among his intimate friends. One day

Fontaine,
Fontain-
bleau.

day being invited to dinner at a farmer-general's, he eat a great deal, but did not speak. Rising up from table very early, under pretext of going to the academy, one of the company represented to him that it was not yet a proper time: "Well (says he), if it is not, I will stay a little longer." He had one son by his wife in the year 1660. At the age of 14, he put him into the hands of M. de Harley, the first president, recommending to him his education and fortune. It is said that having been a long time without seeing him, he happened to meet him one day visiting, without recollecting him again, and mentioned to the company that he thought that young man had a good deal of wit and understanding. When they told him it was his own son, he answered in the most tranquil manner, "Ha! truly I am glad on't." An indifference, or rather an absence of mind, influenced his whole conduct, and rendered him often insensible to the inclemency of the weather. Madame de Bouillon going one morning to Versailles, saw him, abstracted in thought, sitting in an arbour; returning at night she found him in the same place, and in the same attitude, although it was very cold and had rained almost the whole day. He carried this simplicity so far, that he was scarce sensible of the bad effects some of his writings might occasion, particularly his tales. In a great sickness, his confessor exhorting him to prayer and alms-deeds: "As for alms-deeds (replied Fontaine), I am not able, having nothing to give; but they are about publishing a new addition of my Tales, and the bookseller owes me a hundred copies; you shall have them to sell, and distribute their amount amongst the poor." Another time P. Pognet exhorting him to repent of his faults, "If he has committed any (cried the nurse), I am sure it is more from ignorance than malice, for he has as much simplicity as an infant." One time having composed a tale, wherein he made a profane application of these words of the Gospel, "Lord, five talents thou didst deliver to me," he dedicated, it by a most ingenious prologue, to the celebrated Arnauld telling him, it was to show to posterity the great esteem he had for the learned doctor. He was not sensible of the indecency of the dedication, and the profane application of the text, till Boileau and Racine represented it to him. He addressed, another, by a dedication in the same manner to the archbishop of Paris. His Fables are an immortal work, exceeding every thing in that kind, both ancient and modern, in the opinion of the learned. People of taste, the oftener they read them, will find continually new beauties and charms, not to be met with elsewhere. The descendants of this great poet are exempted in France from all taxes and impositions, a privilege which the intendants of Soissons to this day think it an honour to confirm to them.

FONTAINBLEAU, a town in the Isle of France, and in the Gatinois, remarkable for its fine palace, which has been the place where the kings of France used to lodge when they went a-hunting. It was first embellished by Francis I. and all the successive kings have added something thereto; insomuch that it may now be called the finest pleasure-house in the world. It stands in the midst of a forest, consisting of 26,424 arpents of land, each containing 100 square perches, and each perch 18 feet. E. Long. 2. 33. N. Lat. 40. 22.

FONTAINES (Peter Francis), a French critic, was born of a good family at Ronen in 1685. At 15, he entered in to the society of the Jesuits; and at 30, quitted it, for the sake of returning to the world. He was a priest and had a cure in Normandy; but left it, and was, as a man of wit and letters, some time with the cardinal d'Auvergne. Having excited some attention at Paris by certain critical productions, the Abbé Bignon in 1724 committed to him the *Journal des Sçavans*. He acquitted himself well in the department, and was peaceably enjoying the applauses of the public, when his enemies, whom by critical strictures in his Journal he had made such, formed an accusation against him of a most abominable crime, and procured him to be imprisoned. By the credit of powerful friends, he was set at liberty in 15 days: the magistrate of the police took upon himself the trouble of justifying him in a letter to the Abbé Bignon; and this letter having been read amidst his fellow-labourers in the Journal, he was unanimously re-established in his former credit. This happened in 1725. But with whatever repute he might acquit himself in this Journal, frequent disgusts made him frequently abandon it. He laboured mean while in some new periodical works, from which he derived his greatest fame. In 1731, he began one under the title of *Nouvelliste du Parnasse, ou Reflexions sur les Ouvrages nouveaux*; but only proceeded to two volumes; the work having been suppressed by authority, from the incessant complaints of authors ridiculed therein. About three years after, in 1735, he obtained a new privilege for a periodical production, intitled, *Observations sur les Ecrits Modernes*: which, after continuing to 33 volumes, was suppressed again in 1743. Yet the year following, 1744, he published another weekly paper called, *Judgments sur les Ouvrages nouveaux*, and proceeded to 11 volumes: the two last being done by other hands. In 1745, he was attacked with a disorder in the breast, which ended in a dropsy that proved fatal in five weeks. "He was (says M. Freron) born a sentimental person; a philosopher in conduct as well as in principle; exempt from ambition; and of a noble firm spirit, which would not submit to sue for preferments or titles. In common conversation he appeared only a common man; but when subjects of literature, or any thing out of the ordinary way, were agitated, he discovered great force of imagination and wit." Besides the periodical works mentioned above, he was the author of many others: his biographer gives us no less than 17 articles; many of them critical, some historical, and some translations from English writers, chiefly from Pope, Swift, Fielding, &c. The Abbé de la Porte, published, in 1757, *L'Esprit de l'Abbé des Fontaines*, in 4 vols 12mo; prefixed to which is the Life of Fontaines, a catalogue of his works, and another catalogue of writings against him.

FONTANELLA, in anatomy, imports the quadrangular aperture found betwixt the os frontis and ossa sincipitis, in children just born; which is also called *fons pulsatilis*.

FONTARABIA, a sea port town of Spain in Biscay, and in the territory of Guipuscoa, seated on a peninsula on the sea shore, and on the river Bidassoa. It is small, but well fortified both by nature and art: and has a good harbour, though dry at low water. It is

Fontaines
||
Fontarabia

Fontenay is built in the form of an amphitheatre, on the declivity of an hill, and surrounded on the land side by the high Pyrenean mountains. It is a very important place, being accounted the key of Spain on that side. W. Long. 1. 43. N. Lat. 43. 23.

FONTENAY, (John Baptist Blain de), a very famous painter of fruit and flowers, was born at Caen in 1654. Louis XIV. gave him a pension, and an apartment in the galleries of the Louvre; and he was nominated counsellor of the Academy of Painting. His fruit and flowers have all the freshness and beauty of nature; the very dew seems to trickle down their stalks, with all the lustre and transparency of the diamond, while the insects upon them seem perfectly alive and animated. This ingenious painter died at Paris in 1715.

FONTENELLE, (Bernard de), a celebrated French author, was born in 1657, and died in 1756, when he was near 100 years old. He discharged the trust of perpetual secretary to the Academy of Sciences above 40 years with universal applause; and his History of the Academy of Sciences throws a great light upon their memoirs, which are very obscure. The eulogies which he pronounced on the deceased members of the academy, have this peculiar merit, that they excite a respect for the sciences as well as for the author. In his poetical performances, and the Dialogues of the Dead, the spirit of Voiture was discernible, though more extended and more philosophical. His Plurality of Worlds, is a work singular in its kind; the design of which was to present that part of philosophy to view in a gay and pleasing dress. In his most advanced years, he published comedies, which, though they showed the elegance of Fontenelle, were little fitted for the stage; and An Apology for Des Cartes's Vortices. M. de Voltaire, who declares him to have been the most universal genius the age of Louis XIV. produced, says, "We must excuse his comedies, on account of his great age; and his Cartesian opinions, as they were those of his youth, when they were universally received all over Europe."

FONTENOY, a town or village of the Austrian Netherlands, in the province of Hainault, and on the borders of Flanders; remarkable for a battle fought there between the allies and the French on the first of May 1745. The French were commanded by Marechal Saxe, and the allies by the Duke of Cumberland. The latter behaved with great bravery; but through the superiority of the numbers of the French army, and likewise the superior generalship of their commander, the allies were defeated with great slaughter. The British troops behaved with astonishing intrepidity, as their enemies themselves owned. It is even said, that the battle was lost through the cowardice of the Dutch, who failed in their attack on the village of Fontenoy, on which the event of the day depended. E. Long. 2. 20. N. Lat. 50. 25.

FONTENOY, a village of France, in the duchy of Burgundy, remarkable for a bloody battle fought there in 841, between the Germans and the French, in which were killed above 100,000 men; and the Germans were defeated. E. Long. 3. 48. N. Lat. 47. 28.

FRONTEVAUX, or **FRONTEVAUX** (Order of), in ecclesiastical history, a religious order instituted by Robert d'Arbrissel, about the latter end of the 11th cen-

tury, and taken under the protection of the holy see by pope Pascal II. in 1106, confirmed by a bull in 1113, and invested by his successors with very extraordinary privileges. The chief of this order is a female, who is appointed to inspect both the monks and nuns. The order is divided into four provinces, which are those of France, Aquitaine, Auvergne, and Bretagne, in each of which they have several priories.

FONTICULUS, or **FONTANELLA**, in surgery, an issue, seton, or small ulcer, made in various parts of the body, in order to eliminate the latent corruption out of it.

FONTINALIA, or **FONTANALIA**, in antiquity, a religious feast held among the Romans in honour of the deities who presided over fountains or springs. Varro observes, that it was the custom to visit the wells on those days, and to cast crowns into fountains. Scaliger, in his conjectures on Varro, takes this not to be a feast of fountains in general, as Festus insinuates, but of the fountain which had a temple at Rome, near the Porta Capena, called also *Porta Fontinalis*: he adds, that it is of this fountain Cicero speaks in his second book *De legib.* The fontinalia were held on the 13th of October.

FONTINALIS, **WATER-MOSS**, in botany: A genus of the natural order of musci, belonging to the cryptogamia class of plants. The anthera is hooded; the calyptra, or covering of the anthera, sessile, inclosed in a perichæcium or empalement of leaflets different from those of the rest of the plant. There are four species, all of them natives of Britain. They grow on the brinks of rivulets, and on the trunks of trees. The most remarkable is the antipyretica, with purple stalks. The Scandinavians line the insides of their chimneys with this moss, to defend them against the fire; for contrary to the nature of all other moss, this is scarcely capable of burning.

FOOD, in the most extensive signification of the word, implies whatever aliments are taken into the body, whether solid or fluid; but, in common language, it is generally used to signify only the solid part of our aliment.

We are told, that in the first ages men lived upon acorns, berries, and such fruits as the earth spontaneously produces; then they proceeded to eat the flesh of wild animals taken in hunting: But their numbers decreasing, and mankind multiplying, necessity taught them the art of cultivating the ground, to sow corn, &c. By and by they began to assign to each other, by general consent, portions of land to produce them their supply of vegetables; after this, reason suggested the expedient of domesticating certain animals, both to assist them in their labours and supply them with food. Hogs were the first animals of the domestic kind that appeared upon their tables; they held it to be ungrateful to devour their beasts that assisted them in their labours.—When they began to make a free use of domestic animals, they roasted them only; boiling was a refinement in cookery which for ages they were strangers to; and fish living in an element men were unused to, were not eaten till they grew somewhat civilized. Menelaus complains, in the *Odyssey*, that they had been constrained to feed upon them.

The most remarkable distinction of foods, in a medical view, is into those which are already assimilated into

Fonticulus
|
Food.

Food. into the animal nature, and such as are not. Of the first kind are animal substances in general; which if not entirely similar, are nearly so, to our nature. The second comprehends vegetables, which are much more difficultly assimilated. But as the nourishment of all animals, even those which live on other animals, can be traced originally to the vegetable kingdom, it is plain, that the principle of all nourishment is in vegetables.

Cullen on the Mat. Med. 1st edit. Though there is perhaps no vegetable which does not afford nourishment to some species of animals or other; yet, with regard to mankind, a very considerable distinction is to be made. Those vegetables which are of a mild, bland, agreeable taste, are proper nourishment; while those of an acrid, bitter, and nauseous nature, are improper. We use, indeed, several acrid substances as food; but the mild, the bland, and agreeable, are in the largest proportion in almost every vegetable. Such as are very acrid, and at the same time of an aromatic nature, are not used as food, but as spices or condiments, which answer the purposes of medicine rather than any thing else. Sometimes, indeed, acrid and bitter vegetables seem to be admitted as food. Thus celeri and endive are used in common food, though both are substances of considerable acrimony; but it must be observed, that, when we use them, they are previously blanched, which almost totally destroys their acrimony. Or if we employ other acrid substances, we generally, in a great measure, deprive them of their acrimony by boiling. In different countries the same plants grow with different degrees of acrimony. Thus, garlic here seldom enters our food; but in the southern countries, where the plants grow more mild, they are frequently used for that purpose. The plant which furnishes cassada, being very acrimonious, and even poisonous, in its recent state, affords an instance of the necessity of preparing acrid substances even in the hot countries: and there are other plants, such as arum-root, which are so exceedingly acrimonious in their natural state, that they cannot be swallowed with safety; yet, when deprived of that acrimony, will afford good nourishment.

The most remarkable properties of different vegetable substances as food, are taken notice of under their different names; here we shall only compare vegetable foods in general with those of the animal kind.

I. *In the Stomach*, they differ remarkably, in that the vegetables always have a tendency to acidity, while animal food of all kinds tend rather to alkalescency and putrefaction. Some animal foods, indeed, turn manifestly acid before they putrify; and it has been asserted, that some degree of acescency takes place in every kind of animal food before digestion. This acescency of animal food, however, never comes to any morbid degree, but the disease is always on the side of putrefaction. The acescency of vegetables is more frequent, and ought to be more attended to, than the alkalescency of animal food; which last, even in weak stomachs, is seldom felt; while acescency greatly affects both the stomach and system.

With regard to their difference of *solution*:—Heaviness, as it is called, is seldom felt from vegetables, except from tough farinaceous paste, or the most viscid substances; while the heaviness of animal food is more frequently noticed, especially when in any great quan-

Food. tity. Difficulty of solution does not depend so much on firmness of texture (as a man, from fish of all kinds, is more oppressed than from firmer substances) as on viscosity; and hence it is more frequent in animal food, especially in the younger animals.

With regard to *mixture*;—There is no instance of difficult mixture in vegetables, except in vegetable oils; while animal foods, from both viscosity and oiliness, especially the fatter meats, are refractory in this respect. Perhaps the difference of animal and vegetable foods might be referred to this head of mixture. For vegetable food continues long in the stomach, giving little stimulus: Now the system is affected in proportion to the extent of this stimulus, which is incomparably greater from the animal viscid oily food, than from the vegetable, firmer, and more aqueous. However, there are certain applications to the stomach, which have a tendency to bring on the cold fit of fever, independent of stimulus, merely by their refrigeration: and this oftener arises from vegetables; as we see, in those hot countries where intermittents prevail, they are oftener induced from a surfeit of vegetable than of animal food. A proof of this is, that when one is recovering of an intermittent, there is nothing more apt to cause a relapse than cold food, especially if taken on those days when the fit should return, and particularly acescent, fermentable vegetables, as salad, melons, cucumbers, &c. *acido dulces*, &c. which according to Dr Cullen, are the most frequent causes of epidemics; therefore, when an intermittent is to be avoided, we shun vegetable diet, and give animal foods, although their stimulus be greater.

II. *In the Intestines*. When the putrescency of animal food has gone too far, it produces an active stimulus, causing diarrhoea, dysentery, &c. But these effects are but rare: whereas from vegetable food and its acid, which, united with the bile, proves a pretty strong stimulus, they more frequently occur; but, luckily, are of less consequence, if the refrigeration is not very great. In the autumnal season, when there is a tendency to dysentery, if it is observed that eating of fruits brings it on, it is rather to be ascribed to their cooling than stimulating the intestines.

As to *stool*—Wherever neither putrefaction nor acidity has gone a great length, animal food keeps the belly more regular. Vegetable food gives a greater proportion of feculent matter, and, when exsiccated by the stomach and intestines, is more apt to stagnate, and produce slow-belly, and costiveness, than animal stimulating food; which, before it comes to the great guts, where stoppage is made, has attained a putrefactive tendency, and gives a proper stimulus: and thus those who are costive from the use of vegetables, when they have recourse to animal food are in this respect better.

III. *In the blood-vessels*. They both give a blood of the same kind, but of different quality. Animal food gives it in greater quantity, being in great part, as the expression is, convertible in *succum et sanguineum*, and of easy digestion; whereas vegetable is more watery, and contains a portion of unconquerable saline matter, which causes it to be thrown out of the body by some excretion. Animal food affords a more dense stimulating elastic blood than vegetable; stretching and causing a greater resistance in the solids, and again exciting their stronger action. It has been supposed, that

Food.

acescency of vegetable food is carried into the blood-vessels, and there exerts its effects; but the tendency of animal fluids is so strong to alkalescency, that the existence of acid acrimony in the blood seems very improbable. Animal food alone will soon produce an alkalescent acrimony; and if a person who lives entirely on vegetables were to take no food for a few days, his acrimony would be alkalescent.

IV. We are next to take notice of the *quantity of nutriment* these different foods afford. Nutriment is of two kinds: the first repairs the waste of the solid fibres: the other supplies certain fluids, the chief of which is oil. Now, as animal food is easier converted, and also longer retained in the system, and as it contains a greater proportion of oil, it will afford both kinds of nutriment more copiously than vegetables.

V. Lastly, *As to the different degrees of perspirability of these foods.* This is not yet properly determined. Sanctorius constantly speaks of mutton as the most perspirable of all food, and of vegetables as checking perspiration. This is a consequence of the different stimulus those foods give to the stomach, so that persons who live on vegetables have not their perspiration so suddenly excited. In time of digestion, perspiration is stopped from whatever food, much more so from cooling vegetables. Another reason why vegetables are less perspirable is, because their aqueo-saline juices determine them to go off by urine, while the more perfectly mixed animal food is more equally diffused over the system, and so goes off by perspiration. Hence Sanctorius's accounts may be understood; for vegetable aliment is not longer retained in the body, but mostly takes the course of the kidneys. Both are equally perspirable in this respect, viz. that a person living on either, returns once a-day to his usual weight; and if we consider the little nourishment of vegetables, and the great tendency of animal food to corpulency, we must allow that vegetable is more quickly perspired than animal food.

As to the question, Whether man was originally designed for animal or vegetable food, see the article **CARNIVOROUS**.

With regard to the effects of these foods on men, it must be observed, that there are no persons who live entirely on vegetables. The Pythagoreans themselves eat milk; and those who do so mostly, as these Pythagoreans, are weakly, sickly, and meagre, labouring under a constant diarrhoea and several other diseases. None of the hardy, robust, live on these; but chiefly such as gain a livelihood by the exertion of their mental faculties, as (in the East-Indies) factors and brokers; and this method of life is now confined to the hot climates, where vegetable diet, without inconvenience, may be carried to great excess. Though it be granted, therefore, that man is intended to live on these different foods promiscuously, yet the vegetable should be in very great proportion. Thus the Laplanders are said to live entirely on animal food: but this is contradicted by the best accounts; for Linnæus says, that besides milk, which they take sour, to obviate the bad effects of animal food, they use also calla, menyanthes, and many other plants, copiously. So there is no instance of any nation living entirely either on vegetable or animal food, though there are indeed some who live particularly on one or other in the great-

3.

est proportion. In the cold countries, e. g. the inhabitants live chiefly on animal food, on account of the rigour of the season, their smaller perspiration, and little tendency to putrefaction.

Of more importance, however, is the following than the former question, viz. *In what proportion animal and vegetable food ought to be mixed?*

I. *Animal food* certainly gives most strength to the system. It is a known aphorism of Sanctorius, that *pondus addit robur*; which may be explained from the impletion of the blood-vessels, and giving a proper degree of tension for the performance of strong oscillations. Now, animal food not only goes a greater way in supplying fluid, but also gives the fluid more dense and elastic. The art of giving the utmost strength to the system is best understood by those who breed fighting cocks. These people raise the cocks to a certain weight, which must bear a certain proportion to the other parts of the system, and which at the same time is so nicely proportioned, as that, on losing a few ounces of it, their strength is very considerably impaired. Dr Robinson of Dublin has observed, that the force and weight of the system ought to be determined by the largeness of the heart, and its proportion to the system: for a large heart will give large blood-vessels, while at the same time the viscera are less, particularly the liver; which last being increased in size, a greater quantity of fluid is determined into the cellular texture, and less into the sanguineous system.— Hence we see how animal food gives strength, by filling the sanguiferous vessels. What pains we now bestow on cocks, the ancients did on the Athletæ, by proper nourishment bringing them to a great degree of strength and agility. It is said, that men were at first fed on figs, a proof of which we have from their nutritious quality: however, in this respect they were soon found to fall far short of animal food; and thus we see, that men, in some measure, will work in proportion to the quality of their food. The English labour more than the Scots; and wherever men are exposed to hard labour, their food should be animal. Animal food, although it gives strength, yet loads the body; and Hippocrates long ago observed, that the athletic habit, by a small increase, was exposed to the greatest hazards. Hence it is only proper for bodily labours, and entirely improper for mental exercises; for whoever would keep his mind acute and penetrating, will exceed rather on the side of vegetable food. Even the body is oppressed with animal food; a full meal always produces dulness, laziness, and yawning; and hence the feeding of gamesters, whose mind must be ready to take advantage, is always performed by avoiding a large quantity of animal food. Farther, with regard to the strength of the body, animal food in the first stage of life is hardly necessary to give strength; in manhood, when we are exposed to active scenes, it is more allowable; and even in the decline of life, some proportion of it is necessary to keep the body in vigour. There are some diseases which come on in the decay of life, at least are aggravated by it; among these the most remarkable is the gout. This, when it is in the system, and does not appear with inflammation in the extremities, has pernicious effects there, attacking the lungs, stomach, head, &c. Now to determine this to the extremities, a large proportion

Food.

Food.

of animal food is necessary, especially as the person is commonly incapable of much exercise.

Animal food, although it gives strength, is yet of many hazards to the system, as it produces plethora and all its consequences. As a stimulus to the stomach and to the whole system, it excites fever, urges the circulation, and promotes the perspiration. The system, however, by the repetition of these stimuli, is soon worn out; and a man who has early used the athletic diet, is either early carried off by inflammatory diseases, or, if he takes exercise sufficient to render that diet salutary, such an accumulation is made of putrescent fluids, as in his after-life lays a foundation for the most inveterate chronic distempers. Therefore it is to be questioned, whether we should desire this high degree of bodily strength, with all the inconveniences and dangers attending it. Those who are chiefly employed in mental researches, and not exposed to too much bodily labour, should always avoid an excess of animal food. There is a disease which seems to require animal food, viz. the hysteric or hypochondriac; and which appears to be very much a kin to the gout, affecting the alimentary canal. All people affected with this disease are much disposed to acescency; which sometimes goes so far, that no other vegetable but bread can be taken in, without occasioning the worst consequences. Here then we are obliged to prescribe an animal diet, even to those of very weak organs; for it generally obviates the symptoms. However, several instances of scurvy in excess have been produced by a long-continued use of this diet, which it is always unlucky to be obliged to prescribe, and when it is absolutely necessary to prescribe, it should be joined with as much of the vegetable as possible, and when a cure is performed we should gradually recur to that again.

2. Next, let us consider the *vegetable* diet. The chief inconveniency of this is difficulty of assimilation; which however, in the vigorous and exercised, will not be liable to occur. In warm climates, the assimilation of vegetable aliment is more easy, so that *there* it may be more used, and when joined to exercise gives a pretty tolerable degree of strength and vigour; and though the general rule be in favour of *animal* diet, for giving strength, yet there are many instances of its being remarkably produced from vegetable. Vegetable diet has this advantage, that it whets the appetite, and that we can hardly suffer from a full meal of it. Besides the disorders it is liable to produce in the *prima via*, and its falling short to give strength, there seem to be no bad consequences it can produce in the blood-vessels; for there is no instance where its peculiar acrimony was ever carried there, and it is certainly less putrifiable than animal food; nor, without the utmost indolence, and a sharp appetite, does it give plethora, or any of its consequences: so that we cannot here but conclude, that a large proportion of vegetable food is useful for the generality of mankind.

There is no error more dangerous, or more common, than the neglect of bread: for it is the safest of vegetable aliment, and the best corrector of animal food; and, by a large proportion of this alone, its bad consequences, when used in a hypochondriac state, have been obviated. The French apparently have as much animal food on their tables as the Britons; and yet,

Food.

by a greater use of bread and the dried acid fruits, its bad effects are prevented: and therefore bread should be particularly used by those who are attached to animal food. Vegetable food is not only necessary to secure health, but long life: and, as we have said, in infancy and youth we should be confined to it mostly; in manhood, and decay of life, use animal food; and, near the end, vegetable again.

There is another question much agitated, viz. *What are the effects of variety in food?* Is it necessary and allowable, or universally hurtful? Variety of a certain kind seems necessary; as vegetable and animal foods have their mutual advantages, tending to correct each other. Another variety, which is very proper, is that of liquid and solid food, which should be so managed as to temper each other; and liquid food, especially of the vegetable kind, is too ready to pass off before it is properly assimilated, while solid food makes a long stay. But this does not properly belong to the question, whether variety of the same kind is necessary or proper, as in animal foods, beef, fish, fowl, &c. It doth not appear that there is any inconvenience arising from this mixture or difficulty of assimilation, provided a moderate quantity be taken. When any inconvenience does arise, it probably proceeds from this, that one of the particular substances in the mixture, when taken by itself, would produce the *same effects*; and, indeed, it would appear, that this effect is not *heightened* by the mixture, but properly *obviated* by it. There are few exceptions to this, if any, e. g. taking a large proportion of acescent substances with milk. The coldness, &c. acidity, flatulency, &c. may appear; and it is possible that the coagulum, from the acescency of the vegetables, being somewhat stronger induced, may give occasion to too long retention in the stomach, and to acidity in too great degree. Again, the mixture of fish and milk often occasions inconveniences. The theory of this is difficult, though, from universal consent, it must certainly be just. Can we suppose that fish gives occasion to such a coagulum as runnet? If it does so, it may produce bad effects. Besides, fishes approach somewhat to vegetables, in giving little stimulus; and are accused of the same bad effects as these, viz. bringing on the cold fit of fever.

Thus much may be said for variety. But it also has its disadvantages, provoking to gluttony; this, and the art of cookery, making men take in more than they properly can digest: and hence, perhaps, very justly, physicians have universally almost preferred simplicity of diet; for, in spite of rules, man's eating will only be measured by his appetite, and satiety is sooner produced by *one* than by *many* substances. But this is so far from being an argument against variety, that it is one for it, as the only way of avoiding a full meal of animal food, and its bad effects, is by presenting a quantity of vegetables. Another mean of preventing the bad effects of animal food, is, to take a large proportion of liquid; and hence the bad effects of animal food are little felt in Scotland, on account of their drinking much with it, and using broths, which are at once excellent correctors of animal food, and preventives of gluttony.

With regard to the differences between ANIMAL FOODS, properly so called, the first regards their solubility,

Food. lity, depending on a lax or firm texture of their different kinds.

1. SOLUBILITY of animal food seems to deserve less attention than is commonly imagined; for there are many instances of persons of a weak stomach incapable of breaking down the texture of vegetables, or even of dissolving a light pudding, to whom hung beef, or a piece of ham, was very grateful and easily digested. None of the theories given for the solution of animal-food in the human stomach seems to have explained that process sufficiently. Long ago has been discarded the supposition of an active corrosive menstruum there; and also the doctrine of trituration, for which, indeed, there seems no mechanism in the human body; and, till lately, physicians commonly agreed with Boerhaave in supposing nothing more to be necessary than a watery menstruum, moderate heat, and frequent agitation. This will account for solution in some cases, but not entirely. Let us try to imitate it out of the body with the same circumstances, and in tentimes the time in which the food is dissolved in the stomach we shall not be able to bring about the same changes. Take the coagulated white of an egg, which almost every body can easily digest, and yet no artifice shall be able to dissolve it. Hence, then, we are led to seek another cause for solution, *viz.* fermentation; a notion, indeed, formerly embraced, but on the introduction of mechanical philosophy, industriously banished, with every other supposition of that process taking place at all in the animal economy.

Many of the ancients imagined this fermentation to be putrefactive. But this we deny, as an acid is produced; though hence the fermentation might be reckoned the vinous, which, however, seems always to be morbid. Neither, indeed, is the fermentation purely acetous, but modified by putrescence; for Pringle has observed, that animal-matters raise and even expedite the acetous process. The fermentation, then, in the stomach is of a mixed nature, between the acetous and putrefactive, mutually modifying each other; though, indeed, in the intestines, somewhat of the putrefactive seems to take place, as may be observed from the state of the feces broke down, and from the little disposition of such substances to be so, which are not liable to the putrefactive process, as the firmer parts of vegetables, &c. Upon this view solution seems to be extremely easy, and those substances to be most easily broke down which are most subject to putrefaction. See ANATOMY, n^o 104. and GASTRIC Juice.

But solution also depends on other circumstances, and hence requires a more particular regard.

1. There is a difference of solubility with respect to the manducation of animal-food, for which bread is extremely necessary, in order to keep the more slippery parts in the mouth till they be properly comminuted*. From want of proper manducation persons are subject to eructations; and this more frequently from the firm vegetable foods, as apples, almonds, &c. than from the animal, though, indeed, even from animal food, very tendinous, or swallowed in unbroken masses, such sometimes occur. Manducation is so much connected with solution, that some, from imperfectly performing that, are obliged to belch up their food, remanducate it, and swallow it again before the stomach can dissolve it, or proper nourishment be extracted. Another

VOL. VII.

Food. proof of our regard to solubility, is our rejecting the firmer parts of animal-food, as bull-beef, and generally carnivorous animals.

2. Its effects with regard to solubility seem also to be the foundation of our choice between *fat* and *lean*, *young* and *old meats*. In the *lean* although perhaps a single fibre might be sufficiently tender, yet these, when collected in *fasciculi*, are very firm and compact, and of difficult solution; whereas in the *fat* there is a greater number of vessels, a greater quantity of juice, more interposition of cellular substance, and consequently more solubility. Again, in young animals, there is probably the same number of fibres as in the older, but these more connected: whereas, in the older, the growth depending on the separation of these, and the increase of vessels and cellular substance, the texture is less firm and more soluble; which quantities, with regard to the stomach, are at that time too increased, by the increased alkalescency of the animal. To this also may be referred our choice of castrated animals, *viz.* on account of their disposition to fatten after the operation.

3. It is with a view to the solubility, that we make a choice between meats recently killed, and those which have been kept for some time. As soon as meat is killed, the putrefactive process begins; which commonly we allow to proceed for a little, as that process is the most effectual breaker down of animal matters, and a great assistance to solution. The length of time during which meat ought to be kept, is proportioned to the meat's tendency to undergo the putrid fermentation, and the degree of those circumstances which favour it: Thus, in the torrid zone, where meat cannot be kept above four or five hours, it is used much more recent than in the northern climates.

4. *Boiled* or *roasted* meats create a difference of solution. By boiling we extract the juices interposed between the fibres, approximate them more to each other, and render them of more difficult solubility; which is increased too by the extraction of the juices, which are much more alkalescent than the fibres: but when we want to avoid the stimulus of alkalescent food, and the quick solution, as in some cases of disease, the roasted is not to be chosen. Of roasted meat it may be asked, which are more proper, those which are most or least roasted? That which is least done is certainly the most soluble: even raw meats are more soluble than dressed, as Dr Cullen was informed by a person who from necessity was obliged, for some time, to eat such. But at the same time that meats little done are very soluble, they are very alkalescent; so that, wherever we want to avoid alkalescency in the *primæ viæ*, the most roasted meats should be chosen. Those who throw away the broths of boiled meat do very improperly; for, besides their supplying a fluid from their greater alkalescency they increase the solubility of the meat. Here we shall observe, that pure blood has been thought insoluble. Undoubtedly it is very nutritious; and though out of the body, like the white of eggs, it seems very insoluble, yet, like that too, in the body it is commonly easily digested. Moses very properly forbade it the Israelites, as in warm countries it is highly alkalescent; and even in Britain when it was used in great quantity, the scurvy was

T t

more

* See the article Bread.

Food.

more frequent: but to a moderate use of it, in these climates, no such objection takes place.

5. Solubility is varied from another source, *viz.* viscosity of the juice of aliment. Young animals, then, appear more soluble than old, not only on account of the compactness and firmness of texture in the latter, but also their greater viscosity of juice. And nothing is more common, than to be longer oppressed from a full meal of veal, than from the same quantity of beef, &c. Upon account, too, of their greater viscosity of juice, are the tendons and ligamentous parts of animals longer retained than the purely muscular, as well as on account of their firmness of texture. Even fishes, whose muscular parts are exceedingly tender, are, on account of their gluey viscosity, longer of solution in the stomach. And eggs, too, which are exceedingly nourishing, have the same effect, and cannot be taken in great quantity: For the stomach is peculiarly sensible to gelatinous substances; and by this means has nature perhaps taught us, as it were by a sort of instinct, to limit ourselves in the quantity of such nutritive substances.

6. With regard to solution, we must take in the oils of animal-food; which, when tolerably pure, are the least putrescent part of it, and, by diminishing the cohesion of the fibres, render them more soluble. On this last account is the lean of fat meat more easily dissolved than other lean. But when the meat is exposed to much heat, this oil is separated, leaving the solid parts less easily soluble, and becoming itself empyreumatic, rancid, and of difficult mixture in the stomach. Fried meats, from the reasons now given, and baked meats, for the same, as well as for the tenacity of the paste, are preparations which diminish the solubility of food. From what has been said, the preparation of food by fattening it, and keeping it for some time after killed, although it may administer to gluttony, will yet, it must be confessed, increase the solution of the food.

II. The second difference of animal-food is with regard to ALKALESCENCY.

Of this we have taken a little notice already under the head of *Solubility*.

1. From their too great alkalescency we commonly avoid the carnivorous animals, and the *feræ*; and choose rather the granivorous. Some birds, indeed, which live on insects, are admitted into our food; but no man, without *nausea*, can live upon these alone for any length of time. Fishes, too, are an exception to this rule, living almost universally on each other. But in these the alkalescency does not proceed so far; whether from the viscosity of their juice, their want of heat, or some peculiarity in their economy, is not easy to determine.

2. Alkalescency is determined by difference of age. The older animals are always more alkalescent than the young, from their continual progress to putrefaction. Homberg always found, in his endeavours to extract an acid from human blood, that more was obtained from the young than from the old animals.

3. A third circumstance which varies the alkalescency of the food, is the wildness or tameness of the animal; and this again seems to depend on its exercise. Dr Cullen knew a gentleman who was fond of cats for food: but he always used to feed them on vegetable

food, and kept them from exercise; and in the same manner did the Romans rear up their rats, when intended for food. In the same way the flesh of the partridge and the hen seems to be much the same; only, from its being more on the wing, the one is more alkalescent than the other. Again, tame animals are commonly used without their blood; whereas the wild are commonly killed in their blood, and upon that account, as well as their greater exercise, are more alkalescent.

4. The alkalescency of food may be determined from the quantity of volatile salt it affords. The older the meat is, it is found to give the greater proportion of volatile salt.

5. The alkalescency of aliment may also, in some measure, be determined from its colour, the younger animals being whiter and less alkalescent. We also take a mark from the colour of the gravy poured out, according to the redness of the juices judging of the animal's alkalescency.

6. The relish of food is found to depend much on its alkalescency, as does also the stimulus it gives and the fever it produces in the system. These effects are also complicated with the viscosity of the food, by which means it is longer detained in the stomach, and the want of alkalescency supplied.

Having mentioned animal food as differing in solubility and alkalescency, which often go together in the same subject, we come to the third difference, *viz.*

III. QUANTITY of Nutriment. Which is either absolute or relative: absolute with respect to the quantity it really contains, sufficient powers being given to extract it; relative, with respect to the assimilatory powers of those who use it. The absolute nutriment is of some consequence; but the relative, in the robust and healthy, and except in cases of extraordinary weakness, may, without much inconvenience, be disregarded. In another case is the quantity of nourishment relative, *viz.* with regard to its *perspirability*; for if the food is soon carried off by the excretions, it is the same thing as if it contained a less proportion of nourishment. For, giving more fluid, that which is longer retained affords most; and, for the repair of the solids, that retention also is of advantage. Now, gelatinous substances are long retained; and besides, are themselves animal substances dissolved: so that, both absolutely and relatively, such substances are nutritious. Of this kind are eggs, shell-fish, &c. In adults, though it is disputed whether their solids need any repair, yet, at any rate, at this period, fluid is more required; for this purpose the alkalescent foods are most proper, being most easily dissolved. They are, at the same time, the most perspirable; on one hand that alkalescency leading to disease, while on the other their perspirability obviates it. Adults, therefore, as writers justly observe, are better nourished on the alkalescent; the young and growing, on gelatinous foods. All this leads to a comparison of young and old meats; the first being more gelatinous, and the last more alkalescent. This, however, by experience, is not yet properly ascertained. Mr Geoffroy is the only person who has been taken up with the analysis of foods. See *Memoirs de l'Academie*, l'an. 1731 &c 1732. His attempt was certainly laudable, and in some respects usefully performed; but, in general, his experiments

Food.

Food.

ments were not sufficiently repeated, nor are indeed sufficiently accurate. He has not been on his guard against the various circumstances which affect meats; the cow kinds liking a moist succulent herbage, which is not to be got in warm climates; while the sheep are fond of a dry food, and thrive best there. Again, some of his experiments seem contradictory. He says, that veal gives more solution than beef, while lamb gives less than mutton; which is much to be doubted. If both he and Sanctorius had examined English beef, the result probably would have been very different as to its perspirability, &c. Besides, Mr Geoffroy has only analysed beef and veal when raw; has made no proper circumstantial comparisons between quadrupeds and birds; and has examined these last along with their bones, and not their muscles, &c. by themselves, as he ought to have done, &c. If a set of experiments of this kind were properly and accurately performed, they might be of great use; but at present, for the purpose of determining our present subject we must have recourse to our alkalescency, solubility, &c.

IV. The fourth difference of animal foods is, *The NATURE of the FLUIDS they afford.* The whole of this will be understood from what has been said on alkalescency; the fluid produced being more or less dense and stimulating, in proportion as that prevails.

V. The fifth difference of animal-foods is with respect to their

PERSPIRABILITY. The sum of what can be said on this matter is this, that such foods as promote an accumulation of fluid in our vessels, and dispose to plethora, are the least perspirable, and commonly give most strength; that the more alkalescent foods are the most perspirable, though the viscid and less alkalescent may attain the same property by long retention in the system. The authors on perspirability have determined the perspiration of foods as imperfectly as Mr Geoffroy has done the solubility, and in a few cases only. We must not lay hold on what Sanctorius has said on the perspirability of mutton, because he has not examined in the very same way other meats in their perfect state; far less on what Keil says of oysters, as he himself was a valetudinarian, and consequently an unfit subject for such experiments, and probably of a peculiar temperament.

As to the effects of FOOD on the MIND, we have already hinted at them above. It is plain, that delicacy of feeling, liveliness of imagination, quickness of apprehension, and acuteness of judgment, more frequently accompany a weak state of the body. True it is indeed, that the same state is liable to timidity, fluctuation, and doubt; while the strong have that steadiness of judgment, and firmness of purpose, which are proper for the higher and more active scenes of life. The most valuable state of the mind, however, appears to reside in somewhat less firmness and vigour of body. Vegetable aliment, as never over distending the vessels or loading the system, never interrupts the stronger motions of the mind; while the heat, fulness and weight, of animal food, are an enemy to its vigorous efforts. Temperance, then, does not so much consist in the quantity, for that always will be regulated by our appetite, as in the quality, *viz.* a large proportion of vegetable aliment.

A considerable change has now taken place in the

articles made use of as food by the ancients, by substituting, instead of what were then used, particularly of the vegetable kind, a number of more bland, agreeable, and nutritive juices. The acorns and nuts of the primitive times have given way to a variety of sweeter farinaceous seeds and roots. To the malvaceous tribe of plants so much used by the Greeks and Romans, hath succeeded the more grateful spinach; and to the blite, the garden orach. The rough borage is supplanted by the acescent sorrel; and asparagus has banished a number of roots recorded by the Roman writers under the name of *bulbs*; but Linnæus is of opinion, that the parsnip has undeservedly usurped the place of the skirret. The bean of the ancients, improperly so called, being the roots as well as other parts of the *nymphaea nelumbo* or Indian water-lily, is superseded by the kidney-bean. The garden rocket, eaten with and as an antidote against the chilling qualities of the lettuce, is banished by the more agreeable cress and tarragon; the apium by the meliorated celery; the pompon, and others of the cucurbitaceous tribe, by the melon; and the sumach berries, by the fragrant nutmeg. The silphium, or succus Cyrenaicus, which the Romans purchased from Persia and India, at a great price, and is thought by some to have been the asafetida of the present time, is no longer used in preference to the alliaceous tribe.

To turn from the vegetable to some of the animal substitutes, we may mention the carp among fishes as having excluded a great number held in high estimation among the Romans. The change oil for butter; or honey for sugar; of mulsa, or liquors made of wine, water, and honey, for the wines of modern times, and that of the ancient zythus for the present improved malt liquors; not to mention also the *callida* of the Roman taverns; analogous to our tea and coffee.

Food of plants. See AGRICULTURE, n^o 1—6. and PLANTS; also the article COMPOSTS.

FOOL, according to Mr Locke, is a person who makes false conclusions from right principles; whereas a madman, on the contrary, draws right conclusions from wrong principles. See FOLLY.

Fool-stones, in botany. See ORCHIS.

FOOSHT, an island in the Red Sea; situated according to the observations of Mr Bruce, in N. Lat. 15° 59' 43". It is described by him as above four miles in length from north to south, though only *nine* in circumference. It is low and sandy in the southern part, but the north rises in a black hill of inconsiderable height. It is covered with a kind of bent-grass, which never arrives at any great length by reason of want of rain and the constant browsing of the goats. There are great appearances of the black hill having once been a volcano; and near the north cape the ground sounds hollow like the Solfaterra in Italy. There are a vast number of beautiful fish met with upon the coasts, but few fit for eating; and our traveller observed, that the most beautiful were the most noxious when eaten; none, indeed, being salutary food excepting those which resemble the fish of the northern seas. There are many beautiful shell-fish, as the concha veneris, of several colours and sizes; sea-urchins, &c. Sponges are likewise found all along the coast. There are also pearls, but neither large nor of a good water; in consequence of which they sell at no great price. They are produced by a species of bivalve shells. Several

Food

||

Foosht.

Foot.

veral large shells, from the fish named *biffer*, are met with upon stones of ten or twelve tons weight along the coast. They are turned upon their faces and sunk into the stones, as in a paste, the stone being raised all about them in such a manner as to cover the edge of the shell; "a proof (says Mr Bruce) that this stone must some time lately have been soft or liquefied: for had it been long ago, the sun and air would have worn the surface of the shell; but it seems perfectly entire, and is set in that hard brown rock as the stone of a ring is in a golden chafing."—The water in this island is very good.

The inhabitants of Footst are poor fishermen of a swarthy colour; going naked, excepting only a rag about their waist. They have no bread but what they procure in exchange for the fish they catch. What they barter in this manner is called *seajan*. But besides this they catch another species, which is flat, with a long tail, and the skin made use of for shagreen, of which the handles of knives and swords are made. There is a small town on the island, consisting of about 30 huts, built with faggots of bent grass or spartum, supported by a few sticks, and thatched with grass of the same kind of which they are built.

FOOT, a part of the body of most animals whereon they stand, walk, &c. See ANATOMY. n^o 63.

FOOT in the Latin and Greek poetry, a metre or measure, composed of a certain number of long and short syllables.

These feet are commonly reckoned 28: of which some are simple, as consisting of two or three syllables, and therefore called *dissyllabic* or *trisyllabic feet*; others are compound, consisting of four syllables, and are therefore called *tetrasyllabic feet*.

The dissyllabic feet are four in number, *viz.* the pyrrhichius, spondeus, iambus, and trocheus. See PYRRHICHIUS, &c.

The trisyllabic feet are eight in number, *viz.* the dactylus, anapæstus, tribrachys, molossus, amphibrachys, amphimacer, bacchius, and antibacchius. See DACTYL, &c.

The tetrasyllabic are in number 16, *viz.* the procleusmaticus, dispondeus, choriambus, antispastus, diambus, dichoreus, ionicus a majore, ionicus a minore, epitritus primus, epitritus secundus, epitritus tertius, epitritus quartus, pæon primus, pæon secundus, pæon tertius, and pæon quartus. See PROCLEUSMATICUS, &c.

FOOT is also a long measure consisting of 12 inches.

Geometricians divide the foot into 10 digits and the digit into 10 lines.

Foot-Halt, the name of a particular disorder incident to sheep. It takes its source from an insect, which when it comes to a certain maturity, resembles a worm of two, three, or four inches in length. The first appearance of the malady is, when the sheep gives signs of being lame, which increases to so high a degree as to prevent grazing; when, what with want of sufficient food and pain, the poor animal suffers greatly, and lingers till it dies a natural death, if not properly attended to by extracting the insect or worm; the sooner the better as it is very easily performed.

As soon as the lameness is perceived, let the foot that is lame be examined between the clove of the

claws, and it will be found that in the skin where the clove separates is a small hole (not natural), through which the insect, when yet small, gets its entrance, and by degrees has worked itself upwards along the leg, between the outward skin and bone, and obtains its largest magnitude. Proportionally it finds its nourishment, and is left undisturbed. This worm must be extracted by moving the claws backward and forward in contrary directions; and it will not be long before the under part of the worm makes its appearance at the abovementioned small hole, and continuing the same operation of moving the claws, the whole worm will work itself out; which is better than when at its first appearance it should be drawn out with danger, of breaking off, and part of it should remain in the sheep's leg, and by its rotting there may be hurtful. This easy and simple operation will be found effectual without any other kind of application whatever, nature herself curing the channel which the worm had made along the leg.

It is observed, this malady is in some years more prevalent than in others, particularly in wet seasons than in drier; more observed to begin in spring and autumn than in summer and winter; notwithstanding what with snow, &c. sheep suffer more by the wet in winter than in any of the other seasons (possibly it is not then the season for this sort of insect). In high healthy grounds, the sheep are less liable to it than in low marshy and meadow grounds: from all which circumstances it may be supposed, that this insect in its first state, has for its most natural element either the earth, water, or air; and only gets accidentally between the clove of the claws of the sheep, and finds there what is sufficient for its nourishment and security.

Foot Square, is the same measure both in breadth and length containing 144 square or superficial inches.

Cubic or Solid Foot, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches.

Foot of a Horse, in the manege, the extremity of the leg, from the coronet to the lower part of the hoof.

Foot-Level, among artificers, an instrument that serves as a foot rule, a square, and a level. See LEVEL, RULE, and SQUARE.

FOOTE (Samuel, Esq), the modern Aristophanes, was born at Truro, in Cornwall; and was descended from a very ancient family. His father was member of parliament for Tiverton, in Devonshire; and enjoyed the post of commissioner of the prize-office and fine-contract. His mother was heiress of the Dinely and Goodere families. In consequence of a fatal misunderstanding between her two brothers, Sir John Dinely Goodere, Bart. and Samuel Goodere, Esq; captain of his majesty's ship the Ruby, which ended in the death of both, a considerable part of the Goodere estate, which was better than 5000 l. *per annum*, descended to Mr Foote.

He was educated at Worcester college, Oxford, which owed its foundation to Sir Thomas Cookes Winford, Bart. a second cousin of our author's. On leaving the university, he commenced student of law in the Temple; but as the dryness of this study did not suit the liveliness of his genius, he soon relinquished it.

He

Foot,
Foote.

Foote.

He married a young lady of a good family and some fortune; but their tempers not agreeing, a perfect harmony did not long subsist between them. He now launched into all the fashionable foibles of the age, gaming not excepted; and in a few years spent his whole fortune. His necessities led him to the stage, and he made his first appearance in the character of Othello. He next performed Fondlewife with much more applause; and this, indeed, was ever after one of his capital parts. He attempted Lord Foppington likewise, but prudently gave it up. But as Mr Foote was never a capital actor in the plays of others, his salary was very unequal to his gay and extravagant turn; and he contracted debts which forced him to take refuge within the verge of the court. On this occasion he relieved his necessities by the following stratagem. Sir Francis D—l—l had long been his intimate friend, and had dissipated his fortune by similar extravagance. Lady N—t—t, who was likewise an intimate acquaintance of Foote's, and who was exceeding rich, was fortunately at that time bent upon a matrimonial scheme. Foote strongly recommended to her to consult upon this momentous affair the conjurer in the Old Bailey, whom he represented as a man of surprising skill and penetration. He employed an acquaintance of his own to personate the conjurer; who depicted Sir Francis D—l—l at full length; described the time when, the place where, and the dress in which she would see him. The lady was so struck with the coincidence of every circumstance, that she married D—l—l in a few days. For this service Sir Francis settled an annuity upon Foote; and this enabled him once more to emerge from obscurity.

In 1747 he opened the little theatre in the Haymarket, taking upon himself the double character of author and performer; and appeared in a dramatic piece of his own composing, called the *Diversions of the Morning*. This piece consisted of nothing more than the exhibition of several characters well known in real life; whose manner of conversation and expression this author very happily hit off in the diction of his drama, and still more happily represented on the stage, by an exact and most amazing imitation, not only of the manner and tone of voice, but even of the very persons, of those whom he intended to take off. In this performance, a certain physician, Dr L—n, well known for the oddity and singularity of his appearance and conversation, and the celebrated chevalier Taylor, who was at that time in the height of his popularity, were made objects of Foote's ridicule; the latter, indeed, very deservedly; and, in the concluding part of his speech, under the character of a theatrical director, Mr Foote took off, with great humour and accuracy, the several styles of acting of every principal performer on the English stage. This performance at first met with some opposition from the civil magistrates of Westminster, under the sanction of the act of parliament for limiting the number of playhouses, as well as from the jealousy of one of the managers of Drury-lane playhouse; but the author being patronised by many of the principal nobility, and other persons of distinction, this opposition was over-ruled, and having altered the title of his performance, Mr Foote proceeded, without further molestation, to give *Tea in a Morning* to his friends, and represented it through a run of

40 mornings, to crowded and splendid audiences.—The ensuing season he produced another piece of the same kind, which he called *An Auction of Pictures*. In this performance he introduced several new and popular characters; particularly Sir Thomas de Veil, then the acting justice of peace for Westminster, Mr Cock the celebrated auctioneer, and the equally famous orator Henley. This piece also had a very great run.—His *Knights*, which was the produce of the ensuing season, was a performance of somewhat more dramatic regularity: but still, although his plot and characters seemed less immediately personal, it was apparent that he kept some particular real persons strongly in his eye in the performance; and the town took upon themselves to fix them where the resemblance appeared to be the most striking.—Thus Mr Foote continued from time to time to select, for the entertainment of the public, such characters, as well general as individual, as seemed most likely to engage their attention. His dramatic pieces, exclusive of the interlude called *Piety in Pattens*, are as follow: Taste, The Knights, The Author, The Englishman in Paris, The Englishman returned from Paris, The Mayor of Garrat, The Liar, The Patron, The Minor, The Orators, The Commissary, The Devil upon Two Sticks, The Lame Lover, The Maid of Bath, The Nabob, The Cozeners, The Capuchin, The Bankrupt, and an unfinished comedy, called the Slanderer.—All these works are only to be ranked among the *petites piéces* of the theatre. In the execution they are somewhat loose, negligent, and unfinished; the plots are often irregular, and the catastrophes not always conclusive: but, with all these deficiencies, they contain more strength of character, more strokes of keen satire, and more touches of temporary humour, than are to be found in the writings of any other modern dramatist. Even the language spoken by his characters, incorrect as it may sometimes seem, will on a closer examination be found entirely dramatical; as it abounds with those natural minutiae of expression which frequently form the very basis of character, and which render it the truest mirror of the conversation of the times in which he wrote.

In the year 1766, being on a party of pleasure with the late duke of York, lord Mexborough, and Sir Francis Delaval, Mr. Foote had the misfortune to break his leg, by a fall from his horse; in consequence of which, he was compelled to undergo an amputation. This accident so sensibly affected the duke, that he made a point of obtaining for Mr Foote a patent for life: whereby he was allowed to perform, at the little theatre in the Haymarket, from the 15th of May to the 15th of September every year.

He now became a greater favourite of the town than ever: his very laughable pieces, with his more laughable performance, constantly filled his house: and his receipts were some seasons almost incredible. Parsimony was never a vice to be ascribed to Mr Foote; his hospitality and generosity were ever conspicuous; he was visited by the first nobility, and he was sometimes honoured even by royal guests.

The attack made upon his character by one of his domestics, whom he had dismissed for misbehaviour, is too well known to be particularized here. Suffice it to say, he was honourably acquitted of that charge: but it is believed by some, that the shock which he received

Foote.

Forbes.
||
Forbes.

ceived from it accelerated his death ; others pretend, that his literary altercation with a certain *then* duchess, or rather her agents, much affected him, and that from that time his health declined. It is probable, however, that his natural volatility of spirits could scarcely fail to support him against all impressions from either of these quarters.

Mr Foote, finding his health decline, entered into an agreement with Mr Colman, for his patent of the theatre ; according to which, he was to receive from Mr Colman L.1600 *per annum*, besides a stipulated sum whenever he chose to perform. Mr Foote made his appearance two or three times in some of the most admired characters ; but being suddenly affected with a paralytic stroke one night whilst upon the stage, he was compelled to retire. He was advised to bathe ; and accordingly repaired to Brightelmstone, where he apparently recovered his former health and spirits, and was what is called the *fiddle of the company* who resorted to that agreeable place of amusement. A few weeks before his death he returned to London ; but, by the advice of his physicians, set out with an intention to spend the winter at Paris and in the south of France. He had got no farther than Dover, when he was suddenly attacked by another stroke of the palsy, which in a few hours terminated his existence. He died on the 21st of October 1777, in the 56th year of his age, and was privately interred in the cloisters of Westminster-Abbey.

FOP, probably derived from the *vappa* of Horace, applied in his first satire in his first book to the wild and extravagant Nævius, is used among us to denote a person who cultivates a regard to adventitious ornament and beauty to excess.

FORAMEN, in anatomy, a name given to several apertures or perforations in divers parts of the body ; as, 1. The external and internal foramina of the cranium or skull. 2. The foramina in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membranæ tympani.

FORAMEN *Ovale*, an oval aperture or passage through the heart of a fœtus, which closes up after birth. It arises from the coronal vein, near the right auricle, and passes directly into the left auricle of the heart, serving for the circulation of the blood in the fœtus, till such time as the infant breathes, and the lungs are open ; it being generally reckoned one of the temporary parts of the fœtus, wherein it differs from an adult ; although almost all anatomists, Mr Cheselden excepted, assures us, that the foramen ovale has sometimes been found in adults. See FOETUS.

FORBES (Patrick), bishop of Aberdeen, was born in 1654, when the affairs of the church of Scotland were in much confusion ; to the settlement of which he greatly contributed. As chancellor of the university of Aberdeen, he improved that seat of learning by repairing the fabric, augmenting the library, and reviving the professorships. He published a *Commentary on the Revelations*, at London, in 1613 ; and died in 1635.

FORBES (John), the son of Patrick, but of much more extensive learning than his father, was perhaps excelled by none of his age, which will be allowed by those who read his *Historical and Theological Institutes*. He was bishop of Aberdeen ; but was expelled by the

Covenanters, and forced to fly beyond sea. He continued in Holland two years ; and, upon his return, lived private on his estate at Corfe, until he died in 1648. An edition of all his works was printed in two volumes folio at Amsterdam, in 1703.

FORBES (William), a learned bishop of Edinburgh, born in 1585. His ill-health and the anti-episcopal disposition of the Scots, confined him chiefly to a retired life ; but when Charles I. in 1633, founded an episcopal church at Edinburgh, he thought none more worthy to fill the see than Mr Forbes ; who, however, died three months after his consecration, in 1634. Though very able and learned, he published nothing ; but wrote a treatise to pacify controversies, which was printed at London 24 years after his death.

FORBES (Duncan, Esq. of Culloden), was born in the year 1685. In his early life, he was brought up in a family remarkable for hospitality ; which, perhaps, led him afterwards to a freer indulgence in social pleasures. His natural disposition inclined him to the army : but, as he soon discovered a superior genius, by the advice of his friends he applied himself to letters. He directed his studies particularly to the civil law ; in which he made a quick progress, and in 1709 was admitted an advocate. From 1722 to 1737, he represented in parliament the boroughs of Inverness, Fortrose, Nairn, and Forres. In 1725, he was made king's advocate ; and lord president of the court of session in 1737. In the troubles of 1715 and 1745 he espoused the royal cause ; but with so much prudence and moderation did he conduct himself at this delicate conjuncture, that not a whisper was at any time heard to his prejudice. The glory he acquired in advancing the prosperity of his country, and in contributing to re-establish peace and order, was the only reward of his services. He had even impaired, and almost ruined, his private fortune in the cause of the public ; but government did not make him the smallest recompence. The minister, with a meanness for which it is difficult to account, desired to have a state of his disbursements. He was so much shocked at the rudeness of this treatment, that he left the minister without making any reply. Throughout the whole course of his life he had a lively sense of religion, without the least taint of superstition ; and his charity was extended to every sect and denomination of religionists indiscriminately. He was well versed in the Hebrew language ; and wrote, in a flowing and oratorical style, concerning religion natural and revealed, some important discoveries in theology and philosophy, and concerning the sources of incredulity. He died in 1747, in the 62d year of his age ; and his works have since been published in two volumes octavo.

FORCE, in philosophy, denotes the cause of the change in the state of a body, when, being at rest, it begins to move, or has a motion which is either not uniform or not direct. While a body remains in the same state, either of rest or of uniform or rectilinear motion, the cause of its remaining in such a state is in the nature of the body, and it cannot be said that any extrinsic force has acted on it. This internal cause or principle is called *inertia*.

Mechanical forces may be reduced to two sorts ; one of a body at rest, the other of a body in motion.

The

Forbes,
Force.

Force.

The force of a body at rest, is that which we conceive to be in a body lying still on a table, or hanging by a rope, or supported by a spring, &c. and this is called by the names of *pressure, tension, force, or vis mortua, sollicitatio, conatus movendi, conamen, &c.* To this class also of forces we must refer centripetal and centrifugal forces, though they reside in a body in motion; because these forces are homogeneous to weights, pressures, or tensions of any kind.

The force of a body in motion is a power residing in that body so long as it continues its motion; by means of which it is able to remove obstacles lying in its way; to lessen, destroy, or overcome the force of any other moving body, which meets it in an opposite direction; or to surmount any dead pressure or resistance, as tension, gravity, friction, &c. for some time, but which will be lessened or destroyed by such resistance as lessens or destroys the motion of the body. This is called *moving force, vis motrix*, and by some late writers *vis viva*; to distinguish it from the *vis mortua* spoken of before; and by these appellations, however different, the same thing is understood by all mathematicians; namely, that power of displacing, of withstanding opposite moving forces, or of overcoming any dead resistance, which resides in a moving body, and which, in whole or in part, continues to accompany it, so long as the body moves. See MECHANICS.

We have several curious as well as useful observations in Desaguliers's Experimental Philosophy, concerning the comparative forces of men and horses, and the best way of applying them. A horse draws with the greatest advantage when the line of direction is level with his breast; in such a situation, he is able to draw 200lb. eight hours a-day, walking about two miles and an half an hour. And if the same horse is made to draw 240lb. he can work but six hours a-day, and cannot go quite so fast. On a carriage, indeed, where friction alone is to be overcome, a middling horse will draw a 1000lb. But the best way to try a horse's force, is by making him draw up out of a well, over a single pulley or roller; and in such a case, one horse with another, will draw 200lb. as already observed.

Five men are found to be equal in strength to one horse, and can, with as much ease, push round the horizontal beam of a mill, in a walk 40 feet wide; whereas three men will do it in a walk only 19 feet wide.

The worst way of applying the force of a horse, is to make him carry or draw up hill: for if the hill be steep, three men will do more than a horse, each man climbing up faster with a burden of 100lb. weight, than a horse that is loaded with 300lb. a difference which is owing to the position of the parts of the human body being better adapted to climb than those of a horse.

On the other hand, the best way of applying the force of a horse, is an horizontal direction, wherein a man can exert least force: thus a man, weighing 140lb. and drawing a boat along by means of a rope coming over his shoulders, cannot draw above 27lb. or exert above one-seventh part of the force of a horse employed to the same purpose.

The very best and most effectual posture in a man,

is that of rowing; wherein he not only acts with more muscles at once for overcoming the resistance, than in any other position; but as he pulls backwards, the weight of his body assists by way of lever. See Desaguliers, Exp. Phil. vol. i. p. 241. where we have several other observations relative to force acquired by certain positions of the body, from which that author accounts for most feats of strength and activity. See also a *Memoire* on this subject by M. de la Hire, in Mem. Roy. Acad. Sc. 1629; or in Desaguliers, Exp. &c. p. 267, &c. who has published a translation of part of it with remarks.

FORCE, in law, signifies any unlawful violence offered to things or persons, and is divided into simple and compound. *Simple force* is what is so committed, that it has no other crime attending it; as where a person by force enters on another's possession without committing any other unlawful act. *Compound force*, is where some other violence is committed with such an act which of itself alone is criminal; as if one enters by force into another's house, and there kills a person, or ravishes a woman. There is likewise a force implied in law, as in every trespass, rescue, or disseisin, and an actual force with weapons, number of persons, &c.—Any person may lawfully enter a tavern, inn, or victualling-house; so may a landlord his tenant's house to view repairs, &c. But if, in these cases, the person that enters commits any violence or force, the law will intend that he entered for that purpose.

FORCEPS, in surgery, &c. a pair of scissors for cutting off or dividing the fleshy membranous parts of the body, as occasion requires. See SURGERY.

FORCIBLE ENTRY, is a violent and actual entry into houses or lands; and a forcible detainer, is where one by violence with-holds the possession of lands, &c. so that the person who has a right of entry is barred, or hindered, therefrom.

At common law, any person that had a right to enter into lands, &c. might retain possession of it by force. But this liberty being abused, to the breach of the peace, it was therefore found necessary that the same should be restrained: Though at this day, he who is wrongfully dispossessed of goods may by force retake them. By statute, no persons shall make an entry on any lands or tenements, except where it is given by law, and in a peaceable manner, even tho' they have title of entry, on pain of imprisonment: and where a forcible entry is committed, justices of peace are authorized to view the place, and enquire of the force by a jury, summoned by the sheriff of the county; and they may cause the tenements, &c. to be restored, and imprison the offenders till they pay a fine. Likewise a writ of forcible entry lies, where a person seized of freehold, is by force put out thereof.

FORCIBLE Marriage, of a woman of estate, is felony. For by the the statute 3 H. 7. c. 2. it is enacted, "That if any persons shall take away any woman having lands or goods, or that is heir-apparent to her ancestor, by force, and against her will, and marry or defile her; the takers, procurers, abettors, and receivers, of the woman taken away against her will, and knowing the same, shall be deemed principal felons; but as to procurers, and accessories, they are, before the offence be committed, to be excluded the benefit of clergy, by

Force

Forcible.

Forcible,
Forcing.

39 Eliz. c. 9. The indictment on the statute 3 H. 7. is expressly to set forth, that the woman taken away had lands or goods, or was heir apparent; and also that she was married or defiled, because no other case is within the statute; and it ought to allege that the taking was for lucre. It is no excuse that the woman at first was taken away with her consent: for if she afterwards refuse to continue with the offender, and be forced against her will, she may from that time properly be said to be taken against her will; and it is not material whether a woman so taken away be at last married or defiled with her own consent or not, if she were under force at the time; the offender being in both cases equally within the words of the act.

Those persons who, after the fact, receive the offender, are but accessories after the offence, according to the rules of common law; and those that are only privy to the damage, but not parties to the forcible taking away, are not within the act, H. P. C. 119. A man may be indicted for taking away a woman by force in another country; for the continuing of the force in any country, amounts to a forcible taking there. *Ibid.* Taking away any woman-child under the age of 16 years and unmarried, out of the custody and without the consent of the father or guardian, &c. the offender shall suffer fine and imprisonment; and if the woman agrees to any contract of matrimony with such person, she shall forfeit her estate during life, to the next of kin to whom the inheritance should descend, &c. Stat. 4 & 5. P. & M. c. 8. This is a force against the parents; and an information will lie for seducing a young man or woman from their parents, against their consents, in order to marry them, &c. See MARRIAGE.

FORCING, in gardening, a method of producing ripe fruits from trees before their natural season. The method of doing it is this: A wall should be erected ten feet high; a border must be marked out on the south side of it, of about four feet wide, and some stakes must be fastened into the ground all along the edge of the border; these should be four inches thick. They are intended to rest the glass lights upon, which are to slope backwards to the wall, to shelter the fruit as there shall be occasion; and there must be, at each end, a door to open either way, according as the wind blows. The frame should be made moveable along the wall, that when a tree has been forced one year, the frame may be removed to another, and so on; that the trees may each of them be forced only once in three years, at which rate they will last a long time. They must be always well-grown trees that are chosen for forcing; for young ones are soon destroyed, and the fruit that is produced from them is never so well tasted. The fruits most proper for this management are the avant or small white nutmeg, the albemarle, the early newington, and the brown nutmeg peaches; Mr Fairchild's early, and the elrugo and newington nectarines; the masculine apricot, and the may-duke and may cherry. For grapes, the white and black sweet-water are the properest; and of gooseberries the Dutch white, the Dutch early green, and the walnut gooseberry; and the large Dutch white and large Dutch red currants.

The dung, before it is put to the wall, should be laid together in a heap for five or six days, that it may

heat uniformly through; and when thus prepared it must be laid four feet thick at the base of the wall, and go sloping up till it is two feet thick at the top. It must be laid at least within three or four inches of the top of the wall; and when it sinks, as it will sink two or three feet, more dung must be laid on; for the first heat will do little more than just swell the blossom-buds. The covering the trees with glasses is of great service; but they should be taken off to admit the benefit of gentle showers to the trees, and the doors at the ends should be either left entirely open, or one or both of them opened, and a mat hung before them, at once to let the air circulate and keep off the frosts.

The dung is never to be applied till towards the end of November; and three changes of it will be sufficient to ripen the cherries, which will be very fine in February. As to the apricots, grapes, nectarines, peaches, and plums, if the weather be milder, the glasses are to be opened to let in sunshine or gentle showers.

If a row or two of scarlet strawberries be planted at the back of the frame, they will ripen in February or the beginning of March; the vines will blossom in April, and the grapes will be ripe in June.

It should be carefully observed, not to place early and late ripening fruits together, because the heat necessary to force the late ones will be of great injury to the early ones after they have fruited.

The masculine apricot will be ripe in the beginning of April, the early nectarines will be ripe about the same time, and the forward sort of plums by the latter end of that month. Gooseberries will have fruit fit for tarts in January or February, and will ripen in March; and currants will have ripe fruit in April.

The trees need not be planted so distant at these walls as at others, for they do not shoot so freely as in the open air; nine feet asunder is sufficient. They should be pruned about three weeks before the heat is applied.

FORCING, in the wine trade, a term used by the wine-coopers for the fining down wines, and rendering them fit for immediate draught. The principal inconvenience of the common way of fining down the white-wines by isinglass; and the red by whites of eggs, is the slowness of the operation; these ingredients not performing their office in less than a week, or sometimes a fortnight, according as the weather proves favourable, cloudy or clear, windy or calm: this appears to be matter of constant observation. But the wine-merchant frequently requires a method that shall, with certainty, make the wines fit for tasting in a few hours. A method of this kind there is, but it is kept in a few hands a valuable secret. Perhaps it depends upon a prudent use of a tartarized spirit of wine, and the common forcing, as occasion is, along with gypsum, as the principal; all which are to be well stirred about in wine, for half an hour before it is suffered to rest.

FORDOUN (John of), the father of Scottish history, flourished in the reign of Alexander III. towards the end of the 13th century. But of his life there is nothing known with certainty, though there was not a monastery that possessed not copies of his work. The first five books of the history which bears his

Fordwich his name were written by him: the rest were fabricated from materials left by him, and from new collections by different persons. A manuscript of vellum of this historian is in the library of the university of Edinburgh.

Foreign.

FORDWICH, a town of Kent, called in the Doomsday-Book "the little Borough of Fordwich," is a member of the port of Sandwich, and was anciently incorporated by the style of the Barons of the town of Fordwich, but more lately by the means of the mayor, jurats, and commonalty, who enjoy the same privileges as the cinque-ports. This place is famous for excellent trouts in its river Stour.

FORDYCE (David), an elegant and learned writer of the present age, was professor of philosophy in the Marischal-college, Aberdeen. He was originally designed for the ministry; to prepare himself for which was the whole aim of his ambition, and for a course of years the whole purpose of his studies. How well he was qualified to appear in that character, appears from his "Theodorus, a dialogue concerning the art of preaching." After having finished this work, he went abroad on his travels, in order to obtain fresh stores of knowledge; but after a successful tour through several parts of Europe, he was unfortunately cast away in a storm on the coast of Holland. Besides the above work, he wrote Dialogues on Education, 8vo, and a Treatise of Moral Philosophy published in the Preceptor. The third edition of his Theodorus was published in London, after his untimely death, by his brother the Rev. Mr James Fordyce, an eminent dissenting minister, in 1755.

FORE, applied to a ship, denotes all that part of a ship's frame and machinery which lies near the stem.

FORE and aft is used for the whole ship's length, or from end to end.

FORECASTLE of a SHIP, that part where the fore mast stands. It is divided from the rest by a bulk-head.

FOREIGN, something extraneous, or that comes from abroad. The word is formed from the Latin *fores*, "doors;" or *foris*, "out of doors;" or *forum*, "market," &c.

Foreign minister, foreign prince, foreign goods, &c. are those belonging to other nations. See **MINISTER**, &c.

Foreign to the purpose, signifies a thing remote or impertinent.

FOREIGN, in the English law, is used in various significations. Thus,

FOREIGN Attachment, is an attachment of the goods of foreigners found within a city or liberty, for the satisfaction of some citizens to whom the foreigner is indebted; or it signifies an attachment of a foreigner's money in the hands of another person.

FOREIGN Kingdom, a kingdom under the dominion of a foreign prince.

At the instance of an ambassador or consul, any offender against the laws may be sent for from a foreign kingdom to which he hath fled. And, where a stranger of Holland, or any foreign country, buys goods at London, for instance, and there gives a note under his hand for payment, and then goes away privately into Holland; in that case, the seller may have a certificate from the lord mayor, on the

VOL. VII.

proof of the sale and delivery of such goods, whereupon a process will be executed on the party in Holland.

FOREIGN Opposer, or *Apposer*, an officer in the English exchequer that opposes or makes a charge on all sheriffs, &c. of their green wax; that is to say, fines, issues, amerciements, recognizances, &c.

FOREIGN Plea, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction.

FOREIGN Seamen, serving two years on board British ships, whether of war, trade, or privateers, during the time of war shall be deemed natural-born subjects.

FOREIGNER, the natural-born subject to some foreign prince.

Foreigners, in Britain, though made denizens, or naturalized, are disabled to bear any office of government, to be of the privy counsel, or members of parliament, &c. This is by the acts of the settlement of the crown. Such persons as are not freemen of a city or corporation, are also called *foreigners*, to distinguish them from the members of the same.

FOREJUDGER, in English law, signifies a judgment whereby one is deprived or put by a thing in question.

To be *forejudged the court*, is where an officer or attorney of any court is expelled the same for malpractice, or for not appearing to an action on a bill filed against him, &c. And where an attorney of the common-pleas is sued, the plaintiff's attorney delivers the bill to one of the criers of the court, who calls the attorney defendant, and solemnly proclaims aloud, that if he does not appear thereto, he will be forejudged: likewise a rule is given by the secondary for his appearance; and if the attorney appears not in four days, then the clerk of the warrants strikes such an attorney off the roll of attorneys; after which he becomes liable to be arrested like any other person; but where an attorney is forejudged, he may be restored on clearing himself from his contumacy, and making satisfaction to the plaintiff, &c.

FORELAND, or **FORENESS**, in navigation, a point of land jutting out into the sea.

North FORELAND, in the isle of Thanet, Kent, of which it is the N. E. point is the promontory ascertained by act of parliament to be the most southern part of the port of London, which is thereby extended N. in a right line to the point called the Naze on the coast of Essex, and forms that properly called the Mouth of the Thames. A sea mark was erected here by the Trinity-House corporation at the public expence which is a round brick-tower near 80 feet high. The sea gains so much upon the land here by the winds at S. W. that within the memory of some that are living above 30 acres of land have been lost in one place. All vessels that pass on the south-side of this head land are said to enter the Channel, which is the name for the narrow sea between England and France: and all the towns and harbours between London and this place, whether on the Kentish or Essex shore, are called members of the port of London.

South FORELAND, in Kent, a head of land forming the east point of the Kentish shore: and called *South*, in respect to its bearing from the other Foreland, which is about six miles to the north. Its situation

U u

is

Foreign
||
Foreland.

Fore-locks
||
Forest.

is of great security to the Downs, the road between both, which would be a very dangerous road for ships, did not this point break the sea off, that would otherwise come rolling up from the west to the Flats or bank of sands, which for three leagues together and at about a league or a league and a half from the shore run parallel with it and are dry at low water: so that those two capes breaking all the force of the sea on the S. E. and S. W. make the Downs accounted a good road, except when the wind blows excessive hard from S. E. E. by N. or E. N. E. when ships in the Downs are driven from their anchors, and often run a-shore, or are forced on the sands, or into Sandwich bay or Ramsgate pier.

FORE-ROCKS, in the sea-language, little flat wedges made with iron, used at the ends of bolts, to keep them from flying out of their holes.

FORE-MAST of a SHIP, a large round piece of timber, placed in the fore-part or fore-castle, and carrying the fore-fail and fore-top-fail yards. Its length is usually $\frac{3}{4}$ of the main-mast, and the fore-top-gallant-mast is $\frac{1}{2}$ the length of the fore-top.

FOREMAST-Men, are those on board a ship that take in the top sails, sling the yards, furl the sails, bowse, trice, and take their turn at the helm, &c.

FOREST, in geography, a huge wood: or, a large extent of ground covered with trees. The word is formed of the Latin *foresta*, which first occurs in the capitulars of Charlemagne, and which itself is derived from the German *frost*, signifying the same thing. Spelman derives it from the Latin *foris restat*, by reason forests are out of towns. Others derive *foresta* from *feris*, q. d. *Foresta, quoad sit tuta statio ferarum*, as being a safe station or abode for wild beasts.

The Caledonian and Hercynian forests are famous in history. The first was a celebrated retreat of the ancient Picts and Scots; the latter anciently occupied the greatest part of Europe; particularly Germany, Poland, Hungary, &c. In Cæsar's time it extended from the borders of Alsacia and Switzerland to Transylvania; and was computed 60 days journey long and 9 broad: some parts or cantons thereof are still remaining.

The ancients adored forests, and imagined a great part of their gods to reside therein; temples were frequently built in the thickest forests; the gloom and silence whereof naturally inspire sentiments of devotion, and turn mens thoughts within themselves.

For The like reason the Druids made forests the place of their residence, performed their sacrifices, instructed their youth, and gave laws therein.

FOREST, in law, is defined, by Manwood, a certain territory of woody grounds and fruitful pastures, privileged for wild beasts and fowls of forest, chase, and warren, to rest and abide under the protection of the king, for his princely delight: bounded with unremoveable marks and meres, either known by matter of record or prescription; replenished with wild beasts of venery or chase, with great coverts of vert for the said beasts; for preservation and continuance whereof, the vert and venison, there are certain particular laws, privileges, and officers.

Forests are of such antiquity in England, that excepting the New-Forest in Hampshire, erected by William the Conqueror, and Hampton Court, erected by

Henry VIII. it is said that there is no record or history which makes any certain mention of their erection, though they are mentioned by several writers and in several laws and statutes. Ancient historians tell us, "that New-forest was raised by the destruction of 22 parish-churches, and many villages, chapels, and manors, for the space of 30 miles together, which was attended with divers judgments on the posterity of William I. who erected it: for William Rufus was there shot with an arrow, and before him Richard the brother of Henry I.; and Henry nephew to Robert, the eldest son of the Conqueror, did hang by the hair of the head in the boughs of the forest, like unto Ab-salom." *Blount*.

Besides the New-forest, there are 68 other forests in England, 13 chases, and more than 700 parks; the four principal forests are New-forest on the sea, Shire-wood-forest on the Trent, Dean-forest on the Severn, and Windsor-forest on the Thames.

A forest in the hands of a subject is properly the same thing with a CHASE: being subject to the common law, and not to the forest laws. But a chase differs from a forest, in that it is inclosed; and likewise, that a man may have a chase in another man's ground as well as his own; being indeed the liberty of keeping beasts of chase, or royal game therein, protected even from the owner of the land, with a power of hunting them thereon. See PARK.

The manner of erecting a forest is thus: Certain commissioners are appointed under the great seal, who view the ground intended for the forest, and fence it round; this commission being returned into chancery, the king causeth it to be proclaimed throughout the county where the land lieth, that it is a forest; and prohibits all persons from hunting there, without his leave. Though the king may erect a forest on his own ground and waste, he may not do it on the ground of other persons without their consent; and agreement with them for that purpose ought to be confirmed by parliament.

A forest directly taken, cannot be in the hands of any but the king: for no person but the king has power to grant a commission to be justice in eyre of the forest: yet if he grants a forest to a subject, and that on request made in the chancery, that subject and his heirs shall have justices of the forest, in which case the subject has a forest in law.

A second property of a forest is, the courts thereof. See FOREST-Court, *infra*.

A third property is the officers belonging to it, as the justice, warden, verderer, forester, agistor, regarder, keeper, bailiff, beadle, &c. See the articles AGISTOR, BAILIFF, FORESTER, &c.

By the laws of the forest, the receivers of trespasses in hunting or killing of the deer, if they know them to be the king's property, are principal trespassers. Likewise, if a trespass be committed in a forest, and the trespasser dies, after his death, it may be punished in the life-time of the heir, contrary to common law. The Norman kings punished such as killed deer in any of their forests with great severity; also in various manners; as by hanging, loss of limbs, gelding, and putting out eyes. By *magna charta de foresta*, it is ordained, that no person shall lose life or member for killing the king's deer in forests, but shall be fined; and

Forest.

if

Forest if the offender has nothing to pay the fine, he shall be imprisoned a year and a day, and then be delivered, if he can give security not to offend for the future, &c. 9 Hen. III. c. 1.

Before this statute, it was felony to hunt the king's deer; and by a late act, persons armed and disguised, appearing in any forest, &c. if they hunt, kill, or steal any deer, &c. are guilty of felony. 9 Geo. I. c. 22.

He who has any licence to hunt in a forest or chase, &c. is to take care that he does not exceed his authority; otherwise he shall be deemed a trespasser from the beginning, and be punished for the fact, as if he had no licence. See further, the articles GAME, and Game-LAW.

Beasts of the forest are, the hart, hind, buck, doe, boar, wolf, fox, hare, &c. The seasons for hunting whereof are as follow, viz. that of the hart and buck begins at the feast of St John Baptist, and ends at Holy-rod day; of the hind and doe, begins at Holy rod, and continues till Candlemas; of the boar, from Christmas to Candlemas; of the fox begins at Christmas, and continues till Lady-day; of the hare at Michaelmas, and lasts till Candlemas.

FOREST-Courts, courts instituted for the government of the king's forests in different parts of the kingdom, and for the punishment of all injuries done to the king's deer or venison, to the vert or greenward, and to the covert in which such deer are lodged. These are the courts of ATTACHMENTS, of REGARD, of SWEINMOTE, and of JUSTICE-SEAT. 1. The court of attachments, woodmote, or forty-days court, is to be held before the verderors of the forest once in every forty days; and is instituted to inquire into all offenders against vert and venison: who may be attached by their bodies, if taken with the mainour (or *mainœuvre, à manu*) that is, in the very act of killing venison, or stealing wood, or in the preparing so to do, or by fresh and immediate pursuit after the act is done; else they must be attached by their goods. And in this forty-days court the foresters or keepers are to bring in the attachments, or presentments *de viridi et venatione*; and the verderors are to receive the same, and to enrol them, and to certify them under their seals to the court of justice-seat or sweinmote: for this court can only enquire of, but not convict, offenders. 2. The court of regard, or survey of dogs, is to be holden every third year for the lawing or expeditation of mastiffs; which is done by cutting off the claws of the fore-feet, to prevent them from running after deer. No other dogs but mastiffs are to be thus lawed or expeditated, for none other are permitted to be kept within the precincts of the forest: it being supposed that the keeping of these, and these only, was necessary for the defence of a man's house. 3. The court of sweinmote is to be holden before the verderors, as judges, by the steward of the sweinmote, thrice in every year; the sweins or freeholders within the forest composing the jury. The principal jurisdiction of this court is, first, to inquire into the oppressions and grievances committed by the officers of the forest; "*de super-operatione forestariorum, et aliorum ministrorum forestæ; et de eorum oppressionibus populo regis illatis*:" and, secondly, to receive and try presentments certified from the court of attachments against offences in vert and venison. And this court may not only inquire, but convict also; which conviction shall be certified to the court of justice-seat un-

der the seals of the jury, for this court cannot proceed to judgement. But the principal court is, 4. The court of justice-seat, which is held before the chief justice in eyre, or chief itinerant judge, *capitalis justitiarius itinere*, or his deputy: to hear and determine all trespasses within the forest, and all claims of franchises, liberties, and privileges, and all pleas and causes whatsoever therein arising. It may also proceed to try presentments in the inferior courts of the forests, and to give judgment upon conviction of the sweinmote. And the chief justice may therefore, after presentment made or indictment found, but not before, issue his warrant to the officers of the forest to apprehend the offenders. It may be held every third year; and 40 days notice ought to be given of its sitting. This court may fine and imprison for offences within the forest, it being a court of record: and therefore a writ of error lies from hence to the court of king's-bench, to rectify and redress any mal-administration of justice; or the chief justice in eyre may adjourn any matter of law into the court of king's-bench.

FOREST-Laws, are peculiar laws different from the common law of England. Before the making of *Charta de Foresta*, in the time of king John and his son Henry III. confirmed in parliament by 9 Henry III. offences committed therein were punished at the pleasure of the king in the severest manner. By this charter, many forests were disafforested and stripped of their oppressive privileges, and regulations were made for the government of those that remained, particularly, killing the king's deer was made no longer a capital offence, but only punished by fine, imprisonment, or abjuration of the realm: yet even in the charter there were some grievous articles, which the clemency of later princes have since by statute thought fit to alter *per assisas forestæ*. And to this day, in trespasses relating to the forest, *voluntas reputabitur pro facto*; so that if a man be taken hunting a deer, he may be arrested as if he had taken a deer.

FOREST-Towns, in geography, certain towns of Suabia in Germany, lying along the Rhine, and the confines of Switzerland, and subject to the house of Austria. Their names are *Rhinefeld; Seckingen, Lausenbourg, and Waldshut*.

FORE-STAFF, an instrument used at sea for taking the altitudes of heavenly bodies. The fore-staff, called also *cross-staff*, takes its denomination hence, that the observer, in using it, turns his face towards the object; in contradistinction to the back-staff, where he turns his back to the object.

The fore or cross staff, represented in Plate CXCIV. consists of a straight square staff, A B, graduated like a line of tangents and four crosses or vanes, F F, E E, D D, C C, which slide thereon. The first and shortest of these vanes, F F, is called the *ten cross*, or *vane*, and belongs to that side of the instrument whereon the divisions begin at three degrees and end at ten. The next longer vane, E E, is called the *thirty cross*, belonging to that side of the staff wherein the divisions begin at ten degrees and end at thirty, called the *thirty scale*. The next vane, D D, is called the *sixty cross*, and belongs to the side where the divisions begin at twenty degrees and end at sixty. The last and longest, C C, called the *ninety cross*, belongs to the side whereon the divisions begin at thirty degrees and end at ninety.

Fore-staff
||
Forester.

The great use of this instrument is to take the height of the sun and stars, or the distance of two stars: and the ten, thirty, sixty, or ninety crosses, are to be used according as the altitude is greater or less; that is, if the altitude be less than ten degrees, the ten cross is to be used; if above ten, but less than thirty, the thirty cross is to be used, &c. *Note*, For altitudes greater than thirty degrees, this instrument is not so convenient as a quadrant or semicircle.

To observe an altitude by this instrument.—Apply the flat end of the staff to your eye, and look at the upper end of the cross for the centre of the sun or star, and at the lower end for the horizon. If you see the sky instead of the horizon, slide the cross a little nearer the eye; and if you see the sea instead of the horizon, slide the cross farther from the eye: and thus continue moving till you see exactly the sun or star's centre by the top of the cross, and the horizon by the bottom thereof. Then the degrees and minutes, cut by the inner edge of the cross upon the side of the staff peculiar to the cross you use, give the altitude of the sun or star.

If it be the meridian altitude you want, continue your observation as long as you find the altitude increase, still moving the cross nearer to the eye. By subtracting the meridian altitude thus found from 90 degrees, you will have the zenith distance. To work accurately, an allowance must be made for the height of the eye above the surface of the sea, viz. for one English foot, 1 minute; for 5 feet, $2\frac{1}{2}$; for 10 feet, $3\frac{1}{2}$; for 20 feet, 5; for 40 feet, 7, &c. These minutes subtracted from the altitude observed, and added to the zenith distance observed, give the true altitude and zenith distance.

To observe the distance of two stars, or the moon's distance from a star, by the fore-staff.—Apply the instrument to the eye, and looking to both ends of the cross, move it nearer or farther from the eye till you see the two stars, the one on the one end, and the other on the other end, of the cross; then the degrees and minutes cut by the cross on the side proper to the vane in use give the stars distance.

FORESTALLER, a person who is guilty of forestalling. See the next article.

FORESTALLING, in law, buying or bargaining for any corn, cattle, victuals, or merchandise, in the way as they come to fairs or markets to be sold, before they get thither, with an intent to sell the same again at a higher price.

The punishment in Britain for this offence, upon conviction at the quarter-sessions by two or more witnesses, is, the first time, two months imprisonment and the loss of the goods, or the value; for the second offence, the offender shall be imprisoned six months, and lose double the value of the goods; for the third offence, he shall suffer imprisonment during the king's pleasure, forfeit all his goods and chattels, and stand on the pillory: but the statute does not extend to maltsters buying barley, or to badgers licensed.

FORESTER, a sworn officer of the forest, appointed by the king's letters-patent, to walk the forest at all hours, and watch over the vert and venison; also to make attachments and true presentments of all trespasses committed within the forest.

If a man comes in a forest in the night, a forester cannot lawfully beat him before he makes some resist-

ance; but in case such a person resists the forester, he may justify a battery. And a forester shall not be questioned for killing a trespasser that, after the peace cried to him, will not surrender himself, if it be not done on any former malice; though, where trespassers in a forest, &c. do kill a person that opposes them, it is murder in all, because they were engaged in an unlawful act, and therefore malice is implied to the person killed.

FORETHOUGHT-FELONY, in Scots law, signifies premeditated murder. See **MURDER**.

FORFAR, a parliament-town of Scotland, and capital of the county of that name, situated in N. Lat. 56. 25. W. Long. 2. 32. This town, with Dundee, Cupar, Perth, and St Andrew's, jointly send one member to the British parliament. It stands in the great valley of Strathmore that runs from Perth north-east to the sea, almost in a straight line, about 50 miles long and betwixt four and five miles broad, bordered on either side by hills, rising gently on the south side, and on the north by the famous Grampians, a little more elevated.

Though history is silent as to the etymology of the name *Forfar*, yet we are sure it is of very ancient date, and that in the days of old it was the residence of royal majesty.—Here Malcom Canmore, a wife and magnanimous prince, held his first parliament in 1057. The ruins of his palace are still to be seen on the top of an artificial mount of a circular form, resting upon a base of about three acres of ground, and rising 50 feet high above the level of the circumambient plain. A wall of stone of a great thickness, so strongly cemented with run-lime that it is scarce possible to break the place; and a mote of at least 20 feet broad, and in some parts a great deal more, and 12 feet deep, encompassed the whole. Adjoining to this is a field of about six acres of ground called the *Queen's Manor*, surrounded in those days with a large sheet of water, and accessible only by boats. In clearing away some of the rubbish of the palace a few years ago, a tea-kettle of a conical figure, and a bunch of barbed arrows, were found in the ruins. A pit of about 18 feet deep, very prettily built of hewn stone, with a human body in a state of extreme putrefaction, was also discovered. The lake of Forfar, stretching two miles in length from east to west, and half a mile in breadth, and covering the palace on the north, afforded not only a plentiful supply of water for every purpose, but also added to the strength of the place. This lake abounds with trout, pike, perch, and eel. Of late years it has been greatly reduced by draining; to which the immense quantity of fine marle at the bottom was the principal inducement. This excellent manure is found here in large strata from two to six and eight feet deep, and generally below moss ten feet deep.

This lake has proved fatal to many of the human race; but particularly and deservedly so to the murderers of Malcom II. who having fled after perpetrating the bloody deed at the castle of Glamis, about five miles distant, in the year 1036, missed their way, owing to a deep fall of snow, and wandered in the fields for some time, till at last they came upon the ice on the lake, which not being firm, suddenly gave way under them, and they all perished. When the thaw

came

Fore-
though,
Forfar.

Forfar. came, their bodies were found; and being discovered to be the murderers of the king, they were all hung on gibbets on the sides of the highways.

Within this lake were formerly two islands raised by art, with buildings on each; to which Margaret, Malcom Canmore's queen, retired after the decease of her husband. Part of the ruins of these edifices are still to be seen. To this queen, tradition says, we owe the custom of the grace-drink; she having established it as a rule at her table, that whoever staid till grace was said was rewarded with a bumper.

From this time we have little or no accounts of Forfar till the middle of the 17th century, except an act passed in the 13th parliament of James VI. 21st July 1593, in the following words: "Our sovereigne Lorde, understanding that be acte and ordinance maid anent observation of the Sabbath-daie within this realme, the mercatte-daie of the burgh of Forfare, being the head burgh of the schire, quilk was Sundaie, is taken from them; and his hiennesse not willing that they in onie waies sould be prejudged hereby, therefore his hiennesse, with advice of the estaites of this present parliament, alteris and changis their said mercatte-daie from Sundaie to Fridaie, and willis the samen Friday oukly to be their mercatte-daie to them in all times hereafter; and the samen to stande with the like priviledges and freedoms as the Sundaie did of before." Whether this change took place, or how long it continued, is uncertain; but the market-day is presently held on Saturday, and has been so past memory of man.

During the usurpation of Oliver Cromwell, a detachment of his forces, after sacking Dundee, came to Forfar and burnt all the public records of the place; and the only charter the town now has is one granted by Charles II. after his restoration, confirming all its ancient rights and privileges.

As an evidence of the ignorance and barbarity of the times, it appears from the records of the trials kept in the charter chest of Forfar, that nine persons were condemned and burnt here for witchcraft betwixt the years 1650 and 1662. These innocent people were all tried by a special commission from the lords of the privy-council at Edinburgh; and although the commission expressly discharged torturing them on purpose to extort a confession of their guilt, yet, as it was then thought meritorious to obtain confession of guilt by whatever means, many inhuman cruelties were exercised upon the unfortunate objects, particularly, an iron boot was drawn upon one of their legs, and a wedge driven with great force between it and the leg. Another instrument, still carefully preserved here, was likewise used, and is called the *witch-bridle*. It is made of iron, in the shape of a dog's collar, with two pikes on the inside, about four inches distant, and two and a half long. These pikes were put into the mouth, and the collar afterwards buckled strait on the back of the head, to which was affixed an iron chain, whereby the condemned persons were led to the place of execution called the *Play-Field*, about a quarter of a mile to the northward of the town.

The inhabitants of Forfar are a hospitable, free, and generous set of people: they are at least doubled in number within these 30 years, being now about 3300, the houses have also increased more in proportion, besides being vastly improved. The church here has just

been rebuilt on an elegant and extensive plan calculated to contain 2000 hearers.

FORFAR Shire, a county of Scotland, of which Forfar is the capital. Including Angus, Glenila, Glensik, and Glenprassin, it extends 29 miles from east to west, and 16 where broadest, though in some places the breadth does not exceed five miles. On the north it is divided from the Brae of Mar by a ridge of the Binnichin mountains; it is bounded on the south by the Frith of Tay and the British ocean, on the east by Mearns, and on the west by Perthshire. Part of the Grampian mountains runs through this county, which is agreeably diversified with hill and dale. It produces lead and iron in abundance, together with quarries of freestone and slate, with which the inhabitants drive a considerable traffic. The county is well watered with lakes, rivers, rivulets, and fountains, shaded with large forests, roughened with brown mountains, and waved with green hills interspersed with fields and meadows, and adorned with fine seats and plantations. Their heaths and woods abound with hart, hind, roebuck and moor game; their streams are stocked with trout and salmon. Their hills are covered with flocks of sheep, and their fields afford plentiful harvests of wheat, and all sorts of grain. The mountains to the west and north are inhabited by Highlanders: but the Lowlanders possess the towns and champaign country, and are remarkable for their politeness and hospitality.

FORFEITURE, originally signifies a transgression, or offence against some penal law. The word is formed of the base Latin *forisfactura*: whence *forfaitura* and *forfaitura*; and the French *forfait*. *Forisfactura* comes of *forisfacere*; which, according to Isidore, signifies to "hurt or offend," *facere contra rationem*, and which is not improbably derived of *foris* "out," and *facere*, "to do," q. d. an action out of rule, or contrary to the rules. Borel will have *forfait* derived from the using of force or violence: Lobineau in his glossary will have *forisfacta* properly to signify a mulct or amend, not a *forfeit*; which latter he derives from the base British *forfed*, "a penalty."

But, with us, it is more frequently used for the effect of such transgression; or the losing some right, privilege, estate, honour, office, or effects, in consequence thereof; than for the transgression itself.

Forfeiture differs from *confiscation*, in that the former is more general; while confiscation is particularly applied to such things as become forfeited to the king's exchequer; and goods confiscated are said to be such as nobody claims.

Forfeitures may be either in *civil* or *criminal* cases.

I. With respect to the first, a man that hath an estate for life or years, may forfeit it many ways, as well as by treason or felony; such as alienation, claiming a greater estate than he hath, or affirming the reversion to be in a stranger, &c. When a tenant in tail makes leases not warranted by the statute; a copyholder commits waste, refuses to pay his rent, or do suit of court; and where an estate is granted upon condition, on non-performance thereof, &c. they will make a forfeiture.

Entry for a forfeiture ought to be by him who is next in reversion, or remainder, after the estate forfeited. As if tenant for life or years commits a forfeiture, he who has the immediate reversion or remainder ought

Forfar,
Forfeiture:

Forfeiture. ought to enter; though he has the fee, or only an estate-tail.

II. Forfeiture in criminal cases is twofold; of real, and personal estates.

*Blackst.
Comment.*

I. As to real estates, by **ATTAINDER** in high-treason, a man forfeits to the king all his lands and tenements of inheritance, whether fee-simple or fee-tail; and all his rights of entry on lands and tenements, which he had at the time of the offence committed, or at any time afterwards, to be for ever vested in the crown; and also the profits of all lands and tenements, which he had in his own right for life or years, so long as such interest shall subsist. This forfeiture relates backwards to the time of the treason committed; so as to avoid all intermediate sales and incumbrances, but not those before the fact: and therefore a wife's jointure is not forfeitable for the treason of her husband; because settled upon her previous to the treason committed. But her dower is forfeited, by the express provision of Statute 5 and 6 Edw. VI. c. 11. And yet the husband shall be tenant by the curtesy of the wife's lands, if the wife be attainted of treason: for that is not prohibited by the statute. But, though after attainder the forfeiture relates back to the time of the treason committed, yet it does not take effect unless an attainder be had, of which it is one of the fruits; and therefore, if a traitor dies before judgment pronounced, or is killed in open rebellion, or is hanged by martial law, it works no forfeiture of his land: for he never was attainted of treason. But if the chief justice of the king's bench (the supreme coroner of all England) in person, upon the view of the body of him killed in open rebellion, records it and returns the record into his own court, both lands and goods shall be forfeited.

The natural justice of forfeiture or confiscation of property, for treason, is founded on this consideration: That he who hath thus violated the fundamental principles of government, and broken his part of the original contract between king and people, hath abandoned his connections with society, and hath no longer any right to those advantages which before belonged to him purely as a member of the community; among which *social* advantages, the right of transferring or transmitting property to others is one of the chief. Such forfeitures, moreover, whereby his posterity must suffer as well as himself, will help to restrain a man, not only by the sense of his duty, and dread of personal punishment, but also by his passions and natural affections; and will interest every dependant and relation he has to keep him from offending: according to that beautiful sentiment of Cicero, "*nec vero me fugit quam sit acerbum, parentum scelera filiorum pœnis lui: sed hoc præclare legibus comparatum est, ut caritas liberorum amiciores parentes reipublicæ redderet.*" And therefore Aulus Cascellius, a Roman lawyer in the time of the triumvirate, used to boast that he had two reasons for despising the power of the tyrants; his old age and his want of children: for children are pledges to the prince of the father's obedience. Yet many nations have thought, that this posthumous punishment favours of hardship to the innocent; especially for crimes that do not strike at the very root and foundation of society, as treason against the government expressly does. And therefore, although confiscations were very frequent in the times of the earlier emperors, yet Arca-

dius and Honorius, in every other instance but that of treason, thought it more just, *ibi esse pœnam, ubi et noxa est*; and ordered, that "*peccata suos teneant auctores, nec ulterius progrediatur metus, quam reperitur delictum:*" and Justinian also made a law to restrain the punishment of relations; which directs the forfeiture to go, except in the case of *crimen majestatis*, to the next of kin to the delinquent. On the other hand, the Macedonian laws extended even the capital punishment of treason, not only to the children, but to all the relations of the delinquent: and of course their estates must be also forfeited, as no man was left to inherit them. And in Germany, by the famous golden bull (copied almost *verbatim* from Justinian's code), the lives of the sons of such as conspire to kill an elector are spared, as it is expressed, by the emperor's *particular bounty*. But they are deprived of all their effects and right of succession, and are rendered incapable of any honour ecclesiastical and civil; to the end that, being always poor and necessitous, they may for ever be accompanied by the infamy of their father; may languish in continual indigence; and may find (says this merciless edict) their punishment in living, and their relief in dying."

In England, forfeiture of lands and tenements to the crown for treason is by no means derived from the feudal policy, but was antecedent to the establishment of that system in that island; being transmitted from their Saxon ancestors, and forming a part of the ancient Scandinavian constitution. But in certain treasons relating to the coin (which seems rather a species of the *crimen falsi* than the *crimen læsæ majestatis*), it is provided by some of the modern statutes which constitute the offence, that it shall work no forfeiture of lands, save only for the life of the offenders; and by all, that it shall not deprive the wife of her dower. And, in order to abolish such hereditary punishment entirely, it was enacted by Statute 7 Ann. c. 21. that, after the decease of the late pretender, no attainder for treason should extend to the disinheriting of any heir, nor to the prejudice of any person, other than the traitor himself. By which the law of forfeitures for high treason would by this time have been at an end, had not a subsequent statute intervened to give them a longer duration. The history of this matter is somewhat singular, and worthy observation. At the time of the union, the crime of treason in Scotland was, by the Scots law, in many respects different from that of treason in England; and particularly in its consequence of forfeitures of entailed estates, which was more particularly English; yet it seemed necessary, that a crime so nearly affecting government should, both in its essence and consequences, be put upon the same footing in both parts of the united kingdoms. In new-modelling these laws, the Scots nation and the English house of commons struggled hard, partly to maintain, and partly to acquire, a total immunity from forfeiture and corruption of blood: which the house of lords as firmly resisted. At length a compromise was agreed to, which is established by this statute, *viz.* that the same crimes, and no other, should be treason in Scotland that are so in England; and that the English forfeitures and corruption of blood should take place in Scotland till the death of the then pretender, and then cease throughout the whole of Great Britain: the lords artfully proposed this temporary clause, in hopes (it

Forfeiture. is said) that the prudence of succeeding parliaments would make it perpetual. This has partly been done by the statute 17 Geo. II. c. 39. (made in the year preceding the late rebellion), the operation of these indemnifying clauses being thereby still farther suspended till the death of the son of the pretender.

In petit treason and felony, the offender also forfeits all his chattel interests absolutely, and the profits of all freehold estates during life; and after his death all his lands and tenements in fee simple (but not those in tail) to the crown, for a very short period of time: for the king shall have them for a year and a day and may commit therein what waste he pleases; which is called the king's year, day and waste. Formerly the king had only a liberty of committing waste on the lands of felons, by pulling down their houses, extirpating their gardens, plowing their meadows, and cutting down their woods. And a punishment of a similar spirit appears to have obtained in the oriental countries from the decrees of Nebuchadnezzar and Cyrus in the books of Daniel and Ezra; which, besides the pain of death inflicted on the delinquents there specified, ordain, "that their houses shall be made a dunghill." But this tending greatly to the prejudice of the public, it was agreed in the reign of Henry I. in England, that the king should have the profits of the land for one year and a day in lieu of the destruction he was otherwise at liberty to commit: and therefore *magna charta*, provides, that the king shall only hold such lands for a year and a day, and then restore them to the lord of the fee, without any mention made of waste. But the statute 17 Edw. II. *de prerogativa regis*, seems to suppose, that the king shall have his year, day, and waste; and not the year and day instead of waste: which Sir Edward Coke (and the author of the Mirror before him) very justly look upon as an encroachment, though a very ancient one, of the royal prerogative. The year, day, and waste, are now usually compounded for; but otherwise they regularly belong to the crown; and after their expiration the land would naturally have descended to the heir (as in gavelkind tenure it still does), did not its feudal quality intercept such descent, and give it by way of escheat to the lord. These forfeitures for felony do also arise only upon attainder: and therefore a *felo de se* forfeits no lands of inheritance or freehold, for he never is attainted as a felon. They likewise relate back to the time the offence was committed as well as forfeitures for treason, so as to avoid all intermediate charges and conveyances. This may be hard upon such as have unwarily engaged with the offender: but the cruelty and reproach must lie on the part, not of the law, but of the criminal; who has thus knowingly and dishonestly involved others in his own calamities.

2. The forfeiture of goods and chattels accrues in every one of the high kinds of offence; in high treason, or misprision thereof, petit treason, felonies of all sorts whether clergyable or not, self-murder or felony *de se*, petty larceny, standing mute, &c. For flight also, on an accusation of treason, felony, or even petit larceny, whether the party be found guilty or acquitted, if the jury find the flight, the party shall forfeit his goods and chattels: for the very flight is an offence, carrying with it a strong presumption of guilt, and is at least an endeavour to elude and stifle the

course of justice prescribed by the law. But the jury very seldom find the flight; forfeiture being looked upon, since the vast increase of personal property of late years, as too large a penalty for an offence to which a man is prompted by the natural love of liberty.

There is a remarkable difference or two between the forfeiture of lands and of goods and chattels. (1.) Lands are forfeited upon *attainder*, and not before: goods and chattels are forfeited by *conviction*. Because in many of the cases where goods are forfeited, there never is any attainder; which happens only where judgment of death or outlawry is given; therefore, in those cases the forfeiture must be upon conviction, or not at all; and being necessarily upon conviction in those, it is so ordered in all other cases, for the law loves uniformity. (2.) The forfeiture of lands has relation to the time the fact was committed, so as to avoid all subsequent sales and incumbrances; but the forfeiture of goods and chattels has no relation backwards; so that those only which a man has at the time of conviction shall be forfeited. Therefore a traitor or felon may *bona fide* sell any of his chattels, real or personal, for the sustenance of himself and family between the fact and conviction: for personal property is of so fluctuating a nature, that it passes through many hands in a short time: and no buyer could be safe, if he were liable to return the goods which he had fairly bought, provided any of the prior vendors had committed a treason or felony. Yet if they be collusively and not *bona fide* parted with, merely to defraud the crown, the law (and particularly the statute 13 Eliz. c. 5.) will reach them; for they are all the while truly and substantially the goods of the offender: and as he, if acquitted, might recover them himself, as not parted with for a good consideration; so, in case he happens to be convicted, the law will recover them for the king.

FORFEX, in Roman antiquity, was a way of drawing up an army in the form of a pair of sheers. It was intended to receive the *cuneus* or wedge, if the enemy should make use of that figure. For when the forfex opened to admit the wedge, they had an opportunity of defeating their design, and cutting them in pieces.

FORFICULA, the EAR-WIG, in zoology, a genus of insects belonging to the order of coleoptera. The antennæ are bristly; the elytra are dimidiated; the wings are covered; and the tail is forked. There are two species, *viz.* the auricularia, or common ear-wig, with the tops of the elytra white; and the minor, with testaceous and unspotted elytra.—This genus of insects is one of the best known, the forceps at the extremity of their abdomen forming a very distinctive character. It is this seeming weapon that has occasioned those insects to be called *forficulae* in Latin: and the formidable name of *ear-wigs* has been given them in English, from a notion that the insect frequently introduces itself into the ears, causing great pain and even death. Mr Barbut, however, assures us, that the forceps which the ear-wig carries at his tail, and with which he seems provided for his defence, is not so formidable as it at first appears, being destitute of strength sufficient to produce the least sensible impression. The larva of the ear-wig differs very little from the perfect insect.

Forge.

Ear-wigs are very mischievous vermin in gardens, especially where carnations are preserved; for they are so fond of these flowers, that if care is not taken to prevent them, they will entirely destroy them, by eating off the sweet part at the bottom of the petals or leaves. To prevent which, most people have stands erected, which have a basin of earth or lead round each supporter, which is constantly kept filled with water. Others hang the hollow claws of crabs and lobsters upon sticks in divers parts of the garden into which those vermin get; and by often searching them, you will destroy them without much trouble, which will be of great service to your wall-fruit, for these are great destroyers also of all soft fruits.

FORGE, properly signifies a little furnace, wherein smiths and other artificers of iron or steel, &c. heat their metals red-hot, in order to soften them and render them more malleable and manageable on the anvil.

An ordinary forge is nothing but a pair of bellows, the nozzle of which is directed upon a smooth area, on which coals are placed. The nozzle of a pair of bellows may be also directed to the bottom of any furnace, to excite the combustion of the coals placed there, by which a kind of forge is formed. In laboratories there is generally a small furnace consisting of one cylindrical piece, open at top, which has at its lower side a hole for receiving the nozzle of a double bellows. This kind of forge-furnace is very convenient for fusions, as the operation is quickly performed, and with few coals. In its lower part, two inches above the hole for receiving the nozzle of the bellows, may be placed an iron-plate of the same diameter, supported upon two horizontal bars, and pierced near its circumference with four holes diametrically opposite to each other. By this disposition, the wind of the bellows, pushed forcibly under this plate, enters at these four holes; and thus the heat of the fire is equally distributed, and the crucible in the furnace is equally surrounded by it. This contrivance is used in the forge-furnaces for melting copper with this difference only, that these furnaces are square, which is a matter of no consequence.

As the wind of bellows strongly and rapidly excites the action of the fire, a forge is very convenient when a great heat is to be applied quickly; but it is not suitable when the heat is to be gradually increased.

The forge, or blast of bellows, is used in several operations in small; as to fuse salts, metals, ores, &c. It is also much used in works in the great, which require strong heat, without much management; and chiefly in the smelting of ores, and fusion of metallic matters.

FORGE is also used for a large furnace, wherein iron-ore, taken out of the mine, is melted down: or it is more properly applied to another kind of furnace, wherein the iron-ore melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

FORGE, in the train of artillery, is generally called a *travelling forge*, and may not improperly be called a portable smith's shop: at this forge all manner of smith's work is made, and it can be used upon a march as well as in camp. Formerly they were very ill contrived, with 2 wheels only, and wooden supporters to

to prop the forge for working when in the park. Of late years they are made with 4 wheels, which answers their purpose much better.

FORGE for red-hot Balls, is a place where the balls are made red-hot before they are fired off: it is built about five or six feet below the surface of the ground, of strong brick-work, and an iron grate, upon which the balls are laid, with a very large fire under them.

FORGER, in law, one guilty of FORGERY.

FORGERY (from the French *forger*, i. e. *accudare, fabricare*, "to beat on an anvil, forge, or form,") may be defined at common law, to be "the fraudulent making or alteration of a writing to the prejudice of another man's right:" for which the offender may suffer fine, imprisonment, and pillory. And also, by a variety of statutes a more severe punishment is inflicted on the offender in many particular cases, which are so multiplied of late as almost to become general. We shall mention the principal instances.

By statute 5 Eliz. c. 14. to forge or make, or knowingly to publish or give in evidence, any forged deed, court-roll, or will, with intent to affect the right of real property, either freehold or copyhold, is punished by a forfeiture to the party grieved of double costs and damages; by standing in the pillory, and having both his ears cut off, and his nostrils slit, and seared; by forfeiture to the crown of the profits of his lands, and by perpetual imprisonment. For any forgery relating to a term of years or annuity, bond, obligation, acquittance, release or discharge of any debt or demand of any personal chattels, the same forfeiture is given to the party grieved; and on the offender is inflicted the pillory, loss of one of his ears, and half a year's imprisonment: the second offence, in both cases, being felony without benefit of clergy.

Besides this general act, a multitude of others, since the revolution (when paper-credit was first established), have inflicted capital punishment on the forging, altering, or uttering as true when forged, of any bank, bills, or notes, or other securities; of bills of credit issued from the exchequer; of south-sea bonds, &c.; of lottery tickets or orders; of army or navy debentures; of East-India bonds; of writings under seal of the London or royal-exchange assurance; of the hand of the receiver of the pre-fines, or of the accountant-general and certain other officers of the court of chancery; of a letter of attorney or other power to receive or transfer stock or annuities; and on the personating a proprietor thereof, to receive or transfer such annuities, stock, or dividends: also on the personating, or procuring to be personated, any seaman or other person, intitled to wages or other naval emoluments, or any of his personal representatives; and the taking, or procuring to be taken, any false oath in order to obtain a probate or letters of administration, in order to receive such payments; and the forging, or procuring to be forged, and likewise the uttering or publishing, as true of any counterfeited seaman's will or power: to which may be added, though not strictly reducible to this head, the counterfeiting of Mediterranean passes, under the hands of the lords of the admiralty, to protect one from the piratical states of Barbary; the forging or imitating of any stamps to defraud the public revenue: and the forging of any marriage register or licence: all which are, by distinct acts of parliament,

Forge
||
Forgery.

Forging. liament, made felonies without benefit of clergy. By statutes 13 Geo. III. c. 52. & 59. forging or counterfeiting any stamp or mark to denote the standard of gold and silver plate, and certain other offences of the like tendency, are punished with transportation for 14 years. By statute 12 Geo. III. c. 48. certain frauds on the stamp-duties, therein described, principally by using the same stamps more than once, are made single felony, and liable to transportation for seven years. And the same punishment is inflicted by statute 13 Geo. III. c. 38. on such as counterfeit the common seal of the corporation for manufacturing plate-glass (thereby created), or knowingly demand money of the company by virtue of any writing under such counterfeit seal.

There are also two general laws, with regard to forgery; the one 2 Geo. II. c. 25. whereby the first offence in forging or procuring to be forged, acting or assisting therein, or uttering or publishing as true, any forged deed, will, bond, writing obligatory, bill of exchange, promissory note, endorsement or assignment thereof, or any acquittance or receipt for money or goods, with intention to defraud any person (or corporation), is made felony without benefit of clergy. And by statute 7 Geo. II. c. 22. it is equally penal to forge, or cause to be forged, or utter as true, a counterfeit acceptance of a bill of exchange, or the number of any accountable receipt for any note, bill, or any other security for money, or any warrant or order for the payment of money, or delivery of goods. So that, through the number of these general and special provisions, there is now hardly a case possible to be conceived, wherein forgery, that tends to defraud, whether in the name of a real or fictitious person, is not made a capital crime.

FORGING, in law, the act of **FORGERY**.

FORGING, in smithery, the beating or hammering iron on the anvil, after having first made it red hot in the forge, in order to extend it into various forms, and fashion it into works. See **FORGE**.

There are two ways of forging and hammering iron. One is by the force of the hand, in which there are usually several persons employed, one of them turning the iron and hammering likewise, and the rest only hammering. The other way is by the force of a water-mill, which raises and works several huge hammers beyond the force of man; under the strokes whereof the workmen present large lumps or pieces of iron, which are sustained at one end by the anvils, and at the other by iron-chains fastened to the ceiling of the forge. See **MILL**.

This last way of forging is only used in the largest works, as anchors for ships, &c. which usually weigh several thousand pounds. For the lighter works, a single man serves to hold, heat, and turn with one hand, while he hammers with the other.

Each purpose the work is designed for requires its proper heat; for if it be too cold, it will not feel the weight of the hammer, as the smiths call it, when it will not batter under the hammer; and if it be too hot, it will red-fear, that is, break or crack under the hammer.

The several degrees of heat the smiths give their irons, are, first, a blood-red heat; secondly, a white-flame-heat; and, thirdly, a sparkling or welding heat.

FORISFAMILIATION, in laws. When a child, upon receiving a portion from his father, or otherwise renounces his legal title to any further share of his father's succession, he is said to be *forisfamiliated*.

FORK, a well-known instrument, consisting of a handle and blade, divided at the end into two or more points or prongs.

The *pitch-fork* is a large utensil of this construction, employed in hay-making, &c.

The *table fork*, an instrument now so indispensable, did not come into use in England till the reign of James I. as we learn from a remarkable passage in Coryat. The reader will probably smile at the solemn manner in which this important discovery or innovation is related: "Here I will mention a thing that might have been spoken of before in discourse of the first Italian towns. I observed a custom in all those Italian cities and townes through which I passed, that is not used in any other country that I saw in my travels, neither do I thinke that any other nation of Christendome doth use it, but only Italy. The Italian and also most strangers that are commonant in Italy, doe always at their meals use a little fork when they eat their meate; for while with their knife which they hold in one hand they cut the meate out of the dish, they fasten the fork which they hold in the other hand upon the same dish, so that whatsoever he be that sitting in the company of any others at meale should unadvisedly touch the dish of meat with his fingers from which all the table doe cut, he will give occasion of offence unto the company as having transgressed the lawes of good manners, in so much that for his error he shall be at least-brow-beaten if not reprehended in wordes. This form of feeding I understand is generally used in all parts of Italy, their forkes for the most part being made of yronn, steele, and some of silver, but those are used only by gentlemen. The reason of this their curiosity is, because the Italian cannot by any means indure to have his dish touched with fingers, seeing all mens fingers are not alike cleane. Hereupon I myself thought good to imitate the Italian fashion by this forked cutting of meate, not only while I was in Italy, but also in Germany, and often times in England since I came home: being once quipped for that frequently using my forke, by a certain learned gentleman a familiar friend of mine, Mr Lawrence Whitaker; who in his merry humour doubted not to call me a table *Furcifer*, only for using a fork at feeding, but for no other cause."

FORLI, an ancient and considerable town of Italy, and capital of a territory of the same name, in Romagna, with a bishop's see. The public structures are very handsome; and it is seated in a fertile, healthy, and pleasant country, 10 miles south-east of Faenza, and 45 north-east of Florence. E. Long. 12. 1. N. Lat. 44. 28.

FORLORN-HOPE, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle; or, at a siege, to storm the counter-scarp, mount the breach, or the like. They are so called from the great danger they are unavoidably exposed to; but the word is old, and begins to be obsolete.

FORM, in physics, denotes the manner of being peculiar to each body; or that which constitutes it such

Form.

a particular body, and distinguishes it from every other. Mr Harris uses the term *form* likewise in another sense, as an efficient animating principle; to which he supposes Ovid to refer in the first lines of his *Metamorphosis*,

*In nova fert animus mutatas dicere formas
Corpora*

These animating forms are of themselves no objects either of the ear or of the eye; but their nature or character is understood in this, that were they never to exert their proper energies on their proper subjects, the marble on which the sculptor exercises his art would remain for ever shapeless, and the harp from which the harper calls forth sounds would remain for ever silent.

Thus, also, the animating form of a natural body is neither its organization nor its figure, nor any other of those inferior forms which make up the system of its visible qualities; but it is the power, which is yet able to produce, preserve, and employ these. It is the power, which first moves and then conducts that latent process, by which the acorn becomes an oak, and the embryo becomes a man; by which digestion is performed in plants and animals, and, which departing, the body ceases to live, and its members putrefy; and by which every being produces another like itself, and every species is continued. In animals, it is that higher faculty, which, by employing the organs of sense, peculiar to them as animals, distinguishes them as sensitive beings from vegetables; and it is also that more noble faculty, which by its own divine vigour, unassisted perhaps with organs, makes and denominates him a being intellectual and rational. So that Mr Harris reckons two sorts of forms, those which are passive elements, and those which are efficient causes. And all of them agree in this, that they give to every being its peculiar and distinctive character: and on the whole he concludes, that form appears in part to be an element, and in part an efficient cause, *i. e.* a cause which associates the constituent elements of natural substance, and which employs them, when associated, according to their various and peculiar characters.

The philosophers generally allow two principles of bodies: *matter*, as the common basis or substratum of all; and *form*, as that which specifies and distinguishes each; and which, added to a quantity of common matter, determines or denominates it this or that; wood, or fire, or ashes, &c.

Substantial forms seem to have been first broached by the followers of Aristotle, who thought matter, under different modes or modifications, not sufficient to constitute different bodies; but that something substantial was necessary to set them at a greater distance; and thus introduced substantial forms, on the footing of souls, which specify and distinguish animals. What led to this erroneous notion was the circumstances of life and death: For observing, that, as soon as the soul was departed out of a man, all motion, respiration, nutrition, &c. immediately ceased, they concluded, that all these functions depended on the soul, and consequently that the soul was the form of the animal body, or that which constituted it such: that, the soul was a substance, independent of matter, no body doubted; and hence the forms of other bodies

were concluded equally substantial. But to this it is answered, that though the soul be that by which a man is man, and consequently is the form of the human body, as human; yet it does not follow, that it is properly the form of this body of ours, as it is a body: nor of the several parts thereof, considered as distinct from each other: For those several parts have their proper forms so closely connected with their matter, that it remains inseparable therefrom long after the soul has quitted the body: thus, flesh has the form of flesh, bone of bone, &c. long after the soul is removed as well as before. The truth is, the body does not become incapable of performing its accustomed functions because the soul has deserted it; but the soul takes its leave, because the body is not in a condition to perform its functions.

The ancient and modern corpuscular philosophers, therefore, with the Cartesians, exclude the notion of substantial forms: and show, by many arguments, that the form is only the modus or manner of the body it is inherent in. And as there are only three primary modes of matter, *viz.* figure, rest, or motion, with two others arising therefrom, *viz.* magnitude and situation, the form of all bodies they hold to consist therein: and suppose the variations these modes are capable of, sufficient to present all the variety observable in bodies.

Forms are usually distinguished into *essential* and *accidental*.

Essential. Though the five modes abovementioned, generally taken, be adventitious; yet to this or that body, *e. gr.* to fire or water, they are essential: thus, it is *accidental* to iron, to have this or that magnitude, figure, or situation, since it might exist in different ones; yet to a knife or hammer, the figure, magnitude, and position of parts, which constitute it a hammer or knife, are essential; and they cannot exist or be conceived without them. Hence it is inferred, that though there be no substantial, there are essential, forms, whereby the several species of bodies become what they are, and are distinguished from all others.

Accidental forms, are those really inherent in bodies, but in such manner as that the body may exist in all its perfection without them. Such is whiteness in a wall, heat in water, a figure of a man in wax, &c.

FORM is also used, in a moral sense, for the manner of being or doing a thing according to rules: thus we say, a form of government, a form of argument, &c.

FORM, in law, the rules established and requisite to be observed in legal proceedings—The formal part of the law, or method of proceeding, cannot be altered but by the supreme power; for if once these outworks were demolished, there would be an inlet to all manner of invocation in the body of the law itself.

FORM, in carpentry, is used to denote the long seats or benches in the choirs of churches or in schools, for the priests, prebends, religious, or scholars, to sit on. Du Cange takes the name to be derived from hence, that the backs of the seats were anciently enriched with figures of painting and sculpture, called in Latin *formæ et typi*. In the life of St William of Roschild, we meet with *forma* as signifying a seat for an ecclesiastic, or religious, in a choir; and in that of St Lupi-

Form.

Form
|
Forman.

Lupicin, we have formula in the same sense. In the rule of the monastery of St Cæsarea, the nun who presides over the choir is called *primiceria, vel formari*.

At schools, the word *form* is frequently applied to what is otherwise termed a *class*. See CLASS.

FORM also denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness.

FORM is also used among mechanics, for a sort of mould whereon any thing is fashioned or wrought.

PRINTERS *Form*, an assemblage of letters, words, and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press the printed sheets are drawn.

Every form is inclosed in an iron-chase, wherein it is firmly locked by a number of pieces of wood: some long and narrow, and others of the form of wedges. There are two forms required for every sheet, one for each side; and each form consists of more or fewer pages according to the size of the book.

Hatters *FORM*, is a large block or piece of wood, of a cylindrical figure; the top thereof rounded, and the bottom quite flat. Its use is, to mould or fashion the crown of the hat, after the matter thereof has been beaten and felled.

Paper-maker's *FORM*, is the frame or mould wherein the sheets are fashioned. See PAPER.

FORMA PAUPERIS, in law is when the person has just cause of suit, but is so poor that he cannot defray the usual charges of suing at law or in equity; in which case, on making oath that he is not worth L.5 in the world, on all his debts being paid, and producing a certificate from some lawyer that he has good cause of suit, the judge will admit him to sue in *forma pauperis*; that is, without paying any fee to counsellors, attorneys, or clerk: the statute 11 Hen. VII. c. 12. having enacted, that counsel and attorneys, &c. shall be assigned to such poor persons *gratis*. Where it appears that any pauper has sold or contracted for the benefit of his suit whilst it is depending in court such a cause shall be thenceforth totally dismissed and a person suing in *forma pauperis*, shall not have a new trial granted him, but is to acquiesce in the judgment of the court.

FORMAL, something belonging to or constituting the form of a thing. See FORM.

FORMALITY, the quality of a form, or formula, or that which constitutes and denominates them such.

FORMALITY, as defined in the schools, is any manner wherein a thing is conceived; or a manner in any object, importing a relation to the understanding, whereby it may be distinguished from another object. Thus, animality and rationality are formalities. The Scottists make great use of formalities, in opposition to the virtuality of the Thomists.

FORMALITIES, in matters of law are frequently used for the formulas themselves, or the rules prescribed for judicary proceeding. In contracts of strict law, all the formalities must be strictly observed: an omission of the least formality may ruin the whole convention.

The term is also used for a certain order, or decorum to be observed.

FORMAN (Andrew), archbishop of St Andrew's,

Forman.
 earl of Pittenweem, and of Cottingham in England, one of the lords of the regency appointed by the states during the minority of king James V. of Scotland, legate a-latere, Primate of all the kingdom of Scotland, and archbishop of Bourges in France, was descended from the family of the Formans of Hutton in the shire of Berwick, and is considered to have been one of the best statesmen of the age in which he lived. He was employed in 1514, along with Robert Blackader archbishop of Glasgow and Patrick earl of Bothwell, to negotiate a match between Ja. IV. of Scotland and Margaret eldest daughter of Hen. VII. of England: which next year was ratified by the Scottish ambassadors. He was afterwards frequently employed as Scots ambassador to Rome, England, and France upon the most important occasions. In 1514 he was translated from the see of Moray, to which he had been appointed in 1502, to that of St Andrew's. During the time of his possessing the former, he was employed as mediator betwixt Pope Julius II. and Louis XII. of France, who were at that time at variance; and he happily succeeded in conciliating the difference. Having taken leave of the Pope, he passed through France on his return home, where he was kindly received by the king and queen who bestowed upon him the bishopric of Bourges in France, which annually brought him in 400 tons of wine, 10,000 franks of gold, and other smaller articles. Besides all this he was most liberally rewarded by Pope Julius; who promoted him to the archbishopric of St Andrew's, as has been already mentioned: conferred on him the two rich abbeys of Dunfermline and Aberbrothick: and made him his legate a-latere. At that time, however there were two other candidates for the archiepiscopal see. The learned Gavin Douglas bishop of Dunkeld having been nominated by the queen, had actually taken possession of it; but John Hepburn, a bold and factious man, having been preferred by the monks, drove out the officers of Gavin Douglas, and placed a strong garrison in the castle. So great was the power of this man, that when Forman was nominated by the Pope, no person could be found who durst proclaim the bulls for his election. At last lord Home, at that time the most powerful nobleman in Scotland, was induced, by large promises, besides some gifts of great consequence, among which was the donation of the abbacy of Coldingham to his youngest brother David, to undertake the task. It was executed at Edinburgh and St Andrew's; to which places lord Home's brother went with 10,000 men; though the doing of it, contrary to Forman's inclination, proved a source of much trouble to that nobleman afterwards. The quarrel betwixt Hepburn and Forman, however, was at last terminated by the latter surrendering the bishopric of Moray, as well as some years revenue of the archbishopric itself; paying Hepburn also 3000 French crowns annually out of his ecclesiastical revenues. On the appointment of the duke of Albany to the regency, Hepburn endeavoured to undermine the primate's credit with that noblemen, by representing him as one who had in a manner collected all the money in the country, and who consequently might endanger the tranquillity of the kingdom. These insinuations, however, were but little regarded by the regent: and Forman had the good fortune afterwards to make up a

Formation
Formiæ.

difference between him and the nobility, which was likely to be attended with much bloodshed. In 1517 the archbishop was appointed by the states one of the lords of the regency, on occasion of the duke of Albany's going to France. We have already mentioned his embassy to Pope Julius II. In M^rKenzie's lives we are informed that in the collection of the Letters of the Scottish Kings from the year 1505 till the year 1626, in the lawyers library, there is a letter from that pope to king James IV. wherein he not only highly commends Forman, but likewise promises that at the first creation of cardinals he should be made one. This letter is dated the 6th of May 1511: but the pope died before he had an opportunity of performing his promise. In the same collection there is a letter from the duke of Albany to Leo X. Julius's successor, wherein he presses the pope to advance him to the dignity of a cardinal promised him by his predecessor, and to continue him his legate a-latere. Archbishop Forman died in 1521, and was buried at Dunfermline. Dempster says that he wrote a book against Luther, a book concerning the Stoic Philosophy, and a collection out of the Decretals.

FORMATION, in philosophy, an act whereby something is formed or produced.—For the formation of the foetus in the womb, see ANATOMY, n^o 109, 110.

FORMATION of Stones. See STONE.

FORMATION of Metals and Minerals. See METAL and MINERAL.

FORMATION, in grammar, signifies the manner of forming one word from another: thus *accountantship* is formed from *accountant*, and this last from *account*.

FORMEDON, in law, (*breve de forma donationis*), a writ that lies for a person who has a right to lands or tenements, by virtue of any entail, arising from the statute of Westm. 2 Ch. II.

This writ is of three kinds, viz. a descender, remainder and reverter. Formedon in *descender*, lies where a tenant in tail infeoffs a stranger, or is disseised and dies, and the heir may bring this writ to recover the lands. Formedon in *remainder*, lies where a man gives lands, &c. to a person in tail, and for default of issue of his body the remainder to another in tail: here if the tenant in tail die without issue, and a stranger abates and enters into the land, he in remainder shall have this writ. Formedon in *reverter*, lies where lands are entailed on certain persons and their issue, with remainder over for want of issue: and, on that remainder failing, then to revert to the donor and his heirs: in this case, if the tenant in tail dies without issue, and also be in remainder, the donor and his heirs, to whom the reversion returns, may have this writ for the recovery of the estate, though the same be alienated, &c.

FORMIÆ, or FORMIA, (anc. geog.), a maritime town of the Adjected or New Latium, to the south-east of Cajeta; built by the Lacedæmonians, (Strabo;) called originally *Hormiæ*, on account of its commodious harbour. An ancient municipium. *Formiani* the people who were admitted to the liberty of the city the very year in which Alexandria was built; but not to the right of suffrage till a long time after the second Punic war, (Livy). *Formiæ* at this day lies in ruins, near a place now called *Mola*.

FORMICA, or the ANT, in zoology; a genus of insects belonging to the order of hymenoptera, the characters of which are these: there is a small scale, betwixt the breast and belly and the joint is so deep, that the animal appears as if it were almost cut thro' the body. The females, and the neuters or working ants which have no sexual characteristics, are furnished with a hidden sting; and both the males and females have wings, but the neuters have none. There are 18 species most of them distinguished by their colours.

These insects keep together in companies like the bees, and maintain a sort of republic. Their nest is not exactly square, but longer one way than the other and in it there are a sort of paths, which lead to different magazines. Some of the ants are employed in making the ground firm, by mixing it with a sort of glue, for fear it should crumble and fall down upon them. They may be sometimes seen to gather several twigs, which serve them for rafters, which they place over the paths, to support the covering; they lay others across them, and upon them rushes, weeds, and dried grass, which they heap up into a double declivity, which serves to turn off the water from their magazines. Some of these serve to lay up their provisions, in and in others they lay their eggs.

As for the provisions, they lay up every thing that is fit for them to eat; and you may often see one loaded with pippin or grain of fruit, another with a dead fly, and several together with the carcase of a may-bug or other insect. If they meet with any they cannot bring away they eat it upon the spot, or at least so much of it as may reduce it to a bulk small enough for them to carry. They do not run about where they please, at all adventures: for some of them are sent abroad to make discoveries; and if they bring back news that they have met with a pear, or a sugar-loaf, or a pot of sweetmeats, they will run from the bottom of a garden, as high as the third story of a house, to come at it. They all follow each other in the same path, without wandering to the right or left; but in the fields they are more at their liberty, and are allowed to run about in search of game. There is a sort of green fly*, that does a great deal of mischief among the flowers, and which curls up the leaves of peach and pear trees: and these are surrounded with a sort of glue, or honey, which the ants hunt after very greedily; for they touch neither the plant nor the flies themselves. Next to this their greatest passion is to lay up hoards of wheat and other corn; and for fear the corn should sprout by the moisture of the subterraneous cells, they gnaw off the end which would produce the blade. The ants are often seen pushing along grains of wheat or barley much larger than themselves. It is remarkable, that if one ant meets another that is loaded, it always gives way to let it pass freely; or will help it if it be overburdened.

The ant lays eggs in the manner of the common flies; and from these eggs are hatched the larvæ, a sort of small maggots or worms without legs: these are sharp at one end and blunt at the other: and are white, but so transparent that the intestines are seen through the skin. These, after a short time, change into large white aureliæ, or chrysalids, which are what are usually called *ants eggs*. That end which is to be the tail is the

Formica.
Plate
CXCVI.

* The *Aphis*.

Formica. the largest, and that which is the head is somewhat transparent. The ants move these about at pleasure with their forceps. It is well known, that when a nest of these creatures is disturbed, and the aureliæ scattered about, the ants are at infinite pains to get together all that are unhurt, and make a nest for them again: nay, any ants will do this, and those of one nest will often take care of the aureliæ of another.

The care these creatures take of their offspring is remarkable. Whenever a hill is disturbed, all the ants are found busied in consulting the safety, not of themselves, but of the eggs or those larger bodies inclosing the maggot or young ant; they carry these down any way so as to get them out of sight, and will do this over and over as often as they are disturbed. They carry away the eggs and vermicles together in their confusion; but, as soon as the danger is over, they carefully separate them, and place each sort in parcels by themselves under shelter of different kinds, and at various depths, according to the different degrees of warmth and coverture the different states require. In the warm season of the year, they every morning bring up the eggs, as they are usually called, to the surface, or nearly so; and from ten in the forenoon to five in the afternoon, or thereabouts, all these will be found just under the surface: and if the hills be examined towards eight in the evening, they will be found to have carried them all down; and if rainy weather be coming on, it will be necessary to dig a foot deep or more, in order to find them. All human precautions have not hitherto been able to supply that degree of warmth and minute attention which the ants put in practice to forward the instant of their last metamorphosis. The insect, issuing forth to a new life, tears its white transparent veil; it is then a real ant, destitute of wings, if it has no sex; winged, if it be male or female, always to be known by a small erect scale placed on the thread which connects the body and thorax. Ants transact their amours in the air. The males, who are much smaller, seldom frequent the common habitation: but the females much larger, repair to it to deposit their eggs, which is all the labour they undergo; the winter's cold destroys them. As to the males it is uncertain whether they fall victims to the severity of winter, or are made over to the rage of the labouring ants.—These last pass the winter in a torpid state, as some other insects do, till spring restores them to their wonted activity: they have therefore no stores for winter, no consumption of provisions. What are commonly sold in markets for ant's eggs, are grubs newly hatched, of which pheasants, nightingales, and partridges, are very fond. The chief enemies to ants are the *formica leo*, magpies, and some other birds and beasts.

In the hotter countries, as Italy, Spain, and the West-Indies, ants are the greatest pest of the fields. Trees, which they are said to injure greatly, may be preserved from them by encompassing the stem, for four fingers breadth, with a roll of wool, newly pulled from the sheep's belly; or by laying saw-dust all round the stump of it. Some anoint the tree with tar, which has the same effect. But whatever harm they may do in pasture-lands, by making up hills for their habitation and imparing or drying up the grass, their damaging fruit-trees appears to be an unjust reproach.—On the contrary, in Switzerland they are made sub-

servient to the destruction of caterpillars. This is *Formica* done by hanging a pouch filled with ants upon a tree; and they, making their escape through an aperture contrived on purpose, run over the tree without being able to reach down to the ground, because care has been previously taken to besmear the foot of the tree with wet clay or soft pitch; in consequence of which, compelled by hunger, they fall upon the caterpillars and devour them. People pretend to say, that ants, taken inwardly, give a spring to the urinary ducts and to the organs of generation. The red colour which they communicate to blue paper, when crushed upon it, proves that they contain an acid (see CHEMISTRY, n^o 2d 907).

The large, black, winged ants of America, to avoid the great rains which fall there at particular seasons, make to themselves large nests on trees, with a covered way for them to go up and down on the lee-side of the tree. These nests are roundish on the outside, made of light brown earth, plastered smooth. They are larger than a bushel; and in the inside are many sinuous caverns or lodgings communicating with one another. See Plate CXCVI. A, The ants nest; B, The tubular passage, made of the same materials.

As to those insects called *white ants*, which abound in Africa and the East-Indies, they belong to a different genus; for which see the article TERMES.

FORMICA-LEO, the *Ant-Lion*, in zoology, an insect so called from its devouring great numbers of ants. It is the caterpillar or worm of a fly much resembling the libellæ or dragon-flies: and feeds chiefly upon ants, from which property it derives its name.

It is somewhat of the nature of the spider in its way of taking its prey, its manner of spinning, and the figure and softness of its body. It has, in its general figure, somewhat of the appearance of the millepes or wood-louse, so that some have mistaken it at first sight for that animal. It is of a dirty greyish colour, marked with some black spots; and these are also composed of many points when viewed with a microscope, which make it resemble a hedge-hog or porcupine. Its body is composed of several small rings, and has thence a wrinkled look. It has six legs, four are joined to the breast, and the other two to a longer part, which may be taken for its neck. Its head is small and flat, and it has two remarkable horns: these are about a sixth part of an inch long, and as thick as a hair: they are hard, hollow, and hooked at end like the claws of a cat. At the origin of each of these horns, it has a clear and bright black eye, which sees very distinctly, and gives the creature notice to escape on the sight of the smallest object.—This creature is not able to hunt after its prey, nor to destroy large insects; it can only draw into its snares such as come near its habitation, and of these very few are such as he can manage: all the winged kind are able to escape by flight; and the beetle kinds, and others that have hard shells upon their bodies, are of no use to him, as his horns cannot pierce them. The smallness of the ant, and the want of wings in the nenters, make them the destined prey of this devourer. The manner in which he catches his prey is as follows.

He usually encamps under an old wall, that he may be sheltered from the injuries of the weather; and he always chooses a place where the soil is composed of a fine dry sand. In this he makes a pit of the shape of

Formica.

a funnel, or an inverted hollow cone. If he intends the pit to be but small, he thrusts down his hinder part into the sand, and by degrees plunges himself backward into it; and when he has got to a certain depth, he tosses out the loose sand which has run down with his head, artfully throwing it off beyond the edges of his pit. Thus he lies at the bottom of a small hollow, which is widest at the top, and comes sloping down to his body.

But if he is to make a larger pit, more pains are required to bring it to perfection. He first traces, in the surface of the sand, a large circle, which is the erected base or mouth of the pit he is to make in form of an inverted cone. He then buries himself in the sand near the edge of this circle, and carefully throws up the sand above him, with his head tossing it out beyond the circumference of the circle. Thus he continues his work, running down backwards in a spiral line all the way, and carefully throwing off the sand from above him, till he is come to the place of his rest, which is the point or reverted apex of the hollow cone he has formed by his passage. The length of his neck, and the flatness of his head, gives him a power of using the whole as a spade, and throwing off the sand with great ease; and his strength in this part is so great, that he is able to throw off a quantity of it to six inches distance. This is a power he exerts oftner, however, in throwing away the remains of the animals he has fed upon, that his den may not become frightful to others of the same species, by seeing their fellow carcasses about it.

When he has finished his pit, he buries himself at the bottom of it among the sand, leaving no part above ground but the tips of his two horns, which he expands to the two sides of the pit. In this condition he lies and waits for his prey, and never comes up afterwards. When an ant, or any other such creature, chances to walk over the edges of his pit, its steps throw down a little of the sand, which naturally running down to the bottom of the pit, gives the enemy notice of his prey; he then tosses up the sand which covers his head, to bury the ant, and bring him down with its returning force to the bottom; and as one such attempt cannot be sufficient to prevent the ant's escape, he throws more and more sand upon him, till he by degrees brings him down. All the endeavours of the ant to escape, when once it is within the verge of the pit, are in vain; for as it attempts to climb, the sand runs away from under its feet, and it sinks the lower for every attempt. This motion of the sand also informs the enemy where it is, and directs him to throw up more sand in the right place; which it does, till the poor ant falls to the bottom between its horns. It then plunges the points deep into the ant's body; and having sucked all the juice out of the prey, it throws out the empty skin as far from the hole as it can. This done, it mounts up the edges of its pit, and if it has suffered any injury, repairs it with great care, and immediately buries itself again in the centre, to wait for another meal. The horns of this creature are its only organs for receiving nourishment; it never brings any animal which it has seized near to its head, but always holds it at the tip of the horns. They therefore plainly serve as syringes, to draw into its stomach the juices of the bodies of the insects it feeds upon: neither is there any mouth or

Formica.

trunk, or any other organ to be discovered about its head, which could serve the purpose of eating; the head seeming only intended for throwing away the sand in forming the pit. The horns of this animal being so necessary to its life, nature has provided for the restoring them in case of accidents; and, if cut off, they are found to grow again.

The food this creature procures by its pit can be but little; and as it has no power of catching its prey any other way, its motion being only backwards, and that slowly, and by small spaces at a time, some people have believed its catching now and then an ant by this means was rather for diversion than hunger. But though the formica-leo will live a long time without food, and even pass through all its changes when shut up in a box, yet it is always ready to eat when food is offered it; it always appears starved and small when kept thus; and if a fly is given it in this hungry state, it will so suck out all its juices, that the shell remaining may be rubbed to powder between the fingers, while the body of the creature that has sucked it appears remarkably swelled and distended; so that it is plain that the juices of the prey are conveyed into the body of the creature; though it is not easy to see by what means, the horns not appearing to have any perforation.

When the formica-leo has lived a proper time in this state, it leaves its pit, and is only seen drawing lines and traces on the surface of the sand. After this it buries itself under the surface; and there incloses itself in a fine web, in which it is to pass its transformation into the winged state. This case is made of a sort of silk which the creature spins in the manner of the spider, and of a quantity of the grains of sand cemented together by a glutinous humour which flows from its pores. This case, however, would be too harsh and coarse for the body of the creature, and therefore it serves only for the outer covering to defend it from injuries; the creature spinning one of pure and incomparably fine silk, of a beautiful pearl colour, within it, which covers its whole body.

When the creature has lain some time in this case, it throws off its outer skin, with the eyes, the horns, and every other part necessary to its life before, and becomes an oblong nymph, in which a careful eye may trace the form of the fly into which it is to be transformed. There may be seen, through its transparent covering, new eyes, new horns, wings, and all the other parts of the animal in its perfect state. This nymph makes its way about half out of the shell, and remains in this condition, but without farther life or motion, till the perfect fly makes its way out at a slit in the back. In this last state it much resembles the libellæ or dragon-flies common about the waters. The male couples with the female in this state only; and M. Poupert, to whom the world is obliged for this curious description, is of opinion, that the females lay only one egg; but this is very different from the course of nature in the other animals of the same class.

When this insect forms its pit in a bed of pure sand, it is made and repaired with great ease; but where it meets with other substances among the sand, the labour becomes greatly the more embarrassing. If, for instance, when the creature has half formed its pit, and then comes to a stone of some moderate size, it does not desert the work for this, but goes on, intending to

remove

Forming. remove that impediment at last. When the pit is finished, the creature crawls backward up the side of the place where the stone is, and getting its backside under it, takes great pains and time to get it on a true poise, and then begins to crawl backward with it up the edge to the top of the pit, to get it out of the way. It is a very common thing to see a formica-leo in this manner labouring at a stone four times as big as its own body; and as it can only move backward, and the poise is hard to keep, especially up a slope of such crumbly matter as sand, which moulders away from under its feet, and necessarily alters the position of its body, the stone very frequently falls down when near the verge, and then it is sure to roll to the bottom. In this case the animal attacks it again in the same way, and often is not discouraged by five or six miscarriages of this kind; but, after all, attempts again, and at length gets it over the verge of the place. When it has done this, it does not leave it there, lest it should roll in again: but is always at the pains of pushing it farther on, till it has removed it to a necessary distance from the edge of the pit.

The common formica-leo moves only backward; but Mr Brouet has observed a species which moves forward in the common way of other animals, and makes no pit of this kind to entrap its prey, but seizes other insects by force.

FORMING is used for the act of giving being or birth to any thing.

The word is also simply used for giving the figure to any thing. The potter forms his vessels as he pleases. Geometry teaches how to form all kinds of figures.

It is likewise used for the producing of a thing: thus, the lineaments of the face began to be formed.

FORMING of a Siege, is the making lines of circumvallation to fortify the camp, and disposing things for the attack of a place in form.

They also say, to form a squadron or battalion; meaning, to range the soldiers in form of a squadron, &c.

FORMING the Line, is drawing up infantry, cavalry, and artillery, into line of battle. See **LINE**.

FORMING is also used in grammar, in speaking of certain tenses of verbs, which are made from others by a change of certain letters. The present tense is formed from the infinitive. Compound and derivative words also and even all that have any etymology, are said to be formed.

FORMOSA, an island in the Pacific Ocean, between, 119° and 122° of E. Long. and 22° and 25° N. Lat. about 100 miles east of Canton in China. It is subject to the Chinese; who, however, notwithstanding its vicinity, did not know of its existence until the year 1430. It is about 85 leagues in length, and 25 in breadth. A long chain of mountains which runs from north to south, divides it into two parts, the eastern and western. The Dutch formed an establishment in the western part in 1634, and built the fort of Zealand, which secured to them the principal port of the island; but they were driven from thence in 1659 or 1661 by a celebrated Chinese pirate, who made himself master of all the western part, which afterwards submitted in 1682 to the authority of Kang-he emperor of China.

This western part of Formosa is divided into three distinct governments, all subordinate to the governor of **TAI-OUAN**, the capital of the island, who is himself subject to the viceroys of the province of **FOKIEN**.

This island presents extensive and fertile plains, watered by a great number of rivulets that fall from the eastern mountains. Its air is pure and wholesome; and the earth produces in abundance corn, rice, and the greater part of other grains. Most of the Indian fruits are found here, such as oranges, bananas, pine-apples, guavas, papaws cocoa-nuts; and part of those of Europe, particularly peaches, apricots, figs, raisins, chestnuts, pomegranates, water-melons, &c. Tobacco, sugar, pepper, camphire, and cinnamon, are also common. Horses, sheep, and goats, are very rare in this island: there are even few hogs, although these animals abound in China. Domestic poultry, such as fowls, geese, and ducks, are exceedingly plenty; pheasants also are sometimes seen; and monkeys and stags, have multiplied so much, that they wander through the country in large flocks.

The inhabitants of Formosa rear a great number of oxen, which they use for riding, for want of horses and mules. They accustom them early to this kind of service, and by daily exercise train them to go as well and as expeditiously as the best horses. These oxen are furnished with a bridle, saddle, and crupper. A Chinese looks as big and proud when mounted in this manner as if he were carried by the finest Barbary courser.

Wholesome water fit for drinking is the only thing wanting in the island of Formosa. It is very extraordinary, that every kind of water in it is a deadly poison to strangers, for which no remedy has hitherto been found. "One of the governor's servants," says Father de Mailla, "whom I had in my train (a strong and robust man, trusting too much to the force of his constitution, would not believe what had been told him concerning this water: he drank some of it: and died in less than five days, after every medicine and antidote had been administered without success. There is none but the water of the capital which can be drunk: the mandarins of the place therefore always took care to transport a sufficiency of it in carts for our use." Our author adds, that at the bottom of a mountain a league distant from Fong-kan-hien, there is a spring that produces a stream, the water of which is of a whitish blue colour, and so noxious, that no one can approach it.

There are few mulberry-trees in Formosa, consequently little silk is made in the country. Numerous manufactures however, would soon be introduced into it, were the Chinese permitted indiscriminately to transport themselves thither, and to form establishments in the island. Those who go to it must be protected by passports from the Chinese mandarins, and these passports are sold at a dear rate: securities are besides required. This is not all: when they arrive, money must be given to the mandarins who are appointed to examine those who enter or quit the island, and who generally discharge this duty with the most rigid severity. If they give no present, or offer only a trifle they meet with little mercy; and are sure to be sent back, whatever passport they may have. The Chinese through policy, connive at these exactions, to prevent

Formosa. too great a number of people from emigrating to this island, which is rendered a place of great importance by its proximity to China. They fear, and with great reason (especially since Tartar emperors have been on the throne), that if any revolt should happen in Formosa, its influence might spread and occasion great disturbance in the whole empire. On this account, the Tartars keep a garrison there of 10,000 men; which they take care to change every three years, or even oftener if they judge it necessary.

Besides the capital, the Chinese have also two other cities, and some villages, where they inhabit alone; for they do not permit the Indians, who are their subjects, to live among them; they suffer none to remain but those who are either their slaves or domestics. These Indians are united into 45 villages; 36 of which lie to the north, and 9 towards the south. The northern villages are very populous, and the houses are built almost after the Chinese manner. The habitations of the southern islanders are only heaps of huts or cottages of earth. In these huts they have neither chairs, benches, tables, beds, nor any piece of furniture; the middle part is occupied by a kind of hearth or chimney, raised two feet high, and constructed of earth, upon which they dress their victuals. Their ordinary food is rice, other small grain, and the game which they catch by coursing or kill with their arms. These islanders run with such surprising swiftness, that they can almost outstrip the fleetest greyhound. The Chinese attribute this agility to the precaution they take of confining their knees and reins by a close bandage until the age of 14 or 15. Their favourite arms are lances, which they dart to the distance of 60 or 80 feet with the greatest dexterity and precision. They use bows and arrows, and can kill a pheasant on wing with as much certainty as an European sportsman could with a fusée. These people are very dirty in their manner of eating. They have neither plates, dishes, nor spoons, nor even the small sticks used in China. Whatever they dress is placed on a plain board or mat, and they make use of their fingers for conveying it to their mouths. They eat flesh half raw; and provided it has been only presented to the fire, it appears to them excellent. Their beds are formed of fresh-gathered leaves. They go almost naked, and wear only a piece of cloth which hangs from their girdle to their knees. Those among them who, according to the judgment of the chiefs of the village, have borne away the prize for agility in running or dexterity in the chase, obtain the honourable privilege of making on their skin, by a very painful operation, several fantastical figures of flowers, trees, and animals. All have the right of blackening their teeth, and of wearing ornaments of bracelets and crowns made of shells and crystal.

The islanders who inhabit the northern part, where the climate is something colder, clothe themselves with the skins of the stags which they kill in hunting. They make a kind of dress of them without sleeves, that pretty much resembles a dalmatic, or vestment worn at the altar by the Roman clergy. They wear on their heads caps in the form of a cylinder, made of palm-leaves, and ornamented with several crowns placed one above another, on the top of which they fix plumes composed of the feathers of a cock or pheasant.

Formosa. The marriage ceremonies of the inhabitants of Formosa approach near to the simple laws of nature. They neither purchase, as in China, the women whom they espouse, nor does interest ever preside over their unions. Fathers and mothers are scarcely ever consulted. If a young man has a mind to marry, and has fixed his affection on a young girl, he appears for several days following near the place where she lives with a musical instrument in his hand. If the young woman is satisfied with the figure of her gallant, she comes forth and joins him: they then agree, and settle the marriage-contract. After this they give notice to their parents, who prepare a wedding-dinner, which is always given in the house where the young woman resides, and where the bridegroom remains without returning again to his father. The young man afterwards considers the house of his father-in-law as his own. He becomes the whole support of it, and he has no farther connection with that of his father; like married women in Europe, who generally quit their paternal home in order to live with their husbands. These islanders therefore seldom offer up vows for obtaining male children: they prefer daughters, because they procure them sons-in-law, who become the supports of their old age.

Although the Formosans are entirely subjected to the Chinese, they still preserve some remains of their ancient government. Each village chooses three or four old men from among those who have the greatest reputation for probity. By this choice they become the rulers and judges of the rest of the hamlet. They have the power of finally determining all differences; and if any one should refuse to abide by their judgment, he would be immediately banished from the village, without hopes of ever being able to re-enter it, and none of the inhabitants would afterwards dare to receive him.

The natives pay in grain the tribute imposed on them by the Chinese. To regulate every thing that concerns the laying on and collecting of this impost, government have established a Chinese in every village, who is obliged to learn the language, and act as interpreter to the mandarins. These interpreters are most cruel extortioners to the miserable people, whom they ought rather to protect: they are such insatiable leeches, that they can scarcely ever be satisfied. This daily and domestic tyranny has already caused the defection of three villages in the southern part of the island, where formerly there were twelve. The inhabitants of these villages revolted, expelled their interpreters, refused to pay tribute any longer to the Chinese, and have united themselves to the independent nation in the eastern part of the island.

It was in the island of Formosa that John Struys affirms to have seen with his own eyes a man who had a tail more than a foot in length, covered with red hair, and greatly resembling that of an ox. This man with a tail said, that his deformity, if it was one, proceeded from the climate, and that all those of the southern part of the island were born with tails like his.—But John Struys is the only author who attests the existence of this extraordinary race of men; no other writer who has spoken of Formosa makes the least mention of them. Another circumstance, no less singular, and which appears to be little better authenticated,

Formosa. ticated, is, that in this island women are not permitted to bring forth children before they are 35, although they are at liberty to marry long before that age. Rechteren * thus expresses himself concerning this strange custom:

* *Dutch East India Company Voyages*, vol. v. p. 96.

“When women are first married, they bring no children into the world; they must, before that is permitted, have attained the age of 35 or 37. When they are big with child, their priestesses pay them a visit, and tread on their bellies with their feet, if it be necessary, and make them miscarry, with perhaps greater pains than they would have in being brought to bed. It would be not only a shame, but an enormous crime, to bring forth a child before the term prescribed. I have seen some females who had already destroyed the fruit of their womb 15 or 16 times, and who were big for the 17th when it was lawful for them to bring forth a living child.”

To our description of Formosa we shall add the following account of the dreadful disaster that lately befel this unhappy island. The details were conveyed by a letter from Peking, addressed to M. Bertin, and dated the 14th of July 1782.

“The waters of the ocean have well nigh deprived China of one of its most valuable maritime possessions. The island of Tay-ouan, known in Europe by the name of Formosa, has been almost swallowed up by them. It has been reported here, that part of the mountain which divides the island, has sunk and disappeared; that the rest has been overturned; and that the greater part of the inhabitants have perished. Such have been for some days the popular reports in this capital. Government, however, has put a stop to them, by informing the public of the real truth; such as it has been announced to the emperor by the officers who have this small portion of his territories under their jurisdiction. I cannot do better than transcribe what they have written. The dispatches of the Chinese officers addressed to the emperor, run thus:

“Bechen, governor-general of the provinces of Fokien and Tche-Kyang-ya, viceroy of Fokien, and others, make known to your majesty the disaster that has lately befallen the island of Tay-ouan. Mon-hahon, and other principal officers of this island, have acquainted us, that on the 21st of the fourth moon (May 22d, 1782), a most furious wind, accompanied with heavy rain and a swell of the sea greater than ever remembered, had kept them under continual apprehension of being swallowed up by the waves, or buried in the bowels of the earth, from the hour of *yn* until the hour *ouei* (A). This dreadful tempest seemed to blow at the same time from the four cardinal points of the compass, and continued with equal violence during the abovementioned time. The buildings where the tribunals were held, the public granaries, the barracks, salt warehouses, and works, have been totally destroyed, and every thing they contained is lost: warehouses and work-shops, as well as private houses, for the most part, present nothing but ruins and heaps of rubbish. Of 27 ships of war which were in the harbour 12 have disappeared; two others have been dashed to pieces,

VOL. VII.

and 10 are shattered in such a manner that they are rendered entirely unfit for service; other smaller vessels of different sizes, above 100 in number, have shared the same fate; eighty have been swallowed up; five others, which had just taken in a lading of rice for Fokien, have sunk, and their cargoes, which amounted to 100,000 bushels, are wholly lost. With regard to other vessels, whether small or great, which had not entered the harbour, 10 or 12 of the largest are reckoned to have been swallowed up; those of inferior size, as well as a prodigious number of barks, boats, and other small vessels of different kinds, have disappeared, without leaving the least piece of wreck behind them. As the whole island has been covered with water, the provisions have been either swept away or spoilt, so as to render them prejudicial to the health of those who use them in their present state. The crops are entirely lost. When we shall have been informed of particulars, we shall not fail to give your majesty the earliest intelligence of them.—After having received this letter from Mon-hahon, and the other principal officers residing at Tay-ouan, I employed the utmost diligence to give every assistance in my power to this unfortunate island; and I ordered the travelling commissary, and Trey-ouer, general of the province, to get particular information of the number of those who have perished, of the houses destroyed, and of the quantity of salt and other provisions that have been lost: I have likewise enjoined them to rebuild with the utmost expedition the tribunals, granaries, and other public edifices; to dispatch proper persons to search for the vessels and ships that have disappeared; to repair those which are not altogether unfit for service, and to send immediately to the neighbouring countries for salt and other necessary provisions; but above all, to ascertain in the most accurate manner the different losses sustained by the inhabitants, and the precise number of people that have perished, in order that I may be able to give the fullest information to your majesty.”

“The emperor of China caused a particular detail of these losses to be published, together with the following letter:

“Tchang-yu, &c. Tchem-hoei-Thon-Tsong-tou of Fokien, and others, have informed me of the dismal event that hath taken place in the island of Tay-ouan, which is a district of the province of Fokien. They have written to me, that on the 21st of the fourth moon. [Here the emperor repeats what is contained in the preceding letter, and continues thus]: I command Tsong-tou to get the best information he can of the different losses sustained by the inhabitants of the island, and to transmit the particulars to me, in order that I may give them every assistance to repair them. My intention is, that all the houses which have been thrown down shall be rebuilt entirely at my expence; that those be repaired which are only damaged; and that provisions, and every thing which the people stand in immediate want of, be supplied them. I should feel much pain, were even one among them to be neglected: I therefore recommend the utmost diligence

Y y

ligence

ligence and strictest inquiry, as I am desirous that none of my subjects should entertain the least doubt of the tender affection which I have for them; and that they should know that they are all under my eyes, and that I myself will provide for their wants. With regard to my ships of war, tribunals, and public edifices, let them be restored to their former state with money taken from the public treasury, and let the general account of the whole expence be laid before me."

The missionary who sent this account farther says, from these letters it evidently appears, that this disaster happened in consequence of an earthquake; but he adds, that the volcano which occasioned it must be at a prodigious depth below the sea. He does not pretend to give an explanation of it; he is contented with observing, that the same scene seems to have passed at the island of Formosa as at Lima and Lisbon.

FORMULA, or FORMULARY, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

FORMULA, in church-history and theology, signifies a profession of faith.

FORMULA, in medicine, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consistence.

FORMULARY, a writing, containing the form or formula of an oath, declaration, attestation, or abjuration, &c. to be made on certain occasions.

There are also formularies of devotion, of prayers, &c. Liturgies are formularies of the public service in most churches.

FORNACALIA, or FORNICALIA, in Roman antiquity, a festival instituted by Numa, in honour of Fornax, the goddess of ovens; wherein certain cakes were made, and offered in sacrifice before the ovens.

FORNICATION (*Fornicatio*, from the *fornices* in Rome, where the lewd women prostituted themselves for money), is whoredom, or the act of incontinency, between single persons; for if either of the parties is married, it is *adultery*. Formerly court-leets in England had power to inquire of and punish fornication and adultery; in which courts the king had a fine assessed on the offenders, as appears by the book of Domesday.

In the year 1650, when the ruling powers found it for their interest to put on the semblance of a very extraordinary strictness and purity of morals, not only incest and wilful murder were made capital crimes, but also the repeated act of keeping a brothel, or committing fornication, were (upon a second conviction) made felony without benefit of clergy. But, at the restoration, when men, from an abhorrence of the hypocrisy of the late times, fell into a contrary extreme of licentiousness, it was not thought proper to renew a law of such unfashionable rigour. And these offences have been ever since left to the feeble coercion of the spiritual court, according to the rules of the canon law; a law which has treated the offence of incontinence, nay, even adultery itself, with a great degree of tenderness and lenity; owing perhaps to the constrained celibacy of its first compilers. The temporal courts therefore take no cognisance even of the crime of adultery otherwise than as a private injury. See ADULTERY.

The evils of fornication, which too many wish to

consider as no sin, may be judged of from the following particulars.

1. The malignity and moral quality of each crime is not to be estimated by the particular effect of one offence, or of one person's offending, but by the general tendency and consequence of crimes of the same nature. In the present case, let the libertine consider and say, what would be the consequence, if the same licentiousness in which he indulges were universal? or what should hinder its becoming universal, if it be innocent or allowable in him?

2. Fornication supposes prostitution; and by prostitution the victims of it are brought to almost certain misery. It is no small quantity of misery in the aggregate, which, between want, disease, and insult, is suffered by those outcasts of human society who infest populous cities; the whole of which is a general consequence of fornication, and to the increase and continuance of which every act and instance of fornication contributes.

3. Fornication produces habits of ungovernable lewdness, which introduce the more aggravated crimes of seduction, adultery, violation, &c. The criminal indulgences between the sexes prepare an easy admission for every sin that seeks it; they are, in low life, usually the first stage in mens progress to the most desperate villainies; and in high life, to that lamented dissoluteness of principle, which manifests itself in a profligacy of public conduct, and a contempt of the obligations of religion and moral probity.

4. Fornication perpetuates a disease, which may be accounted one of the worst maladies of human nature, and the effects of which are said to visit the constitution of even distant generations.

The passion being natural, proves that it was intended to be gratified; but under what restrictions, or whether without any, must be collected from different considerations.

In the Scriptures, fornication is absolutely and peremptorily condemned. 'Out of the heart proceed evil thoughts, murders, adulteries, fornication, thefts, false witness, blasphemies; these are the things which defile a man.' These are Christ's own words; and one word from him upon the subject is final. The apostles are more full upon this topic. One well-known passage in the Epistle to the Hebrews may stand in the place of all others; because, admitting the authority by which the apostles of Christ spake and wrote, it is decisive. 'Marriage and the bed undefiled is honourable amongst all men, but whoremongers and adulterers God will judge; which was a great deal to say, at a time when it was not agreed even amongst philosophers that fornication was a crime.

Upon this subject Mr Paley adds the following observations*.

"The Scriptures give no sanction to these austerities which have been since imposed upon the world under the name of Christ's religion, as the celibacy of the clergy, the praise of perpetual virginity, the *prohibitio concubitus cum gravida uxore*; but with a just knowledge of, and regard to the condition and interest of the human species, have provided in the marriage of one man with one woman an adequate gratification for the propensities of their nature, and have restrained them to that gratification.

"The avowed toleration, and in some countries the licensing, taxing, and regulating of public brothels, has appeared to the people an authorizing of fornication, and has contributed, with other causes, so far to vitiate the public opinion, that there is no practice of which the immorality is so little thought of or acknowledged, although there are few in which it can more plainly be made out. The legislators who have patronized receptacles of prostitution ought to have foreseen this effect, as well as considered, that whatever facilitates fornication, diminishes marriages. And as to the usual apology for this relaxed discipline, the danger of greater enormities if access to prostitutes were too strictly watched and prohibited; it will be time enough to look to that, after the laws and the magistrates have done their utmost. The greatest vigilance of both will do no more, than oppose some bounds and some difficulties to this intercourse. And after all, these pretended fears are without foundation in experience. The men are in all respects the most virtuous in countries where the women are most chaste.

"If fornication be criminal, all those incentives which lead to it are accessaries to the crime; as lascivious conversation, whether expressed in obscene or disguised under modest phrases; also wanton songs, pictures, books; the writing, publishing, and circulating of which, whether out of frolic or for some pitiful profit, is productive of so extensive a mischief from so mean a temptation, that few crimes within the reach of private wickedness have more to answer for, or less to plead in their excuse.

"Indecent conversation, and by parity of reason all the rest, are forbidden by St Paul, Eph. iv. 29. 'Let no corrupt communication proceed out of your mouth; and again, Col. iii. 8. 'Put filthy communication out of your mouth.'

"The invitation or voluntary admission of impure thoughts, or the suffering them to get possession of the imagination, falls within the same description, and is condemned by Christ, Matt. v. 28. 'Whosoever looketh on a woman to lust after her, hath committed adultery with her already in his heart.' Christ, by thus enjoining a regulation of the thought, strikes at the root of the evil."

FORNIX, in anatomy, is part of the corpus callosum in the brain; so called, because of a distant resemblance it hath to the arches of ancient vaults when viewed in a particular manner.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, grass, clover, &c. brought into the camp by the troopers, for the sustenance of their horses.

It is the business of the quarter-master general to appoint the method of forrage, and post proper guards for the security of the foragers.

FORRES, a parliament town of Scotland in the county of Murray, classing with Inverness, Fortrose, and Nairn. It is a small well-built town, pleasantly situated on an eminence near the river Findhorn. The country about it has a cheerful appearance, having a few gentlemen's seats, with some plantations about them. On a hill west of the town are the remains of a castle; and a melancholy view of a number of sand-hills, that now cover that tract of land which was formerly the estate of a Mr Cowben in the parish of Dyke. This inundation was occasioned by the influx

of the sea and the violence of the wind. It had been the custom to pull up the bent, a long spiry grass near the shore for litter for horses, by which means the sand was loosened, and gave way to the violence of the sea and wind, which carried it over several thousand acres of land. The people having being prevented from pulling up any more of the grass, the progress of the sand is now nearly stopped, and the sea has retired; but the wind has blown some of the sand from the hills over Colonel Grant's land, and destroyed near 100 acres. A sand-bank, which is all dry at low-water, runs out from this place for several miles into the Murray-Firth. Some of the land, which has been long forsaken by the water is now beginning to be useful again, and is turned into grazing land. At Forres, coarse linen and sewing thread are made. About a mile from the town, on the left-hand side of the road, is a remarkable obelisk, said to be the most stately monument of the Gothic kind to be seen in Europe. It has been the subject of many able pens; but totally overlooked by Dr Johnson, who says, "At Forres, we found good accommodation, but nothing worthy of particular remark."—It is thus described by Mr Cordiner, in a letter to Mr Pennant: "In the first division, underneath the Gothic ornaments at the top, are nine horses with their riders, marching forth in order: in the next is a line of warriors on foot, brandishing their weapons, and appear to be shouting for the battle. The import of the attitudes in the third division is very dubious, their expression indefinite. The figures which form a square in the middle of the column are pretty complex but distinct; four serjeants with their halberds guard a company, under which are placed several human heads, which have belonged to dead bodies piled up at the left of the division; one appears in the character of executioner severing the head from another body; behind him are three trumpeters founding their trumpets, and before him two pair of combatants fighting with sword and target. A troop of horse next appears, put to flight by infantry, whose first line have bows and arrows; the three following, swords and targets. In the lowermost division now visible, the horses seem to be seized by the victorious party, their riders beheaded, and the head of their chief hung in chains or placed in a frame; the others being thrown together beside the dead bodies under an arched cover. The greatest part of the other side of the obelisk, occupied by a sumptuous cross, is covered over with an uniform figure, elaborately raised and interwoven with great mathematical exactness. Under the cross are two august personages, with some attendants, much obliterated, but evidently in an attitude of reconciliation; and if the monument was erected in memory of the peace concluded between Malcolm and Canute, upon the final retreat of the Danes, these large figures may represent the reconciled monarchs. On the edge below the fretwork are some rows of figures joined hand-in-hand, which may also imply the new degree of confidence and security which took place, after the feuds were composed, which are characterized on the front of the pillar. But to whatever particular transaction it may allude, it can hardly be imagined, that in so early an age of the arts in Scotland as it must have been raised, so elaborate a performance would have been undertaken but in consequence of an event

Forres.

||
Vitrified
Forts.

of the most general importance; it is therefore surprising, that no distinct traditions of it arrived at the era when letters were known. The height of this monumet (called *King Sueno's stone*) above the ground is 23 feet; besides 12 or 15 feet under ground. Its breadth is 3 feet 10 inches by 1 foot 3 inches in thickness."

FORSKOHLEA, in botany: A genus of the pentagynia order, belonging to the decandria class of plants. The calyx is pentaphyllous, and longer than the corolla. There are ten petals spatulated, *i. e.* roundish before, with a linear base.

FORESTERA, in botany: A genus of the triandria order, belonging to the gynandria class of plants. The perianthium is double; the exterior one beneath three leaved; the exterior one above, and six-cleft; the corolla tubular.

FORT, in the military art a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground, or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-bastions. Some again are in form of a square, others of a pentagon. A fort differs from a citadel, as this last is built to command some town.

Vitrified Forts, a very singular kind of structures found in the highlands and northern parts of Scotland, in which the walls have the appearance of being melted into a solid mass, so as to resemble the lava of a volcano, for which indeed they have been taken by several persons who have visited them.

These walls were taken notice of by Mr Williams an engineer, who wrote a treatise upon the subject, and was the first who supposed them to be the works of art; other naturalists having attributed them to a volcanic origin. These works are commonly situated on the tops of small hills, commanding an extensive view of the adjacent valley or low country. The area on the summit, varying, as is supposed, according to the number of cattle the proprietor had to protect, or the dependants he was obliged to accommodate, is surrounded with an high and strong wall, of which the stones are melted, most of them entirely; while others, in which the fusion has not been so complete, are sunk in the vitrified matter in such a manner as to be quite inclosed with it; and in some places the fusion has been so perfect, that the ruins appear like masses of coarse glass. Mr Williams has not only absolutely determined the walls in question to be the works of art, but has even hazarded a conjecture as to the manner in which they were constructed, and which, according to him, was as follows. Two parallel dikes of earth or sod being raised, in the direction of the intended wall, with a space between them sufficient for its thickness, the fuel was put in, and set on fire. The stones best adapted for the purpose, called the *plum-pudding stone*, are every where to be found in the neighbourhood. These were laid on the fuel, and when melted, were kept by the frame of earth from running off; and by repeating the operation, the wall was raised to a sufficient height. This opinion of the stones being thrown in without any order; is thought to be con-

firmed by the circumstance of there not being any where a large one to be seen, nor a stone laid in any particular direction, nor one piece which has not in some degree been affected by the fire. Mr Williams mentions a fact tending to confirm his hypothesis, viz. of a brick kiln situated on the declivity of an eminence, so as to be exposed to the wind, which happening to rise briskly one time when the kiln was burning, so increased the heat, that the bricks were melted, and ran, like a lava, for a considerable way down the hill.

The opinion of Mr Williams has been embraced by several other authors; particularly Mr Freebairn and Dr Anderson, the latter having published two treatises upon these buildings in the *Archæologia*. In the same work, however, we meet with a paper by the Hon. Daines Barrington, in which the author expresses quite different sentiments. He observes, that Mr Williams, and the other antiquaries, who suppose the walls in question to be the works of art, imagine that the reason of their being constructed in this manner was the ignorance of cement, which in these remote ages prevailed in Scotland: but with respect to this circumstance, he says, that if one side of the wall only was heated, and that to any considerable height, the matter in fusion would in all likelihood drop down to the bottom, without operating as any cement to the loose stones thrown in amongst it. This circumstance of the walls being vitrified only on one side, is indeed remarkable, and takes place in most of the forts of this kind to be met with at present: but with regard to it, Mr Barrington observes, that he himself has been twice in the Highlands of Scotland, and has found very few hills of any height which were clothed with wood; the trouble therefore of carrying it up to the top of such a mountain would be very considerable. But to this it might easily be replied, that we cannot by any means argue from the present state of the hills in the Highlands to their state in a very remote period of antiquity. At that time, it is neither impossible nor in the least improbable, that most of the hills in Scotland were evergrown with wood; or at any rate, there undoubtedly was plenty of peat, which is still used as fuel in Scotland, and which affords such a strong heat as to be advantageously employed in smelting iron*, as we are informed by M. Magellan. A third particular mentioned by Mr Williams is, that these inclosures were intended as places of defence; and in support of this opinion alleges, that there are dried wells found within most of them. But on this Mr Barrington observes, that shelter from the weather was also necessary "upon the top of a bleak Scotch hill, whilst whisky (or a succedaneum for it) would be often in greater request than the bare element of water." This objection, however, as well as the last, is evidently very frivolous for these buildings might have roofs as well as any other; and whatever necessity there might be for whisky occasionally, water was certainly an indispensable requisite.

Mr Barrington having thus given his reasons for dissenting from the opinion of Mr Williams and the antiquaries just mentioned, proceeds to state his own. He tells us, that having travelled for 21 years the most mountainous circuit in Wales, he has frequently observed inclosures of dry stones, particularly

Vitrified
Forts.

* See the
article *Peat*

Vitrified
Forts.

larly a long tract in the western part of Merionethshire, called in the language of the country *Duffryn*, i. e. *the vale*. On first viewing these small inclosures made with walls of thick stones, he was at a loss to imagine how it could be worth while to construct such strong fences for so inconsiderable a piece of ground as they inclosed: but, on examining the adjacent country, he found it almost entirely covered with stones of a similar kind; and, of consequence, the smaller the space to be cleared, the less expensive would be the removal. "For the same reason (says he), such dry walls are often of a great thickness, and sometimes the corners of the inclosures are filled with stones to a great width, this being the only possible means of procuring pasture." To a practice of the same kind our author would ascribe the origin of the works in question: but the objection occurs very strongly, that the walls in Scotland, are vitrified, and it is not to be supposed that such trouble would be taken with fences made in such a fortuitous manner. This objection our author owns, would indeed be unanswerable, on the supposition that the vitrification was made on purpose to strengthen the walls of the fortrefs; "but (says he) may not the vitrification have been occasioned by volcanoes, or by what are called *blowmeries*? The same effect may be produced likewise on dry walls of stone by lightning passing along them. The loose stones in either case would not be rejected because they were glassy, and would be piled up in the fence of the inclosure; as the great point upon these occasions is to clear the ground, and remove the incumbering stones to the smallest distance. One of the advocates for the designed and not fortuitous vitrification, says, that the pieces he had procured did not resemble what is called *lava*. But every volcano is not necessarily an Etna or a Vesuvius; and consequently the matter disgorged from the crater must perpetually vary both in substance and form. Vitrified masses, larger or smaller, will likewise be produced by the same means. It may be contended indeed, that pasture thus procured, by clearing the ground, would be more convenient at the bottom or on the sides, than on the top of the hills: but to this I answer, that in rocky countries you must get what pittance you can of soil, and often it will happen that the only detached and removeable stones are on the summit. When such inclosures have been made, they became very convenient for putting cattle into; and hence perhaps some of the wells which Mr Williams hath mentioned."

Our author concludes his dissertation on this subject by observing, that if vitrification answered the purpose of cement, it is very extraordinary that the ancient inhabitants of Scotland did not apply it to the houses or huts in which they constantly lived, but reserved this troublesome and expensive process merely for a fortification, which might not perhaps be used in half a century against an enemy. On this it is almost superfluous to observe that in the ages of barbarity and bloodshed, in which these inclosures, whether natural or artificial, were supposed to be used as fortresses, war was so frequent, that a defence against an enemy might seem to be necessary every day, instead of once in half a century. Before we proceed further in the argument, however, it will be necessary to give some

account of the situation and appearance of these fortresses.

According to Mr Cardonnel, the largest of them is situated on the hill of Knockfarril, to the south of the valley of Strathpeffer, two miles west from Dingwall in Rossshire. The inclosure is 120 feet long and 40 broad within the walls; strengthened on the outside with works at each end. A range of habitations seem to have been erected against, or under, the shade of the outward wall; of which those on the south-side seem to have been higher and larger than those on the north. There are two wells in the middle, which, on being cleared out, filled with water. On the skirts of the hill to the south are many detached buildings; which, from the stratum of dung found on removing the ruins, appears plainly to have been used for securing the cattle. This place seems to have been anciently of consequence, and the residence of some powerful chief, from a road which leads through the hills to the north-west sea. To the east of the works are a number of vitrified ruins, extending for a considerable way along the ridge of the hill. The end next the fort seems to have joined the outer wall, and consisted either of two parallel walls, closed above, with a passage between them under cover, or a high wall broad enough to walk on. In this wall there is the vestige of a break about the middle, over which a bridge has been laid, to be drawn up or removed as occasion might require.

The fort next in consequence to that of Knockfarril is situated on the hill of Craig-Phadrick near Inverness, "which (says Mr Cardonnel) has this peculiar circumstance that there appears to have been two vitrified walls quite round the area. The inner one seems to have been very high and strong: the outer wall but low: probably the space between was intended for securing their cattle, as there are no remains of dry-stone buildings, such as are found near the rest. Several parts of this outer wall appear quite entire, sticking to the firm bare rock, where it was first run. The area within the inner wall is near 80 paces long, and 27 broad." Of this we have an account † by Alexander Fraser-Tyler Esq: professor of civil history in the university of Edinburgh, who visited it in the year 1782. The hill itself is a small conical eminence, forming the eastern extremity of that ridge of mountains which bounds Loch-Nefs on the northwest side. It is situated about a mile to the north of Inverness, and is accessible on two different quarters, viz. the west and south-east; the former affording entrance by a narrow level ridge joining the hills on Loch-Nefs, and the latter by an easy ascent from the high ground above Inverness. On approaching the hill from the west we first meet with a road cut through the rock from the bottom to the top, in most places 10 feet broad and nearly as deep; winding, for about 70 feet, with an easy serpentine direction, by which we gain an ascent over a steep rock otherwise quite inaccessible from that quarter. This road in our author's opinion, is undoubtedly the work of art, and the vitrified matter on the top is the only thing which indicates the effect of fire: there being neither an appearance of pumice stone, lava, nor basalt about the hill otherwise. There is indeed plenty of plum-pudding stone; which

Vitrified
Forts.† *Edin. Phil. Transact.*
vol. ii. class
ii. art. 11.

Vitrified
Forts.

which some have supposed to be of the nature of volcanic tufa; but this opinion is rejected by our author as erroneous. "But the circumstance (says he) which in my apprehension evinces, in the most satisfactory manner, that these appearances of the effect of fire on the summit of this hill are not the operation of nature but of art, is the regular order and disposition of those materials, the form of the ground, and the various traces of skill and contrivance which are yet discernible, though considerably defaced either by external violence or the obliterating hand of time." To investigate this matter regularly, he begins with the winding road already mentioned, and which is evidently cut through the rock for the purpose of gaining an easy ascent from the level ridge to the summit, which would otherwise have been impracticable. In ascending by this road, there appears towards the middle, on the right hand, a small platform overhanging the passage, and inclining by a very gentle declivity to the very edge of the rock. Four enormous stones are placed upon the platform, and on the edge and extremity of it, which have evidently been guided by art into to that position: it being impossible that they could have rested there, had they been rolled down from the higher parts. The obvious reason for placing them in such a position has been, that on an alarm of danger they might be projected into the path below, which could be done by the efforts of a very few men; and when this was done, the passage would be entirely obstructed, or at least rendered so difficult that it could be defended by a few against any number of assailants. Some other large stones are placed on an eminence to the left, probably with a view to block up an hollow channel, by which an enemy might have attempted to ascend. When we come to the top of the hill, a few feet below the rampart which crowns the whole, there appears an outward wall approaching on the sides of the hill so near the upper rampart, as to have only a trench of 10 or 12 feet wide between them. This outward wall is in some places so low as to be almost level with the rock, though in other places it rises to the height of two or three feet; but even where lowest, it may be traced by a line of vitrified matter sticking fast to the rock all along, and nearly of the same breadth, which is about nine feet. The remains of this wall are strongly vitrified, except in one place on the north side, where, for about 70 yards, the rampart is formed only of dry stones and earth. At the east side, where the hill is more accessible, there is a prodigious mound of vitrified matter, extending itself to the thickness of above 40 feet. At the south-east corner and adjoining to this immense mound, is an outwork, consisting of two semicircular vitrified walls with a narrow pass cut through them in the middle: which appears to have been another, and perhaps the principal, entry to the fort.

The inner wall, surrounding the summit of the hill, incloses an oblong level area of about 75 yards long and 30 broad, rounded at each of the ends like the outward wall. It is of considerable height, and nearly of the same thickness with the outward one.—It has some appearance of having been defended with four turrets or bastions: but the traces are so imperfect, that Mr Tytler does not lay much stress on his observations in this respect; a number of small tumuli

of earth with a stone in the centre, were more discernible. On the east side a portion of the internal space appears separated from the rest by two ranges of stones fixed strongly in the earth, and forming a right-angled parallelogram. "This separation (says our author) is immediately discernible by the eye, from this circumstance that the whole of the inclosed summit has been most carefully cleared from stones, of which there is not one to be seen, unless those that form this division, and the single one in the middle of the circle of tumuli abovementioned. What has been the design of this separated space, it is difficult to conjecture. It might perhaps have marked the residence of those of a higher rank, or served as a temple for the purposes of devotion." On the east end of the large area on the summit is a well of about six feet in diameter, which has probably been sunk very deep in the rock, though now it is filled up with rubbish to within a yard of the top.

The other fortified hills mentioned by Mr Cardonnel are those of Dun-Evan in the shire of Nairn; Tor-dun castle, near fort Augustus; and another on the west side of Gleneves in Lochaber, three miles to the south of Fort William. The Castle-hill of Finhaven, in the county of Angus, has likewise some considerable ruins of the same kind.

Dun-Evan and the hill of Finhaven have likewise been visited by Mr Tytler, who gives an account of them in the paper already quoted; of which the following is an abstract. "On the summit of the hill of Dun-Evan, whose name implies that it had been originally a place of defence, are the remains of two walls surrounding an oblong space like that of Craig-Phadrick already described, but somewhat smaller in size. [Mr Cardonnel says that it is about 70 paces long and 30 broad]. There are likewise the traces of a well in the inclosed area; and at the east end are the remains of a prodigious mass of building, much more extensive than that on Craig-Phadrick." Here, however, our author could not perceive any marks of fire; and Mr Williams owns that the vitrified ruins here are more wasted than on Knockfarril or Craig-Phadrick. But with regard to the vitrifications here, our author is inclined to suppose Mr Williams to have been entirely in a mistake. On the Castle-hill of Finhaven, however, the vitrified remains are very visible all round the summit, which is cleared of stones and levelled, unless at one end, where there is a great hollow space separated from the rest of the area, and probably destined exclusively for the keeping of cattle. The inclosed area is about 140 yards long and upwards of 40 broad.

Besides these fortifications, the hill of Noth affords a remarkable appearance of the same kind: of which Mr Cordiner gives the following description, not from his own observation, but those of a gentleman of credit who visited the place. "On the top of the hill there is an oblong hollow, as I could guess, of about an English acre, covered with a fine sward of grass: in the middle toward the east end of this hollow is a large and deep well. The hollow is surrounded on all sides with a thick rampart of stones. On three sides of this rampart, from 8 to 12 feet thick, is one compact body of stones and minerals which have been in a state of fusion, resembling a mixture of stone and iron

Vitrified
Forts.

Vitrified
Forts.

iron-ore, all vitrified, calcined, and incorporated. On the north side, the rampart consists of broken pieces of rock, which have the appearance of having been torn to pieces by some extraordinary violence. If the calcined compact wall exists under them, it is not at present visible."

Such are the descriptions of the most remarkable of these curious fortifications, which of late seem to have engaged the attention of the learned in a considerable degree. We have already taken notice, that by some they are supposed to be the works of art, by others the productions of a volcano. Mr Cardonnel adopts the opinion of Mr Williams as the most probable, both with respect to their use and manner of construction. Mr Tytler takes notice of the remarkable difference of opinion among those who have viewed the places in question. "It is curious to remark (says he) how the same appearances, to different observers, lead to the most opposite opinions and conclusions. The two gentlemen abovementioned (Mr Williams and Dr Anderson), seem not to have entertained the smallest doubt, that the vitrified materials on the tops of these hills were the vestiges of works of art, and the remains of structures reared for the purposes of security and defence. The bishop of Derry, when on the tour to the north of Scotland, visited the hill of Craig-Phadrick near Inverness, and expressed his opinion, that the mounds of vitrified matter were not the remains of any artificial work, but the traces of an ancient volcano. In the Phil. Transf. of the Royal Society of London for 1777, Part II. n^o 20. is an account of *Creck Paterick*, there termed a *Volcanic hill near Inverness*, in a letter from Thomas West, Esq; to Mr Law, F. R. S. in which the writer does not hesitate to pronounce this hill an extinguished volcano: and having sent specimens of the burnt matter for the inspection of the Royal Society, the secretary subjoins a note to the paper, intimating, that these specimens having been examined by some of the members well acquainted with volcanic production, were by them judged to be real lava. Such was likewise the opinion of the late Andrew Crosbie, Esq; who, in an account which he gave to the Philosophical Society of Edinburgh in 1780, offered some very curious conjectures with regard to the process of nature, by which he supposed the whole of this hill to have been thrown up from the bottom of the sea by the operation of intestine fire.

Mr Tytler agrees with those who think the vitrified structures to be artificial works: but he differs from Mr Williams and others, who think that they were vitrified on purpose for cementing the materials together. His reason for this is, that the number of forts that show marks of vitrification is inconsiderable when compared with those that do not. He therefore considers the vitrification as accidental; and that it must have been accomplished in the following manner. In the rude state in which we must suppose Scotland to have been in early times, is very probable that their buildings, both for habitation and defence, would be frequently constructed of loose stones of an irregular shape; of which, by themselves, it would scarce be possible to fabricate a wall of any tolerable strength. Hence it became necessary to use wood as well as stone in their construction. This kind of building then, in our au-

thor's opinion, was begun by raising a double row of pallisades or strong stakes in the form of the intended structure in the same way as in that ancient mode of building described by Palladio under the name of *riempita a cassa*, or coffer-work. These stakes were probably warped across by boughs of trees laid very closely together, so as to form two fences running parallel to each other at the distance of some feet, and so close as to confine all the materials of whatever size that were thrown in between them. Into this intermediate space Mr Tytler supposes were thrown boughs and trunks of trees, earth and stones of all sizes, large or small as they could quarry or collect them. Very little care would be necessary in the disposition of these materials, as the outward fence would keep the mound in form. In this way it is easy to conceive that a very strong bulwark might be reared with great dispatch; which, joined to the natural advantage of a very inaccessible situation, and that improved by artful contrivances for increasing the difficulty of access, would form a structure capable of answering every purpose of security or defence. The most formidable attack against such a building would be fire, which would no doubt be always attempted, and often with success, by an enemy who undertook the siege. If the besiegers prevailed in gaining an approach to the ramparts, and, surrounding the external wall, set fire to it in several places, the conflagration must speedily have become universal, and the effect may be easily imagined. If there happened to be any wind at the time to increase the heat, the stony parts could not fail to come into fusion; and as the wood burnt away, sinking by their own weight into a solid mass, there would remain a wreck of vitrified matter tracking the spot where the ancient rampart had stood; irregular and of unequal height, from the fortuitous and unequal distribution of the stony materials of which it had been composed. This conjecture appears very probable from their appearance at this day. They do not seem to have ever been much higher than they are at present, as the fragments that have fallen from them, even where the wall is lowest, are very inconsiderable. The durable nature of the materials would prevent them from suffering any changes by time; though, from the gradual increase of the soil, they must in some places have lost considerably of their apparent height, and in others been quite covered. Mr Williams, in making a cut through the ramparts at Knockfarril, found in many places the vitrified matter covered with peat-moss half a foot thick.

In confirmation of this opinion, our author likewise urges, that in the fortification on Craig-Phadrick, a large portion of the outward rampart bears no marks of vitrification. The reason of this seems to be, that the steepness of the hill on that side renders a low fence of stones and turf sufficient; and no wood had probably been employed in its construction. "It appears therefore highly probable (concludes our author), that the effect of fire upon these hill-fortifications has been entirely accidental; or, to speak more properly, that fire has been employed not in the construction, but towards the demolition of such buildings: and for the latter purpose it would certainly prove much more efficacious than for the former. It is much to be doubted, whether it would be at all possible, even in the present

Vitrified
Forts.

Vitrified
Forts.

sent day, by the utmost combination of labour and of skill, to surround a large space of ground with a double rampart of stones compacted by fire, of such height and solidity as to answer any purpose of security or defence against an enemy. Any structure of this kind must have been irregular, low, fragile, easily scaled, and quite insecure; a much weaker rampart, in short, than a simple wall of turf or wooden palisade. The vestiges yet remaining, as I have already observed, give no room to suppose that the vitrified mound has ever been much more entire than it is at present. The effect of fire upon structures reared in the manner I have supposed them to have been, will account most perfectly for their present appearance. It was from necessity that the builders of these fortifications betook themselves to a mode of structure so liable to be destroyed by fire. In those parts where stones could be easily quarried, of such size and form as to rear a rampart by themselves of sufficient strength and solidity, there was no occasion to employ wood or turf in its construction; and it was therefore proof against all assaults by fire. Such are the ramparts which appear on the hill of Dun-Jardel, Dun-Evan, and many others, on which there is not the smallest appearance of vitrification. But on Craig Phadrick, and the other hills above described, where, from the nature of the rock, the stones could be procured only in irregular and generally small fragments, it was necessary to employ some such mode of construction as I have supposed; and these ramparts, though solid and well calculated for defence against every attack by force or stratagem, were not proof against an assault by fire."

Mr Cordiner is of opinion, that the vitrifications in question cannot have been the works of art, and ridicules the contrary hypothesis; though without adducing any argument against it. The hill of Noth is by him supposed to have been a volcano. He describes it as "a most majestic mountain, in general brown, with moss and heath, interspersed with bare rock, in many places crumbling down. The highest part of it is a circular hill, whose verdure, as well as height, distinguishes it from the rest of the mountain. This is called the *Top of Noth*; and bears the strongest resemblance to every description of a volcanic mount. At the distance of many miles, one can distinguish those ridges which are the boundaries of the crater, indicating the hollow in the top." The gentleman from whom Mr Cordiner received the account of the vitrifications on the summit, informs us, that on first seeing specimens of them, he imagined that they had been pieces of stone calcined by the burning down of a castle; as he had found something very like them on the castle-hill at Cullen, in parts where the sward of grass was broken: but on reaching the top, and viewing the appearances on it already described, he altered his opinion. "That men hardly-beset (says he) might climb up with some provisions to this as a place of refuge, is probable: but that, on a barren mountain-top, far from cultivated ground, half a day's journey from the plain; that there, in any period of society, man should have been tempted to build that amazing rampart, is not to be imagined: they have found it a natural and extensive fortress, and in critical circumstances have made use of it accordingly. That it has been occupied as a place of strength and of refuge, is

very evident; for, some hundred yards lower down on the hill, there are the remains of another rampart or wall, consisting of loose stones piled together without any cement, carried quite round the hill. This last has been built for an additional defence to those who made their abode on the top. The top of Noth, for two-thirds downwards, is covered with a green sward; below that, it is brown with heath: this is the very reverse of the adjacent mountains; and the greater verdure of the upper part I imputed to a new soil created by the ashes of the volcano. The opening, called a *well*, I suppose to have been the latest crater. About a mile south, down towards the lower grounds of the *Cabrock*, there is a very pretty regular green hill; which I ascribe to a later eruption than those which may have formed the contiguous hills now covered with heath. There is an extraordinary luxuriant spring of water rushes out at once from the sides of the hill of Noth; which is likewise some confirmation of the opinion that a volcano has some time existed there, which has occasioned great hollows and reservoirs of water in the heart of the mountain. And the wild irregularities of nature through all the *Cabrock*, the hideous and strange projection of rocks from the sides of the hills, would seem to indicate some vast convulsions which the earth must have suffered in these parts.

"The traces of ancient volcanoes (says Mr Cordiner) are far from being unfrequent in Scotland. The hill of Finhaven is one instance; and not only abundant in this species of lava, but with *tarras*, or the *pulvis puteolanus*, an *amalgama*, as Condamine calls it of calcined stones mixed with scorias and iron-rust reduced to powder. The hill of Beregonium, near Dunstaffage castle, is another, yielding vast quantities of pumices or scoria of different kinds; many of which are of the same species with those of the volcanic Iceland. The noble assemblage of basaltic columns at Staffa, those in the Isle of Sky, and the rock Humble, are but so many evidences of the ancient volcanoes of this country. And finally, the immense stratum of pumex vitreus or Iceland agate, on the hill of Dun-ffin in Arran, is the last proof I shall bring in support of the question."

On this dispute we can only observe, that whatever side we embrace, the difficulties seem to be very great, nay almost insurmountable. When we consider the great thickness of the walls on the top of Noth, from 8 to 12 feet, and the vast mound of vitrified matter, no less than 40 feet in breadth, mentioned by Mr Tytler, we can scarce conceive it possible that less than a volcanic fire could be able to form them. We may easily allow, that, in the way this gentleman mentions, there might be considerable vitrifications formed; but that such immense masses should be brought into perfect fusion by the small quantity of fuel which could be put round them in palisades, or intermixed with the materials themselves, will be incredible to every one acquainted with the extreme difficulty with which stones of any magnitude are brought into complete fusion. We see even in the insides of furnaces, though sometimes built of no more unfusible materials than common brick, no such effects follow. There is a slight vitrification indeed, but it scarce ever penetrates to the depth of an inch or two, though very violent fires are kept

Vitrified
Forts.

Vitrified
Forts.

kept up for a much longer time than we could suppose the wood surrounding those walls to require for its being consumed. In conflagrations, where houses are consumed, which are the only similar examples we have, no such effect is perceived. Even in the great fire at London in 1666, where so many buildings were destroyed, we do not hear of their walls being vitrified, though the materials of many of them were undoubtedly as fusible as the rocks and stones of Craig-Phadrick, or the Top of Noth. If, on the other hand, we reject this, and adhere to the volcanic hypothesis, our difficulties are equally great. For where shall we find in any other part of the world an example of volcanoes ejecting lava in the form of walls inclosing a regular area? This would be attributing such a singularity to the volcanoes of Scotland as the most extravagant imagination cannot admit. We must therefore conclude, that though these ruins are certainly the works of art we have not yet sufficient data to decide the question with respect to their construction, but that the subject requires a further investigation.

In the paper already quoted, Mr Tytler observes, that "these ancient fortifications present a more curious and interesting object of speculation, than those uncertain and indeed fruitless conjectures as to the mode in which they have been reared." This, he justly observes, must have been before the use of mortar was known; for as the country aboundeth in limestone, and the builders certainly would exert all their powers in giving them a proper degree of strength, it would undoubtedly have been used. Hence we are led to ascribe to these a very considerable degree of antiquity; for as the Britons were taught the use of mortar by the Romans, it is probable that we must date the origin of the structures in question before the time of the invasion of that people, or at least soon after it: so that we must look upon them to be more than 1650 years old; but how far beyond that period we are to search for their origin, does not appear. "All that we can conclude with certainty (says our author), is, that they belong to a period of extreme barbarism. They must have been constructed by a people scarcely removed from the state of savages, who lived under no impression of fixed or regulated property in land; whose only appropriated goods were their cattle; and whose sole security, in a life of constant depredation, was the retreat to the summits of those hills of difficult access, which they had fortified in the best manner they could. As the space inclosed was incapable of containing a great number of men, especially if occupied in part by cattle, it is presumable, that these retreats were formed chiefly for the security of the women and children of the canton and of their herds. They could be defended by a few men, while the rest of the tribe were engaged with their enemies in the field."

Our author concludes his dissertation with a conjecture, which indeed seems well supported, that the forts in question were constructed, not only before the Roman invasion, but before the introduction of the rites of the Druids into Britain; as "there appears no probability that the inhabitants either lived under such a government as we know to have prevailed under the influence of the Druids, or had any acquaintance with those arts which it is certain they cultivated."

VOL. VII.

FORTALICE, in Scots law, signified anciently a small place of strength, originally built for the defence of the country; and which, on that account, was formerly reckoned *inter regalia*, and did not go along with the lands upon which it was situated without a special grant from the crown. Now, fortalices are carried by a general grant of the lands; and the word is become synonymous with manor-place, messuage, &c.

FORTESCUE (Sir John), lord chief justice of the king's bench, and lord high chancellor of England, in the reign of king Henry VI. was descended from the ancient family of Fortescue, in the county of Devon. He studied the municipal laws of England in Lincoln's Inn, of which he was made one of the governor's in the fourth and seventh years of the reign of king Henry VI. In 1430 he was called to the degree of a serjeant at law, and in 1441 was constituted the king's serjeant. The following year he was made lord chief justice of the king's bench; in which honourable station he continued till near the end of that king's reign, who showed him many particular marks of his favour, and advanced him to the post of lord high chancellor of England. During the reign of king Edward IV. he followed the fortunes of the house of Lancaster, and was many years in exile with queen Margaret and prince Edward her son. At length, they having a prospect of retrieving their desperate fortunes, the queen and prince returned to England, and Sir John Fortescue, with many others, accompanied them: but soon after the decisive battle of Tewksbury, he was thrown into prison and attainted, with other Lancastrians; but found means to procure his pardon from Edward IV. He wrote, 1. A learned commentary on the politic laws of England, for the use of prince Edward; to one edition of which Mr Selden wrote notes: 2. The difference between an absolute and limited monarchy, as it more particularly regards the English constitution (which was published, with some remarks, by John Fortescue, afterwards lord Fortescue, in 8vo. in 1714; and a second edition was published, with amendments, in 1719): And several works, which still remain in manuscript. He died near 90 years of age; and was buried in the parish church of Ebburton, where a monument was erected to his memory, in 1677, by one of his descendants.

FORTH, one of the most noble and commodious rivers in Scotland. It takes its rise near the bottom of Lomond hills; and running from west to east, receives in its passage many considerable streams, deriving their waters from the eminences in the midland counties of North Britain. Between Stirling and Alloa, the Forth winds in a most beautiful and surprising manner; so that, though it is but four miles by land, it is 24 by water between those two places. Below Alloa the river expands itself to a great breadth between the counties of Lothian and Fife, till at Queen's-ferry it is contracted by promontories shooting into it from both coasts; so that, from being four or five, there it is not above two miles broad. In the middle of the channel lies a small island called *Inchgarvy*, which has a spring of fresh water: upon the island there is an ancient fort, which has been lately repaired; and if there were either forts or blockhouses on the opposite promontories, that part of the river which lies between Alloa and Queen's-ferry would be as secure and con-

Fortalice
|
Forth.

Z z

venient

Forth

venient a harbour as could be desired. A little below this, near the north shore, lies Inchcomb, on which are the remains of an ancient monastery of considerable extent; and opposite to Leith stands the island of Inchkeith, formerly fortified, but now in ruins. Below Queen's-ferry the north and south shores receding, the body of the water gradually enlarges till it becomes two or three leagues broad, affording several safe harbours on both sides, and excellent roads throughout, unembarrassed with latent rocks, shoals, or sands; and allowing secure anchorage to the largest ships within a league of the coast in almost any part of the Frith, and to vessels of a smaller size within a mile or less. The Firth, or (as it is commonly written) the *Frith*, of Forth, is, at the mouth of it, from North Berwick to Fifeness, full five leagues broad; having the little island of May (on which there is a light-house, and there might also be a fort) in the middle of it, and to the west of this, the rocky island of Bass; notwithstanding which, the largest fleet may enter and sail up it many miles with the utmost facility and in the greatest safety. In 1781, Admiral Parker's fleet lay some weeks opposite to Edinburgh, accompanied by 500 sail of merchantmen, the whole in full view of the city and castle.

The Forth was known to the ancients by the name of *Bodotria*, or (as Ptolemy calls it) *Boderia*, and has been ever famous for the number of its havens; some of which are, indeed, in their present condition, scarce worthy of that name. It is navigable for merchantmen, as high as Alloa, 50 miles from the sea; and for coasters as far as Stirling, 24 miles further by water, though only four by land in a direct line, as already observed. The tide flows only a full mile above Stirling to a place called *Craigforth*, where the proprietor intercepts the passage of the salmon by a cruiue or weir, very injurious to the large tract of country, which stretches as far as Lomond westward. The river from Stirling to the bridge of Aberfoil, at the entrance into the West-Highlands, is only passable for man or horse at few places, and these in dry seasons. It glides gently thro' a dead flat, from Gartmore eastward; "and on these accounts (says Mr Knox*) it might be made navigable for barges, at a trifling expence to the proprietors of the lands, an improvement much wanted in a rich, extensive, and populous valley, without market towns, coal and lime. Supposing this work to be executed, of which there is some probability, the whole extent of

* *View of the British Empire*, vol. ii. p. 518:

navigation on the Forth, will, including all its windings, exceed 200 miles, through a coast of nearly 100 miles; fertile, populous, industrious; and from Stirling eastward, almost lined with towns, anciently the seats of commerce and navigation, till they were ruined by the English depredations; in which miserable state, some of them still remain, while others begin to resume the appearance of business. The principal object of these towns was the fisheries, which they prosecuted with great vigour as far as Iceland, till the time of the Union, from which period the eastern fisheries gradually dwindled away; and the poor fishermen, unable to subsist themselves upon air and water, took up the trade of smuggling; but so soon as the fishery laws shall be amended, the salt duties abolished, and an adequate bounty extended to boats as well as buffes, these people will readily fall into the track of their ancestors, live by honest industry, and add new vigour to our naval strength. Many of the ports are nearly choaked up, others want repairs, which neither the individuals nor the corporations of those decayed places can accomplish. Though the harbours on the Forth are in general small, the depth of water might be made sufficient for vessels of 200 tons burden, which fully answers the purposes of their coasting and Baltic trade; but to obtain this, or even a less depth of water, an aid of 50,000*l.* would be requisite."

By this river and the Clyde, Scotland is almost divided into two parts. The Forth falls into the east sea below Edinburgh, and has an easy communication with the whole eastern coast of Great-Britain; with France, Ostend, Holland, Hamburg, Prussia, Dantzic, Russia, Sweden, Denmark, Norway, and Greenland. The Clyde falls into the Atlantic ocean below Glasgow, and communicates with the western coast of Great Britain; with Ireland, the south of France, Portugal, Spain, the Mediterranean, America, and the West-Indies. These two rivers, thus falling in opposite directions into the two seas which environ the island, and the neck of land between them, amounting scarcely to 24 miles, gave rise to the idea of a junction, so as to open a communication across the kingdom, and thereby cut off the long dangerous navigation by the Land's End and the Pentland Frith: an object of vast utility, and which has lately been happily accomplished. See the article CANAL.

Forth.

F O R T I F I C A T I O N ;

THE art of fortifying a town or other place; or of putting them in such a posture of defence, that every one of its parts defends, and is defended by, some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end that a small number of men within may be able to defend themselves for a considerable time against the assaults of a numerous army without, so that the enemy in attacking them must of necessity suffer great loss.

The origin and rise of fortification is undoubtedly owing to the degeneracy of mankind. In the first ages of the world, men were dispersed up and down the

countries in separate families, as we are told in the histories of the Jews and Scythians, who wandered from one place to another, for the sake of finding pasture for their cattle. These families became in time so numerous as to form large communities, which settled all together in a place; from whence villages and towns had their origin and rise: but they found it was necessary, for the common security, to surround those towns with walls and ditches, to prevent all violences from their neighbours, and sudden surprises. This was sufficient for some time, till offensive weapons were invented, and conquering became a fashion. Then walls

with

with loop-holes were made at proper distances, in order to screen the defenders against the arrows of the assailants: but finding that, as soon as the enemy got once close to the walls, they could from no part be discovered or repulsed; for this reason they added square towers at proper distances from each other, so that every part of the wall might be defended by the adjacent sides of the towers. However, this manner of inclosing of towns was found to be imperfect, because there remained still one of the faces of the towers which fronted the field that could not be seen from any other part, and therefore could not be defended. To remedy this, they made the towers round instead of square, imagining this figure to be the strongest to resist the battering engines, as likewise to be better defended from the other parts of the wall.

Notwithstanding the superiority of this method above the former, there remained yet a part of these towers unseen and incapable of being defended; which made them change the figure of the towers again; that is, they made them square as before; but, instead of presenting a face to the field as formerly, they presented an angle; by this means they effectually found out such a disposition of their works, that no part could be attacked without being seen or defended by some other part.

This last method was used a long while; and would in all probability have continued to this day, if gun-powder had not been found out: but the violence of the guns and mortars soon convinced the world, that such towers and walls were but a weak defence against these thundering engines; and besides, as the nature of the attack was entirely changed, it was also necessary to change that of fortifying likewise.

From that time ramparts were added to the walls, the towers enlarged into bastions, and all sorts of out-works have been added, such as ravelins, counter-guards, horn and crown works, and others of the like nature, in order to render the defence in some measure equivalent to the attack.

Notwithstanding all the improvements which have been made in the art of fortifying since the invention of gun-powder, that of attacking is still superior to it: engineers have tried in vain to render the advantages of a fortification equal to those of the attack; the superiority of the besiegers fire, together with the greater number of men, obliges generally, sooner or latter, the besieged to submit.

The greatest improvement made in the art of attacking happened in the year 1697, when M. Vauban made first use of ricochet-firing at the siege of Ath, whereby the besieged placed behind the parapets were as much exposed to the fire of the besiegers as if there had been none; whereas, before, they had been secure as long as the parapet was not demolished; and the worst is, that there can be no remedy found to prevent this enfilading, without falling into inconveniences almost as bad as those which we endeavour to avoid.

FORTIFICATION is either regular or irregular. *Regular* fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. *Irregular* fortification, on the contrary, is that where the sides and angles are not uniform, equidistant, or equal;

which is owing to the irregularity of the ground, valleys, rivers, hills, and the like.

SECT. I. Of Regular Fortification.

ALTHOUGH authors agree as to the general form in the present manner of fortifying, yet they mostly differ in particular constructions of the parts. As it would be both needless and superfluous to treat of all the different methods hitherto proposed, we shall content ourselves with explaining those only which are most esteemed by the best judges, and have been mostly put in practice.

Construction of M. VAUBAN's Method.

This method is divided into little, mean, and great; the *little* is chiefly used in the construction of citadels, the *mean* is that of all sorts of towns, and the *great* in particular cases only.

We shall give the construction of the mean, as being most useful; and refer the reader to the table hereafter, for those dimensions which are different in these several fortifications.

Plate
CXCVII.

Inscribe in a circle a polygon of as many sides as the fortification is designed to have fronts; let AB be one of the sides of half an hexagon, which bisect by the perpendicular CD; divide half AC of it into nine equal parts, and one of these into ten others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them is supposed to be a toise or fathom, that is, six French feet; and therefore the whole side AB is supposed to be 180 toises.

As the dividing a line into so many equal parts is troublesome and tedious; it is more convenient to have a scale of equal parts by which the works may be constructed.

If therefore, in this case, the radius is taken equal to 180 toises, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, you will have an hexagon inscribed; AB being bisected by the perpendicular CD as before, set off 30 toises from C to D, and draw the indefinite lines ADG, BDF; in which take the parts AE, BH, each equal to 50 toises; from the centre E describe an arc through the point H, meeting AD in G, and from the centre H describe an arc through the point E, meeting BD in F; or which is the same, make each of the lines EG, HF, equal to the distance EH; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front.

If the same construction be performed on the other side of the polygon, you will have the principal or outline of the whole fortification.

If, with a radius of 20 toises, there be described circular arcs, from the angular points B, A, M, T, and lines are drawn from the opposite angles E, H, &c. so as to touch these arcs, their parts *ab*, *bc*, &c. together with these arcs, will represent the outline of the ditch.

DEFINITIONS.

1. The part FEALN, is called the bastion.
2. AE, AL, the faces of the bastion.
3. EF, LN, the flanks.
4. FG; the curtain.

Of
Orillons.
Plate
CXCIV.

5. FN, the gorge of the bastion.
6. AG, BF, the lines of defence.
7. AB, the exterior side of the polygon.
8. CD, the perpendicular.
9. Any line which divides a work into two equal parts, is called the capital of that work.
10. *abc*, the counterscarp of the ditch.
11. A, M, the flanked angles.
12. H, E, L, the angles of the shoulder, or shoulder only.
13. G, F, N, the angles of the flank.
14. Any angle whose point turns from the place is called a *salient angle*, such as A, M; and any angle whose point turns towards the place, *re-entering angle*, such as b, F, N.
15. If there be drawn two lines parallel to the principal or outline, the one at 3 toises distance, and the other at 8 from it; then the space *yx* included between the principal one and that farthest distant, is called the *rampart*.

And the space *xx*, contained by the principal line, and that near to it, and which is generally stained black, is called the *parapet*.

16. There is a fine line drawn within four feet of the parapet, which expresses a step called *banquette*.
N. B. All works have a parapet of three toises thick, and a rampart from 8 to 10, besides their slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground and the particular constructions of engineers.

The parapet is a part of the rampart elevated from 6 to 7½ feet above the rest, in order to cover the troops which are drawn up there from the fire of the enemy in a siege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; so that when the troops stand upon it, they may just be able to fire over the parapet.

17. The body of the place, is all that which is contained within this first rampart: for which reason, it is often said to construct the body of the place; which means properly, the construction of the bastions and curtains.

18. All the works which are constructed beyond the ditch before the body of the place are called *out-works*.

T A B L E .

	Forts.						Little Fortif.				Mean.		Great.	
Side of Polyg.	80	90	100	110	120	130	140	150	160	170	180	190	200	260
Perpendicul.	10	11	12½	14	15	16	20	21	23	25	30	31	25	22
Faces batt.	22	25	28	30	33	35	40	42	45	47	50	52	55	60
Cap. of rav.	25	28	30	35	38	40	45	50	50	52	55	55	60	50

In the first vertical column are the numbers expressing the lengths of the exterior sides from 80 to 260. In the second, the perpendiculars answering to these sides. In the third, the lengths of the faces of bastions; and in the fourth, the lengths of the capitals of the ravelins.

The forts are mostly, if not always, square: for which reason the perpendiculars are made one-eighth of the exterior sides; because if they were more, the gorges of the bastions would become too narrow.

The little fortification is chiefly designed for citadels, and are commonly pentagons; the perpendiculars are made one-seventh of the exterior side: the mean is used in all kinds of fortifications from an hexagon upwards to any number of sides: and the great is seldom used but in an irregular fortification, where there are some sides that cannot be made less without much expence; or in a town which lies near a great river, where the side next the river is made from 200 to 260 toises; and as that side is less exposed to be attacked than any other, the perpendicular is made shorter, which saves much expence.

The faces of the bastions are all 2/7ths of the exterior sides, or nearly so, because the fractions are neglected.

It may be observed in general, that in all squares the perpendicular is 1/8th of the exterior side, and all pentagons 1/7th, and in all the rest upward 1/6th.

1. Construction of Orillons and retired Flanks.

DESCRIBE the front MPQRST as before, and divide the flank into three equal parts, of which suppose

Sr to be one; from the opposite flanked angle M draw a line Mr, in which take the part *mr* of 5 toises; take likewise Rn in the line of defence MR, produced, equal to 5 toises, and join *mn*, upon which as a base describe the equilateral triangle *npm*, and from the angle *p*, opposite to the base as centre, is described the circular flank *nm*.

And if Sr be bisected by the perpendicular 1, 2, and another be erected upon the face ST, at S; the intersection 2 of these two perpendiculars will be the centre of the arc which forms the orillon.

The orillons are very useful in covering the retired flanks, which cannot be seen but directly in the front; and as these orillons are round, they cannot be so easily destroyed as they would be if they were of any other figure.

2. Construction of Ravelins or Half Moons.

FIG. 2. Set off 55 toises, from the re-entering angle O of the counterscarp, on the capital OL or on the perpendicular produced, and from the point L draw lines to the shoulder AB; whose parts LM, LN, terminated by the counterscarp, will be the faces, and MO, ON, the femigorges of the ravelin required.

This is Mr Vauban's method of constructing ravelins, according to some authors: and others will have the faces of the ravelin terminate on those of the bastions within 3 toises of the shoulders; which seems to be the best way, for these ravelins cover the flanks much better than the others.

The ditch before the ravelin is 12 toises its counterscarp

Of *Tenailles*.
Plate
CXCVII.

scarp parallel to the faces of the ravelins ; and is made in a circular arc, before the salient angle : as likewise all ditches are in general.

When the ravelins are made with flanks, as in fig. 3. the faces should terminate on those of the bastions, at least 5 toises from the shoulders.

The flanks are made by setting off 10 toises from the extremities of the faces, from *f* to *b*, and from *m* to *l* ; and from the points *b*, *l*, the flanks *b k*, *l p*, are drawn parallel to the capital LO of the ravelin.

There are sometimes redoubts made in the ravelin, such as in fig. 2. which is done by setting off 16 toises from the extremities of the faces on the semi-gorges from N to *b*, and from M to *a* ; and from the points *b*, *a*, the faces are drawn parallel to those of the ravelin : the ditch before the redoubt is 6 toises, and its counterscarp parallel to the faces.

3. Construction of *Tenailles*.

A *tenaille* is a work made in the ditch before the curtains, the parapet of which is only 2 or 3 feet higher than the level ground of the ravelin. There are three different forts : the first are those as fig. 4. which are made in the direction of the lines of defence leaving a passage of 3 toises between their extremities and the flanks of the bastions, as likewise another of 2 in the middle for a bridge of communication to the ravelin.

The second fort are those as in fig. 5. Their faces are in the lines of defence, and 16 toises long, besides the passage of 3 toises between them and the flanks of the bastions ; their flanks are found by describing arcs from one shoulder of the *tenaille* as centre through the other, on which are set off 10 toises for the flanks desired.

And the third fort are those as in fig. 6. Their faces are 16 toises, as in the second fort, and the flanks are parallel to those of the bastions.

The use in general of *tenailles*, is to defend the bottom of the ditch by a grazing fire, as likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which can be defended from no where else so well as from them.

The first fort do not defend the ditch so well as the others, as being too oblique a defence : but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places as may be seen in the citadel of Lille, at Laudau, New Brisac, and in a great many other places.

The second fort defend the ditch much better than the first, and add a low flank to those of the bastions ; but as these flanks are liable to be enfiladed they have not been much put in practice. This defect might however be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work.

As to the third fort, they have the same advantage as the second, and are likewise liable to the same objections ; for which reason, they may be used with the same precautions which have been mentioned in the second.

Tenailles are esteemed so necessary, that there is hardly any place fortified without them : and it is not without reason. For when the ditch is dry, the part

behind the *tenailles* serves as a place of arms, from which the troops may fall, destroy the works of the enemy in the ditch, oppose their descent, and retire with safety ; and the communication from the body of the place to the ravelin becomes easy and secure : which is a great advantage ; for by that means the ravelin may be a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the passage over the ditch whenever they please ; and the communication from the *tenailles* to the ravelin, becomes likewise much easier than it would be without them.

4. Construction of *Lunettes*.

FIG. 7. *Lunettes* are placed on both sides of the ravelin, such as B, to increase the strength of a place : they are constructed, by bisecting the faces of the ravelin with the perpendicular LN ; on which is set off 30 toises from the counterscarp of the ditch for one of its faces ; the other face, PN, is found by making the semi-george TP of 25 toises ; the ditch before the *lunettes* is 12 toises, the parapet 3, and the rampart 8, as in the ravelin.

There is sometimes another work made to cover the salient angle of the ravelin, such as A, called *bonnet*, whose faces are parallel to those of the ravelin, and when produced bisect those of the *lunettes* ; the ditch before it is 20 toises.

There are likewise *lunettes*, such as D in fig. 8. whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle ; and their semi-gorges are only 10 toises.

These kind of works may make a good defence, and cost no very great expence ; for as they are so near the ravelin, the communication with it is very easy, and one cannot well be maintained till they are all three taken.

5. Construction of *Tenailions*.

FIG. 9. Produce the faces of the ravelin beyond the counterscarp of the ditch, at a distance MN of 30 toises, and take on the counterscarp of the great ditch 15 toises from the re-entering angle *p* to *q*, and draw N *q*, then *q* NM *p* will be the *tenailions* required ; its ditch is 12 toises, that is, the same as that of the ravelin. Sometimes there is made a retired battery in the front of the *tenailions*, as in B ; this battery is 10 toises from the front to which it is parallel, and 15 toises long.

There are commonly retrenchments made in the *tenailions*, such as O ; their parapets are parallel to the fronts MN, and bisect the side *q* N ; the ditch before this retrenchment is 3 toises : and there is a banquette before the parapet next to the ditch of about 8 feet, called *berm* ; which serve, to prevent the earth of the parapet (which seldom has any revetment) from falling into the ditch.

It is to be observed, that the ravelin, before which *tenailions* are constructed, must have its salient angle much greater than the former construction makes them ; otherwise the salient angles of the *tenailions* become too acute ; for which reason we made the capital of this

Of
Lunettes,
&c.
Plate
CXCVII.

Of
Counter-
guards, &c.
Plate
CXCVII.

this ravelin 45 toises, and the faces terminate within 3 toises of the shoulders.

6. Construction of Counterguards.

FIG. 10, 11. When the counterguard is placed before the ravelin, set off 40 toises on the capital of the ravelin from the salient angle A to the salient angle B, of the counterguard; and 10 from C to D, on the counterscarp of the ditch.

When the counterguard is before the bastion, such as in fig. 2. its salient angle F is 50 toises from the salient angle E of the bastion, and the breadth near the ditch of the ravelin 10 toises as before.

The ditch before the counterguards is 12 toises, and its counterscarp parallel to the faces.

Counterguards are made before the ravelin on some particular occasions only; but are frequently constructed before the bastions, as covering the flanks wonderfully well. Some authors, as Mr Blondel and Mr Coehorn, will have them much narrower than they are here.

Construction of Hornworks.

FIG. 12. Produce the capital of the ravelin beyond the salient angle A, at a distance AB; of about 80 toises; draw DBE at right angles to AB; in which take BD, BE, each equal to 55 toises; and on the exterior side DE, trace a front of a polygon in the same manner as that of the body of the place, making the perpendicular BF 10 toises, and the faces 30.

The branches D a, E b, of the hornwork, when produced, terminate on the faces of the bastions, within 5 toises of the shoulders. The ditch of the hornwork is 12 toises, and its counterscarp parallel to the branches; and in the front terminates at the shoulders, in the same manner as the great ditch before the bastions.

The capital of the ravelin before the front of the hornwork is 35 toises, and the faces terminate on the shoulders, or rather 2 or 3 toises beyond them: and the ditch before the ravelin is 8 toises.

There are sometimes retrenchments made within the hornwork, such as S, S; which are constructed by erecting perpendiculars to the faces of the ravelins, within 25 toises of their extremities. This retrenchment, like all others, has a parapet turfed only with a berm of 8 feet before it: as likewise a ditch from 3 to 5 toises broad.

Fig. 13. When a horn work is made before the bastion, the distance DL of the front from the salient angle of the bastion is 100 toises, and the branches terminate on the faces of the adjacent ravelins within 5 toises from their extremities; all the rest is the same as before.

1. Construction of Crown-works.

Plate
CXCVIII.

FROM the salient angle, A (fig. 1.) of the ravelin, as a centre, describe an arc of a circle with a radius of about 120 toises, cutting the capital of the ravelin, produced at C; from the point C, set off the cords CB, CF, each of them equal the 110 toises; and on each of which, as an exterior side, construct a front of a polygon of the same dimensions as in the hornwork that is, the perpendicular should be 81 toises, the faces

30, and the branches terminate on the faces of the bastions within 25 toises of the shoulders.

The ditch is 12 toises, the capital of the ravelin 35, and its ditch 8; that is the same as in the hornwork.

Sometimes the crownwork is made before the bastion, as in fig. 2. The arc is described from the salient angle A of the bastion, with a radius of 120 toises, as before; and the branches terminate on the faces of the adjacent ravelins within 25 toises of their extremities: the rest of the dimensions and constructions are the same as before.

Hornworks as well as crownworks, are never made but when a large spot of ground falls beyond the fortification, which might be advantageous to an enemy in a siege, or to cover some gate or entrance into a town.

9. Construction of Covert-ways and Glacis.

ALTHOUGH we have not hitherto mentioned the covert-way nevertheless all fortifications whatsoever have one; for they are esteemed to be one of the most essential parts of a modern fortification; and it is certain, the taking the covert-way, when it is in a good condition and well defended, is generally the most bloody action of the siege.

After having constructed the body of the place and all the outworks which are thought necessary, lines are drawn parallel to the outmost counterscarp of the ditches, at 6 toises distant from it; and the space *mn*, *m n*, included between that line and the counterscarp will be the covert-way required.

Fig. 3. There is in every re-entering angle of the counterscarp a place of arms *m*; which is found by setting off 20 toises from the re-entering angle *a*, on both sides from *a* to *b*, and from *a* to *c*; and from the points *b*, *c*, as centres, arcs are described with a radius of 25 toises, so as to intersect each other in *d*; then the lines drawn from this intersection to the points *b*, *c*, will be the faces of the places of arms.

If lines are drawn, parallel to the lines which terminate the covert way, and the places of arms, at 20 toises distant from them, the space *x*, *x*, *x*, between these lines and those which terminate the covert-way, will be the glacis.

At the extremities of the places of arms, are traverses made, such as *v*, *v*, which serve to inclose them; these traverses are 3 toises thick, and as long as the covert-way is broad; and a passage is cut in the glacis round them, of about 6 or 8 feet, in order to have a free communication with the rest of the covert-way.

There are also traverses of the same dimensions before every salient angle of the bastion and outworks, and are in the same direction as the faces of those works produced; and the thickness lies at the same side as the parapets.

The passages round these last traverses are likewise from 6 to 8 feet wide.

In each place of arms are two sally ports *z z*, which are 10 or 12 feet wide, for the troops to sally out; in time of a siege they are shut up, with barriers or gates.

10. Construction of Arrows and Detached Redoubts.

An arrow is a work made before the salient angles of the glacis, such as A, fig. 3. It is composed of a parapet

Of
Covert-
ways, &c.
Plate
CXCVIII.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Of Covert-ways, &c. Plate CXCVIII. parapet of 3 toises thick, and 40 long; and the ditch before it 5 toises, terminating in a slope at both ends. The communication from the covert-way into these arrows is 4 or 5 toises wide; and there is a traverse, *r*, at the entrance, of 3 toises thick, with a passage of 6 or 8 feet round it.

A detached redoubt is a kind of work much like a vavelin, with flanks placed beyond the glacis; such as B: they are made in order to occupy some spot of ground which might be advantageous to the besiegers; likewise to oblige the enemy to open their trenches farther off than they would do otherwise.

Their distance from the covert-way ought not to exceed 120 toises, that it may be defended by musket-shot from thence.

The gorge *ab* is 40 toises; the flanks *ac*, *bf*, which are perpendicular to the gorge, 10; and the faces *cd*, *fd*, 30: the ditch before it is 6 toises, ending in slopes at both ends; the covert-way 4; the branches of the covert-way are 42 toises long, or thereabouts; the faces of the places of arms *yy*, which are perpendicular to the branches, 10; and the other which is parallel to them, 14.

The communication from the covert-way into the redoubt is 5 or 6 toises wide; and there is a traverse made just at the entrance, and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis.

If these redoubts are above 50 toises distant from the covert-way the besiegers carry their trenches round, and enter through the gorge; by which the troops that are in them are made prisoners of war, if they do not retire betimes; to prevent which, some other outworks should be made to support them.

11. Construction of Second Ditches and Covert-ways.

Fig. 4. When the ground is low, and water to be found, there is often a ditch about 10 or 12 toises made round the glacis; and opposite to the places of arms are constructed lunettes, beyond the ditch: such as D, whose breadth on the counterscarp of the ditch is 10 toises, from *b* to *a*, and from *c* to *d*; and the faces *aL*, *dL*, are parallel to those of the places of arms; the ditch before them is from 8 to 10 toises wide.

The second covert-way is 4 toises, the semi-gorges of the places of arms, *m*, about 15, and the faces perpendicular to the counterscarp; the second glacis is from 15 to 18 toises broad.

This second covert-way has traverses every where, in the same manner as the first.

12. Construction of Profiles

A PROFILE is the representation of a vertical section of a work; it serves to show those dimensions which cannot be represented in plans, and is necessary in the building of a fortification. Profiles are generally constructed upon a scale of 30 feet to an inch. It would be endless to describe all their particular dimensions; we shall therefore lay down the principal rules only, given by M. Vauban on this subject.

1. Every work ought to be at least 6 feet higher than that before it, so that it may command those before it; that is, that the garrison may fire from all the works at the same time, with great and small arms, at

the besiegers in their approaches. Notwithstanding this specious pretence, there are several authors who object against it. For, say they, if you can discover the enemy from all the works, they can discover, by the same reason, all the works from their batteries, so that they may destroy them without being obliged to change their situation, and thereby dismount all the guns of the place before they come near it.

But if all the works were of the same height, those within cannot be destroyed, till such time as those before them are taken: guns might be placed in the covert-way and outworks to obstruct the enemy's approach; and when they come near the place, they might be transported into the inner-works: and as the body of the place would be much lower, the expence would be considerably diminished.

But when works are low, they are easily enfiladed by the ricochet batteries, which is a kind of firing with a small quantity of powder, by giving the gun an elevation of 10 or 12 degrees: this might however be partly prevented, by making the parapets near the salient angles, for the space of 8 toises on each side 5 or 6 feet higher than the rest of the works.

2. The covert way should be lower than the level-ground, otherwise the body of the place must be raised very high, especially where there are several outworks: this is to be understood only when the works exceed each other in height, otherwise it need not be below the level.

3. The bases of all inward slopes of earth should be at least equal to the height, if not more.

4. The bases of all outward slopes of earth, two-thirds of their heights.

5. The slopes of all walls or revetments should be one-fifth of their height; or one-sixth might perhaps be sufficient; the height of a wall is estimated from the bottom of the ditch, and not from the beginning of its foundation.

6. The slopes of all parapets and traverses are one-sixth of their breadth; that is, 3 feet towards the field; or the inside, where the banquettes should be 3 feet higher than the outside.

7. When the revetment of a rampart goes quite up to the top, 4 feet of the upper part is a vertical wall of 3 feet thick, with a square stone at the top of it projecting six inches; and a circular one below, or where the slope begins, of 8 or 10 inches diameter; they go quite round the rampart, and the circular projection is called the *cordon*.

Where the straight part of the wall ends and the slope begins, the wall is always made 5 feet thick: and the counterforts or buttresses reach higher than that place.

8. When the rampart is partly walled and partly turfed, then one-fifth of the height which is turfed must be added to 5 feet, to get the thickness of the wall above.

And having the thickness of any wall above, by adding one-fifth of its height from the bottom of the ditch, the sum will be the thickness of the wall at the bottom; but if a sixth part is only taken for the slope, then a sixth part must be added.

For instance, suppose a rampart of 30 feet high from the bottom of the ditch, and that 10 of which are to be turfed; then the fifth part of 10, which is 2, added

Of
Irregular
Fortifica-
tion.

Plate
CXCIX.

to 5, gives 7 for the wall above; and as this wall is 20 feet high, the fifth of which is 4, and 4 added to the thickness 7 above, gives 11 for the thickness near the foundation.

Fig. 1. Represents, in military perspective, the profiles of the body of a place, the ravelin and covert-way; which gives a clear idea of what is meant by a profile, and from which those of all other works may be easily conceived.

SECT. II. *Of Irregular Fortification.*

THE most essential principle in fortification consists in making all the fronts of a place equally strong, so that the enemy may find no advantage in attacking either of the sides. This can happen no otherwise in a regular fortification situated in a plain or even ground: but as there are but few places which are not irregular either in their works or situations, and the nature of the ground may be such as makes it impracticable to build them regular without too great expence; it is so much the more necessary to show in what consists the strength or weakness of a town irregularly fortified, so that the weakest part may be made stronger by additional outworks; as likewise, if such a place is to be attacked, to know which is the strongest or weakest part.

I. *Construction of an irregular place situated in an open country.*

If the place to be fortified is an old town, inclosed by a wall or rampart, as it most frequently happens, the engineer is to consider well all the different circumstances of the figure, situation, and nature of the ground; and to regulate his plan accordingly, so as to avoid the disadvantages, and gain all the advantages possible: he should examine, whether by cutting off some parts of the old wall or rampart, and taking in some ground, the place can be reduced into a regular figure, or nearly so; for if that can be done without increasing the expence considerably, it should by no means be omitted. Old towns have often towers placed from distance to distance, as Douay, Tournay, and many other places, which are generally made use of, and mended when it may be done. If there is a rampart, without bastions or towers, it must be well considered whether bastions may not be added, or if it is not better to make only some outworks: if the ditch about this rampart is not too wide and deep, it would be advantageous to make detached bastions; otherwise ravelins and counterguards must be constructed. Special care must be taken to make all the sides of the polygon as nearly equal as possible, and that the length of the lines of defence do not exceed the reach of musket-shot; but if that cannot be done, those sides which are on the narrowest part should be made the longest.

If it should happen that some of the sides are inaccessible or of very difficult approach, either on account of some precipice, marshy ground, or inundation, they may be made much longer than the others which are of easy access, and the flanks need not be so large as the rest; by doing so, there will be some expences saved, which may be used in making the other sides stronger by adding more outworks.

There are few situations but what are more advan-

tageous in some parts than in others; it is therefore the business of an engineer to distinguish them and to render those side strong by art which are not so by nature.

If the situation is low and watery, lunettes or tenailons, and such other small outworks, should be constructed; because they are not of any great expence, and may make a very good defence. But if one side of the place only is low, and running water is to be had, a second ditch and covert-way with lunettes may be made, by observing that if the first glacis is made to slope, so as to become even with the level of the water in the second ditch; or if the water can be swelled by means of dykes or sluices, so as to overflow the best part of the first glacis, it should be done; for by so doing these works will be able to make a very good defence, since the besiegers will find it a difficult matter to lodge themselves upon this glacis; which cannot be done but within a few toises of the first covert-way, where the besieged are ready to receive them, and to destroy their works with great advantage; whereas the enemy cannot support their workmen but from the second covert-way, which is too far off to be of any great service to them.

But if the situation is of a dry nature, without any water about it, caponiers should be made in the great ditch, from the curtains to the ravelin, and batteries raised in the entrance of the ditch before the ravelin, whose parapet must slope off into a glacis so as to afford no cover for the enemy behind them. Arrows and detached redoubts are likewise very proper to be used in such a case; and sometimes horn or crown works, if it should be thought convenient; but these works should never be constructed without an absolute necessity, either to occupy a spot of ground which might be advantageous to the enemy, or to cover some gate or entrance into the town; for they are of great expence, and their defence seems not to be answerable to it.

Most of the places in Flanders are fortified with horn-works, such as Ipres, Tournay, Lille, and others.

If the place to be fortified is new, and the situation will not admit of a regular construction, particular care must be taken in choosing such a spot of ground as is most advantageous; and least liable to any disadvantages either in the building or in the maintaining of it. All hills or rising grounds should be avoided, which might command any part of the works; marshy grounds, because such situations are unwholesome; or lakes and standing waters for the same reason, excepting a lake is or may be made navigable. Good water should be had either within the place or near it, for it is absolutely necessary for men and cattle; the air should be wholesome; otherwise the continual sickness that may reign in such a place might prevent people from coming to live in it, and the garrison would not be in a condition to defend themselves as they ought to do. In short, all the different circumstances attending such an undertaking should be maturely considered before a resolution is taken to fortify any place.

When a situation is fixed upon, the next thing to be considered is, the bigness of the town and the number of its outworks; which must absolutely depend upon the consequence such a place is of to a nation. If it is only to guard a pass or entrance into a country, it need not be so large: but if it is to be a place either to promote

promote or to protect trade, it should be large and commodious: the streets should be wide, and the buildings regular and convenient. As to what regards the fortification, its construction should depend on the nature of the situation, and the number of works, on the funds or expence a prince or a nation will be at; which, however, ought to be according to the benefit arising from such a place: for as such undertakings are of very great expence, an engineer cannot be too sparing in his works; on the contrary, the greatest economy should be used both in regard to the number of works and to the construction. The body of the place may have (A) revetments quite up to the top, or only in part, and the rest turfed; but as to the outworks, they should have half revetments, or they may be made with turf only: as being not so necessary to prevent the place from being surpris'd, which may nevertheless make a good defence.

Fig 2. is the plan of an octagon, one half of which is similar and equal to the other half; it being supposed, that the situation would not admit of fortification quite regular. The exterior sides are each 180 toises, and the works are constructed according to our method: but because the sides AB, EF, are weaker than the rest, as has been proved before, we have added tenailles, redoubts in the ravelins, and lunettes, to render them nearly equal in strength with the others; and if counter-guards were made before the bastions A and B, it would effectually secure that front. Instead of lunettes, any other works may be made, as may be thought convenient and according to the nature of the ground. If it should be judged necessary to add other outworks to the ravelins all round the place, care must be taken to add likewise more to the fronts AB, EF, in order to render the advantages and disadvantages of attacking on either side equal.

2. Construction of an irregular place situated on a hill or rock.

In the construction of such places, care must be taken that no neighbouring hill commands any part of the works. The town should always be built on the highest part; but if it should be thought more convenient to place it lower, then the upper part must be fortified with a fort. The situation should be made level as near as possible, by removing the earth from some places to fill up others; and if it cannot well be levelled without extraordinary expence, works must be made on the highest part, so as to command and protect the lower. The works ought to occupy all the upper part of the hill; but if it should be too extensive to be all inclosed, or so irregular as not to be fortified without great inconvenience, the parts which fall without should be fortified with some detached works, and a communication with the place must be made either above or under ground. There should be no cavity or hollow roads within cannon-shot round about the place, where the enemy might be able to approach under cover. If there should happen to be a spring near the top of the hill, it should be inclosed in the fortification; or if that cannot be done, by some work or other: for there is

VOL. VII.

nothing more necessary, and at the same time scarcer, in such situations, than water; for which reason there cannot be too much care in providing it: several cisterns are to be made to receive the rain-water, and to preserve it; wells should be dug likewise, though ever so deep, the water of which will serve for common use.

Places built on hills or rocks should never be large; for their use is generally to guard passes or inlets into a country, and are seldom useful in traffic; and it is a difficult matter to provide for a large garrison in such situations, neither should any such place be built without some very material reasons: but when it is absolutely necessary, great care and precaution should be taken to render the works as perfect as the situation will admit of, and at the same time to be as frugal in the expence as possible.

3. Construction of irregular fortifications situated near rivers, lakes, or the sea.

As the intent of building these kind of places is chiefly to facilitate and protect trade, they are of more importance than any other kind, especially in maritime countries, where the principal strength and power depends on them: for which reason we shall treat of this construction more largely than of any other.

The first thing to be considered is their situation, which ought to be such as to afford a good harbour for shipping, or a safe and easy entrance in stormy weather; but as it is hardly possible to find any where ships may go in and lie secure with all winds, care should be taken to make them safe to enter with those winds which are most dangerous: but it is not sufficient that the harbour is safe against stormy weather, they should likewise be so against an enemy both by land and water; for it often happens, that ships are destroyed where it was imagined they were secure, which is of too great consequence not to be provided against; for which reason, forts or batteries must be built in the most convenient places, to prevent the enemy's ships from coming too near, so as to be able to cannonade those in the harbour, or sling shells among them; and if there is any danger of an enemy's approach by land, high ramparts and edifices must be built, so as to cover them.

When a river is pretty large, and it is not convenient for making a harbour without great expence, the ships may ride along the shore; which, for that reason, must be made accessible for ships of burthen: this may be done by advancing the quay into the river if the water is too shallow, or by digging the river sufficiently deep for that purpose.

And to prevent an enemy from coming up the river, forts must be built on both sides, especially where there are any turnings or windings. Antwerp is such a place: for the Scheldt is sufficiently deep to carry ships of great burthen, which may come quite near the town-wall; and several forts are built below it on both sides, so that it would not be an easy matter for an enemy to come up the river.

When the river is but small, so that no ships of bur-

3 A

den

(A) Revetments are chiefly made to prevent a place from being surpris'd: outworks do not want to be made so; the taking them by surpris'e is of no great consequence, except in a siege, when other cautions are used to prevent it.

den can come through it, it is sufficient to make it run through some of the works, where proper landing-places are contrived, from whence the goods may be carried in to the place; as at Sarrelouis, where a horn-work is built beyond the Sarre, in the gorge of which the goods are landed.

If the breadth of the river does not exceed 200 yards, it commonly passes through the middle of the town, and proper quays are made on each side; in such a case, the fortification is so contrived, as that the river passes through the curtain, in order to have a bastion on each side to defend the coming in and going out.

When M. Vauban fortified near rivers, he made always the exterior side near the water much longer than any of the others: such as Hunninghen on the Rhine, and Sarrelouis on the Sarre; but for what reason he fortified these places in that manner, has not been told by any author.

But it is plain that the sides which terminate at the river are the weakest; because the besiegers trenches being secured by the river, they may draw most of their troops off, and act therefore with more vigour and strength on the other side: besides, as the strength of a side increases in proportion as the angle of the polygon is greater, by making the side next the river longer, the angles at its extremities become wider, and consequently the adjacent sides stronger.

There are other advantages, besides those mentioned already, which arise from the lengthening that side: for if the river is pretty deep so as not to be fordable, that side is not liable to be attacked; and by increasing its length, the capacity of the place increases much more in proportion to the expence, than if more sides were made; the centre of the place will be likewise nearer the river, which makes it more convenient for transporting the goods from the water-side to any part of the town.

Fig. 3.

To illustrate this method of M. Vauban's we shall give the plan of Hunninghen: this place was built for the sake of having a bridge over the Rhine, for which reason he made it only a pentagon; the side AB next to the river is 200 toises, and each of the others but 180.

About the space abc , which lies before the front AB, is a stone wall; and the passages xx are shut up with sluices, to retain the water in the ditches in dry seasons: and to prevent an enemy from destroying the sluice near the point c , whereby the water would run out and leave the ditches dry, the redoubt y was built in the little island hard by, in order to cover that sluice; without which precaution the place might be insulted from the river side, where the water is shallow in dry seasons.

The hornwork K beyond the Rhine was built to cover the bridge; but as this work cannot be well defended cross the river, the hornwork H was made to support the other.

Before finishing the description of this plan, we shall show how to find the long side AB.

After having inscribed the two sides GE, GF, in a circle, draw the diameter CD, so as to be equally distant from the line joining the points EF that is parallel to it. On this diameter set off 100 toises on each side of the centre; from these points draw two indefinite perpendiculars to the diameter; then if from the points EF, as centres, two arcs are described with a radius of 180 toises, their intersections, A and B, with the said perpendiculars, will determine the long side AB, as likewise the other two FB and EA. In like manner may be found the long or short side of any polygon whatsoever.

When a place near a river is to be fortified for the safety of commerce, particular care should be taken in leaving a good space between the houses and the water-side, to have a key or landing place for goods brought by water; it should also be contrived to have proper places for ships and boats to lie secure in stormy weather, and in time of a siege; and as water-carriage is very advantageous for transporting goods from one place to another, as likewise for bringing the necessary materials, not only for building the fortifications, but also the place itself, the expences will be lessened considerably when this convenience can be had; for which reason, places should never be built any where else but near rivers, lakes, or the sea; excepting in extraordinary cases, where it cannot be avoided.

F O R

Fortin
Fortitude.

FORTIN, FORTELET, or *Field-fort*, a sponce or little fort, whose flanked angles are generally 120 fathoms distant from one another.

The extent and figure of fortins are different, according to the situation and nature of the ground; some of them having whole bastions, and others demi-bastions. They are made use of only for a time, either to defend the lines of circumvallation, or to guard some passage or dangerous post.

FORTISSIMO, in music, sometimes denoted by FFF, or *fff*, signifies, to sing or play very loud or strong.

FORTITUDE, a virtue or quality of the mind, generally considered as the same with COURAGE; tho' in a more accurate sense they seem to be distinguishable. Courage may be a virtue or a vice, according to circumstance; *fortitude* is always a virtue; we speak

F O R

Fortitude.

of desperate courage, but not of desperate fortitude. A contempt or neglect of danger, without regard to consequences, may be called *courage*; and this some brutes have as well as we: in them it is the effect of natural instinct chiefly; in man it depends partly on habit, partly on strength of nerves, and partly on want of consideration. But fortitude is the virtue of a rational and considerate mind, and is founded in a sense of honour and a regard to duty. There may be courage in fighting a duel, though that folly is more frequently the effect of cowardice: there may be courage in an act of piracy or robbery; but there can be no fortitude in perpetrating a crime. Fortitude implies a love of equity and of public good: for, as Plato and Cicero observe, courage exerted for a selfish purpose, or without a regard to justice, ought to be called audacity rather than fortitude.

This

Fortitude,
Fortuna.

This virtue takes different names, according as it acts in opposition to different sorts of evil; but some of those names are applied with considerable latitude. With respect to danger in general, fortitude may be termed *intrepidity*; with respect to the dangers of war, *valour*; with respect to pain of body or distress of mind, *patience*; with respect to labour, *activity*; with respect to injury, *forbearance*; with respect to our condition in general, *magnanimity*.

Fortitude is very becoming in both sexes; but courage is not so suitable to the female character: for in women, on ordinary occasions of danger, a certain degree of timidity is not unseemly, because it betokens gentleness of disposition. Yet from those of very high rank, from a queen or an empress, courage in emergencies of great public danger would be expected, and the want of it blamed; we should overlook the sex, and consider the duties of the station. In general, however, masculine boldness in a woman is disagreeable; the term *virago* conveys an offensive idea. The female warriors of antiquity, whether real or fabulous, Camilla, Thalestris, and the whole community of AMAZONS, were unamiable personages. But female courage exerted in defence of a child, a husband, or a near relation, would be true fortitude, and deserve the highest encomiums.

The motives to fortitude are many and powerful. This virtue tends greatly to the happiness of the individual, by giving composure and presence of mind, and keeping the other passions in due subordination. To public good it is essential; for without it, the independence and liberty of nations would be impossible. It gives to a character that elevation which poets, orators, and historians, have in all ages vied with one another to celebrate. Nothing so effectually inspires it as rational piety; the fear of God is the best security against any other fear. A true estimate of human life; its shortness and uncertainty; the numberless evils and temptations to which by a long continuance in this world we must unavoidably be exposed; ought by no means to discourage or to throw any gloom on our future prospects: they should teach us, that many things are more formidable than death; and that nothing is lost, but much gained, when, by the appointment of Providence, a well-spent life is brought to a conclusion.

Let it be considered too, that pusillanimity and fearfulness can never avail us any thing. On the contrary they debase our nature, poison all our comforts, and make us despicable in the eyes of others; they darken our reason, disconcert our schemes, enfeeble our efforts, extinguish our hopes, and add tenfold poignancy to all the evils of life. In battle, the brave soldier is in less danger than the coward; in less danger even of death and wounds, because better prepared to defend himself; in far less danger of infelicity; and has before him the animating hope of victory and honour. So in life, the man of true fortitude is in less danger of disappointment than others are, because his understanding is clear, and his mind disencumbered; he is prepared to meet calamity without the fear of sinking under it; and he has before him the near prospect of another life, in which they who piously bear the evils of this will obtain a glorious reward.

FORTUNA, a goddess worshipped with great de-

votion by the ancient Greeks and Romans; who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure. See FORTUNE.

Fortunate;
Fortune.

FORTUNATE-ISLANDS, in ancient geography, certain islands (concerning the situation of which authors are not agreed) famous for the golden apples of the HESPERIDES.—The common opinion is, that they are the CANARY Islands.

FORTUNE (*Tύχη*), a name which among the ancients seems to have denoted a principle of fortuity, whereby things came to pass, without being necessitated thereto: but what and whence that principle is, they do not seem to have ever precisely thought.—Hence their philosophers are often intimating, that men only framed the phantom *Fortune* to hide their ignorance; and that they call *Fortune* whatever befalls a man without his knowing for what purpose. Hence Juvenal (sat. x. ver. 366.) affirms, there were men who made a deity of Fortune.

*Nullum numen abest, si sit prudentia; sed te
Nos facimus, Fortuna, deam, caeloque locamus.*

The ingenious Mr Spence gives another reading of this passage:

*Nullum numen habes, si sit prudentia; sed te
Nos facimus, Fortuna, deam caeloque locamus.*

This reading, he thinks, agrees best with the context: Juvenal says, ver. 356. that the two things we should pray for are good health and good sense, that we might be the authors of our own happiness if we pleased, ver. 363; that virtue is the only way to true happiness, ver. 364; that if we ourselves are prudent, Fortune has no power over us; and that, in truth, she is no goddess at all, and has only usurped a seat in heaven from the folly of mankind, ver. 366. Fortune was not considered as a deity by the old Romans, but was made so by the devotion and folly of the vulgar; and Mr Spence says, that he has seen an ancient gem, in which Cybele, the mother of the gods, is represented as turning away her head from Fortune, in an attitude of disowning and rejecting her; (*Polymetis*, p. 150, 154. &c.)

According to the opinion of the heathens, therefore, fortune in reality was only the arrival of things in a sudden and unexpected manner, without any apparent cause or reason: so that the philosophical sense of the word coincides with what is vulgarly called *chance*.

But in religion it had a farther force; altars and temples in great numbers were consecrated to this Fortune, as a deity. This intimates, that the heathens had personified, and even deified, their chance; and conceived her as a sort of goddess, who disposed of the fate of men at her pleasure. Hence that invocation of Horace, *O diva, gratum quæ regis Antium*, in the 35th ode of the first book, where he recommends Augustus, then preparing for a visit to Britain, to her protection. From these different sentiments it may be inferred, that the ancients at one time took Fortune for a peremptory cause, bent upon doing good to some, and persecuting others; and sometimes for a blind inconstant cause, without any view or determination at all.

If then the word *fortune* had no certain idea in the mouth of those who erected altars to her, much less can it be ascertained what it denotes in the mind of

Fortune
||
Forum.

those who now use the word in their writings. They who would substitute the name *Providence* in lieu of that of *Fortune*, cannot give any tolerable sense to half the phrases wherein the word occurs.

Horace paints the goddess, preceded by Necessity, holding nails and wedges in her hands, with a cramp-iron, and melted lead to fasten it; rarely accompanied with Fidelity, unless when she abandons a family; for in that case Fidelity never fails to depart with her, as well as friends.

She is disrespectfully spoken of by most of the Roman writers, and represented as blind, inconstant, unjust, and delighting in mischief, (*Ovid ad Liv.* ver. 52. ver. 374. *Hor.* lib. i. od. 34. ver. 26. lib. iii. od. 29. ver. 51. *Statius*, *Theb.* xii. ver. 505.) However, they had a good as well as a bad Fortune, a constant and inconstant Fortune; the latter of which was represented with wings, and a wheel by her, (*Hor.* lib. iii. od. 29. ver. 56.) Juvenal alludes to a statue of Fortune, which exhibited her under a very good character, as the patroness of the poor infants that were exposed by their parents in the streets, (*Sat.* vi. ver. 605.)

The painters represent her in a woman's habit, with a bandage before her eyes, to show that she acts without discernment, and standing on a wheel, to express her instability. The Romans, says Lactantius, represented her with a cornucopia, and the helm of a ship, to show that she distributes riches, and directs the affairs of the world. In effect, it is with such characters that we see her represented on so many medals, with the inscriptions, FORTVNA AVG. FORTVNA REDVX. FORTVNE AVG. OR REDVCIS, &c. Sometimes she is seen pointing at a globe before her feet, with a sceptre in one hand, and holding the cornucopia in the other.

The Romans had a virile as well as a muliebrian Fortune, for the objects of their adoration: the *Fortuna virilis* was honoured by the men, and the *Fortuna muliebris* by the women. They honoured Fortune also under a variety of other appellations.

The Romans derived the worship of Fortune from the Greeks, under the reign of Servius Tullius, who dedicated the first temple to her in the public market. Nero also built a temple to Fortune. The Fortune worshipped at Antium was probably of the most exalted character of any among the Romans; if we may judge by the account which Horace gives us of the great solemn processions that were made to her, (*Hor.* lib. i. od. 35. ver. 22) But the most celebrated temple of Fortune was at Prænestæ. Statius speaks of several Fortunes there, and calls them the *Prænestinæ sorores*, (*Lib.* i. *Sylv.* iii. ver. 80.)

FORTUNE-Tellers. Persons pretending to tell fortunes are to be punished with a year's imprisonment, and standing four times on the pillory. *Stat.* 9 *Geo.* II. c. 5.

FORTY-DAYS Court, the court of attachment or woodnote, held before the verderors of the forest once every forty days, to inquire concerning all offenders against vert and venison. See ATTACHMENT.

FORUM, in Roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.

FORUM was also used for a place of traffic, answering to our market-place. These were generally called

fora venalia; in contradistinction to the former, which were called *fora civilia*.

Forum.

The *fora civilia* were public courts of justice, very magnificent in themselves, and surrounded with porticos and stately edifices; of these there were six very remarkable: 1. *Forum Romanum*. 2. *Julianum*. 3. *Augustum*. 4. *Palladium*. 5. *Forum Trajani*. 6. *Forum Salustii*. The *Forum Romanum* was the most noted, and is often called simply *Forum*, by way of eminence. Here was the pleading-place called *Rostra*, the *Comitium*, the sanctuary of *Saturn*, temple of *Castor*, &c. See ROSIRA, COMITIUM, &c.

The *fora venalia*, or market-places, were very numerous. The chief of them were the *forum boarium* for oxen or beef; *suarium* for swine; *pistorium* for bread; *cupedinarium* for dainties; *elitorium* for garden stuff.

The Grecian *Αγοραι* exactly corresponds with the Roman *fora*, being places where courts and markets were held. At Athens they had many *fora*, but the chief of them were the *old* and the *new*.

FORUM Indicere, was the act of the prætor appointing the place in Rome where causes were to be tried. *Agere forum* denoted the bringing on causes out of Rome, in a Roman province (*Cicero*, *Suetonius*); the same with *agere conventum* (*Florus*).

The term *forum* added to a proper name, denoted some market town or borough; as,

FORUM Alienii, a place mentioned only by *Tacitus*; and, from what he says of it, thought to be *Ferrara*, capital of the duchy of that name in Italy. E. Long. 12. 5. N. Lat. 44. 46.

FORUM Apii (*Cicero*, *Luke*); a town of the *Volsci*, in *Latium*, on the *Via Appia*, a little beyond the *Tres Tabernæ*; set down in the *Jerusalem Itinerary* as situated near the river *Nymphæus*: now entirely extinct.

FORUM Cornelii, a town of the *Cispadana*, built by *Sylla*: Now *Imola*, a city in the *Romania*, and territory of the pope. E. Long. 12. 12. N. Lat. 44. 30.

FORUM Domitii, a town of *Gallia Narbonensis*; probably built by *Ahenobarbus Domitius*, who commanded in those parts: Now *Frontignan*, or *Frontigniac*, in *Languedoc*, near the *Mediterranean*. E. Long. 3. 30. N. Lat. 43. 30.

FORUM Fulvii, a town of *Liguria*, surnamed *Valentinum*; from which it is conjectured that it is now *Valenza*, in the duchy of *Milan*; which is confirmed by *Peutinger's* distances. E. Long. 9°. N. Lat. 45°.

FORUM Gallorum, a small town of the *Cispadana*, on the *Via Emilia*, eight miles from *Mutina*, beyond the river *Scultenna*. Here *Antony* defeated *Pansa*, and was in his turn defeated by *Hirtius*: Now *Castelfranco*, in the territory of *Bologna*.—Another *Forum Gallorum*, a town of the *Vascones* in the *Hither Spain*: Now *Currea*, a small town of *Arragon*.

FORUM Julium. There are several towns of this name; as a *Forum Julium*, of *Gallia Narbonensis*; or *Forojukum*: Now *Frejus*, or *Frejules*, in *Provence*, at the mouth of the *Argens*. *Forum Julium Carnorum*, to the north of *Aquileia*, in the *Transpadana*; Now *Cividale di Friuli*, formerly *Cividale d' Austria*, in the territory of *Venice*.

FORUM Jutuntorum, a town of the *Insubres*, in the *Transpadana*: Now *Crema*, capital of the *Cremafco*.

Forum in the territory of Venice. E. Long. 10. 15. N. Lat. 45. 20.

Fosse. **FORUM Livii**, a town of the Sæmnonæ, in the Cispadana: Now *Forli*, in Romania. E. Long. 12. 45. N. Lat. 44. 25.

FORUM Segusianorum, situated on the east side of the Liger, in Gallia Celtica: Now *Feurs*, on the Loire, in the Lionnois, capital of the territory of Forez. E. Long. 4. 15. N. Lat. 45. 44.

FORUM Tiberii, a town of the Pagus Tigurinus, in Belgica, on the left or south side of the Rhine: Now *Kayserstull*; literally the tribunal of Tiberius, which he held there when commander in the Rhetian war.

FORUM Vulcani (Strabo): the *Campi Phlegræi* of Pliny: a plain in Campania, encompassed with rocky eminences, near Puteoli, and distant from it two miles towards Naples, emitting smoke, and in some places flame, like a large extensive furnace, and yielding sulphur: Now called *Solfataræ*, in the Terra di Lavoro.

FORUM, is also used, among casuists, &c. for jurisdiction: thus they say, *In foro legis*, &c.

FOSS, or **FOSSE**, in fortification, &c. a ditch or moat. The word is French, formed of the Latin participle *fossus*, of the verb *fodio* "I dig."

Foss, *Fossa*, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation. When the aperture is very narrow, it is called a *sinus*.

Foss is particularly used for the cavity or denture in the back part of the neck.

FOSSA MAGNA, or **NAVICULARIS**, is an oblong cavity, forming the inside of the *pudendum muliebre*, and which presents itself upon opening the labia; and in the middle whereof are the *carunculæ myrtiformes*. See **ANATOMY**, p. 470.

FOSSA, in our ancient customs, was a ditch full of water, where women committing felony were drowned; as men were hanged: *Nam et ipsi in omnibustenenentis suis omnem ab antiquo legalem habere justitiam, videlicet ferrum, fossam, furcas, et similia*. In another sense it is taken for a grave, as appears by these old verses:

*Hic jacent in fossa Bedæ venerabilis ossa;
Hic est fossatus, qui bis erat hic cathedratus.*

Foss-way was anciently one of the four great Roman high-ways of England: so called, according to Camden, because it was ditched on both sides, which was the Roman method of making highways.

FOSSARII, in antiquity, a kind of officers in the eastern church, whose business was to inter the dead.

Ciaconius relates, that Constantine created 950 fossaries, whom he took out of the divers colleges or companies of tradesmen: he adds, that they were exempted from taxes, services, burdensome offices, &c.

F. Goar, in his notes on the Greek Euchologion, insinuates that the fossarii were established in the times of the apostles; and that the young men, who carried off the body of Ananias, and those persons full of the fear of God who interred St Stephen, were of the number.

St Jerom assures us, that the rank of fossarii held the first place among the clerks; but he is to be understood of those clerks only who had the direction and intendance of the interment of the devout.

FOSSE, the Roman Military-way in South Britain,

begins at Totness, and passes through Exeter, Ivelchester, Shepton-Mallet, Bath, Cirencester, Leicester, the Vale of Belvoir, Newark, Lincoln, to Barton upon the Humber, being still visible in several parts, tho' of 1400 years standing. It had the name from the fosses or ditches made by the sides of it.

FOSSIL, in natural history, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, stones, salts, earths, and other minerals; or extraneous, repositied in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c. See **METAL**, **STONE**, &c.

Native fossils, according to Dr Hill, are substances found either buried in the earth, or lying on its surface of a plain simple structure, and showing no signs of containing vessels or circulating juices. These are subdivided by the same author, 1. Into fossils naturally and essentially simple. Of these, some are neither inflammable nor soluble in water; as simple earths, talcs, fibrariæ, gypsum, selenitæ, crystal, and spars: others, though uninflammable, are soluble in water; as all the simple salts: and others, on the contrary, are inflammable, but not soluble in water; as sulphur, auripigmentum, zarnich, amber, ambergris, gagates, asphaltum, ampelites, lithanthrax, naphtha, and pissaphalta. 2. The second general subdivision of fossils comprehends all such as are naturally compound, but nonmetallic. Of these, some are neither inflammable, nor soluble in water; as compound earths, stones, septariæ, siderochita, femipellucid gems, &c. others are soluble in water, but not inflammable; as all the metallic salts: and, lastly, some are inflammable, but not soluble in water; as the marcasites, pyritæ, and phlogonia. 3. The third, and last, general division of fossils comprehends all the metallic ones; which are bodies naturally hard, remarkably heavy, and fusible in fire. Of these, some are perfectly metallic, as being malleable when pure; such are gold, lead, silver, copper, iron, and tin: others are imperfectly metallic, as not being malleable even in their purest state; such are antimony, bismuth, cobalt, zinc, and quicksilver or mercury. Of all which substances, the reader will find a particular description under their respective heads.

Extraneous fossils are bodies of the vegetable or animal kingdoms accidentally buried in the earth. Of the vegetable kingdom, there are principally three kinds, trees or parts of them, herbaceous plants, and corals; and of the animal kingdom there are four kinds, sea-shells, the teeth or bony palates and bones of fishes, complete-fishes, and the bones of land-animals. See **BONES**, **TREE**, **WOOD**, **PLANT**, **SHELL**, &c.

These adventitious or *extraneous* fossils, thus found buried in great abundance in divers parts of the earth, have employed the curiosity of several of our latest naturalists, who have each their several system to account for the surprising appearances of petrified sea-fishes, in places far remote from the sea, and on the tops of mountains; shells in the middle of quarries of stone; and of elephants teeth, and bones of divers animals, peculiar to the southern climates, and plants only growing in the east, found fossil in our northern and western parts.

Some will have these shells, &c. to be real stone, and

Fossil.

Foster.

and stone plants, formed after the usual manner of other figured stones; of which opinion is the learned Dr Lister.

Another opinion is, that these fossil shells, with all their foreign bodies found within the earth, as bones, trees, plants, &c. were buried therein at the time of the universal deluge; and that, having been penetrated either by the bituminous matter abounding chiefly in watery places, or by the salts of the earth, they have been preserved entire, and sometimes petrefied.

Others think, that those shells, found at the tops of the highest mountains, could never have been carried thither by the waters, even of the deluge; inasmuch as most of these aquatic animals, on account of the weight of their shells, always remain at the bottom of the water, and never move but close along the ground. They imagine, that a year's continuance of the waters of the deluge, intermixed with the salt waters of the sea, upon the surface of the earth, might well give occasion to the production of shells of diverse kinds in different climates; and that the universal saltiness of the water was the real cause of their resemblance to the sea-shells, as the lakes formed daily by the retention of rain or spring water produce different kinds.

Others think, that the waters of the sea, and the rivers, with those which fell from heaven, turned the whole surface of the earth upside down; after the same manner as the waters of the Loire, and other rivers, which roll in a sandy bottom, overturn all their sands, and even the earth itself, in their swellings and inundations; and that in this general subversion, the shells came to be interred here, fishes there, trees there, &c. See DELUGE.

Dr Woodward, in his Natural History of the Earth, pursuing and improving the hypothesis of Dr Burnet, maintains the whole mass of earth, with every thing belonging thereto, to have been so broken and dissolved at the time of the deluge, that a new earth was then formed on the bosom of the water, consisting of different strata, or beds of terrestrial matter, ranged over each other usually according to the order of their specific gravities. By this means, plants, animals, and especially fishes and shells, not yet dissolved among the rest, remained mixed and blended among the mineral and fossil matters; which preserved them, or at least assumed and retained their figures and impressions either indentedly, or in reliev.

See more on this subject under the article EARTH, *passim*. See also PETRIFACTIONS and STRATA.

FOSILLE Pitch. See PETROLEUM.

FOSTER (Dr James), a most distinguished and popular dissenting minister, born at Exeter in 1697. He began to preach in 1718; and strong disputes arising soon after, among the dissenters, concerning the Trinity and subscription to tests, his judgment determining him to the obnoxious opinions, the clamour grew loud against him, and occasioned more than one removal. His talents were hid among obscure country congregations, until 1724; when he was chosen to succeed Dr Gale in Barbican, where he laboured as pastor above 20 years. The Sunday evening-lecture, begun in the Old Jury meeting-house in 1728, and which he conducted with such uncommon applause for more than 20 years, indisputably showed his abilities as a preacher. Persons of all persuasions and ranks in life

2

flocked to hear him: and Mr Pope has honoured him with a commendatory couplet in his satires; which, however, his commentator laboured to destroy the intention of by a frivolous note. In 1746, he attended the unhappy lord Kilmarnock, at his execution on Tower-hill; an office which those who lived with him imagined made too deep an impression on his sympathizing spirit, as his vivacity abated from that time. He died in 1753; after having published several valuable compositions and sermons; particularly. 1. A Defence of Christianity, against Tindal's Christianity as old as the Creation. 2. An Essay on Fundamentals. 3. Four volumes of Sermons. 4. Discourses on Natural Religion and Social Virtue, in 4to.

FOSTER (Samuel), an ingenious English mathematician of the last century, and astronomical professor in Gresham college, was one of that learned association which met for cultivating the new philosophy during the political confusions, and which Charles II. established into the Royal Society. Mr Foster, however, died in 1652, before this incorporation took place; but wrote a number of mathematical and astronomical treatises, too many to particularize. There were two other mathematical students of this name; William Foster, a disciple of Mr Oughtred, who taught in London; and Mark Foster, author of a treatise on trigonometry, who lived later than the former two.

FOTHER, or FODDER, is a weight of lead, containing eight pigs, and every pig one and twenty stone and a half; so that it is about a ton or common cart-load. Among the plumbers in London, it is nineteen hundred and a half; and at the mines it is two and twenty hundred and a half. The word is of Teutonic origin, from *fuder*.

FOTHERGILL (Dr George), was born in Westmoreland in 1705, where his family had been long seated on a competent estate that had descended regularly for several generations. After an academical education in Queen's college, Oxford, of which he became a fellow, he was, in 1751, elected principal of St Edmund's-hall, and presented to the the vicarage of Brumley in Hampshire. Having been long afflicted with an asthma, he died in 1760. He was the author of a collection of much esteemed sermons, in 2 vols 8vo. The first volume consists of occasional discourses, published by himself; the second printed from his MSS.

FOTHERGILL (Dr John), a late eminent physician, son of John and Margaret, quakers, was born in 1712, at Carr End in Yorkshire, where his father, who had been a brewer at Knaresborough (after having travelled from one end of America to the other), lived retired on a small estate which he cultivated. The Doctor was the second of five children (four sons and a daughter), and received his education under the care of his grandfather Thomas Hough, a person of fortune in Cheshire (which gave him a predilection for that county), and at Sedburg in Yorkshire. He afterwards served his time to one Mr Bartlett an apothecary at Bradford. From thence he removed to London, and became a pupil of Dr (afterwards Sir Edward) Wilmot at St Thomas's Hospital. He then went to the university of Edingburgh to study physic, and took his doctor's degree there. From Edingburgh he went to Leyden: whence, after a short stay, he returned to London, and began to practise about the year 1740,

in

Fothergill.

Fothergill. in a house in White-hart Court, Lombard-street, where he resided during the greatest part of his life, and acquired most of his fortune. In 1746, he was admitted a licentiate of the college of physicians in London; and in 1754 a fellow of that of Edinburgh, to which he was a considerable benefactor. He afterwards became a member of the Royal Medical Society at Paris, and a member both of the Royal and Antiquarian Societies. He continued his practice with uninterrupted success till within the last two years of his life, when the illness which he had brought on himself by unremitting attention, obliged him to give up a considerable part of it. Besides his application to medical science, he had imbibed an early taste for natural history, improved by his friend Peter Collinson, and employed himself on coquillage and smaller objects of botany. He was for many years a valuable contributor to the Gentleman's Magazine; where his observations on the weather and diseases were begun in April 1751, and discontinued in the beginning of 1756, being disappointed in his views of exciting other experienced physicians in different parts to imitate the example. He had very extensive practice, but he did not add to his art any great or various improvements. His pamphlet on the ulcerous sore throat is, on every account, the best of his publications; but owes much of its merit to the information of the late Dr Letherland. It was first printed in 1748, on the re-appearance of that fatal disorder which in 1739 had carried off the two only sons of Mr Pelham. In 1762 Dr Fothergill purchased an estate at Upton in Essex; and formed a botanic garden there, the second in Europe: Kew is the first. In 1766 he began regularly to withdraw, from Midsummer to Michaelmas, from the excessive fatigue of his profession, to Lee-Hall, near Middlewich, in Cheshire; which, though he only rented it by the year, he had spared no expence to improve. He took no fees during this recess, but attended to prescribe gratis at an inn at Middlewich once a-week. In 1767, after he found himself obliged to relax his attention to business, he removed from his house in the city, to reside in Harpur-street, Red-Lion Square. Some time before his death he had been industrious to contrive a method of generating and preserving ice in the West-Indies. He was the patron of Sidney Parkinson, and drew up the preface prefixed to his account of the voyage to the South Seas. At his expence also was made and printed an entire new translation of the whole Bible, from the Hebrew and Greek originals, by Anthony Purver, a Quaker, in two volumes, 1764, folio, and also, in 1780, an edition of bishop Piercy's "Key to the New Testament," adapted to the use of a seminary of young Quakers, at Acworth, near Leeds in Yorkshire, founded in 1778 by the Society, who purchased, by a subscription in which Dr Fothergill stood foremost, the house and an estate of thirty acres which the Foundling Hospital held there, but which they found inconvenient for their purpose on account of distance. The Doctor himself first projected this on the plan of a smaller institution of the same kind at Gildersomes. He also endowed it handsomely by his will. It now contains above 300 children of both sexes, who are clothed and instructed. Among the other beneficent schemes suggested by Dr Fothergill were those of bringing fish to London by land car-

riage, which, though it did not in every respect succeed, tended to destroy a supposed combination; and of rendering bread much cheaper, though equally wholesome, to the poor, by making it with one part of potatoes and three parts of household flour. But his public benefactions, his encouragements of science, the instances of his attention to the health, the police, the convenience of the metropolis, &c. we cannot pretend to specify. The fortune which Dr Fothergill had acquired was immense; and, taking all things together, the house and moveables in Harpur-street, the property in Essex, and the estate in Cheshire (which he held on a lease), and his ready money, amounted to L.80,000. His business when he was in full practice was calculated at near L. 7000 per annum. In the influenza of 1775 and 1776, he is said to have had 60 patients on his list daily, and his profit was estimated at L. 8000 per annum.

The disorder which hastened his death was a scirrhous of the prostata, and an obstruction in the bladder (in which were found after his death two quarts of water), which had been gradually coming on him for six years past, occasioned by a delicacy, which made him unwilling to alight from his carriage; and when, after his temporary recovery from it the year before he died, he submitted to use relief in his carriage, it was too late. He died at his house in Harpur-street, December 26. 1780; and his remains were interred, January 5. in the Quakers burying-ground at Winchmore-hill, whither they were accompanied by more than 70 coaches and post-chaises, notwithstanding the intention of the executors to have the funeral private. The Doctor by his will appointed, that his shells, and other pieces of natural history, should be offered to the late Dr Hunter at L. 500 under the valuation he ordered to be taken of them. Accordingly Dr Hunter bought them for L. 1200. The drawings and collections in natural history were also to be offered to Mr (now Sir Joseph) Banks at a valuation. His English portraits and prints, which had been collected by Mr John Nickolls of Ware, and purchased by him for 80 guineas, were bought for 200 guineas by Mr Thane. His books were sold by auction, April 30. 1781, and the eight following days. His house and garden at Upton, in which 15 men were constantly employed, were valued at L. 10,000. He spared no expence to augment this as well as his other collections. He had an ingenious artist qualified to collect for him at the Cape of Good Hope, and another on the Alps, and employed for several years before his death a painter in natural history at Leeds.

Dr Fothergill's character was excellent. A transaction, indeed, with regard to one Dr Leeds, gave occasion to some of his enemies to blame him; but how unjustly, has been abundantly shown by his biographers Dr Elliott and Dr Lettsome. Besides the pamphlet already mentioned, Dr Fothergill wrote a considerable number of Tracts, which are now collected into one volume 8vo, by Dr Elliott. He sometimes wrote in the newspapers, and is said to have been the author of more than 100 letters in the *Gazeteer* concerning the New Pavement.

FOTHERGILLA, in botany: A genus of the digynia order, belonging to the polyandria class of plants.

The

Fothergill,
Fothergilla

Fothering
||
Foul.

The calyx is lobed, most entire; there is no corolla; the germen bifid; the capsule bilocular; and the cells two valved; the seeds solitary and bony.

FOTHERING, a peculiar method of endeavouring to stop a leak in the bottom of a ship while she is afloat, either under sail or at anchor. It is usually performed in the following manner: A basket is filled with ashes, cinders, and chopped rope-yarns, and loosely covered with a piece of canvas; to this is fastened a long pole, by which it is plunged repeatedly in the water, as close as possible to the place where the leak is conjectured to lie. The oakum or chopped rope-yarns being thus gradually shaken through the twigs, or over the top of the basket, are frequently tuck'd into the holes along with the water, so that the leak becomes immediately choaked; and the future entrance of the water is thereby prevented.

FOTHERINGAY, a town of Northamptonshire, about four miles from Staneford, situated on the river Avon or Nen, and consisting of one street. Edward duke of York in the reign of Henry V. founded and endowed a fine collegiate church here, in which he was interred. At the dissolution the college and the choir were pulled down, and the bodies of the founder and his family left exposed till queen Elizabeth's time, who ordered them to be interred, and the present monuments to be erected. On the north side of the church is a free school, founded by Henry VII. or Edward VI. endowed with L.20 *per annum* for a master, payable out of the exchequer by the receiver of the county. The bridge over the river here was first built by queen Elizabeth, 1573, of timber, with three pillars upon the foundation. Daniel, first earl of Nottingham, and the other trustees for William Saville, marquis of Halifax, rebuilt it, in 1722, of freestone from King's Cliffe. On the south-east side of the Cliffe stood the castle; which was of great antiquity and considerable strength. Mary queen of Scots, who had been in the custody of Sir Amias Powlet here, was tried and beheaded in the hall; and her son afterwards, forgiving and even taking into favour her greatest enemy Cecil, only took the childish revenge of beating down the castle; which he so completely demolished, that no more than the earthworks now remain. Within the first work is a farm-house with some carved stones wrought into it, and at the south-west corner of the inner trench are some masses of stone-walls. Sir Robert Cotton carried the wainscot of the hall to Connington.

FOU-TCHEOU, a city of China, in the province of FO-KIEN. It carries on a considerable trade; but is chiefly remarkable for the magnificence of its principal bridge, which has more than 100 arches, constructed of white stone, and ornamented with a double balustrade throughout. This city is the residence of a viceroy, and has under its jurisdiction nine cities of the third class.

FOUGADE, or **FOUGASSE**, in the art of war, a little mine, about 8 or 10 feet wide, and 10 or 12 deep, dug under some work or post, which is in danger of falling into the enemy's hands; and charged with sacks of powder, covered with stones, earth, and whatever else can make great destruction. It is set on fire like other mines, with a fauciffe. See **MINE**.

FOUL, or **FOULE**, in the sea-language, is used when a ship has been long untrimmed, so that the

grafs-weeds, or barnacles, grow to her sides under water. A rope is also foul when it is either tangled in itself, or hindered by another, so that it cannot run or be over-hawled.

FOUL imports, also, the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of the people on board, to ships in the same convoy, and to ships in port by means of others coming in. The damages occasioned by running foul, are of the nature of those in which both parties must bear a share. They are usually made half to fall upon the sufferer, and half upon the vessel which did the injury: but in cases where it is evidently the fault of the master of the vessel, he alone is to bear the damage.

FOUL-Water. A ship is said to make foul-water, when, being under sail, she comes into such shoal-water, that though her keel does not touch the ground, yet it comes so near it, that the motion of the water under her raises the mud from the bottom.

FOUL is also a disease in cattle, proceeding from blood, and a waterish rheum that falls down into the legs, and makes them swell.

FOUL or **Pimpled Face**. See **GUTTA Rosacea**.

FOULA, or **FOUL Island**, one of the Shetland isles, lying between six and seven leagues west from the main land. It is about three miles long, narrow, and full of rough, steep, and bare rocks; one of which is so large, and runs up to such an height, that it may be clearly seen from Orkney. This, therefore, may be reckoned with the greatest probability to be the Thule of Tacitus, whatever might be the Thule of the Phenicians and Greeks. It has scarce any pasturage, and but very little arable land; but that, however small in extent, is very fertile, out of the produce of which, with fowl and fish, the poor inhabitants subsist. They have nothing that can be called a port; and the only commodities they have are stock-fish, train-oil, and feathers.

FOUMART, in zoology, a species of **MUSTELA**.

FOUNDATION, in architecture, is that part of a building which is under-ground. See **ARCHITECTURE**, n^o 96 *et seq.* and n^o 130, &c.

Palladio allows a sixth part of the height of the whole building for the hollowing or under-digging; unless there be cellars under ground, in which case he would have it somewhat lower.

FOUNDATION, denotes also a donation or legacy, either in money or lands, for the maintenance and support of some community, hospital, school, &c.

The king only can found a college, but there may be a college in reputation founded by others. If it cannot appear by inquiry who it was that founded a church or college, it shall be intended, that it was the king, who has power to found a new church, &c. The king may found and erect an hospital, and give a name to the house upon the inheritance of another, or license another person to do it upon his own lands; and the words *fun do, cre o*, &c. are not necessary in every foundation, either of a college or hospital, made by the king; but it is sufficient if there be words equivalent: the incorporation of a college or hospital is the very foundation; but he who endows it with lands is the founder; and to the erection of an hospital, nothing more is requisite but the incorporation and foundation.

Persons

Founder, Foundry. Persons seized of estates in fee-simple, may erect and found hospitals for the poor by deed enrolled in chancery, &c. which shall be incorporated, and subject to such visitors as the founder shall appoint, &c. stat. 39 Eliz. c. 5.

FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious house, or other charitable institution. See **FOUNDATION**.

FOUNDER, also implies an artist who casts metals, in various forms, for different uses, as guns, bells, statues printing-characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See **FOUNDRY**.

FOUNDER, in the sea language: A ship is said to founder, when by an extraordinary leak, or by a great sea breaking in upon her, she is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer, but lie like a log; and not being able to swim long, will at last sink.

FOUNDERED, in farriery. See there, § xli.

FOUNDRY, or **FOUNDRI**, the art of casting all sorts of metals into different forms. It likewise signifies the work-house or smelting-hut wherein these operations are performed.

FOUNDRY of Small Works, or Casting in Sand. The sand used for casting small-works is at first of a pretty soft, yellowish, and clammy nature: but it being necessary to strew charcoal-dust in the mould, it at length becomes of a quite black colour. This sand is worked over and over, on a board, with a roller, and a sort of knife; being placed over a trough to receive it, after it is by these means sufficiently prepared.

This done, they take a wooden board of a length and breadth proportional to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and apply them so to the mould, and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass cylinder, as the chief canal for the metal to run through, when melted, into the models or patterns; and from this chief canal are placed several others which extend to each model or pattern placed in the frame. After the frame is finished, they take out the patterns, by first loosening them all round, that the sand may not give way.

Then they proceed to work the other half of the mould with the same patterns in just such another frame only that it has pins, which entering into holes that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame, thus moulded, is carried to the melter; who after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and strewing mill dust over them, dries them in a kind of oven for that purpose.

Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, by reason of the melted metal passing thro' the chief cylindrical canal, they are screwed or wedged up like a kind of press.

While the moulds are thus preparing, the metal is

fusing in a crucible of a size proportionate to the quantity of metal intended to be cast. **Foundry.**

When the moulds are coolish, the frames are unscrewed, or unwedged, and the cast work taken out of the sand, which sand is forked over again for other castings.

FOUNDRY of Statues. The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with stone, or brick; or, when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulsion of the melted metal.

The inner mould, or core, is a rude mass to which is given the intended attitude and contours. It is raised on an iron grate, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potter's clay, mixed with hair and horse-dung; or of plaster of Paris mixed with brick dust. The use of the core is to support the wax, the shell, and lessen the weight of the metal. The iron bars and the core are taken out of the brass figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron bars of the core, that contribute to the steadiness of the projecting part, within the brass figure.

The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core: Though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brickdust, whereby the inner core is proportioned as the sculptor carries on the wax.

When the wax, which is the intended thickness of the metal, is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of the work; and as vent-holes, to give passage to the air which would otherwise occasion great disorder when the hot metal came to encompass it.

The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water to the consistence of a colour fit for painting: accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whites. For the second impression, they add horse-dung and natural earth to the former composition. The third impression is only horse-dung and earth. Lastly, the shell is finished, by laying on several more impressions of this last matter, made very thick with the hand.

The shell, thus finished, is secured by several iron girths,

Foundery. girths, bound round it, at about half a foot distance from each other, and fastened at the bottom to the grate under the statue, and at the top to a circle of iron where they all terminate.

If the statue be so big that it would not be easy to move the moulds with safety, they must be wrought on the spot where it is to be cast. This is performed two ways: in the first, a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-stone or brick. At the bottom is made a hole of the same materials, with a kind of furnace, having its aperture outwards: in this is a fire made to dry the mould, and afterwards, melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, at one of the edges of the square pit is made another large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and grate underneath. When finished, four walls are to be run around it, and by the side thereof a massive made for a melting-furnace. For the rest the method is the same in both. The mould being finished, and inclosed as described, whether under ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks that the wax may melt gently down, and run out at pipes contrived for that purpose, at the foot of the mould, which are afterwards exactly closed with earth, so soon as the wax is carried off. This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace augmented till such time as both the bricks and mould become red hot. After this the fire being extinguished, and every thing cold again, they take out the bricks, and fill up their place with earth moistened, and a little beaten to the top of the mould, in order to make it the more firm and steady. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is the office of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From this last aperture, which is kept very close, while the metal is in fusion, a small tube is laid, whereby the melted metal is conveyed into a large earthen basin over the mould, into the bottom of which all the big branches of the jets or casts, which are to convey the metal into all the parts of the mould, are inserted.

These casts or jets are all terminated with a kind of plugs, which are kept close, that, upon opening the furnace, the brass, which gushes out with violence may not enter any of them, till the basin be full enough of matter to run into them all at once. Upon which occasion they pull out the plugs, which are long iron rods, with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part; the rest being a sculptor's or carver's business, who taking the figure out of the mould and earth wherewith it is encompassed, saws off the jets with which it appears covered over, and repairs it with chissels, gravers, puncheons, &c.

Foundery of Bells. The metal, it is to be observed, is different for bells from what it is for statues; there being no tin in the statue-metal: but there is a fifth, and sometimes more, in the bell-metal.

The dimensions of the core and the wax for bells, if a ring of bells especially, are not left to chance, but must be measured on a scale, or diapason, which gives the height, aperture, and thickness necessary for the several tones required.

It is on the wax that the several mouldings and other ornaments and inscriptions, to be represented in relief on the outside of the bell, are formed. The clapper or tongue is not properly a part of the bell, but is furnished from other hands. In Europe, it is usually of iron, with a large knob at the extreme; and is suspended in the middle of the bell. In China, it is only a huge wooden mallet, struck by force of arm against the bell; whence they can have but little of that consonancy so much admired in some of our rings of bells. The Chinese have an extraordinary way of increasing the sound of their bells; viz. by leaving a hole under the cannon; which our bell-founders would reckon a defect.

The proportions of our bells differ very much from those of the Chinese. In ours, the modern proportions are, to make the diameter 15 times the thickness of the brim, and the height 12 times. The parts of a bell are, 1. The sounding bow, terminated by an inferior circle, which grows thinner and thinner. 2. The brim or that part of a bell whereon the clapper strikes, and which is thicker than the rest. 3. The outward sinking of the middle of the bell, or the point under which it grows wider to the brim. 4. The waist or furniture, and the part that grows wider and thicker quite to the brim. 5. The upper vase, or that part which is above the waist. 6. The pallet which supports the staple of the clapper within. 7. The bent and hollowed branches of metal uniting with the cannons, to receive the iron keys, whereby the bell is hung up to the beam, which is its support and counterpoise, when rung out.

The business of bell-foundery is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould: And, 3. The melting of the metal. There are two kinds of proportions, viz. the simple and the relative; the former are those proportions only that are between the several parts of a bell to render it sonorous; the relative proportions establish a requisite harmony between several bells.

The method of forming the profile to a bell, previous to its being cast, in which the proportion of the several parts may be seen, is as follows: the thickness of the brim, CI (Plate CXCIV.) is the foundation of every other measure, and is divided into three equal parts. First, draw the line HD, which represents the diameter of the bell; bisect it in F and erect the perpendicular Ff; let DF and HF be also bisected in E and G, and two other perpendiculars Ee, or Gg, be erected at E and G: GE will be the diameter of the top or upper vase, *i. e.* the diameter of the top will be half that of the bell; and it will therefore, be the diameter of a bell which will sound an octave to the other. Divide the diameter of the bell or the line HD into 15 equal parts, and one of these will give CI the thickness of the brim; divide again each of these

Foundery these 15 equal parts into three other equal parts, and then form a scale. From this scale take 12 of the larger divisions or $\frac{1}{3}$ of the whole scale in the compass, and setting one leg in D describe an arc to cut the line E e in N; draw N D, and divide this line into 12 equal parts; at the point 1 erect the perpendicular $1C=10$, and C 1 will be the thickness of the brim $=\frac{1}{3}$ of the diameter: draw the line C D: bisect DN; and at the point of bisection 6 erect the perpendicular $6K=1\frac{1}{2}$ of the larger divisions on the scale. With an opening of the compass equal to twice the length of the scale or 30 brims, setting one leg in N, describe an arc of a circle, and with the same leg in K and the same opening describe another arc to intersect the former: on this point of intersection as a centre, and with a radius equal to 30 brims, describe the arc NK; in 6 K produced take $KB=\frac{1}{3}$ of the larger measure of the scale or $\frac{1}{3}$ of the brim, and on the same centre with the radius $30\frac{1}{3}$ brims describe an arc AB parallel to NK. For the arc BC, take 12 divisions of the scale or 12 brims in the compass; find a centre, and from that centre, with this opening, describe the arc BC, in the same manner as NK or AB were described. There are various ways of describing the arc K p; some describe it on a centre at the distance of nine brims from the points p and K; others, as it is done in the figure, on a centre at the distance only of seven brims from those points. But it is necessary first to find the point p, and to determine the rounding of the bell p r. For this purpose, on the point C as a centre, and with the radius C 1, describe the arc 1 p n; bisect the part 1, 2 of the line D n, and erecting the perpendicular p m, this perpendicular will cut the arc 1 p n in m, which terminates the rounding 1 p. Some founders make the bendings K a third of a brim lower than the middle of the line DN; others make the part C 1 D more acute, and instead of making C 1 perpendicular to DN at 1, draw it $\frac{1}{4}$ th of a brim higher, making it still equal to one brim; so that the line 1 D is longer than the brim C 1. In order to trace out the top-part N a, take in the compass eight divisions of the scale or eight brims, on the points N and D as centres, describe arcs to intersect each other in 8: on this point 8, with a radius of eight brims, describe the arc N b; this arc will be the exterior curve of the top or crown: on the same point 8 as a centre, and with a radius equal to $7\frac{1}{3}$ brims, describe the arc A e, and this will be the interior curve of the crown, and its whole thickness will be one third of the brim. As the point 8 does not fall in the axis of the bell, a centre M may be found in the axis by describing, with the interval of eight brims on the centres D and H, arcs which will intersect in M; and this point may be made the centre of the inner and outer curves of the crown as before. The thickness of the cap which strengthens the crown at Q is about one third of the thickness of the brim; and the hollow branches or ears about one-sixth of the diameter of the bell. The height of the bell is in proportion to its diameter as 12 to 15, or in the proportion of the fundamental sound to its third major: whence it follows, that the sound of a bell is principally composed of the sound of its extremity or brim as a fundamental of the sound of the crown, which is an octave to it, and of that of the height which is a third.

The particulars necessary for making the mould of

a bell are, 1. The earth: the most cohesive is the Foundery. best; it must be well ground and sifted, to prevent any chinks. 2. Brick-stone; which must be used for the mine, mould, or core, and for the furnace. 3. Horse-dung, hair, and hemp, mixed with the earth, to render the cement more binding. 3. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards, ranged upon tressels. Upon this they carry the earth, grossly diluted, to mix it with horse-dung, beating the whole with a large spatula.

The compasses of construction is the chief instrument for making the mould, which consist of two different legs joined by a third piece. And last of all, the founders shelve, on which are the engravings of the letters, cartridges, coats of arms, &c.

They first dig a hole of a sufficient depth to contain the mould of the bell, together with the case or cannon, under ground; and about six inches lower than the terreplain, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole, or between one mould and another, when several bells are to be cast. At the centre of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron peg, on which the pivot of the second branch of the compasses turns. The stake is incompassed with a solid brick-work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a *mill-stone*. The parts of the mould are, the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying of each brick, they bring near it the branch of the compasses, on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horse-dung; on which they move the compasses of construction, to make it of an even smoothness every where.

The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut, during the baking, with a cake of earth that has been separately baked. The first consumes the stake, and the fire is left in the core half or sometimes a whole day: the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses,

Foundry. and thoroughly dried before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipped in a vessel of wax in a chafing-dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the rest, sifted very fine; whilst it is tempering in water, it is mixed with cow's hair to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second of the same matter, but somewhat thicker; when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this, they go on with other layers of the shell, by means of the compasses. Here they add to the cow's hair a quantity of hemp, spread upon the layers, and afterwards smoothed by the board of the compasses. The thickness of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. It has seven rings: the seventh is called the *bridge*, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron keys. There are models made of the rings, with masses of beaten earth, that are dried in the fire, in order to have the hollow of them. Those rings are gently pressed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated 12 times for 12 half-moulds, that two and two united may make the hollows of the six rings; the same they do for the hollow of the bridge, and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron-ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapped upon the opening, and foldered with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist to fix on the place, which is strewed at several times upon the cover of the core; and they beat it gently with a pestle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outside of the hollows with mortar, in order to bind them with the

Foundry. bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking. To make room for the metal, they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the millstone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould, they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up and got out of the pit.

When this and the wax are removed, they break the model and the layer of earth, through which the metal must run, from the hollow of the rings, between the shell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and the vent, over the shell, and folder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it strongly all the time round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious ash-hole. The furnace which contains the metal is vaulted, whose bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame reverberates; the second is closed with a stopple that is opened for the metal to run; the others are to separate the dross or scoriæ of the metal by wooden rakes: through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down.

FOUNDRY of Great Guns and Mortar-Pieces. The method of casting these pieces is little different from that of bells: they are run massy, without any core, being determined by the hollow of the shell: and they are afterwards bored with a steel trepan, that is worked either by horses or a water-mill.

For the metal, parts, proportions, &c. of these pieces, see GUNNERY.

Letter-FOUNDRY, or Casting of Printing Letters.

In the business of cutting, casting, &c. letters for printing, the letter-cutter must be provided with a vice, hand-vice, hammers, and files of all sorts for watch-makers use; as also gravers and sculptors of all sorts, and an oil-stone, &c. suitable and sizeable to the several letters to be cut: a flat gage made of box to hold a rod of steel, or the body of a mould, &c. exactly perpendicular to the flat of the using file: a sliding-gage whose use is to measure and set off distances between the shoulder and the tooth, and to mark it off from the end, or from the edge of the work: a face-gage, which is a square notch cut with a file into the edge of a thin plate of steel, iron, or brass, of the thickness of a piece of common tin, whose use is to proportion the face of each sort of letter, viz. long letters, ascending;

Foundery. cending letters, and short letters. So there must be three gages, and the gage for the long letters is the length of the whole body supposed to be divided into 42 equal parts. The gage for the ascending letters Roman and Italic are $\frac{5}{7}$, or 30 parts of 42, and 33 parts for the English face. The gage for the short letters is $\frac{3}{7}$, or 18 parts of 42 of the whole body for the Roman and Italic, and 22 parts for the English face.

The Italic and other standing gages are to measure the scope of the Italic stems, by applying the top and bottom of the gage to the top and bottom lines of the letters, and the other side of the gage to the stem; for when the letter complies with these three sides of the gage, that letter has its true shape.

The next care of the letter-cutter is to prepare good steel punches, well tempered, and quite free from all veins of iron; on the face of which he draws or marks the exact shape of the letter with pen and ink if the letter be large, or with a smooth blunted point of a needle if it be small; and then with sizeable and proper shaped and pointed gravers and sculpters, digs or sculps out the steel between the strokes or marks he made on the face of the punch, and leaves the marks standing on the face. Having well shaped the inside strokes of his letter, he deepens the hollows with the same tools; for if a letter be not deep in proportion to its width, it will, when used at press, print black, and be good for nothing. This work is generally regulated by the depth of the counter-punch. Then he works the outside with proper files till it be fit for the matrice.

But before we proceed to the sinking and justifying of the matrices, we must provide a mould to justify them by, of which you have a draught in Plate CXC. fig. 1. 2.

Every mould is composed of an upper and an under part. The under part is delineated in fig. 1. The upper part is marked fig. 2. and is in all respects made like the under part, excepting the stool behind, and the bow or spring also behind; and excepting a small roundish wire between the body and carriage, near the break, where the under part hath a small rounding groove made in the body. This wire, or rather half-wire, in the upper part makes the nick in the shank of the letter, when part of it is received into the groove in the under part. These two parts are so exactly fitted and gaged into one another (*viz.* the male-gage marked *c* in fig. 2. into the female marked *g* in fig. 1. that when the upper part of the mould is properly placed on, and in the under part of the mould, both together make the entire mould, and may be slid backwards for use so far, till the edge of either of the bodies on the middle of either carriage comes just to the edge of the female gages cut in each carriage: and they may be slid forward so far, till the bodies on either carriage touch each other: and the sliding of these two parts of the mould backwards makes the shank of the letter thicker, because the bodies in each part stand wider asunder; and the sliding them forwards makes the shank of the letter thinner, because the bodies on each part of the mould stand closer together. The parts of the mould are as follow: *viz.* a, The carriage. b, The body. c, The male gage. de, The mouth-piece. fi, The register. g, The female gage. h, The hag. *aaaa*, The bottom plate. *bbb*, The wood on which

the bottom plate lies. *ccc*, The mouth. *dd*, The throat. *edd*, The pallat. *f*, The nick. *gg*, The stool. *hh*, The spring or bow. Foundery.

Then the mould must be justified: and first the founder justifies the body, by casting about 20 proofs or samples of letters; which are set up in a composing stick, with all their nicks towards the right hand; and then by comparing these with the pattern letters, set up in the same manner, he finds the exact measure of the body to be cast. He also tries if the two sides of the body are parallel, or that the body be no bigger at the head than at the foot, by taking half the number of his proofs and turning them with their heads to the feet of the other half; and if then the heads and the feet be found exactly even upon each other, and neither to drive out or get in, the two sides may be pronounced parallel. He farther tries whether the two sides of the thickness of the letter be parallel, by first setting his proofs in the composing stick with their nicks upwards, and then turning one half with their head to the feet of the other half; and if the heads and feet lie exactly upon each other, and neither drive out nor get in, the two sides of the thickness are parallel.

The mould thus justified, the next business is to prepare the matrices. A matrice is a piece of brass or copper of about an inch and a half long, and of a thickness in proportion to the size of the letter it is to contain. In this metal is sunk the face of the letter intended to be cast, by striking the letter punch about the depth of an n. After this, the sides and face of the matrice must be justified and cleared with files of all bunchings made by sinking the punch.

Every thing thus prepared, it is brought to the furnace; which is built of brick upright, with four square sides, and a stone on the top, in which stone is a wide round hole for the pan to stand in. A foundery of any consequence has several of these furnaces in it.

As to the metal of which the types are to be cast, this, in extensive founderies, is always prepared in large quantities; but cast into small bars, of about 20 pounds weight, to be delivered out to the workmen as occasion requires. In the letter foundery which has been long carried on with reputation under the direction of Dr Alex. Wilson and sons at Glasgow, we are informed, that a stock of metal is made up at two different times of the year, sufficient to serve the casters at the furnace for six months each time. For this purpose, a large furnace is built under a shade, furnished with a wheel vent, in order the more equally to heat the sides of a strong pot of cast-iron, which holds when full fifteen hundred weight of the metal. The fire being kindled below, the bars of lead are let softly down into the pot, and their fusion promoted by throwing in some pitch and tallow, which soon inflame. An outer chimney, which is built so as to project about a foot over the farthest lip of the pot, catches hold of the flame by a strong draught, and makes it act very powerfully in melting lead; whilst it serves at the same time to convey away all the fumes, &c. from the workmen, to whom this laborious part of the business is committed. When the lead is thoroughly melted, a due proportion of the regulus of antimony and other ingredients are put in, and some more tallow is inflamed to make the whole incorporate sooner. The workmen now having mixed the contents of the pot very thoroughly

Foundery. roughly by stirring long with a large iron ladle, next proceed to draw the metal off into the small troughs of cast-iron, which are ranged to the number of four-score upon a level platform faced with stone, built towards the right hand. In the course of a day 15 hundred weight of metal can be easily prepared in this manner; and the operation is continued for as many days as are necessary to prepare a stock of metal of all the various degrees of hardness. After this, the whole is disposed into presses according to its quality, to be delivered out occasionally to the workmen.

The founder must now be provided with a ladle, which differs nothing from other iron ladles but in its size; and he is provided always with ladles of several sizes, which he uses according to the size of the letters he is to cast. Before the caster begins to cast, he must kindle his fire in the furnace to melt the metal in the pan. Therefore he takes the pan out of the hole in the stone, and there lays in coals and kindles them; and, when they are well kindled, he sets the pan in again, and puts in metal into it to melt: if it be a small-bodied letter he casts, or a thin letter of great bodies, his metal must be very hot; nay sometimes red-hot, to make the letter come. Then having chosen a ladle that will hold about so much as the letter and break is, he lays it at the stoking-hole, where the flame bursts out, to heat. Then he ties a thin leather, cut with its narrow end against the face to the leather groove of the matrice, by whipping a brown thread twice about the leather-groove, and fastening the thread with a knot. Then he puts both halves of the mould together, and puts the matrice into the matrice-cheek, and places the foot of the matrice on the stool of the mould, and the broad end of the leather upon the wood of the upper half of the mould, but not tight up, lest it might hinder the foot of the matrice from sinking close down upon the stool in a train of work. Then laying a little rosin on the upper wood of the mould, and having his casting-ladle hot, he with the boiling side of it melts the rosin; and, when it is yet melted, presses the broad end of the leather hard down on the wood, and so fastens it to the wood; all this is the preparation.

Now he comes to casting. Wherefore, placing the under half of the mould in his left hand, with the hook or hag forward, he clutches the ends of its wood between the lower part of the ball of his thumb and his three hind fingers; then he lays the upper half of the mould upon the under half, so that the male gages may fall into the female gages, and at the same time the foot of the matrice places itself upon the stool; and, clasping his left-hand thumb strong over the upper half of the mould, he nimbly catches hold of the bow or spring with his right-hand fingers at the top of it, and his thumb under it, and places the point of it against the middle of the notch in the backside of the matrice, pressing it as well forwards towards the mould, as downwards by the shoulder of the notch close upon the stool, while at the same time with his hinder fingers, as aforesaid, he draws the under half of the mould towards the ball of his thumb, and thrusts by the ball of his thumb the upper part towards his fingers, that both the registers of the mould may press against both sides of the matrice, and his thumb and fingers press both halves of the mould close together.

Foundery. Then he takes the handle of his ladle in his right hand, and with the boll of it gives a stroke, two or three, outwards upon the surface of the melted metal, to scum or clear it from the film or dust that may swim upon it; then takes up the ladle full of metal, and having his mould, as aforesaid, in his left hand, he a little twists the left side of his body from the furnace, and brings the geat of his ladle (full of metal) to the mouth of the mould, and twists the upper part of his right hand towards him to turn the metal into it, while at the same moment of time he jilts the mould in his left hand forwards, to receive the metal with a strong shake (as it is called), not only into the body of the mould, but while the metal is yet hot running, swift and strongly, into the very face of the matrice, to receive its perfect form there, as well as in the shank.

Then he takes the upper half of the mould off the under half, by placing his right-hand thumb on the end of the wood next his left-hand thumb, and his two middle-fingers at the other end of the wood; and finding the letter and break lie in the under half of the mould (as most commonly by reason of its weight it does), he throws or tosses the letter, break and all, upon a sheet of waste paper laid for that purpose on the bench, just a little beyond his left hand, and is then ready to cast another letter as before; and also, the whole number that is to be cast with that matrice. A workman will ordinarily cast about three thousand of these letters in a day.

When the casters at the furnace have got a sufficient number of types upon the tables, a set of boys come and nimbly break away the jets from them: the jets are thrown into the pots, and the types are carried away in parcels to other boys, who pass them swiftly under their fingers, defended by leather, upon smooth flat stones, in order to polish their broad-sides. This is a very dexterous operation, and is a remarkable instance of what may be effected by the power of habit and long practice; for these boys, in turning up the other side of the type, do it so quickly by a mere touch of the fingers of the left hand, as not to require the least perceptible intermission in the motion of the right hand upon the stone. The types, thus finely smoothed and flattened on the broad-sides, are next carried to another set of boys, who sit at a square table, two on each side, and there are ranged up on long rulers or sticks, fitted with a small projection, to hinder them from sliding off backwards. When these sticks are so filled, they are placed, two and two, upon a set of wooden pins fixed into the wall, near the dresser, sometimes to the amount of an hundred, in order to undergo the finishing operations. This workman, who is always the most expert and skilful in all the different branches carried on at the foundery, begins by taking one of these sticks, and, with a peculiar address, slides the whole column of types off upon the dressing-stick: this is made of well-seasoned mahogany, and furnished with two end-pieces of steel, a little lower than the body of the types, one of which is moveable, so as to approach the other by means of a long screw-pin, inserted in the end of the stick. The types are put into this stick with their faces next to the back or projection; and after they are adjusted to one another so as to stand even, they are then bound up, by screwing home the moveable end-piece. It is here where the
great

Foundery.

great and requisite accuracy of the moulds come to be perceived; for in this case the whole column, so bound up, lies flat and true upon the stick, the two extreme types being quite parallel, and the whole has the appearance of one solid continuous plate of metal. The least inaccuracy in the exact parallelism of the individual type when multiplied so many times, would render it impossible to bind them up in this manner, by disposing them to rise or spring from the stick by the smallest pressure from the screw. Now, when lying so conveniently with the narrow edges uppermost, which cannot possibly be smoothed in the manner before mentioned by the stones, the workman does this more effectually by scraping the surface of the column with a thick-edged but sharp razor, which at every stroke brings on a very fine smooth skin, like to polished silver; and thus he proceeds till in about half a minute he comes to the farther end of the stick. The other edges of the types are next turned upwards, and polished in the same manner. It is whilst the types thus lie in the dressing-stick that the operation of bearding or barbing is performed, which is effected by running a plane, faced with steel, along the shoulder of the body next to the face, which takes more or less off the corner, as occasion may require. Whilst in the dressing-stick they are also grooved, which is a very material operation. In order to understand this, it must be remembered, that when the types are first broken off from the jets, some superfluous metal always remains, which would make them bear very unequally against the paper whilst under the printing-press, and effectually mar the impression. That all these inequalities may, therefore, be taken away, and that the bearings of every type may be regulated by the shoulders imparted to them all alike from the mould, the workman or dresser proceeds in the following manner. The types being screwed up in the stick, as before mentioned, with the jet-end outermost, and projecting beyond the wood about one-eighth of an inch, the stick is put into an open press, so as to present the jet-end uppermost, and then every thing is made fast by driving a long wedge, which bears upon a slip of wood, which lies close to the types the whole length: then a plough or plane is applied, which is so constructed as to embrace the projecting part of the types betwixt its long sides, which are made of polished iron. When the plane is thus applied, the steel cutter bearing upon that part between the shoulders of the types, where the inequalities lie, the dresser dexterously glides it along, and by this means strips off every irregular part that comes in the way, and so makes an uniform groove the whole length, and leaves the two shoulders standing; by which means every type become precisely like to another, as to the height against paper. The types being now finished, the stick is taken out of the press, and the whole column replaced upon the other stick: and after the whole are so dressed, he proceeds to pick out the bad letters, previous to putting them up into pages and papers. In doing this he takes the stick into his left hand, and turning the faces near to the light, he examines them carefully, and whenever an imperfect or damaged letter occurs, he nimbly plucks it out with a sharp bodkin, which he holds in the right hand for that purpose. Those letters which, from their form, project over the body of the type, and which

cannot on this account be rubbed on the stones, are scraped on the broad-sides with a knife or file, and some of the metal next the face pared away with a pen-knife, in order to allow the type to come close to any other. This operation is called *kerning*.

The excellence of printing types consists not only in the due performance of all the operations above described, but also in the hardness of the metal, form, and fine proportion of the character, and in the exact bearing and ranging of the letters in relation to one another.

FOUNT, or FONT, among printers, &c. a set or quantity of characters or letters of each kind, cast by a letter-founder, and sorted.—We say, a founder has cast a fount of pica, of english, of pearl, &c. meaning that he has cast a set of characters of these kinds.

A complete fount does not only include the running letters, but also large and small capitals, single letters, double letters, points, commas, lines, and numeral characters.

Founts are large or small, according to the demand of the printer who orders them by the hundred weight, or by sheets. When the printer orders a fount of 500, he means that the fount should weigh 500 lb. When he demands a fount of 10 sheets, it is understood, that with that fount he shall be able to compose 10 sheets, or 20 forms, without being obliged to distribute. The founder takes his measures accordingly; he reckons 120 pounds for a sheet, including the quadrates, &c. or 60 pounds for a form, which is half a sheet: not that the sheet always weighs 120 pounds, or the form 60 pounds; on the contrary, it varies according to the size of the form; besides, it is always supposed that there are letters left in the cases.

The letter-founders have a kind of list, or tariff, whereby they regulate their founts: the occasion thereof is, that some letters being in much more use, and oftener repeated than others, their cells or cases, should be better filled and stored than those of the letters which do not return so frequently. Thus the *o* and *i*, for instance, are always greater in quantity than the *k* or *z*.

This difference will be best perceived from a proportional comparison of those letters with themselves, or some others. Suppose a fount of 100,000 characters, which is a common fount; here the *a* should have 5000, the *c* 3000, the *e* 11,000, the *i* 6000, the *m* 3000, the *k* only 300, and the *x*, *y*, and *z*, not many more. But this is only to be understood of the letters of the lower case; those of the upper having other proportions, which it would be here too long to insist on.

FOUNTAIN, a spring or source of water rising out of the earth. Among the ancients, fountains were generally esteemed as sacred: but some were held to be so in a more particular manner. The good effects received from cold baths gave springs and rivers this high reputation; for the salutary influence was supposed to proceed from some presiding deity. Particular reasons might occasion some to be held in greater veneration than others. It was customary to throw little pieces of money into those springs, lakes, or rivers, which were esteemed sacred, to render the presiding divinities propitious; as the touch of a naked bo-

Fount,

Artificial FOUNTAIN, called also a *jet d'eau*, is a contrivance by which water is violently spouted upwards. See HYDRAULICS.

Boiling FOUNTAIN. See ICELAND.

FOUNTAIN-Tree, a very extraordinary vegetable growing in one of the Canary islands, and likewise said to exist in some other places, which distils water from its leaves in such plenty as to answer all the purposes of the inhabitants who live near it. Of this tree we have the following account in Glasse's history of the Canary islands.—“There are only three fountains of water in the whole island of Hierro, wherein the fountain-tree grows. One of these fountains is called *A-cof*, which, in the language of the ancient inhabitants, signifies *river*; a name, however, which does not seem to have been given it on account of its yielding much water, for in that respect it hardly deserves the name of a fountain. More to the northward is another called *Hapio*; and in the middle of the island is a spring, yielding a stream about the thickness of a man's finger. This last was discovered in the year 1565, and is called the *fountain of Anton. Hernandez*. On account of the scarcity of water, the sheep, goats, and swine, here do not drink in the summer, but are taught to dig up the roots of fern, and chew them to quench their thirst. The great cattle are watered at those fountains, and at a place where water distils from the leaves of a tree. Many writers have made mention of this famous tree, some in such a manner as to make it appear miraculous: others again deny the existence of any such tree; among whom is Father Feyjoo, a modern Spanish author, in his *Theatro Critico*. But he, and those who agree with him in this matter, are as much mistaken as those who would make it appear to be miraculous. This is the only island of all the Canaries which I have not been in; but I have sailed with natives of Hierro, who, when questioned about the existence of this tree, answered in the affirmative.

“The author of the *History of the discovery and conquest* has given us a particular account of it, which I shall here relate at large.

“The district in which this tree stands is called *Tigulabe*; near to which, and in the cliff or steep rocky ascent that surrounds the whole island, is a narrow gutter or gully, which commences at the sea, and continues to the summit of the cliff, where it joins or coincides with a valley which is terminated by the steep front of a rock. On the top of this rock grows a tree, called in the language of the ancient inhabitants, *Garse*, “Sacred or Holy Tree,” which for many years has been preserved sound, entire, and fresh. Its leaves constantly distil such a quantity of water as is sufficient to furnish drink to every living creature in Hierro; nature having provided this remedy for the drought of the island. It is situated about a league and a half from the sea. Nobody knows of what species it is, only that it is called *Til*. It is distinct from other trees, and stands by itself: the circumference of the trunk is about 12 spans, the diameter four, and in height from the ground to the top of the highest branch, 40 spans: the circumference of all the branches together is 120 feet. The branches are thick and extended;

the lowest commence about the height of an ell from the ground. Its fruit resembles the acorn, and tastes something like the kernel of a pine apple, but is softer and more aromatic. The leaves of this tree resemble those of the laurel, but are larger, wider, and more curved; they come forth in a perpetual succession, so that the tree always remains green. Near to it grows a thorn which fastens on many of its branches, and interweaves with them; and at a small distance from the garse are some beech-trees, bresos, and thorns. On the north side of the trunk are two large tanks or cisterns, of rough stone, or rather one cistern divided, each half being 20 feet square and 16 spans in depth. One of these contains water for the drinking of the inhabitants; and the other that which they use for their cattle, washing, and such like purposes. Every morning, near this part of the island, a cloud or mist arises from the sea, which the south and easterly winds force against the fore-mentioned steep cliff; so that the cloud having no vent but by the gutter, gradually ascends it, and from thence advances slowly to the extremity of the valley, whence it is stopped and checked by the front of the rock which terminates the valley, and then rests upon the thick leaves and wide-spreading branches of the tree, from whence it distils in drops during the remainder of the day, until it is at length exhausted, in the same manner that we see water drip from the leaves of trees after a heavy shower of rain. This distillation is not peculiar to the garse or til; for the bresos, which grow near it likewise drop water; but their leaves being few and narrow, the quantity is so trifling, that though the natives save some of it, yet they make little or no account of any but what distils from the til, which, together with the water of some fountains, and what is saved in the winter season, is sufficient to serve them and their flocks. This tree yields most water in those years when the Levant or easterly winds have prevailed for a continuance; for, by these winds only the clouds or mists are drawn hither from the sea. A person lives on the spot near which this tree grows, who is appointed by the council to take care of it and its water; and is allowed a house to live in, with a certain salary. He every day distributes to each family of the district seven pots or vessels full of water, besides what he gives to the principal people of the island.

“Whether the tree which yields water at this present time be the same as that mentioned in the above description, I cannot pretend to determine; but it is probable there has been a succession of them; for Pliny, describing the Fortunate Island, says, ‘In the mountains of Ombrion are trees resembling the plant ferula, from which water may be procured by pressure. What comes from the black kind is bitter, but that which the white yields is sweet and potable.’”

Trees yielding water are not peculiar to the island of Hierro; for travellers inform us of one of the same kind on the island of St Thomas, in the bight or gulph of Guiney. In Cockburn's voyages we find the following account of a dropping tree, near the mountains of Fera Paz, in America.

“On the morning of the fourth day we came out on a large plain, where were great numbers of fine deer, and in the middle stood a tree of unusual size, spreading its branches over a vast compass of ground.

Cu-

Fountain,
Fourmont.

curiosity led us up to it. We had perceived, at some distance off, the ground about it to be wet; at which we began to be somewhat surpris'd, as well knowing there had no rain fallen for near six months past, according to the certain course of the season in that latitude: that it was impossible to be occasioned by the fall of dew on the tree, we were convinced, by the sun's having power to exhale away all moisture of that nature a few minutes after its rising. At last, to our great amazement as well as joy, we saw water dropping, or as it were distilling, fast from the end of every leaf of this wonderful (nor had it been amiss as I had said *miraculous*) tree; at least it was so with respect to us, who had been labouring four days through extreme heat, without receiving the least moisture, and were now almost expiring for the want of it.

"We could not help looking on this as liquor sent from heaven to comfort us under great extremity. We caught what we could of it in our hands, and drank very plentifully of it; and liked it so well, that we could hardly prevail with ourselves to give over. A matter of this nature could not but incite us to make the strictest observations concerning it; and accordingly we staid under the tree near three hours, and found we could not fathom its body in five times. We observed the soil where it grew to be very strong; and upon the nicest enquiry we could afterwards make, both of the natives of the country and the Spanish inhabitants, we could not learn there was any such tree known throughout New Spain, nor perhaps all America over: but I do not relate this as a prodigy in nature, because I am not philosopher enough to ascribe any natural cause for it; the learned may perhaps give substantial reasons in nature for what appeared to us a great and marvellous secret."

FOUQUIERES (James), an eminent painter, was born at Antwerp in 1580, and received his chief instructions from Velvet Brughel. He applied himself to the study of the landscapes, and went to Italy to improve himself in colouring; and succeeded so happily, that his works are said to be nearly equal to those of Titian.—He was engaged and much caressed at the court of the elector Palatine, and afterwards spent several years of his life in France; where his works met with universal approbation, and he was proportionably well paid for his paintings. Yet by some misconduct he sunk into poverty, and died in the house of an inconsiderable painter in 1659. He had resided for several years at Rome and Venice, where he acquired that excellent style of colouring and design for which he is so deservedly distinguished.

FOURCHEE, or FOURCHY, in heraldry, an appellation given to a cross forked at the ends. See HERALDRY.

FOURMONT (Stephen), professor of the Arabic and Chinese languages, and one of the most learned men of his time, was born at Herbelia, a village four leagues from Paris, in 1683. He studied in Mazarine college, and afterwards in the Seminary of Thirty-three. He was at length professor of Arabic in the Royal College, and was made a member of the Academy of Inscriptions. In 1738 he was chosen a member of the Royal Society in London, and of that of Berlin in 1741. He was often consulted by the duke of Orleans, first prince of the blood; who had a

VOL. VII.

particular esteem for him, and made him one of his secretaries. He wrote a great number of books; the most considerable of those which have been printed are, 1. The Roots of the Latin Tongue, in verse. 2. Critical Reflections on the Histories of ancient Nations. 2 vols 4to. 3. *Meditationes Sinicæ*, folio. 4. A Chinese Grammar, in Latin, folio. 5. Several Dissertions printed in the Memoirs of the Academy of Inscriptions, &c. He died at Paris in 1745.

He ought not to be confounded with *Michael Fourmont*, his youngest brother; who took orders, was professor of the Syriac language in the Royal College, and a member of the Academy of Inscriptions. He died in 1746.

FOURNESS, in Loynsdale, Lancashire is a track, between the Kent, Leven, and Dudden-Sands, which runs north parallel with the west sides of Cumberland and Westmoreland; and on the south runs out into the sea as a promontory. Here, as Mr Camden expresses it, "the sea, as if enraged at it, lashes it more furiously, and in high tides has even devoured the shore, and made three large bays; viz. Kentsand, into which the river Ken empties itself; Levensand and Dudden-sand between which the land projects in such a manner that it has its name thence; Foreness and Foreland, signifying the same with us as *promontorium anterius* in Latin." Bishop Gibson, however, derives the name of *Fourness*, or *Furness*, from the numerous furnaces, that were there are anciently, the rents and services of which (called *bloomsmithy rents*) are still paid. This whole tract, except on the coast, rises in high hills and vast piles of rocks called *Forness-Fells*: among which the Britons found a secure retreat, trusting to these natural fortresses, though nothing was inaccessible to the victorious Saxons: for we find the Britons settled here 228 years after the arrival of the Saxons: because at that time Egfrid king of Northumberland gave St Cuthbert the land called *Carthmell*, and all the Britans in it, as is related in his life. In these mountainous parts are found quarries of a fine durable blue slate to cover buildings with, which are made use of in many other parts of the kingdom. Here are several cotton mills lately erected; and if fuel for fire were more plentiful, the trade of this country would much increase; but there being no coals nearer than Wigan or Whitehaven, and the coast-duties high, firing is rather scarce, the country people using only turf or peat, and that begins to be more scarce than formerly. In the mosses of Fourness much fir is found, but more oak: the trunks in general lie with their heads to the east, the high winds having been from the west. High Fourness has ever had great quantities of sheep, which browse upon the hollies left in great numbers for them; and produces charcoal for melting iron-ore, and oak-bark for tanners use, in great abundance. The forests abounded with deer and wild boars, and the *legh* or *scofe*, or large stags, whose horns are frequently found under ground here. The low or plain part of Fourness which is so called to distinguish it from the woody or mountainous part produces all sorts of grain, but principally oats, whereof the bread eaten is in this country is generally made; and there are found here veins of a very rich iron-ore, which is not only melted and wrought here, but great quantities are exported to other parts to mix with poorer ores. The three sands

3 C

above

Fournes
||
Fowey.

abovementioned are very dangerous to travellers by the tides and the many quicksands. There is a guide on horseback appointed to Kent or Lancaster sand at 10 l. *per ann.* to Leven at 6 l. *per ann.* out of the public revenue; but to Dudden, which are most dangerous, none; and it is no uncommon thing for persons to pass over it in parties of 100 at a time like caravans, under the direction of the carriers, who go to or fro every day. The sands are less dangerous than formerly, being more used and better known, and travellers never going without the carriers or guides. "Furnis abbey up in the mountains," was begun at Tulket in Amoundernes 1124, by Stephen earl of Boulogne, afterwards king of England, for the monks of Savigni in France, and three years after removed to this valley, then called *Bekangesgill*, or the vale of nightshade." It was of the Cistercian order, endowed with above 800 l. *per ann.* Out of the monks of this abbey, Mr Camden informs us, the bishops of the Isle of Man, which lies over against it, used to be chosen by ancient custom; it being as it were the mother of many monasteries in Man and Ireland. Some ruins, and part of the fosse which surrounded the monastery, are still to be seen at Tulket. The remains at Fournes breathe that plain simplicity of the Cistercian abbeys; the chapter-house was the only piece of elegant gothic about it, and its roof has lately fallen in. Part of the painted glass from the east window, representing the crucifixion, &c. is preserved at Winder-mere church in Bowness, Westmoreland. The church (except the north side of the nave), the chapter-house, refectory, &c. remain, only unroofed.

FOURTH REDUNDANT, in music. See INTERVAL.

FOWEY, or FOY, a town of Cornwall in England, 240 miles from London, with a commodious haven on the Channel. It is a populous place, extending above one mile on the east side of a river of its own name; and has a great share in the fishing trade, especially pilchards. It rose so much formerly by naval wars and piracies, that in the reign of Edward III. its ships refusing to strike when required as they sailed by Rye and Winchelsea, were attacked by the ships of those ports, but defeated them; whereupon they bore their arms mixed with the arms of those two cinque ports, which gave rise to the name of the "Gallants of Fowey." And we learn from Camden, that this town quartered a part of the arms of every one of the cinque-ports with their own; intimating, that they had at times triumphed over them all: and indeed once they were so powerful, that they took several of the French men of war. In the reign of Edward III. they rescued certain ships of Rye from distress, for which this town was made a member of the cinque-ports. Edward IV. favoured Fowey so much, that when the French threatened to come up the river to burn it, he caused two towers, the ruins of which are yet visible, to be built at the public charge for its security: but he was afterwards so disgusted with the inhabitants for attacking the French after a truce proclaimed with Louis XI. that he took away all their ships and naval stores, together with a chain drawn across the river between the two forts abovementioned, which was carried to Dartmouth. It is said they were so insolent, that they cut off the ears of the king's pursuivants: for which some lives were forfeited as well as estates. The corporation con-

sists of a mayor, recorder, 8 aldermen, a town-clerk, and 2 assistants. The market is Saturday, the fairs May-day and Sept. 10. Here are a fine old church, a free-school and an hospital. The toll of the market and fairs, and keyage of the harbour, were vested in the corporation on the payment of a fee-farm rent of about 40s. It does not appear to have sent members to parliament before the 13th of Queen Elizabeth. Here is a coinage for the tin; of which a great quantity is dug in the country to the north and west of it. The river Foy, or Foath, is very broad and deep here, and was formerly navigable as high as Leftwithiel. W. Long. 5°, N. Lat. 50. 27.

FOWL, among zoologists, denotes the larger sorts of birds, whether domestic or wild: such as geese, pheasants, partridges, turkey, ducks, &c.

Tame fowl make a necessary part of the stock of a country farm. See the article POULTRY.

Fowls are again distinguished into two kinds, *viz.* land and water fowl, these last being so called from their living much in and about water: also into those which are accounted *game*, and those which are not. See the article GAME.

FOWLING, the art of catching birds by means of bird-lime, decoys, and other devices, or the killing of them by the gun. See *BIRD-Catching*, *BIRD-Lime*, *DECOY*, *SHOOTING*, and the names of the different birds in the order of the alphabet.

FOWLING, is also used for the pursuing and taking birds with hawks, more properly called FALCONRY or HAWKING. See these articles.

FOWLING-Piece, a light gun for shooting birds. That piece is always reckoned best which has the longest barrel, from 5½ to 6 feet, with a moderate bore; though every fowler should have them of different sizes, suitable to the game he designs to kill. The barrel should be well polished and smooth within, and the bore of an equal bigness from one end to the other; which may be proved by putting in a piece of paste-board, cut of the exact roundness of the top: for if this goes down without stops or slipping you may conclude the bore good. The bridge-pan must be somewhat above the touch-hole, and ought to have a notch to let down a little powder: this will prevent the piece from recoiling, which it would otherwise be apt to do. As to the locks, choose such as are well filed with true work, whose springs must be neither too strong nor too weak. The hammer ought to be well hardened and pliable to go down to the pan with a quick motion.

FOX, in zoology. See CANIS.

The fox is a great nuisance to the husbandman, by taking away and destroying his lambs, geese, poultry, &c. The common way to catch him is by gins; which being baited, and a train made by drawing raw flesh across in his usual paths or haunts to the gin, it proves an inducement to bring him to the place of destruction.

The fox is also a beast of chase, and is taken with grehounds, tarriers, &c. See the article HUNTING.

Fox (John), the martyrologist, was born at Boston in Lincolnshire in the year 1517. At the age of 16 he was entered a student of Brazen-nose college in Oxford; and in 1543 he proceeded master of arts, and was chosen fellow of Magdalen college. He discovered an early genius for poetry, and wrote several Latin comedies, the

Fowl
||
Fox.

Fox.

the subjects taken from scripture, which his son assures us were written in an elegant style. Forfaking the muses, he now applied himself with uncommon assiduity to the study of divinity, particularly church-history; and, discovering a premature propensity to the doctrine of reformation, he was expelled the college as an heretic. His distress on this occasion was very great; but it was not long before he found an asylum in the house of Sir Thomas Lucy of Warwickshire, who employed him as a tutor to his children. Here he married the daughter of a citizen of Coventry. Sir Thomas's children being now grown up, after residing a short time with his wife's father, he came to London; where finding no immediate means of subsistence, he was reduced to the utmost degree of want; but was at length (as his son relates) miraculously relieved in the following manner: As he was one day sitting in St Paul's church, emaciated with hunger, a stranger accosted him familiarly, and, bidding him be of good cheer, put a sum of money into his hand; telling him at the same time, that in a few days new hopes were at hand. He was soon after taken into the family of the duchess of Richmond, as tutor to the earl of Surrey's children, who, when their father was sent to the tower, were committed to her care. In this family he lived, at Ryegate in Surrey, during the latter part of the reign of Henry VIII. The entire reign of Edward VI. and part of that of queen Mary; but at length, persecuted by his implacable enemy bishop Gardiner, he was obliged to seek refuge abroad. Basil in Switzerland was the place of his retreat, where he subsisted by correcting the press. On the death of queen Mary he returned to England; where he was graciously received by his former pupil the duke of Norfolk, who retained him in his family as long as he lived, and bequeathed him a pension at his death. Mr secretary Cecil also obtained for him the rectory of Shipton near Salisbury; and we are assured that he might have had considerable church preferment, had it not been for his unwillingness to subscribe to the canons. He died in the year 1587, in the 70th year of his age; and was buried in the chancel of St Giles's, Cripplegate. He was a man of great industry, and considerable learning; a zealous, but not a violent reformer; a nonconformist, but not an enemy to the church of England. He left two sons; one of which was bred a divine, the other a physician. He wrote many pieces: but his principal work is, the Acts and monuments of the Church, &c. commonly called *Fox's Book of Martyrs*. His facts are not always to be depended on, and he often loses his temper; which, considering the subject, is not much to be wondered at.

FOX (George), the founder of the sect of English Quakers, was a shoemaker in Nottingham. The accounts of those times tell us, that as he wrought at his trade, he used to meditate much on the scriptures: which, with his solitary course of life, improving his natural melancholy, he began at length to fancy himself inspired; and in consequence thereof set up for a preacher.

He proposed but few articles of faith; insisting chiefly on moral virtue, mutual charity, the love of God, and a deep attention to the inward motions and secret operations of the spirit: he required a plain simple worship, and a religion without ceremonies, making it

Fox.

a principal point to wait in profound silence the directions of the Holy Spirit. Fox met with much rough treatment for his zeal, was often imprisoned, and several times in danger of being knocked on the head. But all discouragements notwithstanding, his sect prevailed much, and many considerable men were drawn over to them; among whom were BARCLAY and PENN. He died in 1681. His followers were called *Quakers*, in derision of some unusual shakings and convulsions with which they were seized at their first meetings. See the article *QUAKERS*.

Fox-Glove, in botany. See *DIGITALIS*.

Fox-Islands, the name of a groupe of islands, 16 in number, situated between the eastern coast of Kamtschatka and the western coast of the continent of America. Each island has a particular name; but the general name *Fox-islands* is given to the whole group, on account of the great number of black, grey, and red foxes with which they abound. The dress of the inhabitants consists of a cap and a fur coat, which reaches down to the knee. Some of them wear common caps of a party-coloured bird-skin, upon which they leave part of the wings and tail. On the fore-part of their hunting and fishing caps, they place a small board like a screen, adorned with the jaw-bones of sea-bears, and ornamented with glass-beads, which they receive in barter from the Russians. At their festivals and dancing parties they use a much more showy sort of caps. They feed upon the flesh of all sorts of sea-animals, and generally eat it raw. But if at any time they choose to dress their victuals, they make use of a hollow stone; having placed the fish or flesh therein, they cover it with another, and close the interstices with lime or clay. They then lay it horizontally upon two stones, and light a fire under it. The provision intended for keeping is dried without salt in the open air. Their weapons consist of bows, arrows, and darts; and for defence they use wooden shields.—The most perfect equality reigns among these islanders. They have neither chiefs nor superiors, neither laws nor punishments. They live together in families, and societies of several families united, which form what they call a *race*, who, in case of an attack or defence, mutually help and support each other. The inhabitants of the same island always pretend to be of the same race; and every person looks upon his island as a possession, the property of which is common to all the individuals of the same society. Feasts are very common among them, and more particularly when the inhabitants of one island are visited by those of the others. The men of the village meet their guests beating drums, and preceded by the women, who sing and dance. At the conclusion of the dance, the hosts serve up their best provisions, and invite their guests to partake of the feast. They feed their children when very young with the coarsest flesh, and for the most part raw. If an infant cries, the mother immediately carries it to the sea-side, and whether it be summer or winter, holds it naked in the water until it is quiet. This custom is so far from doing the children any harm, that it hardens them against the cold, and they accordingly go barefooted through the winter without the least inconvenience. They seldom heat their dwellings; but when they are desirous of warming themselves, they light a bundle of hay, and stand

Fracastor,
Fraches.

over it; or else they set fire to train-oil, which they pour into a hollow stone. They have a good share of plain natural sense, but are rather slow of understanding. They seem cold and indifferent in most of their actions; but let an injury, or even a suspicion only, rouse them from this phlegmatic state, and they become inflexible and furious, taking the most violent revenge without any regard to the consequences. The least affliction prompts them to suicide; the apprehension of even an uncertain evil often leads them to despair; and they put an end to their days with great apparent insensibility.

FRACASTOR (Jerome), a most eminent Italian poet and physician, was born at Verona in the year 1482. Two singularities are related of him in his infancy: one is, that his lips adhered so closely to each other when he came into the world, that a surgeon was obliged to divide them with his incision-knife; the other, that his mother was killed with lightning, while he, though in her arms at the very moment, escaped unhurt. Fracastor was of parts so exquisite, and made so wonderful a progress in every thing he undertook, that he became eminently skilled not only in the belles lettres, but in all arts and sciences. He was a poet, a philosopher, a physician, an astronomer, a mathematician, and what not? He was a man of vast consequence in his time; as appears from pope Paul III.'s making use of his authority to remove the council of Trent to Bolougne, under the pretext of a contagious distemper, which, as Fracastor deposed, made it no longer safe to continue at Trent. He was intimately acquainted with cardinal Bembo, Julius Scaliger, and all the great men of his time. He died of an apoplexy at Casti near Verona, in 1553: and in 1559, the town of Verona erected a statue in honour of him.

He was the author of many performances, both as a poet and as a physician; yet never man was more disinterested in both these capacities than he: evidently so as a physician, for he practised without fees; and as a poet, whose usual reward is glory, nothing could be more indifferent. It is owing to this indifference, that we have so little of his poetry, in comparison of what he wrote; and that, among other compositions, his Odes and Epigrams, which were read in manuscript with infinite admiration, yet, never passing the press, were lost. What we have now of his, are the three books of "Siphilis, or of the French disease;" a book of Miscellaneous Poems; and two books of his poem, intitled, *Joseph*, which he began at the latter end of his life, but did not live to finish. And these works, it is said, would have perished with the rest, if his friends had not taken care to preserve and communicate copies of them: For Fracastor, writing merely for amusement, never troubled himself in the least about what became of his works after they once got out of his hands. Fracastor composed also a poem, called *Alcon, sive de cura canum venaticorum*. His poems as well as his other works are written all in Latin. His medical pieces are, *De Sympathia & Antipathia*,—*De contagione & contagionis morbis*,—*De causis criticorum dierum*,—*De vini temperatura*, &c. His works have been printed separately and collectively. The best edition of them is that of Padua 1735, in 2 vols 4to.

FRACHES, in the glass trade, are the flat iron pans into which the glass vessels already formed are

put when in the tower over the working-furnace, and by means of which they are drawn out through the leers, that they may be taken gradually from the fire, and cool by degrees.

Fraction
||
Fragaria:

FRACTION, in arithmetic and algebra, a part or division of an unit or integer; or a number which stands to an unit in the relation of a part to its whole. The word literally imports a broken number.

Fractions are usually divided into decimal, sexagesimal, and vulgar. See ALGEBRA and ARITHMETIC.

FRACTURE, in surgery, a rupture of a bone or a solution of continuity in a bone when it is crushed or broken by some external cause. See SURGERY.

FRÆNUM, or FRENUM, *Bridle*, in anatomy, a name given to divers ligaments, from their office in retaining and curbing the motions of the parts they are fitted to.

FRÆNUM *Linguae*, or *Bridle of the Tongue*; a membranous ligament, which ties the tongue to the os hyoides, larynx, fauces, and lower parts of the mouth. In some subjects the *frænum* runs the whole length of the tongue to the very tip; in which cases, if it were not cut, it would take away all possibility of speech. See TONGUE-TIED.

FRÆNUM *Penis*, a slender ligament, whereby the prepuce is tied to the lower part of the glans of the penis. Nature varies in the make of this part; it being so short in some, that unless divided it would not admit of perfect erection. There is also a kind of little *frænum*, fastened to the lower part of the clitoris.

FRAGA, a strong town with a handsome castle in the kingdom of Arragon in Spain. It is strong by situation among the mountains; having the river Cinca before it, whose high banks are difficult of access; and at its back a hill, which cannot easily be approached with large cannon. Alphonso VII. king of Arragon, and the first of that name of Castile, was killed by the Moors in 1134, when he besieged this town. E. Long. 0. 23. N. Lat. 41. 28.

FRAGARIA, the STRAWBERRY: A genus of the polygynia order, belonging to the icofandria class of plants; and in the natural method ranking under the 35th order, *Senticosæ*. The calyx is decemfid; the petals five; the receptacle of the seeds ovate, in the form of a berry, and deciduous. There is but one species, *viz.* the *vesca*, or cultivated strawberry. The principal varieties are, 1. The *sylvestris*, or wood-strawberry, with oval sawed leaves, and small round fruit. 2. The *Virginian scarlet*, or *Virginia strawberry*, with oblong oval sawed leaves, and a roundish scarlet-coloured fruit. 3. The *Moschata*, or *hautboy*, or *musky strawberry*, having oval, lanceolate, rough leaves, and large pale-red fruit. 4. The *Chiloensis*, or *Chili strawberry*, with large, oval, thick, hairy leaves, large flowers, and very large firm fruit. 5. The *Alpina*, *Alpine*, or *monthly strawberry*, having small oval leaves, small flowers, and moderate-sized, oblong, pointed fruit.

All these varieties are hardy, low, perennials, durable in root, but the leaves and fruit-stalks are renewed annually in spring. They flower in May and June, and their fruit comes to perfection in June, July, and August; the Alpine kind continuing till the beginning of winter. They all prosper in any common garden soil, producing abundant crops annually without

out

Fraguier.
||
Frame.

out much trouble. They increase exceedingly every summer, both by off-sets or suckers from the sides of the plants, and by the runners or strings, all of which separately planted bears a few fruit the following year, and bear in great perfection the second summer. Those of the Alpine kind will even bear fruit the same year that they are formed. All the sorts are commonly cultivated in kitchen-gardens, in beds or borders of common earth, in rows lengthwise 15 or 18 inches distance; the plants the same distance from one another in each row. Patches of the different sorts disposed here and there in the fronts of the different compartments of the pleasure-ground, will appear ornamental both in their flowers and fruit, and make an agreeable variety.

Strawberries eaten either alone, or with sugar and milk, are universally esteemed a most delicious fruit. They are grateful, cooling, subacid, and juicy. Tho' taken in large quantities, they seldom disagree. They promote perspiration, impart a violet smell to the urine, and dissolve the tartareous incrustations on the teeth. People afflicted with the goat or stone have found relief by using them very largely; and Hoffman says, he has known consumptive people cured by them. The bark of the root is astringent.—Sheep and goats eat the plant; cows are not fond of it; horses and swine refuse it.

FRAGUIER (Glaude Francis), a polite and learned French writer, born at Paris, of a noble family, in 1666. He was educated under the Jesuits, and was even admitted into the order, though he afterwards quitted it; and being thus at liberty to follow his inclinations, he soon after assisted the Abbè Bignon in conducting the *Journal de Sçavans*, having all the qualifications for such a work. His works consist of Latin poems, and a great number of very excellent dissertations. He died in 1728.

FRAIL, a basket made of rushes or the like, in which are packed up figs, raisins, &c. It signifies also a certain quantity of raisins, about 75 pounds.

FRAISE, in fortification, a kind of defence, consisting of pointed stakes, six or seven feet long, driven parallel to the horizon in the retrenchments of a camp, a half moon, or the like, to prevent any approach or scalade.

Fraises differ from palisades chiefly in this, that the latter stand perpendicular to the horizon, and the former jet out parallel to the horizon, or nearly so, being usually made a little sloping, or with the points hanging down. Fraises are chiefly used in retrenchments and other works thrown up of earth; sometimes they are found under the parapet of a rampart, serving instead of the cordon of stone used in stone-works.

To FRAISE a Battalion, is to line the musqueteers round with pikes, that in case they should be charged with a body of horse, the pikes being presented, may cover the musqueteers from the shock, and serve as a barricade.

FRAME, in joinery, a kind of case, wherein a thing is set or inclosed, or even supported; as a window-frame, a picture-frame, &c.

FRAME is also a machine used in divers arts; as,

FRAME, among printers, is the stand which supports the cases. See CASE.

FRAME, among founders, a kind of ledge inclosing a board; which, being filled with wetted sand, serves as a mould to cast their works in. See FOUNDERY.

FRAME is more particularly used for a sort of loom, whereon artificers stretch their linens, silks, stuffs, &c. to be embroidered, quilted, or the like.

FRAME, among painters, a kind of square, consisting of four long slips of wood joined together, whose intermediate space is divided by threads into several little squares like a net; and hence sometimes called *reticula*. It serves to reduce figures from great to small; or on the contrary, to augment their size from small to great.

FRAMLINGHAM, a town of Suffex, 88 miles from London. It is a large old place, with a castle, supposed to have been built by some of the first kings of the East-Angles; the walls yet standing, are 44 feet high, 8 thick, with thirteen towers 14 feet above them, 2 of which are watch-towers. To this castle the princess, afterwards queen Mary I. retired, when the Lady Jane Grey was her competitor for the crown.

The town is pleasantly situated, though but indifferently built, upon a clay hill, in a fruitful soil and a healthy air, near the source of the river Ore, by some called Wincknel, which runs through it to Orford. It has a spacious place for the market on Saturday; and a large stately church built all of black flint, with a steeple 100 feet high; two good alms-houses; and a free-school.

FRANC. See FRANK.

FRANCE, a large kingdom of Europe, situated between 5° W. and 7° E. Long. and between 43° and 51° N. Lat. being bounded by the English channel and the Austrian Netherlands on the north; by Germany, Switzerland, Savoy, and Piedmont, in Italy, on the east; by the Mediterranean sea, and the Pyrenean mountains, which separate it from Spain, on the south; and by the bay of Biscay on the west.

The kingdom of France was originally possessed by the *Celtes* or *Gauls*. They were a very warlike people, and often checked the progress of the Roman arms: nor did they yield till the time of Julius Cæsar, who totally subdued their country, and reduced it to the form of a Roman province*. The Romans continued in quiet possession of Gaul, as long as their empire retained its strength, and they were in a condition to repress the incursions of the German nations, whom even in the zenith of their power they had not been able to subdue. But in the reign of the emperor Valerian, the ancient Roman valour and discipline had begun to decline, and the same care was not taken to defend the provinces as formerly. The barbarous nations, therefore, began to make much more frequent incursions; and among the rest the *Franks*, a German nation inhabiting the banks of the Rhine, proved particularly troublesome. Their origin is variously accounted for; but the most probable supposition is, that about the time of the emperor Gordian, the people inhabiting the banks of the Lower Rhine entered into a confederacy with those who dwelt on the Weser, and both together assumed the name of *Franks* or *Freemen*. Their first irruption, we are told by Valerian, happened in the year 254, the second of Valerian's reign. At this time they were but few in number; and were repulsed by Aurelian, afterwards emperor.

First subdued by Julius Cæsar.

France. Not discouraged by this check, they returned two years after in far greater numbers; but were again defeated by Gallienus, whom Valerian had chosen for his partner in the empire. Others, however, continued to pour in from their native country in such multitudes, that Gallienus, no longer able to drive them out by force of arms, made advantageous proposals to one of their chiefs, whom he engaged to defend the frontiers against his countrymen as well as other invaders.

This expedient did not long answer the purpose. In 260 the Franks, taking advantage of the defeat and captivity of Valerian in Persia, broke into Gaul, and afterwards into Italy, committing every where dreadful ravages. Five years afterward they invaded Spain; which they possessed, or rather plundered, for the space of 12 years; nor could they be driven out of Gaul till the year 275, when the emperor Probus not only gave them a total overthrow in that country, but pursued them into their own, where he built several forts to keep them in awe. This intimidated them so much, that nine of their kings submitted to the emperor, and promised an annual tribute.—They continued quiet till the year 287; when in conjunction with the Saxon pirates they plundered the coasts of Gaul, carrying off an immense booty. To revenge this insult, the emperor Maximian entered the country of the Franks the following year, where he committed such ravages that two of their kings submitted to him; and to many of the common people who choose to remain in Gaul, he allowed lands in the neighbourhood of Treves and Cambrai.

The restless disposition of the Franks, however, did not allow them to remain long in quiet. About the year 293, they made themselves master of Batavia and part of Flanders; but were entirely defeated, and forced to surrender at discretion, by Constantius the father of Constantine the Great, who transplanted them into Gaul. Their countrymen in Germany continued quiet till the year 306, when they renewed their depredations; but being overcome by Constantine the Great, two of their kings were taken prisoners, and thrown to the wild beasts in the shows exhibited on that occasion.

All these victories, however, as well as many others said to have been gained by the Romans, were not sufficient to prevent the incursions of this restless and turbulent nation; inasmuch that in the year 335, they had made themselves masters of 40 cities in the province of Gaul. Soon after, they were totally defeated by the emperor Julian, and again by count Theodosius, father to the emperor of that name; but, in the year 388, they ravaged the province with more fury than ever, and cut off a whole Roman army that was sent against them. As the western empire was at this time in a very low state, they for some time found more interruption from other barbarians than from the Romans, till their progress was checked by Aetius.

³
Pharamond
the first
king. When the war with Aetius broke out, the Franks were governed by one *Pharamond*, the first of their kings of whom we have any distinct account. He is supposed to have reigned from the year 417 or 418, to 428; and is thought by archbishop Usher to have been killed in the war with Aetius. By some he is

supposed to have compiled the Salic Laws, with the assistance of four sages named *Wisegast*, *Lofegast*, *Widegast*, and *Solegast*. But Valefius is of opinion that the Franks had no written laws till the time of Clovis.

Pharamond was succeeded by his son *Clodio*, who likewise carried on a war against the Romans. He is said to have received a terrible overthrow from Aetius near the city of Lens; notwithstanding which, he advanced to Cambrai, and made himself master of that city, where for some time he took up his residence. After this he extended his conquests as far as the river Somme, and destroyed the cities of Treves and Cologne, Tournay and Amiens. He died in the year 448, and was succeeded by *Merovæus*.

Authors are not agreed whether the new king was brother, or son, or any relation at all, to *Clodio*. It seems probable indeed, that he was of a different family; as from him the first race of French kings were styled *Merovingian*. He was honoured and respected by his people, but did not greatly enlarge the boundaries of his kingdom. He died in 458.

Merovæus was succeeded by his son *Childeric*, who being no longer kept in awe by Aetius, made war on the Romans, and extended his conquests as far as the river Loire. He is said to have taken the city of Paris after a siege of five years, according to some, and of ten, according to others. The Roman power was now totally destroyed in Italy; and therefore *Clodovæus*, *Clovis*, or *Louis*, for his name is differently written, who succeeded *Childeric*, set himself about making an entire conquest of Gaul. Part of the province was still retained by a Roman named *Syagrius*, who probably had become sovereign of the country on the downfall of the western empire in 476. He was defeated and taken prisoner by *Clovis*, who afterwards caused him to be beheaded, and soon after totally reduced his dominions.

Thus was the French monarchy established by *Clovis* in the year 487. He now possessed all the country lying between the Rhine and the Loire; which, though a very extensive dominion, was yet considerably inferior to what it is at present.

Clovis had been educated in the Pagan religion, and continued in that profession till the 30th year of his age; notwithstanding which he allowed his subjects full liberty of conscience. Having married, however, *Clotilda*, daughter of the duke of Burgundy, this princess, who was a zealous Christian, used all her influence with her husband to persuade him to embrace her religion. For some time he continued to waver; but happening to gain a battle, where, being in great danger, he had invoked the god of *Clotilda* and the Christians, he afterwards gave such a favourable ear to the discourses of *Remigius* bishop of Rheims that he soon declared himself a convert, and was baptised in the year 496. His acknowledgment of the truths of the gospel was not followed by any amendment of life: on the contrary, he employed the remainder of his life in the aggrandisement of himself and extension of his dominions by the most abominable treachery, fraud, and violence. In his attacks on Armorica he proved unsuccessful. The inhabitants of this country, which comprehended the maritime part of ancient Gaul lying between the Rivers Seine and Loire, had united for their defence; and though abandoned by the Ro-

mans,

mans, made a powerful defence against the barbarians who assaulted them on all sides. Clovis, finding them too powerful to be subdued by force, proposed an union with his people, which they readily accepted, and this the more easily on account of his professing the Christian religion. Thus the Christianity of Clovis in several instances proved subservient to the purposes of his ambition, and his power became gradually very formidable. The Burgundians at this time possessed all the country from the forest of Vosges to the sea of Marseilles, under Gondebaud the uncle of Clotilda; who to secure his own authority, had put to death two of his brothers, one of whom was the father of the French queen. The third brother, *Godagesil*, whom he had spared and allowed to possess the principality of Geneva, conspired with Clovis to drive him from his dominions. A war having commenced between the French and Burgundian monarchs, the latter was defeated in a battle by Godagesil, and obliged to fly to Avignon, leaving his antagonist master of the cities of Lyons and Vienne. The victor next laid siege to Avignon; but it was defended with such vigour, that Clovis at last thought proper to accept of a sum of money and an annual tribute from Gondebaud; who was likewise obliged to cede to Godagesil the city of Vienne, and several other places taken during the war.

Gondebaud no sooner found himself at liberty from his enemies, than he assembled a powerful army; with which he advanced towards Vienne, where Godagesil himself resided at that time. The place was garrisoned by 5000 Franks, and might have made considerable resistance; but Gondebaud being admitted through the subterraneous passage of an aqueduct, massacred most of the Franks, sent the rest prisoners to the king of the Visigoths, and put Godagesil to death. This was quickly followed by the submission of all the other places which had owned the authority of Godagesil; and Gondebaud, now thinking himself able to resist the power of Clovis, sent a message to inform him, that he must no longer expect the promised tribute; and though Clovis was very much mortified with this defection, he found himself obliged for the present to put up with the injury, and accept of the alliance and military service of the king of Burgundy.

His next expedition was against the Visigoths, who possessed considerable territories on both sides of the Pyrenean mountains. His motives for this undertaking were expressed in the following speech to his nobility when assembled in the city of Paris, which he considered as the capital of his dominions. "It is with concern (said the religious monarch) that I suffer the Arians to possess the most fertile part of Gaul; let us, with the aid of God, march against them; and having conquered them, annex their kingdom to our dominions." The nobility approved of the scheme; and Clovis marched against a prince for whom he had but lately professed the greatest regard, vowing to erect a church in honour of the holy apostles, if he succeeded in his enterprise. Alaric the king of the Visigoths was a young man destitute of military experience, though personally brave. He did not therefore hesitate at engaging his antagonist; but, unable to contend with the veteran troops of Clovis, his army was utterly defeated on the banks of the Clain, 10

miles south of Poitiers, in the year 507. Alaric, perceiving the ruin of his troops, rushed against Clovis in person, by whom he was killed, and the remainder of the army pursued for some time with great slaughter. After this victory the province of Aquitaine submitted, and Clovis established his winter quarters at Bourdeaux. Tholouse surrendered next spring; and the royal treasures of the Visigoths were transported to Paris. Angouleme was next reduced, and the city of Arles invested. But here the victorious career of Clovis was stopped by Theodoric king of the Ostrogoths, who had overturned the dominion of Odoacer in Italy. He had married Abolfeda the sister of Clovis, but had also given his own daughter in marriage to the king of the Visigoths, and had endeavoured, as much as was in his power, to preserve a good understanding between the two sovereigns. Finding this impossible, however, and that no bounds could be set to the ambition of Clovis, he sent one of his generals with a powerful army against him; by whom the French monarch was defeated with the loss of 30,000 men. By this misfortune Clovis was obliged to raise the siege of Arles with precipitation: however the Franks still retained the greatest part of their conquests, and the province of Aquitaine was indissolubly annexed to their empire.

In 509, Clovis had the title of Roman consul; by which means the people of Rome were insensibly led to pay a peculiar regard to the French monarchs: and Clovis was now supposed to be invested with a just title to all his conquests in whatever manner they had been acquired. He was solemnly invested with his new dignity in the church of St Martin in the city of Tours; after which he entered the cathedral clothed in a purple tunic and mantle, the badges of his office.

Clovis now proceeded to augment his power by the murder of his kinsmen the princes of the Merovingian race. Among those who perished on this occasion were Sigibert king of Cologne, with his son Cloderic, Cararic, another prince whose dominions have not been accurately pointed out by historians; Ranacaire, who governed the present diocese of Cambray; and Renomer king of the territory of Maine. All these Murders, however, were expiated, according to the views of the clergy of those times, by the great zeal he expressed in the cause of Christianity, and his liberality to the church.

Clovis died in the year 511, after having reformed and published the Salic laws: a few lines of which, debarring women from inheriting any part of the Salic lands, have been extended so far as to deprive the females of the royal family of France of their right of succession to the throne of that kingdom.

Clovis was buried in the church of St Peter and St Paul, now Genevieve, in the city of Paris, where his tomb is still to be seen. His dominions were divided among his four sons. Thieri, or Theodoric, the eldest, had the eastern part of the empire; and, from his making the city of Metz his capital, is commonly called the *king of Metz*. Clodomir, the eldest son by Clotilda, had the kingdom of Orleans; Chilbert, and Clotaire, who were both infants, had the kingdoms of Paris and Soissons, under the tutelage of their mother. The prudence of Clotilda kept matters quiet in all the parts of the empire for eight years; but

about

France. about the year 520, a numerous fleet of Danes arrived at the mouth of the Meuse; and their king Cochiliac, having landed his forces, began to destroy the country with fire and sword. Against him Thieri sent his son Theodobert, who defeated the Danish army and navy, and killed their king, forcing the rest to retire with precipitation.

In 522, Hermanfroi king of Thuringia, having destroyed one of his brethren named *Berthaire*, and seized on his dominions, applied to Thieri for assistance against his other brother Balderic, whom he intended to treat in the same manner. In this infamous enterprise Thieri embarked, on condition that he should have one half of Balderic's dominions; but after the unhappy prince was overcome and killed in battle, Hermanfroi seized all his dominions. Thieri had no opportunity of revenging himself till the year 531; when perceiving the power of the Ostrogoths, whom he much dreaded, to considerably lessened by the death of king Theodric, he engaged his brother Clotaire to assist him: and they accordingly entered Thuringia with two powerful armies. They joined their forces as soon as they had passed the Rhine, and were quickly after reinforced by a considerable body of troops under the command of Theodobert. The allies attacked the army of Hermanfroi, which was advantageously posted; and having totally defeated it, he was forced to fly from place to place to place in disguise. Soon after this the capital was taken, and Hermanfroi himself being invited to a conference by Thieri, was treacherously murdered; after which his extensive dominions became feudatory to Thieri.

In the mean time, Clotilda had excited her children to make war on the Burgundians, in order to revenge the death of her father Chilperic, whom Gondebaud king of Burgundy had caused to be murdered. Gondebaud was now dead, and had left his dominions to his sons Sigismund and Godemar. Sigismund's forces were quickly defeated; and he himself was soon after delivered up his own subjects to Clodomir, who caused him to be thrown into a pit, where he perished miserably. By his death Godemar became sole master of Burgundy. Clodomir marched against him, and defeated him; but pursuing his victory too eagerly, was surrounded by his enemies and slain. After the reduction of Thuringia however, Childebert and Clotaire entered the kingdom of Burgundy at the head of a powerful army, and in 534 completed the conquest of it; in which, according to some, Godemar was killed; according to others, he retired into Spain, and from thence into Africa.

10
Clotaire
becomes
sole mo-
arch.

In 560 Clotaire became sole monarch of France. He had murdered the sons of Clodomir, who was killed in Burgundy as above related. Thieri and his children were dead, as was also Childebert; so that Clotaire was sole heir to all the dominions of Clovis. He had five sons; and the eldest of them, named *Chramnes*, had some time before rebelled against his father in Auvergne. As long as Childebert lived, he supported the young prince; but on his death, Chramnes was obliged to implore his father's clemency. He was at this time pardoned; but he soon began to cabal afresh, and engaged the count of Bretagne to assist him in another rebellion. The Bretons, however, were defeated, and Chramnes determined to make his escape; but percei-

ving that his wife and children were surrounded by his father's troops, he attempted to rescue them. In this attempt he was taken prisoner, and with his family was thrust into a thatched cottage near the field of battle; of which the king was no sooner informed, than he commanded the cottage to be set on fire, and all that were in it perished in the flames.

France.

Clotaire did not long survive this cruel execution of his son, but died in 562; and after his death the French empire was divided among his four remaining sons, Caribert, Gontran, Sigebert, and Chilperic.—The old king made no division of his dominions before he died, which perhaps caused the young princes to fall out sooner than they would otherwise have done. After his death, however, they divided the kingdom by lot; when Caribert, the eldest, had the kingdom of Paris; Gontran, the second, had Orleans; Sigebert had Metz (or the kingdom of Austrasia); and Chilperic had Soissons. Provence and Aquitaine were possessed by all of them in common. The peace of the empire was disturbed in 563 by an invasion of the Abares; a barbarous nation, said to be the remains of the Huns. They entered Thuringia, which belonged to the dominions of Sigebert: but by him they were totally defeated, and obliged to repass the Elbe with precipitation. Sigebert pursued them close, but readily concluded a peace with them on their first proposals. To this he was induced, by hearing that his brother Chilperic had invaded his dominions, and taken Rheims and some other places in the neighbourhood. Against him, therefore, Sigebert marched with his victorious army, made himself master of Soissons his capital, and of the person of his eldest son Theodobert. He then defeated Chilperic in battle; and not only recovered the place which he had seized, but conquered the greater part of his dominions: nevertheless, on the mediation of the other two brothers, Sigebert abandoned all his conquests, set Theodobert at liberty, and thus restored peace to the empire.

11
The em-
pire again
divided.

Soon after this, Sigebert married Brunehaut daughter to Athanagilde king of the Visigoths in Spain; and in a little time after the marriage, died Caribert king of Paris, whose dominions were divided among his three brethren. In 567 Chilperic married Galswintha, Brunehaut's eldest sister, whom he did not obtain without some difficulty. Before her arrival, he dismissed his mistress called *Fredegonde*; a woman of great abilities and firmness of mind, but ambitious to the highest degree, and capable of committing the blackest crimes in order to gratify her ambition. The queen, who brought with her immense treasures from Spain, and made it her whole study to please the king, was for some time entirely acceptable. By degrees, however, Chilperic suffered Fredegonde to appear again at court, and was suspected of having renewed his intercourse with her; which gave such umbrage to the queen, that she desired leave to return to her own country, promising to leave behind her all the wealth she had brought. The king, knowing that this would render him extremely odious, found means to dissipate his wife's suspicions, and soon after caused her to be privately strangled, upon which he publicly married Fredegonde.

12
Infamous
conduct of
Chilperic.

Such an atrocious action could not fail of exciting the greatest indignation against Chilperic. His domi-

nions

France. nions were immediately invaded by Sigebert and Gontran, who conquered the greatest part of them; after which they suddenly made peace, Chilperic consenting that Brunehaut should enjoy those places which on his marriage he had bestowed upon Galiwintha, viz. Bourdeaux, Limoges, Cahors, Bigorre, and the town of Bearn, now called *Lescar*.

The French princes, however, did not long continue at peace among themselves. A war quickly ensued, in which Gontran and Chilperic allied themselves against Sigebert. The latter prevailed; and having forced Gontran to a separate peace, seemed determined to make Chilperic pay dear for his repeated perfidy and infamous conduct; when he was assassinated by a contrivance of Fredegonde, who thus saved herself and Chilperic from the most imminent danger. Immediately on his death, Brunehaut fell into the hands of Chilperic; but Gondebaud, one of Sigebert's best general's, made his escape into Austrasia with Childebert, the only son of Sigebert, an infant of about five years of age, who was immediately proclaimed king in room of his father. In a short time, however, Meroveus, eldest son to Chilperic, fell in love with Brunehaut, and married her without acquainting his father. Chilperic, on this news, immediately went to Rouen, where Meroveus and his consort were; and having seized them, sent Brunehaut and her two daughters to Metz, and carried Meroveus to Soissons. Soon after, one of his generals being defeated by Gontran, who espoused Brunehaut's cause, Chilperic, in a fit of rage, caused Meroveus to be shaved and confined in a monastery. From hence he found means to make his escape, and with great difficulty arrived in Austrasia, where Brunehaut would gladly have protected him: but the jealousy of the nobles was so strong, that he was forced to leave that country; and being betrayed into the hands of his father's forces, was murdered at the instigation of Fredegonde, as was generally believed.

The French empire was at this time divided between Gontran king of Orleans, called also king of Burgundy, Chilperic king of Soissons, and Childebert king of Austrasia. Chilperic found his affairs in a very disagreeable situation. In 579, he had a dispute with Varoc count of Bretagne, who refused to do him homage. Chilperic dispatched a body of troops against him; who were defeated, and he was then forced to submit to a dishonourable peace. His brother and nephew lived in strict union, and had no reason to be very well pleased with him. His own subjects, being oppressed with heavy taxes, were miserably poor and discontented. His son Clovis, by a former queen named *Andovera*, hated Fredegonde, and made no secret of his aversion. To add to this embarrassment, the seasons were for a long time so unfavourable, that the country was threatened with famine and pestilence at the same time. The king and queen were both attacked by an epidemic disease which then raged. They recovered: but their three sons, Clodobert, Samson, and Dagobert; died; after which, the sight of Clovis became so disagreeable to Fredegonde, that she caused him to be murdered, and likewise his mother *Andovera*, lest Chilperic's affection for her should return after the tragical death of her son.

In 583 Chilperic himself was murdered by some unknown assassins, when his dominions were on the point

of being conquered by Gontran and Childebert, who had entered into a league for that purpose. After his death Fredegonde implored the protection of Gontran for herself and her infant son Clotaire; which he very readily granted, and obliged Childebert to put an end to the war. He found himself, however, greatly diffculted to keep Fredegonde and Brunehaut in awe; for these two princesses having been long rivals and implacable enemies, were continually plotting the destruction of each other. This, however, he accomplished, by favouring sometimes Brunehaut and sometimes Fredegonde; so that, during his life, neither of them durst undertake any thing against the other.

On the 28th of March 593, died Gontran, having lived upwards of 60, and reigned 32 years. Childebert succeeded to the kingdom without opposition, but did not long enjoy it; he himself died in the year 596, and his queen shortly after. His dominions were divided between his two sons Theodobert and Thierrri; the first of whom was declared king of Austrasia, and the later king of Burgundy. As Theodobert was only in the 11th year of his age, and Thierrri in his 10th, Brunehaut governed both kingdoms with an absolute sway. Fredegonde, however, took care not to let slip such a favourable opportunity as was offered her by the death of Childebert, and therefore made herself mistress of Paris and some other places on the Seine. Upon this Brunehaut sent against her the best part of the forces in Austrasia, who were totally defeated; but Fredegonde died before she had time to improve her victory, leaving her son Clotaire heir to all her dominions.

For some time Brunehaut preserved her kingdom in peace; but in the end her own ambition proved her ruin. Instead of instructing Theodobert in what was necessary for a prince to know, she took care rather to keep him in ignorance, and even suffered him to marry a young and handsome slave of his father's. The new queen was possessed of a great deal of affability and good-nature; by which means she in a short time gained the affection of her husband so much, that he readily consented to the banishment of Brunehaut. Upon this disgrace she fled to Thierrri king of Burgundy, in the year 599. By him she was very kindly received; and instead of exciting jealousies or misunderstandings between the two brothers, she engaged Thierrri to attempt the recovery of Paris, and the other places which had been wrested from their family by Fredegonde, procuring at the same time a considerable body of auxiliaries from the Visigoths. This measure was so acceptable to Theodobert, that he likewise raised a numerous army, and invaded Clotaire's dominions in conjunction with his brother. A battle ensued, in which the forces of Clotaire were totally defeated, and himself soon after obliged to sue for peace; which was not granted, but on condition of his yielding up the best part of his dominions.

This treaty was concluded in the year 600; but three years afterwards, it was broken by Clotaire. He was again attacked by the two brothers, and the war carried on with great vigour till the next spring. At this time Thierrri having forced Landri, Clotaire's general, to a battle, gave him a total overthrow, in which the king's infant son Meroveus, whom he had sent along with Landri, was massacred; to gratify, as Clo-

This, however, was prevented by Theodobert; who no sooner heard of the victory gained by Thierry, than he became jealous of his success, and offered Clotaire such terms of peace as he gladly accepted. The latter having then nothing to fear on the side of Austrasia, quickly compelled Thierry to listen to terms of accommodation also.

This behaviour of Theodobert greatly provoked his brother; and his resentment was highly inflamed by Brunehaut, who never forgot her disgrace in being banished from his court. A war was therefore commenced between the two brothers in 605; but it was so highly disapproved of by the nobility, that Thierry found himself obliged to put an end to it. The tranquillity which now took place was again disturbed in 607, by Theodobert's sending an embassy to demand some part of Childebert's dominions which had been added, by the will of that monarch, to those of Burgundy. The nobility of both kingdoms were so much averse to war, that they constrained their kings to consent to a conference, attended by an equal number of troops; but Theodobert, by a scandalous breach of his faith, brought double the number, and compelled his brother to submit to what terms he pleased. This piece of treachery instantly brought on a war; for Thierry was bent on revenge, and his nobility no longer opposed him. It was necessary, however, to secure Clotaire by a negotiation; and accordingly a promise was made of restoring those parts of his dominions which had formerly been taken from him, provided he would remain quiet. This treaty being finished, Thierry entered Theodobert's dominions, defeated him in two battles, took him prisoner, used him with the utmost indignity; and having caused an infant son of his to be put to death, sent him to his grandmother Brunehaut. By her orders he was first shaved and confined in a monastery; but afterwards, fearing lest he should make his escape, she caused him to be put to death.—Clotaire, in the mean time, thought that the best method of making Thierry keep his word was to seize on those places which he had promised to restore to him, before his return from the war with Theodobert. This he accordingly did; and Thierry no sooner heard of his having done so, than he sent him a message requiring him to withdraw his forces, and, in case of his refusal, declared war. Clotaire was prepared for this; and accordingly assembled all the forces in his dominions, in order to give him a proper reception. But before Thierry could reach his enemies, he was seized with a dysentery; of which he died in the year 612, having lived 26 years, and reigned 17.

18
Death of
Thierry.

On the death of Thierry, Brunehaut immediately caused his eldest son, named *Sigibert*, then in the 10th year of his age, to be proclaimed king. It is probable, that she intended to have governed in his name with an absolute sway; but Clotaire did not give her time to discover her intentions. Having great intelligence in Austrasia and Burgundy, and knowing that the nobility in both kingdoms were disaffected to Brunehaut, he declared war against her; and she being betrayed by her generals, fell into the hands of her enemies. Clotaire gave her up to the nobles; who generally

hated her, and who used her in the most cruel manner. After having led her about the camp, exposed to the insults of all who had the meanness to insult her, she was tied by the leg and arm to the tail of an untamed horse, which, setting off at full speed, quickly dashed out her brains. After this her mangled body was reduced to ashes, which were afterwards interred in the abbey of St Martin at Autun.

France.
19
Brunehaut
put to a
cruel death.

Thus in the year 613, Clotaire became sole monarch of France; and quietly enjoyed his kingdom till his death, which happened in 628. He was succeeded by Dagobert; who proved a great and powerful prince, and raised the kingdom of France to a high degree of splendor. Dagobert was succeeded by his sons Sigebert and Clovis; the former of whom had the kingdom of Austrasia, and the latter that of Burgundy. Both the kings were minors at the time of their accession to the throne, which gave an opportunity to the mayors of the palace (the highest officers under the crown) to usurp the whole authority. Sigebert died in 640, after a short reign of one year; leaving behind him an infant son named *Dagobert*, whom he strongly recommended to the care of Grimoalde his mayor of the palace. The minister caused Dagobert to be immediately proclaimed king, but did not long suffer him to enjoy that honour. He had not the cruelty, however, to put him to death; but sent him to a monastery in one of the Western Islands of Scotland; and then, giving out that he was dead, advanced his own son Childebert to the throne. Childebert was expelled by Clovis king of Burgundy; who placed on the throne Childeric, the second son of Sigebert. Clovis died soon after the revolution, and was succeeded in his dominions by his son Clotaire; who died in a short time, without issue. He was succeeded by his brother Childeric; who, after a short reign, was murdered with his queen, at that time big with child, and an infant son named *Dagobert*; though another, named *Daniel*, had the good luck to escape.

The affairs of the French were now in the most deplorable situation. The princes of the Merovingian race had been for some time entirely deprived of their power by their officers called *mayors of the palace*. In Austrasia the administration had been totally engrossed by Pepin and his son Grimoalde; while Archanbaud and Ebroin did the same in Neustria and Burgundy. On the reunion of Neustria and Burgundy to the rest of the French dominions, this minister ruled with such a despotic sway, that the nobility of Austrasia were provoked to a revolt; electing for their dukes two chiefs named *Martin* and *Pepin*. The forces of the confederates, however, were defeated by Ebroin; and Martin having surrendered on a promise of safety, was treacherously put to death. Pepin lost no time in recruiting his shattered forces; but before he had any occasion to try his fortune a second time in the field of battle, the assassination of Ebroin delivered him from all apprehensions from that quarter. After his death Pepin carried every thing before him, overthrew the royal army under the command of the new minister Bertaire; and, having got possession of the capital, caused himself to be declared mayor of the palace; in which station he continued to govern with an absolute sway during the remainder of his life.

20
Miserable
situation of
France.

Pepin (who had got the surname of *Heristal* from his

France.

his palace on the Meuse) died in the year 714, having enjoyed unlimited power for 26 years. He appointed his grandson Theudobalde, then only six years of age, to succeed him in his post of mayor of the palace. This happened during the reign of Dagobert already mentioned: but this prince had too much spirit to suffer himself to be deprived of his authority by an infant, the adherents of the young mayor were defeated in battle, and this defeat was soon followed by his death. Charles, however, the illegitimate son of Pepin, was now raised to the dignity of duke by the Austrasians, and by his great qualities seemed every way worthy of that honour. The murder of Dagobert freed him from a powerful opponent: and the young king Chilperic, who after Dagobert's death was brought from a cloyster to the throne, could by no means cope with such an experienced antagonist. On the 19th of March 717, Charles had the good fortune to surprise the royal camp as he passed through the forest of Arden; and soon after a battle ensued, in which the king's forces were entirely defeated. On this Chilperic entered into an alliance with Eudes duke of Aquitaine, whose friendship he purchased by the final cession of all the country which Eudes had seized for himself. Charles, however, having placed on the throne another of the royal family named *Clotaire*, advanced against Chilperic and his associate, whom he entirely defeated near Soissons. After this disaster Eudes, despairing of success, delivered up Chilperic into the hands of his antagonist; after having stipulated for himself the same terms which had been formerly granted him by the captive monarch.

Charles now advanced to the summit of power, treated Chilperic with great respect; and, on the death of Clotaire caused him to be proclaimed king of Austrasia: by which, however, his own power was not in the least diminished: and from this time the authority of the kings of France became merely nominal; and so inactive and indolent were they accounted, that historians have bestowed upon them the epithet of *faneans*, i. e. "lazy or idle." Charles, however, had still one competitor to contend with. This was Rainfroy, who had been appointed mayor of the palace; and who made such a vigorous resistance, that Charles was obliged to allow him the peaceable possession of the country of Anjou. No sooner, however, had Charles thus set himself at liberty from domestic enemies, than he was threatened with destruction from foreign nations. The Suevians, Frisons, and Allemanni, were successively encountered and defeated. Eudes also, who had perfidiously broken the treaties to which he had bound himself, was twice repulsed; after which Charles invaded Aquitain, and obliged the treacherous duke to hearken to reason. This was scarce accomplished when he found himself engaged with a more formidable enemy than any he had yet encountered. The Saracens, having over-run great part of Asia, now turned their victorious arms westward, and threatened Europe with total subjection. Spain had already received the yoke; and having passed the Pyrenees, they next invaded France, appearing in vast numbers under the walls of Thoulouse. Here they were encountered and defeated by Eudes; but this proved only a partial check. The barbarians once more passing the Pyrenees, entered France with such a powerful army, that Eudes was no longer able

to resist. He encountered them indeed with his accustomed valour; but being forced to yield to superior power, he solicited the protection and assistance of Charles. On this occasion the latter, on account of his valour and personal strength, acquired the name of *Martel*, i. e. "the hammer," alluding to the violence of the strokes he bestowed on his enemies*. Three hundred and seventy-five thousand of the Infidels, among whom was the commander Abderahman himself, are said to have perished in the battle; notwithstanding which they soon made another irruption: but in this they were attended with no better success, being again defeated by Charles; who by so many victories established his power on the most solid foundation. Having again defeated the Frisons, and with his own hand killed their duke, he assumed the sovereignty of the dominions of Eudes after his decease, reserving to himself the claim of homage, which he ought to have yielded to Thierris his lawful sovereign. At last his fame grew so great that he was chosen by pope Gregory III. for his protector. He offered to shake off the yoke of the Greek emperor, and to invest Charles with the dignity of Roman consul: sending him at the same time the keys of the tomb of St Peter; but while this negotiation was going on successfully, the pope, the emperor, and Charles Martel himself died. After his death, which happened in the year 741, his dominions were divided among his three sons, Carloman, Pepin, and Grippon, according to the disposition he had made in his life-time. By this Carloman, the eldest, had Austrasia; Pepin, the second, Neustria and Burgundy; while Grippon, the third, had only some lands assigned him in France; by which he was so much displeased, that the tranquillity of the empire was soon disturbed. With the assistance of his mother Sonnechilde he seized on the city of Laon, where he endured a violent siege. In the end, however, he was obliged to submit; Sonnechilde was put into a monastery, and Grippon imprisoned in a castle at Arden. The two brothers, having thus freed themselves from their domestic enemy, continued to govern the empire with uninterrupted harmony; but their tranquillity was soon disturbed by the intrigues of Sonnechilde. That enterprising and ambitious woman had negociated a marriage between Odilon duke of Bavaria and Hiltrude the sister of the two princes. This was no sooner accomplished than Odilon, instigated by Sonnechilde, and alarmed at the growing power of the two princes, entered into an alliance with Theodobald duke of the Allemanni and Theodoric duke of the Saxons; who having assembled a formidable army, advanced directly against the princes. They posted themselves in an advantageous manner, with the river Lech in their front; but Carloman and Pepin, passing the river at different fords in the night-time, attacked the camp of the allies with great vigour. The engagement continued doubtful for five hours: but at last the entrenchments were forced on all sides, the Bavarians and Saxons entirely routed, and the vanquished dukes obliged to submit to the clemency of the victors. During their absence on this expedition, Hunalde, whom Charles Martel had appointed duke of Aquitain, having likewise entered into a confederacy with Odilon passed the Loire, ravaged the open country, and burnt the magnificent cathedral of the city of Chartres. The two princes, however, having returned with their vic-

France.

France divided among sons of Charles.

France.

terious army, Hunalde found himself obliged to retreat: and even this availed him but little; for the Franks entering the dutchy of Aquitain, committed such devastations, that Hunalde in despair resigned his dominions to his son, and retired into a convent. This event was soon followed by a similar resignation of Carloman, notwithstanding the uninterrupted success he had met with. He suddenly took the resolution of retiring into a convent, and persisted in his design, notwithstanding the intreaties of Pepin, who, to appearance at least, did all he could to dissuade him.

23
Pepin becomes sole master of the kingdom.

By the resignation of Carloman, which happened in the year 736, Pepin was left sole master of France; and in this exalted station he acquitted himself in such a manner as has justly rendered his name famous to posterity. One of the first acts of his new administration was to release his brother Grippon from prison: but that treacherous prince had no sooner regained his liberty, than he again excited the Saxons to take up arms. His enterprize, however, proved unsuccessful; the Saxons were defeated, their duke Theodoric taken, and his subjects obliged to submit to the will of the conqueror; who upon this occasion caused them make a profession of the Christian religion. Grippon then fled to Hiltrude, his half-sister, whose husband Odilon was now dead, and had left an infant son named *Tassilon*. He met with a favourable reception from her; but, with his usual treachery, seized both her and her son by the assistance of an army of discontented Franks, whom he had persuaded to join him. His next step was to assume the sovereignty and title of duke of Bavaria; but being driven from the throne by Pepin, he was obliged to implore his clemency, which was once more granted. All these misfortunes, however, were not yet sufficient to cure Grippon of his turbulence and ambition: He once more endeavoured to excite disturbance in the court of Pepin; but being finally detected and baffled, he was obliged to take refuge in Aquitain.

24
Assumes the title of king.

Pepin having now subdued all his foes both foreign and domestic, began to think of assuming the title of *king*, after having so long enjoyed the regal power. His wishes in this respect were quite agreeable to those of the nation in general. The nobility, however, were bound by an oath of allegiance to Childeric the nominal monarch at that time; and this oath could not be dispensed with but by the authority of the pope. Ambassadors for this purpose were therefore dispatched both from Pepin and the nobility to pope Zachary, the reigning pontiff. His holiness replied, that it was lawful to transfer the regal dignity from hands incapable of maintaining it to those who had so successfully preserved it; and that the nation might unite in the same person the authority and title of *king*. On this the unfortunate Childeric was degraded from his dignity, shaved, and confined in a monastery for life; Pepin assumed the title of *king of France*, and the line of Clovis was finally set aside.

This revolution took place in the year 751. The attention of the new monarch was first claimed by a revolt of the Saxons; but they were soon reduced to subjection and obliged to pay an additional tribute: and during his expedition against them, the king had the satisfaction of getting rid of his restless and treacherous competitor Grippon. This turbulent prince,

France.

having soon become weary of residing at the court of Aquitain, determined to escape from thence, and put himself under the protection of Astolphus king of the Lombards; but he was killed on attempting to force a pass on the confines of Italy. Pepin in the mean time continued to push his good fortune. The submission of the Saxons was soon followed by the reduction of Brittany; and that by the recovery of Narbonne from the infidels. His next exploit was the protection of pope Stephen third, against Astolphus the king of the Lombards, who had seized on the exarchate of Ravenna, and insisted on being acknowledged king of Rome. The pope, unable to contend with such a powerful rival, hastened to cross the Alps and implore the protection of Pepin, who received him with all the respect due to his character. He was lodged in the abbey of St Dennis, and attended by the king in person during a dangerous sickness with which he was seized. On his recovery Stephen solemnly placed the diadem on the head of his benefactor, bestowed the regal unction on his sons Charles and Carloman, and conferred on the three princes the title of *patricians of Rome*. In return for these honours Pepin accompanied the pontiff into Italy at the head of a powerful army. Astolphus, unable to withstand such a powerful antagonist, shut himself up in Pavia, where he was closely besieged by the Franks, and obliged to renounce all pretensions to the sovereignty of Rome, as well as to restore the city and exarchate of Ravenna, and swear to the observance of the treaty. No sooner was Pepin gone, however, than Astolphus broke the treaty he had just ratified with such solemnity. The pope was again reduced to distress, and again applied to Pepin. He now sent him a pompous epistle in the style and character of St Peter himself; which so much inflamed the zeal of Pepin, that he instantly set out for Italy, and compelled Astolphus a second time to submit to his terms: which were now rendered more severe by the imposition of an annual tribute. Pepin next made a tour to Rome; but finding that his presence there gave great uneasiness both to the Greeks and to the pope himself, he thought proper to finish his visit in a short time. Soon after his return Astolphus died, and his dominions were usurped by his general Didier; who however, obtained the papal sanction for what he had done, and was recognised as lawful sovereign of the Lombards in the year 756.

Pepin returned to France in triumph; but the peace of his dominions was soon disturbed by the revolt of the Saxons, who always bore the French yoke with the utmost impatience. Their present attempts, however, proved equally unsuccessful with those they had formerly made; being obliged to submit and purchase their pardon not only by a renewal of their tribute, but by an additional supply of 300 horse. But while the king was absent on this expedition, Vaifar duke of Aquitain took the opportunity of ravaging Burgundy, where he carried his devastations as far as Chalons. Pepin soon returned, and entering the dominions of Vaifar, committed similar devastations, and would probably have reduced the whole territory of Aquitain, had he not been interrupted by the hostile preparations of his nephew Tassilon the duke of Bavaria. The king, however, contented himself at present with securing his frontiers by a chain of posts, against any
inva-

France. invasion : after which he resumed his enterprize on the dominions of Vaifar. The latter at first attempted to impede the progress of his antagonist by burning and laying waste the country ; but finding this to no purpose, he determined to try his fortune in an engagement. Victory declared in favour of Pepin ; but he refused to grant a peace upon any terms. The French monarch advanced to the banks of the Garonne ; while Vaifar was abandoned by his ally the duke of Bavaria, and even by his own subjects. In this distress he retired with a band of faithful followers into the country of Saintonge, where he defended himself as long as possible, but was at last deprived both of his crown and life by the victor.

Thus the duchy of Aquitain was once more annexed to the crown of France ; but Pepin had scarce time to indulge himself with a view of his new conquest when he was seized with a slow fever, which put an end to his life in the year 768, the 54th of his age, and 17th of his reign. He was of a short stature, whence he had the surname of *Le Bref*, or *the Short* ; but his great actions justly intitled him to the character of an hero ; though under the succeeding reign his own fame seemed to have been entirely forgot, and on his tomb was only inscribed, “ Here lies the father of Charlemagne.”

25
Death of
Pepin.

Pepin was succeeded in his authority by his two sons Charles and Carloman ; to whom with his dying breath he bequeathed his dominions. They continued to reign jointly for sometime ; but the active and enterprising spirit of Charles gave such umbrage to the weak and jealous Carloman, that he regarded him with envy, and was on the point of coming to an open rupture with him, when he himself was taken off by death, and thus the tranquillity of the empire was preserved.

26
Succeeded
by his two
sons.

The first military enterprize of Charles was against Hunalde, the old duke of Aquitain ; who leaving the monastery where he had resided upwards of 20 years, assumed the royal title, and was joyfully received by his subjects, already weary of the French yoke. Charles took the field with the utmost expedition, and with difficulty prevailed upon his brother Carloman, who was then alive, to join him with his forces. But the junction was scarce effected, when Carloman withdrew his forces again, and left his brother to carry on the war in the best manner he could. Charles, though thus deserted, did not hesitate at engaging the enemy ; and having overthrown them in a great battle, Hunalde was obliged to fly to the territories of Lupus duke of Gascony. Charles quickly sent an embassy demanding the fugitive prince ; and Lupus, not daring to disobey the orders of such a powerful monarch, yielded up the unfortunate Hunalde, who was instantly cast into prison, from which, however, he afterwards made his escape.

27
Reign of
Charles the
Great.

The death of Carloman, which happened in the year 771, left Charles sole master of France ; but the revolt of the Saxons involved him in a series of wars from which he did not extricate himself for 33 years. These had long been tributaries to the French, but frequently revolted : and now, when freed from the terror of Pepin's arms, thought they had a right to shake off the yoke altogether. Charles entered their country with a powerful army ; and having defeated them in a num-

ber of small engagements, advanced towards Eresbourg near Paderborn, where they had their capital post, and where was the image of their god Irminful, represented as a man completely armed, and standing on a column. The Saxons made an obstinate defence, but were at last obliged to submit ; and Charles employed his army three days in demolishing the monuments of idolatry in this place ; which so much disheartened the whole nation, that for the present they submitted to such terms as he pleased to impose ; and which were rendered easier than they probably would have been, by the news which Charles now received from Italy. He had concluded a marriage with the daughter of Didier king of the Lombards ; but this had been dissolved by the Pope, who reproached the Lombards with the first stain of the leprosy. Thus all friendship was dissolved betwixt Didier and Charles ; and as the Lombard monarchs seem to have had a kind of natural enmity towards the popes, it is not surprising that it should now break out with uncommon fury. Didier having seized and frightened to death Pope Stephen IV. used his utmost endeavours to reduce his successor Adrian I. to a state of entire dependance on himself. Adrian applied to the French monarch, the usual resource of the pontiffs in those days. Charles was very willing to grant the necessary assistance, but the nobility were averse to an Italian war : so that he was obliged to act with great circumspection. Several embassies were therefore sent to Didier, entreating him to restore to the pope those places which he had taken from him, and at last even offering him a large sum of money if he would do so ; but this proposal being rejected, he obtained the consent of his nobility to make war on the Lombards. Didier disposed his troops in such a manner, that the officers of Charles are said to have been unanimously of opinion that it would be impossible to force a passage. This, however, was accomplished, either through the superior skill of Charles, according to some historians, or a panic which seized the Lombard soldiers, according to others ; after which, Didier, with the old duke of Aquitain, who had escaped from his prison, and taken refuge at his court, shut themselves up in Pavia. Adalgise, the only son of the Lombard monarch, with the widow and children of Carloman, fled to Verona. That city was immediately invested by the conqueror, and in a short time obliged to submit. Adalgise had the good luck to escape to Constantinople, but we are not informed what became of Carloman's widow and children. Charles, after paying a short visit to Rome, returned to the siege of Pavia. The place was vigorously defended, until famine and pestilence obliged the inhabitants to implore the clemency of Charles. Hunalde fell a sacrifice to his own obstinacy in opposing the intention of the people ; Didier was taken prisoner and carried into France ; but we are not informed of his fate afterwards. His kingdom, however, was totally dissolved, and Charles was crowned king of Lombardy at Milan in the year 774.

France.

Having received the oaths of allegiance from his new subjects, Charles set out for Saxony, the inhabitants of which had again revolted, and recovered Eresbourg their capital. The king soon recovered this important post ; but a detachment of his army being cut off, and new troubles arising in Italy, he was obli-

ged

France.

ged to accept of the proposals of the Saxons, though their sincerity was very doubtful. Having therefore only strengthened the fortifications of Eresbourg, and left a sufficient garrison in the place, he set out for Italy, which was all in commotion through the intrigues of the emperor of the East, and Adalgise the son of Didier. The presence of Charles restored tranquillity in that quarter; but in the mean time, the Saxons having taken Eresbourg and destroyed the fortifications, threatened to annihilate the French power in that quarter. On the king's return, he found them employed in the siege of Sigebourg. His sudden arrival struck the barbarians with such terror, that they instantly sued for peace; which the king once more granted, but took care to secure their obedience by a chain of forts along the river Lippe, and repairing the fortifications of Eresbourg. An assembly of the Saxon chiefs was held at Paderborn; and a promise was made, that the nation should embrace the Christian religion: after which the king set out on an expedition to Spain in the year 778.

This new enterprise was undertaken at the request of Ibunala, the Moorish sovereign of Saragossa, who had been driven from his territory. He was restored, however, by the prowess of Charles, who reduced the cities of Pampluna and Saragossa. He reduced also the city of Barcelona, and the kingdoms of Navarre and Arragon; but on his return, he met with a severe check from the Gascons, who attacked and defeated the rear-guard of his army with great slaughter as they passed the Pyrenean mountains. This engagement, which seems to imply some defect in the prudence or military skill of Charles, has been much celebrated among romance writers, on account of the death of Roland a famous warrior.

Next year, 779, he paid a visit to Italy with his two sons Carloman and Louis. Having passed the winter at Pavia, he entered Rome next spring amidst the acclamations of the inhabitants. Here, in the 39th year of his age, he divided his dominions in presence of the pope betwixt his two sons Carloman and Louis. The former, who now took the name of Pepin, had Lombardy; the latter Aquitain. Having then received the submission of Tassilon duke of Bavaria, he set out for Saxony, where he took a most severe revenge on the people of that country for the many treacheries they had been guilty of. The present revolt was chiefly owing to a chief named Witikind, who had twice before fled from the victorious arms of Charles, and taken refuge at the court of Denmark. Returning from thence in the king's absence, he roused his countrymen to action, while the generals of Charles, disagreeing among themselves, neglected to take the proper methods for repelling the enemy. In consequence of this, they were entirely defeated on the banks of the Weser in the year 782. Charles arrived in time to prevent the total destruction of his people, and directly penetrated into the heart of the country. Witikind, unable to resist his antagonist, once more fled into Denmark; but 4500 of his followers perished at once by the hands of the executioner. An universal insurrection was the consequence of this unheard of cruelty; and though during three years the French monarch was constantly successful in the field, he found it impossible by any force whatever to subdue the

France.

spirit of the people. At last therefore he was obliged to have recourse to negotiation. Witikind and several other chiefs were invited to an interview; where Charles represented to them in such strong colours the ruin which must necessarily ensue to their country by persisting obstinately in opposition to him, that they were induced not only to persuade their countrymen finally to submit, but to embrace the Christian religion.

Charles having thus brought his affairs in Saxony to an happy conclusion turned his arms against Tassilon duke of Bavaria, who had underhand supported the Saxons in their revolt. Having entered his country with a powerful army in the year 787, he made such rapid advances, that the total destruction of Tassilon seemed inevitable. Charles had advanced as far as the river Lech, when Tassilon privately entered his camp, and threw himself at his feet. The king had compassion on his faithless kinsman on seeing him in this abject posture; but no sooner did the traitor find himself at liberty than he stirred up the Hunns, the Greek emperor, and the fugitive Adalgise, against the king. He fomented also the discontents of the factious nobles of Aquitain and Lombardy; but his subjects, fearing lest these intrigues should involve them in destruction, made a discovery of the whole to Charles. Tassilon, ignorant of this, entered the diet at Ingelheim, not suspecting any danger, but was instantly arrested by order of the French monarch. Being brought to a trial, the proofs of his guilt were so apparent, that he was condemned to lose his head: the punishment, however, was afterwards mitigated to perpetual confinement in a monastery, and the duchy of Bavaria was annexed to the dominions of Charles.

The Hunns and other enemies of the French monarch continued to prosecute their enterprises without regarding the fate of their associate Tassilon. Their attempts, however, only served to enhance the fame of Charles. He defeated the Hunns in Bavaria, and the Greek emperor in Italy; obliging the latter to renounce for ever the fortune of Adalgise. The Hunns, not disheartened by their defeat, continuing to infest the French dominions, Charles entered their country at the head of a formidable army; and having forced their entrenchments, penetrated as far as Raal on the Danube, but was compelled by an epidemic distemper to retire before he had finished his conquest. He was no sooner returned to his own dominions, than he had the mortification to be informed, that his eldest son Pepin had conspired against his sovereignty and life. The plot was discovered by a priest who had accidentally fallen asleep in a church where the conspirators were assembled. Being awakened by their voices, he overheard them consulting on the proper measures for completing their purpose; on which he instantly set out for the palace, and summoned the monarch from his bed to inform him of the guilt of his son. Pepin was seized, but had his life spared, tho' condemned to expiate his offences by spending the remainder of his days in a monastery.

Charles was no sooner freed from this danger than he was again called to arms by a revolt of the Saxons on the one hand, while a formidable invasion of the Moors distressed him on the other; the Hunns at the same time renewing their depredations on his dominions,

France.

nions. The king did not at present make war against the Moors; probably foreseeing that they would be called off by their Christian enemies in Spain. This accordingly happened; the victories of Alonso the Chaste obliged them to leave France; after which Charles marched in person to attack the Saxons and Hunns. The former consented again to receive the Christian religion, but were likewise obliged to deliver up a third part of their army to be disposed of at the king's pleasure; but the Hunns defended themselves with incredible vigour. Though often defeated, their love of liberty was altogether invincible; so that the war was not terminated but by the death of the king, and an almost total destruction of the people: only one tribe could be induced to acknowledge the authority of the French monarch.

These exploits were finished betwixt the years 793 and 798; after which Charles invaded and subdued the islands of Majorca and Minorca; which the dissensions of the Moorish chiefs gave him an opportunity of doing. The satisfaction he felt from his new conquest, however, was soon damped by the troubles which broke out in Italy. After the death of pope Adrian, his nephew aspired to the papal dignity; but a priest named Leo being preferred, the disappointed candidate determined on revenge. He managed matters so well, that his designs were concealed for four years. At last, on the day of a procession, a furious assault was made on the person of Leo. The unfortunate pontiff was left for dead on the ground; but having with difficulty recovered, and made his escape to the Vatican, he was protected by the duke of Spoleto, at that time general of the French forces. His cause was warmly espoused by Charles, who invited him to his camp at Paderborn in Westphalia; whence he dispatched him with a numerous guard to Rome, promising soon after to visit that metropolis, and redress all grievances. His attention for the present, however, was called by the descents of the Normans on the maritime provinces of his dominions; so that he was obliged to defer the promised assistance for some time longer. Having constructed forts at the mouths of most of the navigable rivers, and further provided for the defence of his territories, by instituting a regular militia, and appointing proper squadrons to cruise against the invaders, he set out for the fourth and last time on a journey to Rome. Here he was received with the highest possible honours. Leo was allowed to clear himself by oath of the crimes laid to his charge by his enemies, while his accusers were sent into exile. On the festival of Christmas, in the year 800, after Charles had made his appearance in the cathedral of St Peter, and assisted devoutly at mass, the pope suddenly put a crown on his head; and the place instantly resounded with acclamations of "Long life to Charles the August, crowned by the hand of God! Long life and victory to the great and pacific emperor of the Romans!" His body was then consecrated and anointed with royal unction; and after being conducted to a throne, he was treated with all the respect usually paid to the ancient Cæsars; from this time also being honoured with the title of *Charlemagne*, or *Charles the Great*. In private conversation, however, he usually protested, that he was ignorant of the pope's intention at this time; and that, had he known it, he would have

28
He is crowned emperor of the west.

disappointed him by his absence: but these protestations were not generally believed; and the care he took to have his new title acknowledged by the eastern emperors, evidently showed how fond he was of it.

Charles, now raised to the supreme dignity in the west, proposed to unite in himself the whole power of the first Roman emperors, by marrying Irene the empress of the east. But in this he was disappointed by the marriage of that princess by Nicephorus: however, the latter acknowledged his new dignity of Augustus, and the boundaries of the two empires were amicably settled. Charles was further gratified by the respect paid him by the great Haroun Al-Rashid, caliph of the Saracens, who yielded to him the sacred city of Jerusalem, and holy sepulchre there. But in the mean time his empire was threatened with the invasion of a very formidable enemy, whom even the power of Charles would have found it hard to resist. These were the Normans, at this time under the government of Godfrey a celebrated warrior, and who by their adventurous spirit, and skill in maritime affairs, threatened all the western coasts of Europe with desolation. From motives of mutual convenience a transitory peace was established, and Charles made use this interval to settle the final distribution of his dominions. Aquitaine and Gascony, with the Spanish march, were assigned to his son Louis; Pepin had Italy confirmed to him; and to this was added the greatest part of Bavaria, with the country now possessed by the Grisons. Charles the eldest had Neustria, Austrasia, and Thuringia. The donation was supposed to be rendered more authentic by the sanction of the pope. This division, however, had scarce taken place, when the princes were all obliged to defend their dominions by force of arms. Louis and Pepin were attacked by the Saracens, and Charles by the Sclavonians. All these enemies were defeated; but while Charles hoped to spend the short remainder of his life in tranquillity, he was once more called forth to martial exertions by the hostile behaviour of Godfrey the Norman leader. Charles sent him a message of defiance, which was returned in the same style by Godfrey: but the former, by artfully fomenting divisions among the northern powers, prevented for a while the threatened danger; but, these disturbances being quelled, the Normans renewed their depredations, and Charles was obliged to face them in the field. An engagement, however, was prevented by the death of Godfrey, who was assassinated by a private soldier; on which the Norman army retreated, and the dominions of the emperor still remained free from these invaders. Still the latter days of Charles were embittered by domestic misfortunes. His favourite daughter Rotrude died, as did also Pepin king of Italy; and these misfortunes were soon followed by the death of his eldest son Charles. The emperor then thought proper to associate his only surviving son Louis with him in the government; which was formally done at Aix-la-Chapelle. Charles himself survived this transaction only a few months: his death happened on the 27th of January 814; in the 71st year of his age, and 47th of his reign.

By the martial achievements of this hero, the French monarchy was raised to its utmost pitch of splendor. He had added the province of Aquitaine to the territories of his ancestors; he had confined the in-

France.

29
Death of Charles the Great.

30
Extent of his territories.

bitants

bitants of Brittany to the shores of the ocean, and obliged them to submit to a disgraceful tribute. He had reduced under his dominion all that part of Spain which extends from the Pyrenees to the river Ebro, and includes the kingdoms of Roussillon, Navarre, Aragon, and Catalonia. He possessed Italy from the Alps to the borders of Calabria; but the duchy of Beneventum, including most of the present kingdom of Naples, escaped the yoke after a transitory submission. Besides these extensive countries, Charles added to his territories the whole of Germany and Pannonia; so that the French now had the jurisdiction of all the country from east to west, from the Ebro in Spain to the Vistula; and from north to south, from the duchy of Beneventum to the river Eyder, the boundary between Germany and the dominions of Denmark. In acquiring these extensive dominions Charles had been guilty of horrid and repeated massacres; for which, however, he had been in some measure excusable by the barbarity and rebellious disposition of the people with whom he had to deal, upon whom no mild measures would probably have had any effect. His establishing of schools throughout the conquered provinces, shewed also his inclination to govern his subjects in peace, and to take proper steps for their civilization; though indeed many parts of his private conduct showed no small inclination to cruelty; particularly the fate of the sons of Carloman, of whom no account could ever be obtained. His advice to his son Louis indeed was excellent; exhorting him to consider his people as his children; to be very mild and gentle in his administration, but firm in the execution of justice; to reward merit; promote his nobles gradually; choose ministers deliberately, but not remove them capriciously or without sufficient reason. All these prudent maxims, however, were not sufficient to enable Louis to govern dominions so extensive, and people so turbulent as he had to deal with. At the time of the decease of his father, this prince was about 36 years of age, and had married Ermengarde, daughter of the count of Hefbai of the diocese of Liege, by whom he had three sons, Lothaire, Pepin, and Louis. Lothaire, the eldest, was associated with himself in the empire, and the two youngest were entrusted with the governments of Aquitain and Bavaria. Every one of the princes proved unfaithful to their father, as well as enemies to one another. The death of Ermengarde, and the marriage of the emperor with Judith a princess of Bavaria, artful but accomplished, proved the first source of calamity to the empire. In the year 823, Charles, the emperor's youngest son was born: and his pretensions became in time more fatal to the public tranquillity than the ambition and disobedience of all the rest. Various parts of the Imperial dominions were likewise assaulted by foreign enemies. The inhabitants of Brittany and Navarre revolted; the Moors invaded Catalonia; while the ambition of Judith produced a war amongst the brothers themselves.

31
Decline of his empire.

32
Civil wars among the sons of Louis the Gentle.

Charles at first had been appointed sovereign of that part of Germany bounded by the rivers Danube, the Maine, the Neckar, and the Rhine; the country of the Grisons and Burgundy, comprehending Geneva and the Swiss Cantons: but this was opposed by the three elder sons. Pepin and Louis advanced with the united forces of Aquitain and Bavaria, while the Im-

perial forces deserted their standard and joined the discontented. The emperor was taken prisoner, and the empress retired to a monastery. Lothaire, the eldest of the young princes, to whom the rest found themselves obliged to submit, was the person who retained the emperor in his possession; but, notwithstanding his breach of duty, his heart was touched with remorse on account of the crimes he had committed. Dreading the reproach of the world at large, and being threatened with the censures of the church, he threw himself at his father's feet, and begged pardon for his guilt, consenting to relinquish the authority he had unjustly usurped. Thus Louis was re-established in his authority by the diet of the empire which had met to depose him. His first step was to recal his empress from the monastery to which she had retired; but this princess, implacable in her resentment, now persecuted Lothaire to such a degree, that he was obliged to join his two brothers Pepin and Louis in a confederacy against their father. The old emperor thought to check this rebellious disposition by revoking his grant of Aquitain to Pepin, and conferring it on his youngest son Charles, then only nine years of age; but pope Gregory IV. conferred the Imperial dignity itself on Lothaire, deposing the unhappy monarch, and again sending the empress to a nunnery in the forest of Arden. The unnatural behaviour of his sons, however, once more excited the compassion of his subjects. Dreux, the bishop of Metz, used his interest with Louis king of Bavaria to arm his subjects in defence of his father and sovereign. In this enterprise the Bavarian monarch was joined by the French and Saxons; so that the aged emperor was once more restored, the empress released from her nunnery, and Charles from his prison, in the year 833.

The ambition of Judith now set matters once more in a flame. Taking advantage of the affection her husband bore her, she persuaded him to invest her son Charles with the sovereignty of Neustria as well as the dominions formerly assigned him. This was productive of great discontents on the part of Lothaire and Pepin; but their power was now too much broken to be able to accomplish any thing by force of arms. The death of Pepin, which happened soon after, produced a new division of the empire. The claims of young Pepin and Charles, sons of the deceased prince, were entirely disregarded, and his French dominions divided between the two brothers Charles and Lothaire, the latter being named guardian to his infant nephew. This enraged Louis of Bavaria, whose interest was entirely neglected in the partition, to such a degree, that he again revolted; but the unexpected appearance, with the hostile preparations of the Saxons, obliged him to submit and ask pardon for his offences. Still, however, the ambition of the empress kept matters in a continual ferment, and the empire was again threatened with all the calamities of civil war; but before these took place, the emperor died, in 831, after a most unfortunate reign of 27 years.

Louis was eminent for the mildness of his manners and peaceful virtues, which procured him the title of *Le Debonnaire*, or "the gentle;" but such was the turbulence and excessive barbarity of the age in which he lived, that all his virtues, instead of procuring him respect

France.

France. respect and esteem, were productive only of contempt and rebellion from those whom both duty and nature ought to have rendered the most submissive and obedient.

The decease of the emperor was followed by a civil war among his sons. The united forces of Lothaire and his nephew Pepin were defeated by those of Charles and Louis in a very bloody battle in the plains of Fontenoy, where 100,000 Franks perished, in the year 842. This victory, however, bloody as it was, did not decide the fortune of the war. The conquerors having through motives of interest or jealousy, retired each into their own dominions, Lothaire found means not only to recruit his shattered forces, but pressed the other two princes so vigorously, that they were glad to consent to a new partition of the empire. By this Lothaire was allowed to possess the whole of Italy, with the whole tract of country between the rivers Rhone and Rhine, as well as that between the Meuse and Scheldt. Charles had Aquitaine with the country lying between the Loire and the Meuse; while Louis had Bavaria with the rest of Germany, from whence he was distinguished by the appellation of *Louis the German*.

33 Division of the empire. By this partition, Germany and France were divided in such a manner as never afterwards to be united under one head. That part of France which was allowed to Lothaire, was from him called *Lotharingia*, and now *Lorraine*, by a gradual corruption of the word. The sovereignty, however, which that prince had pursued at the expence of every filial duty, and purchased at so much blood, afforded him now but little satisfaction. Disgusted with the cares and anxieties of his situation, he sought relief in a monastery in the year 855. On his retreat from the throne, he allotted to his eldest son Louis II. the sovereignty of Italy; to his second son Lothaire the territory of Lorraine, with the title of king; and to his youngest son Charles, surnamed the *Bald*, Provence, Dauphiny, and part of the kingdom of Burgundy; so that he may be considered as properly the king of France.

34 Lothaire resigns. From the year 845 to 857 the provinces subjected to his jurisdiction had been infested by the annual depredations of the Normans, from whom Charles was at last fain to purchase peace at a greater expence than might have carried on a successful war. The people of Brittany had also revolted; and though obliged by the appearance of Charles himself, at the head of a powerful army, to return to their allegiance, they no sooner perceived him again embarrassed by the incursions of the Normans, than they threw off the yoke, and under the conduct of their duke Louis subdued the neighbouring diocese of Rennes; after which exploit Louis assumed the title of king, which he transmitted to his son Herispee. By him Charles was totally defeated; and his subjects, perceiving the weakness of their monarch, put themselves under the protection of Louis the German. His ambition prompted him to give a ready ear to the proposal; and therefore, taking the opportunity of Charles's absence in repelling an invasion of the Danes, he marched with a formidable army into France, and was solemnly crowned by the archbishop of Sens in the year 857. Being too confident of success, however, and fancying himself already established on the throne, he was persuaded

VOL. VII.

to dismiss his German forces; which he had no sooner done, than Charles marched against him with an army, and Louis abandoned his new kingdom as easily as he had obtained it.

Notwithstanding this success, the kingdom of Charles continued still in a very tottering situation. The Normans harassed him in one quarter, and the king of Brittany in another. He marched against the latter in the year 860; but had the misfortune to receive a total defeat after an engagement which lasted two days. The victory was chiefly owing to a noted warrior named Robert le Fort, or the Strong, who commanded the Bretons; but Charles found means to gain him over to his party by investing him with the title of Duke of France, including the country which lies between the rivers Seine and Loire.

For some time the abilities of Robert continued to support the tottering throne of Charles; but his difficulties returned on the death of that hero, who was killed in repelling an invasion of the Danes. Some amends was indeed made for his loss by the death of the king of Lorraine in the year 869; by which event the territories of Charles were augmented by the cities of Lyons, Vienne, Toul, Besançon, Verdun, Cambrai, Viviers, and Urez, together with the territories of Hainault, Zealand, and Holland. Cologne, Utrecht, Treves, Mentz, Strasburgh, with the rest of the territories of Lothaire, were assigned to Louis the German.

All this time the Normans still continued their incursions to such a degree, that Solomon king of Brittany was persuaded to join his forces to those of Charles, in order to repel the common enemy. The event proved unfortunate to the Normans; for their principal leaders were besieged in Angiers, and obliged to purchase leave to depart by relinquishing all the spoil they had taken. Charles thus freed from a formidable enemy, began to aspire to the imperial crown, which about this time became vacant by the death of Louis. This belonged of right to Louis the German; but Charles, having instantly assembled a powerful army, marched with it into Italy before Louis could be apprised of his designs; and being favourably received at Rome, the Imperial crown was put upon his head without any hesitation by the Pope, in the year 873. Louis, enraged at his disappointment, discharged his fury on the defenceless country of Champagne; and though the approach of Charles obliged him for the present to retire, yet he continued his preparations with such vigour, that Charles would in all probability have found him a very formidable adversary, had he not been taken off by death in the year 877. Charles was no sooner informed of his brother's decease, than he invaded the dominions of his son Louis, who possessed Franconia, Thuringia, the Lower Lorraine, with some other territories in that quarter. The enterprise, however, proved unsuccessful. Charles, though superior in numbers, was defeated with great slaughter, and had scarce time to reunite his scattered forces, when he was informed that the Normans had invaded his territories, laid waste part of the country, and taken possession of the city of Rouen. So many disasters affected him in such a manner that he fell dangerously ill, and was scarce recovered of his sickness when he found himself called into Italy to the assistance of the Pope against

3 E

the

France. the Saracens, whose invasions were encouraged by the dukes of Beneventum and the Greek emperor. Charles passed into Italy with only a few followers; but when he came to Pavia, at which place the pontiff had appointed to meet him, was informed that Carloman king of Bavaria, and son of Louis the German, was already in Italy with a powerful army, and laid claim to the imperial title in virtue of his father's right. Charles prepared to oppose him by force of arms; but his generals conspired against him, and the soldiers declared their resolution not to pass the Alps. On this he was obliged to retire to France, at the very moment that Carloman, dreading his power, prepared to return to Germany. This was the last of Charles's enterprises. His journey brought on a return of his indisposition, which was rendered fatal through the treachery of a Jewish physician named Zedechias, who administered poison to him under pretence of curing his malady. He expired in a miserable cottage upon mount Cenis in the 54th year of his age, and 38th of his reign over the kingdom of France.

36

soned.

37
Reign of
Louis the
Stammerer

The ambition of Charles had been productive of much distress both to himself and to his subjects. His son Louis, surnamed, from a defect in his speech, *the Stammerer*, was of a quite different disposition; but his feeble administration was ill calculated to retrieve matters in their present situation. He died on the 10th of April 879, while on a march to suppress some insurrections in Burgundy. He left his queen Adelaide pregnant; who some time after his decease was delivered of a son, named *Charles*. After his death followed an interregnum; during which a faction was formed for setting aside the children of Louis the Stammerer, in favour of the German princes, sons to Louis the brother of Charles the Bald. This scheme, however, proved abortive; and the two sons of the late king, Louis and Carloman, were crowned kings of France. Another kingdom was at that time erected by an assembly of the states, namely, the kingdom of Provence, which consisted of the countries now called *Lyonnois, Savoy, Dauphiny, Franche Comte*, and part of the duchy of Burgundy; and this kingdom was given to duke Boson, brother in law to Charles the Bald. In 881, both kings of France died; Louis, as was suspected, by poison; and Carloman of a wound he received accidentally while hunting. This produced a second interregnum; which ended with the calling in of Charles the Gross, emperor of Germany. His reign was more unfortunate than that of any of his predecessors. The Normans, to whom he had given leave to settle in Friesland, sailed up the Seine with a fleet of 700 ships, and laid siege to Paris. Charles, unable to force them to abandon their undertaking, prevailed on them to depart by a large sum of money. But as the king could not advance the money at once, he allowed them to remain in the neighbourhood of Paris during the winter; and they in return plundered the country, thus amassing vast wealth besides the sum which Charles had promised. After this ignominious transaction Charles returned to Germany, in a very declining state of health both as to body and mind. Here he quarrelled with his empress; and being abandoned by all his friends, he was deposed, and reduced to such distress, that he would not even have had bread to eat,

had not he been supplied by the archbishop of Mentz, France. out of a principle of charity.

On the deposition of Charles the Gross, Eudes count of Paris was chosen king by the nobility during the minority of Charles the son of Adelaide, afterwards named *Charles the Simple*. He defeated the Normans, and repressed the power of the nobility; on which account a faction was formed in favour of Charles, who was sent for, with his mother, from England. Eudes did not enter into a civil war; but peaceably resigned the greatest part of the kingdom to him, and consented to do homage for the rest. He died soon after this agreement in the year 898.

During the reign of Charles the Simple, the French government declined. By the introduction of fiefs, those noblemen who had got into the possession of governments, having these confirmed to them and their heirs for ever, became in a manner independent sovereigns; and as these great lords had others under them, and they in like manner had others under them, and even these again had their vassals; instead of the easy and equal government which prevailed before, a vast number of insupportable little tyrannies were erected. The Normans, too, ravaged the country in the most terrible manner, and desolated some of the finest provinces in France. At last Charles ceded to Rollo, the king or captain of these barbarians, the duchy of Neustria; who thereupon became Christian, changed his own name to *Robert*, and that of his principality to *Normandy*.

During the remainder of the reign of Charles the Simple, and the entire reigns of Louis IV. surnamed the *Stranger*, Lothaire, and Louis V. the power of the Carolingian race continually declined; till at last they were supplanted by Hugh Capet, who had been created duke of France by Lothaire. This revolution happened in the year 987, and was brought about much in the same manner as the former one had been by Pepin. He proved an active and prudent monarch, and possessed such other qualities as were requisite for keeping his tumultuous subjects in awe. He died on the 24th of October 997, leaving his dominions in perfect quiet to his son Robert.

38
Family of
Charles the
Great sup-
planted by
Hugh Ca-
pet.

The new king inherited the good qualities of his father. In his reign the kingdom was enlarged by the death of Henry duke of Burgundy, the king's uncle, to whom he fell heir. This new accession of territory, however, was not obtained without a war of several years continuance on account of some pretenders to the sovereignty of that duchy; and had it not been for the assistance of the duke of Normandy, it is doubtful whether the king would have succeeded.—As Robert was of opinion, that peace and tranquillity were preferable to wide extended dominions with a precarious tenure, he refused the kingdom of Italy, and the imperial crown of Germany, both which were offered him. He died on the 20th of July 1030, having reigned 33 years, and lived 60.

39
Robert

Robert was succeeded by his eldest son Henry I. who in the beginning of his reign met with great opposition from his mother. She had always hated him; and preferred his younger brother Robert, in whose favour she now raised an insurrection. By the assistance of Robert duke of Normandy, however, Henry over-

40
Henry I.

came

France. came all his enemies, and established himself firmly upon the throne. In return for this, he supported William, Robert's natural son, and afterwards king of England, in the possession of the duchy of Normandy. Afterwards, however, growing jealous of his power, he not only supported the pretenders to the duchy of Normandy secretly, but invaded that country himself in their favour. This enterprise proved unsuccessful, and Henry was obliged to make peace: but no sincere reconciliation ever followed; for the king retained a deep sense of the disgrace he had met with, and the duke never forgave him for invading his dominions. The treaty between them, therefore, was quickly broken; and Henry once more invaded Normandy with two armies, one commanded by himself, and the other by his brother. The first was harassed with continual skirmishes, and the last totally defeated; after which Henry was obliged to agree to such terms as the duke thought proper: but the rancour between them never ceased, and was in reality the cause of that implacable aversion which for a long series of years produced perpetual quarrels between the kings of France and those of the Norman race in England.

41
Philip.

Henry died in 1059, not without a suspicion of being poisoned; and was succeeded by his eldest son Philip, at that time in the eighth year of his age. Baldwin earl of Flanders was appointed his guardian; and died in the year 1066, about the time that William of Normandy became king of England. After the death of his tutor, Philip began to show a very insincere, haughty, and oppressive disposition. He engaged in a war with William the Conqueror, and supported his son Robert in his rebellion against him*. But after the death of William, he assisted Robert's brothers against him; by which means he was forced to consent to a partition of his dominions.

* See Eng-land, n^o 89.

In 1092, king Philip being wearied of his queen Bertha, procured a divorce from her under pretence of consanguinity, and afterwards demanded in marriage Emma daughter to Roger count of Calabria. The treaty of marriage was concluded; and the princess was sent over, richly adorned with jewels, and with a large portion in ready money: but the king, instead of espousing her, retained her fortune, and dismissed the princess herself, carrying off from her husband the countess of Anjou, who was esteemed the handsomest woman in France. With her he was so deeply enamoured, that not satisfied with the illegal possession of her person, he procured a divorce between her and her husband, and prevailed upon some Norman bishops to solemnize his own marriage with her. The whole of these transactions, however, were so scandalous, that the pope having caused them to be revised in a council at Autun, in the year 1094, pronounced sentence of excommunication against Philip in case he did not part with the countess. On his repentance, the censure was taken off; but as the king paid no regard to his promises, he was, in 1095, excommunicated a second time. He again professed repentance, and was absolved; but soon after, living with the countess of Anjou as formerly, he was excommunicated a third time. This conduct, so unworthy of a prince, exposed him to the contempt of the people. Too many of the nobility followed his example, and at the same time despised his authority; not only making war up-

on each other, but spoiling and robbing his subjects with impunity. France.

In the year 1110, Philip prevailed on the court of Rome to have his affair reviewed in an assembly at Poitiers; where, notwithstanding his utmost efforts, sentence of excommunication was a fourth time pronounced against him. Yet, in spite of all these sentences, as queen Bertha was dead, and the count of Anjou offered, for a large sum of money, to give whatever assistance was requisite for procuring a dispensation, Philip at last prevailed, and the countess was proclaimed queen of France. But though the king's domestic affairs were now in some measure quieted, his negligence in government had thrown the affairs of the nation into the greatest disorder. He therefore associated with him in the government his eldest son Louis. This prince was the very reverse of his father; and by his activity and resolution, keeping constantly in the field with a considerable body of forces, he reduced the rebellious nobility to subjection, and, according to the best historians, at this time saved the state from being utterly subverted.

For these services the queen looked upon the young prince with so jealous an eye, and gave him so much disturbance, that he found it necessary to retire for some time into England; where he was received by king Henry I. with the greatest kindness. He had not been long at court, before Henry received, by an express, a letter from Philip; telling him, that, for certain important reasons, he should be glad if he closely confined his son, or even dispatched him altogether. The king of England, however, instead of complying with this infamous request, showed the letter to Louis, and sent him home with all imaginable marks of respect. Immediately on his return he demanded justice; but the queen procured poison to be given him, which operated so violently that his life was despaired of. A stranger, however, undertook the cure, and succeeded; only a paleness remained in the prince's face ever afterwards, though he grew so fat that he was surnamed *the Gros*.

On his recovery, the prince was on the point of revenging his quarrel by force of arms; but his father having caused the queen to make the most humble submissions to him, his resentment was at length appeased, and a perfect reconciliation took place.

Nothing memorable happened in the reign of king ⁴² Louis the Gros. Philip after this reconciliation. He died in the year 1108, and was succeeded by his son Louis the Gros. The first years of his reign were disturbed by insurrections of his lords in different places of the kingdom; and these insurrections were the more troublesome, as they were secretly fomented by Henry I. of England, that by weakening the power of France his duchy of Normandy might be the more secure. This quickly brought on a war; in which Henry was defeated, and his son William obliged to do homage to Louis for the duchy of Normandy. As the kings of England and France, however, were rivals, and exceedingly jealous of each other, the latter espoused the cause of William the son of Robert duke of Normandy, whom Henry had unjustly deprived of that duchy. This brought on a new war; in which Louis receiving a great defeat from Henry, was obliged to make peace upon such terms as his antagonist thought

France. proper. The tranquillity, however, was but of short duration. Louis renewed his intrigues in favour of William, and endeavoured to form a confederacy against Henry; but the latter found means not only to dissipate this confederacy, but to prevail upon Henry V. emperor of Germany to invade France with the whole strength of the empire on one side, while he prepared to attack it on the other. But Louis having collected an army of 200,000 men, both of them thought proper to desist. Upon this, the king of France would have marched into Normandy, in order to put William in possession of that duchy. His great vassals, however, told him they would do no such thing; that they had assembled in order to defend the territories of France from the invasion of a foreign prince, and not to enlarge his power by destroying that balance which arose from the king of England's possession of Normandy, and which they reckoned necessary for their own safety. This was followed by a peace with Henry; which, as both monarchs had now seen the extent of each other's power, was made on pretty equal terms, and kept during the life of Louis, who died in 1137, leaving the kingdom to his son Louis VII.

43
Louis VII.
a weak
prince.

The young king was not endowed with any of those qualities which constitute a great monarch. From the superstition common to the age in which he lived, he undertook an expedition into the Holy Land, from whence he returned without glory. In this expedition he took his queen Eleanor along with him; but was so much offended with her gallantries during her stay there, as well as her behaviour afterwards, that he divorced her, and returned the duchy of Guienne which he received with her as a portion. Six weeks after this she married Henry duke of Normandy, count of Anjou and Maine, and heir-apparent to the crown of England. This marriage was a very great mortification to Louis; and procured him the surname of *the Young*, on account of the folly of his conduct. When Henry ascended the throne of England, some wars were carried on between him and Louis, with little advantage on either side: at last, however, a perfect reconciliation took place; and Louis took a voyage to England, in order to visit the shrine of St Thomas of Canterbury. On his return he was struck with an apoplexy; and though he recovered for that time, yet he continued ever after paralytic on the right side. After having languished for about a year under this malady, he died on the 18th of September 1180, leaving the kingdom to his son Philip.

44
Philip the
Great.

This prince, surnamed *The Gift of God*, *The Magnanimous*, and *The Conqueror*, during his lifetime; and, as if all these titles had fallen short of his merit, styled *Augustus* after his death,—is reckoned one of the greatest princes that ever sat on the throne of France, or any other.—It doth not, however, appear that these titles were altogether well founded. In the beginning of his reign he was opposed by a strong faction excited by his mother. Them indeed he repressed with a vigour and spirit which did him honour; but his taking part with the children of Henry II. of England, in their unnatural contests with their father, and his treacherous combination with John to seize his brother's kingdom when he was detained in prison by the emperor of Germany, must be indelible stains in his

character, and for ever exclude him from the title of *Magnanimous*. As to military skill and personal valour, he was evidently inferior to Richard I. of England; nor can his recovering of the provinces held by the English in France, from such a mean and dastardly prince as king John, intitle him with any justice to the surname of *Conqueror*. In politics he was evidently the dupe of the Pope, who made use of him to intimidate John into a submission, by promising him the kingdom of England, which he never meant that he should enjoy. An account of these transactions, which are the principal ones of his reign, is given under the article ENGLAND, n^o 121—141.

Philip died in 1223, and was succeeded by his son Louis VIII. and he, in 1226, by Louis IX. afterwards styled *St Louis*. This prince was certainly possessed of many good qualities, but deeply tinged with the superstition of the times. This induced him to engage in two croisades. The first was against the Saracens in Egypt: in which he was taken prisoner by the Infidels, and treated with great cruelty; but at last obtained his ransom, on condition of paying a million of pieces of gold, and surrendering the city of Damietta. He no sooner regained his liberty, than he entered Syria with a view of doing something worthy of his rank and character. From this expedition he was obliged to return sooner than he intended, by the news of the decease of his mother queen Blanch, whom he had appointed regent in his absence, and who had managed the national affairs with the greatest prudence. The king, however, found many disorders in the kingdom upon his return; and these he set himself to reform with the utmost diligence. Having succeeded in this, he yielded to Henry III. of England, the Limousin, Querci, Perigord, and some other places; on consideration of Henry and his son prince Edward their renouncing, in the fullest manner, all pretensions to Normandy and the other provinces of France which the English had formerly possessed.

45
Reign of
Louis IX.

The reputation of this monarch for candour and justice was so great, that the barons of England, as well as king Henry III. consented to make him umpire of the differences which subsisted between them. But though he decided this matter very justly, his decision was not productive of any good effect. At last the king, having settled every thing relating to his kingdom in a proper manner, set out on another croisade for Africa; where he died of the plague, on the 25th of August 1270.

Notwithstanding the misfortunes of Louis, his successor Philip, surnamed the *Hardy*, continued the war against the Infidels with great vigour. Being reinforced by his uncle Charles king of Sicily, he brought the war to a more fortunate conclusion than his predecessor had been likely to do. The Saracens were defeated in two engagements, and the king of Tunis obliged to sue for peace; offering at the same time to double the tribute he formerly paid to the crown of Sicily; to reimburse the expences of the war; and to permit the Christian religion to be freely propagated throughout his dominions. Having accomplished this, the two princes set sail for Europe; but the seeds of the distemper which had infected the army in Africa not being eradicated, broke forth on their arrival in Sicily, and raged for some time with great violence.

Philip the
Hardy.

Besides

France. Besides a vast number of common people, the king's brother John, his queen Isabella, with his brother and sister-in-law the king and queen of Navarre, and his uncle and aunt the count and countess of Poitiers, perished by this dreadful malady.

On his return to France, Philip took possession of the counties of Provence and Thoulouse; married his second son, though then very young, to the only daughter of the king of Navarre; while he himself espoused Mary the daughter of the duke of Brabant, reckoned one of the most beautiful princesses of the age. He steadily enforced the regulations of his predecessor, who had prohibited the barons from making private wars upon one another; procured the friendship of Edward I. of England by ceding to him the county of Agenois; and entered into a war with Spain in order to support the pretensions of his nephews, the infants de la Cerda, to the throne of Castile.

The events of this war were of no great importance; and the king's attention was quickly called off from them by the death of his eldest son Louis at the age of twelve years. This disastrous event happened in the year 1175, not without a suspicion of poison; and the young queen, Mary, was accused by a surgeon named La Brosse as guilty of his death. Philip gave some credit to the accusation; but having applied to a nun, who pretended to be inspired, for full satisfaction, her answer proved fatal to La Brosse. The queen being cleared by this pretended prophetess, La Brosse was accused of a treasonable correspondence with the king of Castile, and condemned to death. The manner of his trial and execution, however, were such, that the tide of popular favour was turned; La Brosse was by the voice of the people declared to be innocent, and the king and queen themselves loudly condemned. During these unfavourable circumstances, the Sicilians, over whom Charles of Anjou had established his authority, instigated by John of Procida, a noble exile, came to a resolution of freeing themselves at once from the French yoke by a general massacre. This cruel resolution was accordingly put in execution; and the French, to the number of 8000, murdered in one night; after which Peter of Arragon failed to the island, where he was received by the inhabitants as their king and saviour. Charles was sensibly affected by this misfortune; and having laid siege to Messina, failed directly to Marseilles, where he obtained a powerful reinforcement. But during his absence on this occasion his son, to whom he had entrusted the care of the siege, having rashly ventured an engagement with the Spanish fleet, was entirely defeated and taken prisoner; which so much affected the father that he died of grief, and Sicily was inseparably attached to the house of Arragon.

The misfortunes of Charles were followed by others equally great to Philip himself. Pope Martin IV. in the warmth of his zeal for the cause of the duke of Anjou, had excommunicated Pedro king of Arragon, and bestowed his kingdom on Charles of Valois, a younger son of the king of France. In attempting to defend himself against the execution of this unjust sentence, Pedro was mortally wounded; but, soon after, the French fleet being defeated by that of Arragon, the king was so much affected by the misfortune that he fell sick. His disease was augmented by the

heat of the climate and the fatigues of war; so that, quite worn out with grief and infirmities, he expired at Perpignan in the 41st year of his age, and 16th of his reign.

By the death of Philip the Hardy the French crown devolved on his second son, called also Philip, and from the beauty of his person surnamed *the Fair*; who had espoused the princess of Navarre, and at the time of his accession was in his 17th year. By the marriage with this princess he had obtained the counties of Champagne and Brie; yet with all this increase of power he found himself unable to support the war in which his predecessor had engaged. For this reason he thought proper to abandon the interest of the Infants de la Cerda, and settle the differences with Castile. The treaty was concluded by the mediation of Edward I. of England; at whose intercession Charles the Lame, son to the duke of Anjou already mentioned, was released from his captivity; Edward himself paying part of his ransom. On this Charles consented to renounce his claim on Sicily; and Philip himself promised that his kinsman, Philip of Valois, should renounce all pretensions to the crown of Arragon. In return for this generosity, the latter obtained the eldest daughter of Charles, with the territories of Anjou and Maine as a dowry.

The tranquillity procured by this treaty, however, was soon interrupted by differences with Edward the promoter of it; pope Boniface VIII. and Guy de Dampier, count of Flanders. The difference with England took place by a mere accident. A Norman and an English vessel having met off the coast of Bayonne, and having both occasion for water, the crews met and quarrelled at the same spring. A Norman was killed in the squabble by his own weapon, with which he assaulted an Englishman, as the latter pretended; but however the matter was, complaints were made by the Normans to Philip; who, without giving himself much trouble to enquire into the merits of the cause, instantly allowed them to redress their supposed injuries. On this a kind of piratical war commenced between the two nations, in which the two sovereigns for some time took no active part; though other nations interfered; the Irish and Dutch seamen siding with the English, and those of Flanders and Genoa with the French. Thus the powers on both sides were gradually augmented, till at last the affair became so serious, that in one engagement 15,000 French are said to have perished. Philip, alarmed at such a carnage, summoned the king of England as his vassal to attend; and, on his refusal, declared his estates in France to be forfeited. After a number of negotiations, Philip declared that he would be satisfied with the nominal cession of the province of Guienne, which he engaged instantly to restore to the king of England as soon as it should be put into his hands. Edward complied with his demand; but no sooner had the French monarch obtained possession of that country, then he persisted in the forfeiture of the English possessions in France; which treacherous proceeding instantly produced a war betwixt the two nations. Edward, that he might the better defend himself against such a formidable adversary, concluded a treaty with the emperor Adolphus, together with the counts of Brittany, Holland, Bar, Juliers, Gueldres, and Flanders;

cluded.

ders; while Philip strengthened himself by an alliance with John Baliol of Scotland; and this laid the foundation of that strict union which took place between France and Scotland for two centuries. During this war the French made a descent on the coast of England, and destroyed the town of Dover; while Edward, in revenge, landed in Gascony with an army of 50,000 men. No great exploits, however, were performed with this mighty armament; and both parties finding themselves pretty equally matched, consented to a suspension of arms for two years; during which a peace was finally concluded by the mediation of pope Boniface VIII. Guienne was restored; Edward espoused Margaret the sister of Philip; while his daughter Isabella was given in marriage to the prince of Wales.

Both Philip and Edward behaved to the allies whom they had engaged in their cause with equal perfidy. Baliol was abandoned by Philip to the resentment of Edward; while Guy, earl of Flanders, was left equally exposed to the resentment of Philip.

51
Difference
with Pope
Boniface.

The reconciliation betwixt the French and English monarchs was soon followed by a difference with pope Boniface, whom they had appointed mediator between them. Sensible of his assuming disposition, however, they had inserted in the reference made to him, that he was chosen as a private man, and not as the successor of St Peter. The haughty pontiff, however, soon showed, that he was not by any means to be treated as a private person, and a contest with Philip quickly ensued. Boniface began with forbidding the clergy to grant the king any subsidies without first obtaining the consent of the Holy See, under the pain of excommunication. Philip revenged himself by prohibiting any ecclesiastics from sending money out of the kingdom without his leave; and by protecting the Colonnas, who were the implacable enemies of Boniface. By this his holiness was so much irritated that he sent a most abusive letter to Philip; after which he summoned the clergy of France to a council at Rome; which Philip retaliated, by seizing the temporalities of those who obeyed the summons, and recalling his brother Charles of Valois, who had the title of the *pope's general*. Sensible, however, of the danger that attended this contest, he dispatched two emissaries, under pretence of conciliating the differences, to levy such a body of troops as might execute his hostile purposes against the holy father. With these he suddenly invested the pope in his native city of Anagnina; and while the bull was preparing for the excommunication of Philip, and releasing his subjects from their obedience, the pope himself was obliged to surrender prisoner to the troops of the prince whom he designed to anathematize.

52
Death of
Boniface.

Though Boniface had been at this time delivered up to the troops of Philip through the treachery of the people of Anagnina, yet he was no sooner taken prisoner and brought to distress, than they rescued him from his guards and conveyed him to Rome, where he soon after died of grief and shame. His successor Benedict revoked the excommunication of Boniface, and attempted to regain the allegiance of Philip by gentle means: but before this could be effected, he himself was cut off by death, not without strong suspicions of poison. After his decease Philip offered to procure

France:

the papal chair for Bertrand archbishop of Bourdeaux, provided he would condemn the memory of Boniface, restore the honours and estates of the Colonnas which had been forfeited, allow him, for five years, the tenths of the clergy of France, and comply with a request which at that time it was not proper to divulge.

Bertrand having complied with the terms proposed by the king, ascended the papal throne by the name of *Clement V.* but narrowly escaped being killed on his return from the cathedral of Lyons, by the falling of a wall which had been overloaded by the number of people who came to see the procession; by which accident the duke of Brittany was killed, and the king and Count of Valois considerably bruised. The new pope fixed his residence at Avignon, where he punctually complied with all the conditions of the treaty, except that of condemning the conduct of Boniface, which he absolutely refused to do; and, instead of doing so, vindicated with much solemnity, after having inquired into the matter, or pretended to do so. The other condition, which Philip had at first concealed, was discovered by the death of the emperor Albert of Austria; after which event he desired Clement to assist him in placing his brother Charles of Valois on the Imperial throne. But his holiness, apprehensive of the danger which might accrue to himself from being surrounded with the powerful relations of Philip, urged the diet to proceed instantly to an election; recommending to them Henry of Luxemburg as a proper person to fill the Imperial throne. In this scheme he succeeded so well, that the election was over before Philip could arrive at Avignon; and the only consolation the French monarch could obtain for his disappointment was the possession of the city of Lyons, which had hitherto maintained an independency under its archbishop; but was now persuaded to submit to the authority of Philip.

54
The pope
fixes his re-
sidence at
Avignon.

In the mean time Guy, earl of Flanders, being abandoned by his ally Edward king of England, was obliged to throw himself on the mercy of the French monarch, who had sent his brother, Charles of Valois, with a powerful army to invade his dominions. From the latter indeed he had obtained a promise, that if he could not, within a year, compose the difference subsisting between him and Philip, he should be at liberty to retire, and pursue what measures he pleased. But Philip in order to gratify the resentment which his queen entertained against the captive prince detained him, with two of his sons, in close confinement; while he himself entering Flanders in triumph, was every where received as sovereign of the country; and at his departure appointed John de Chatillo, a relation of the queen, to govern those newly acquired territories.

54
Expedition
of Philip
against the
earl of
Flanders.

The new governor took care to repair the fortifications which had been suffered to decay by reason of the assiduous application of the Flemings to trade; but being of a very haughty and tyrannical disposition, and the poverty of the times not allowing his master to keep regular garrisons, an insurrection quickly took place. This would have been effectually quelled by the diligence of the magistrates, had not Chatillon unluckily entered Bruges, and publicly displayed two hogheads of ropes, which he threatened to employ in the execution of the inhabitants. On this they flew

to

France.

France.

to arms, massacred 1500 French; Chatillon himself being obliged to escape their fury by swimming over the town ditch. The insurgents now, daily gathering strength, soon amounted to an army of 60,000 men who laid siege to Courtray. Here they were rashly attacked in their trenches by the count d'Artois, who met with the reward of his temerity, being cut off with 20,000 of his troops. Philip determined on revenge; though the raising another army obliged him to debase the coin of the kingdom. Thus, however, he was enabled to enter Flanders with such force as would probably have subdued the whole country, had not Edward artfully communicated to the queen of France, as a secret, a feigned correspondence between the French nobility and the court of Rome; by which false intelligence the king was induced to abandon the enterprise without performing any thing worthy of the armament he had fitted out. The war was continued for some time longer; but the attempts of Philip were constantly defeated by the steady valour of the Flemings; and the only recompence Philip obtained for all his trouble and expence was the city of Courtray.

means in the power. In this he was assisted by his uncle Charles of Valois, on whom he at length entirely devolved the government of the kingdom. This regent, however, behaved with such cruelty as is supposed to have proved fatal to the king himself; for having put to death a nobleman named *Enguerrand de Poitiers de Marigni*, who enjoyed the confidence of the late king, this cruelty was so much repented, that his friends were thought to have administered poison to the king; who, expired suddenly after drinking a glass of cold water, in the 26th year of his age, and second of his reign. Immediately after his death, Charles prepared to dispute the sovereignty with the brothers of the late sovereign. Philip count of Poitou, the eldest brother, was at that time at Rome assisting in the election of a new pope; and it was not until a month after the death of his brother that he was able to put an end to the intrigues which took place on that occasion: but on his arrival in France, the throne was assigned to him by the unanimous voice of the people. His prospects, however, were for a short time clouded by the queen-dowager Clemence being delivered of a son, who has been inrolled among the kings of France under the name of *John I.* His death in three weeks secured the throne to Philip; who on account of the tallness of his stature was surnamed the *Long*. His conduct proved superior to that of his predecessor, who had unsuccessfully attempted to subdue the Flemings, and had even suffered himself to be duped by their count; but Philip, by his victorious behaviour, so reduced them, that they compelled their sovereign to consent to a peace upon honourable terms. He summoned Edward II. of England to do homage for his possessions in France; but that monarch, finding himself involved in difficulties, which rendered the visit inconvenient, sent excuses to Philip, which he was pleased to accept. As the French monarch had formerly taken the cross during the lifetime of his father, he now proposed to put his vow in execution; but was dissuaded from this by the pope himself, at whose instance he sent an army into Italy to put an end to the contending factions of the Guelphs and Ghibelines, who for so long time filled that country with blood and slaughter. The event proved unfortunate; and the disgrace was rendered more mortifying by a contagious distemper, which swept off many thousands of French subjects. This was supposed by the superstitious people of those times to be occasioned by the Jews, who had conspired with the Saracens to poison the springs; and that the execution of the project was committed to some lepers who lived by themselves in hospitals richly endowed. On this a persecution was instantly commenced against these unfortunate men, and great numbers of them were burnt alive; while the Jews in general were abandoned to the rage of the populace, who insulted their persons, and plundered their houses without remorse.

The remaining part of the reign of Philip was spent in attempting to regulate the internal concerns of his kingdom. A design had been formed by his predecessors of establishing a certain standard for the coin, weights, and measures, throughout France: and this was adopted by Philip; who, in order to carry it more effectually into execution, purchased from the counts of Valois, Clermont, and Bourbon, their right of coinage

53
The conquest of the country prevented by Edward III. of England.

54
Expulsion of the knights Templars.

The other remarkable transactions of this reign were the expulsion and confiscation of the estates of the Templars, who at that time enjoyed immense possessions in France. The confiscations took place without any form of trial, and upwards of 50 of them were put to death in a cruel manner. The grand-master, with three of his principal officers, were burnt by a slow fire in the presence of the king himself. The whole body of these unfortunate knights had been accused of the most gross and abominable sensualities. The particulars were revealed, or pretended to be so, by two criminals who received their pardon for the discoveries they made; and these discoveries were confirmed by the confession of the Templars themselves. But this confession was afterwards retracted, as being extorted from them by the fear of absolute destruction; and those who suffered, maintained their purity to the last: and on the whole, it was believed that Philip consulted his avarice rather than his justice by this cruel execution. The latter part of his life was embittered by domestic misfortunes. His three daughters-in-law, Margaret daughter of the duke, and Jean and Blanch, of the count of Burgundy, who had married his three sons Louis, Philip, and Charles, were accused of infidelity to their husbands. After a severe examination, Margaret and Blanch were condemned to perpetual imprisonment; in which situation Margaret was afterwards strangled by order of her husband Louis. Their paramours, Philip and Walter de Launay, two brothers, were flayed alive, and afterwards hung upon a gibbet, with an usher of the chamber, who had been their confidant. The uneasiness of mind which Philip suffered on this account is supposed to have impaired his health, and he died of a consumption in the year 1395, the 47th of his age, and 30th of his reign.

55
Reign of Louis the Boisterous.

On the accession of Louis, surnamed the *Boisterous* on account of his violent temper, he found his treasury so much exhausted, that he was obliged to delay for some time the ceremony of his coronation with his new queen. Clemence, daughter of the king of Hungary. Finding the kingdom otherwise in a very distracted state, he applied himself very diligently to appease the discontents of his subjects, and conciliate their affection by every

56

57
Unfortunate expedition into Italy.

France. coinage within their own dominions. But notwithstanding all his endeavours for this purpose, he never could bring the scheme to bear; nor indeed could he in any degree conciliate the affection of his subjects. He died of a fever and dysentery in the year 1322, the 28th of his age, and 6th of his reign.

58

Reign of Charles the Fair.

By the death of Philip, the crown of France devolved on his brother Charles IV. who had obtained the surname of *Fair*. After settling some disputes with the duke of Burgundy, his next step was to dissolve his marriage with Blanch, who still continued in prison, and to espouse Mary the daughter of Henry emperor of Germany. This marriage was contracted with a view to the imperial crown itself, which had been so long separated from that of France; and in 1325 an opportunity offered for Charles to gratify his ambition. At that time the Imperial dignity was disputed between Louis of Bavaria and Frederic of Austria; the latter of whom had been taken prisoner in a battle with Louis. But pope John, who entertained an implacable hatred against Louis, fulminated the sentence of excommunication against him, intrusting the execution of it to Leopold the brother of Ferdinand. The king of France was induced to embark in the same cause, by a promise of the spoils of Bavaria; while Frederic himself consented to relinquish his pretensions to the empire which he had so unsuccessfully maintained. Louis, however, by instantly releasing his prisoner, and dismissing him in an honourable manner, engaged his friendship, and disarmed his most formidable antagonist. But the pope was not to be so disappointed. A considerable sum of money induced Leopold to persevere in his hostilities, while it was determined that a new council of electors should be held in order to transfer the Imperial crown to Charles. In pursuit of this visionary scheme the king of France set out for the frontiers of Germany with a splendid army; but soon found that there was no possibility of accomplishing his wishes. Leopold alone, from motives of interest, remained his friend; the rest showed the greatest indifference; and even his brother-in-law the king of Bohemia absented himself from the diet; while in a short time the death of the queen put an end to all connections with that crown.

On the decease of Mary, Charles espoused Joanna daughter to the count of Evreux: and in order to avert the calamities to be feared from an infant succession, he entered into an alliance with Robert king Scotland; by which it was provided, that should either of the sovereigns die without an heir apparent, the states of the kingdom should fill the vacant throne, and the survivor of the two kings should with his whole force support the legality of the nomination against any other competitor: though even this proved insufficient to avert the danger which now threatened the kingdom, as shall be explained in the sequel.

59
Candidates for the regency and kingdom after the death of Charles.

Charles died in the year 1328, in the 34th year of his age, leaving his queen pregnant; and as the succession depended on the fruit of the queen's pregnancy, a regent in the mean time was necessary; and two candidates instantly appeared for this important post, urging at the same time their right to the crown as well as to the regency. These were Philip de Valois, cousin-german to the deceased king; the other, Edward III. king of England, who aspired to the throne

in right of his mother, and the nephew of Charles the Fair. His pretensions, however, were easily set aside, and Philip was confirmed in the regency; from which he soon after stepped into the throne, on the queen being delivered of a daughter; from which circumstance he acquired the surname of *Fortunate*. But though the pretensions of Edward, both to the regency and crown, were unanimously rejected by the people, it was still impossible for Philip to think of the claims of such a formidable rival without uneasiness. He therefore summoned the English monarch to do homage for his possessions in France; and, upon his not answering his summons, forfeited them, and seized his revenues. This at last induced Edward to cross the sea and pay his homage; which Philip consented to receive in any form, upon condition of a proper explanation being afterwards given: but as this was studiously delayed after the return of the king of England, the province of Guienne was again seized by the French monarch. Edward, unwilling to lose his continental dominions, or involve himself in a war for the sake of mere ceremony, sent over a formal deed, by which he acknowledged that he owed liege homage to France. Thus the flame was smothered for the present; and would perhaps have been entirely extinguished, had it not been for the intrigues of Robert of Artois, brother-in-law to the king of France himself, who had been expelled his country, and had taken refuge in England. By him he was persuaded to renew his pretensions to the crown of France, which of necessity produced a war.

France.

Disputes with Edward III. of England.

For some time, indeed, neither party made any open declaration of hostilities; but as both monarchs were possessed of great prudence and sagacity, they soon penetrated each other's designs. Philip, under pretence of taking the cross, began to make prodigious armaments, strengthening himself at the same time by alliances on every side; while Edward, determining to renew his claim to the crown of France, projected the conquest of Scotland. This, however, he could not accomplish; and in the mean time Philip, in order to favour the Scots, with whom he was in alliance, suffered his subjects to make irruptions into Guienne.

61

Edward's first expedition.

In 1337, the war broke out openly. Philip having detached a squadron of his fleet against the Infidels, employed the rest, consisting chiefly of Genoese vessels, against the English. As in this war it was of great importance which side was taken by the Flemings, these people were courted by both parties. Louis count of Flanders declared for Philip, but his subjects were more inclined to king Edward. James Arteville a brewer the most able and artful man in the country, governed them at that time as much as if he had been their prince; and the advantages arising from the English commerce determining him in favour of Edward, that prince, at his request, embarked for Sluys with a numerous army. Here he arrived in 1338; and on his first landing, it was resolved that the German princes in alliance with him should act against France. But for this a pretence was wanting. The vassals of the empire could not act by Edward's orders, or even, as his allies, without directions from the emperor, and he was in league with France. This difficulty, however, was soon overcome: The French had made themselves masters of Cambray, and the emperor resolved that

France. that it should be retaken. With this view he created Edward *Vicar General of the Empire*; an empty title, but which seemed to give him a right of commanding the services of the princes of Germany. The Flemings, who were vassals of France, likewise pretended scruples at invading the territories of their liege lord. To quiet these, Edward, by the advice of Arteville, assumed the title of *King of France*; and by virtue of this right challenged their assistance for dethroning Philip de Valois, the usurper of his kingdom. This step, which he feared would beget endless animosities and jealousies, he did not take without hesitation; and, according to Mr Hume, from this time we may date the commencement of that great animosity which the English have always borne to the French.

Edward's first attempt was upon the city of Cambrai, to which he laid siege; but in a short time he was prevailed upon by Robert d'Artois to raise the siege and march into Picardy. This country he entered with an army of near 50,000 men, composed mostly of foreigners. Philip came within sight of him with an army of near 100,000, composed chiefly of native subjects; and it was daily expected that a battle would ensue. But the English monarch was averse to engage against so great a superiority; and Philip thought it sufficient if he eluded the attacks of his enemy, without running any unnecessary hazard. The two armies faced each other for several days; mutual defiance was sent; and Edward at last retired into Flanders, and dispersed his army.

Such was the fruitless, and almost ridiculous conclusion of Edward's first expedition; which had plunged him into the greatest difficulties. He had contracted near L. 300,000 of debt; he had anticipated all his revenue; he had pawned every thing of value which belonged either to himself or his queen; nay, he was obliged in some measure even to pawn himself to his creditors, by desiring their permission to go over to England in order to procure supply, and by promising on his word of honour to return in person if he did not remit their money. On his arrival in England, however, he procured a large supply, sufficient to enable him to make all the necessary preparations for a new invasion; and so certain were the English that France would now be conquered, that the parliament, before Edward's departure, protested that they owed him no obedience as king of France, but that the two kingdoms must remain for ever distinct and independent.

62 His second expedition. The king of England set out on his second expedition with a fleet of 240 vessels. Philip had prepared a fleet of 400 vessels, manned with 40,000 men; which he stationed off Sluys, in order to intercept him in his passage. The two fleets met on the 13th of June, 1340; but the English, either by the superior abilities of Edward, or the greater dexterity of his seamen, gained the wind of the enemy, and had the sun in their backs; and with these advantages began the action. The battle was fierce and bloody: the English archers, whose force and address were now much celebrated, galled the French on their approach; and when the ships grappled together, the example of the king and the nobility who were with him so animated the seamen and soldiers, that they maintained every where a superiority over the enemy. The Flemings observing the battle, hurried out of their ports, and

VOL. VII.

brought a reinforcement to the English; which coming unexpectedly, had a greater effect than in proportion to its power and numbers. Two hundred and thirty ships were taken; and 30,000 Frenchmen were killed, with two of their admirals: the loss of the English was inconsiderable, compared to the greatness and importance of the victory. None of Philip's courtiers, it is said, dared to inform him of the event; till his fool or jester gave him a hint, by which he discovered the loss he had sustained.

After this great victory, Edward landed his forces, and laid siege to Tournay. Philip marched to its relief with a very numerous army; but acted with so much caution, that Edward found himself in a manner blocked up in his camp: and the countess dowager of Hainault, sister to Philip, mother-in-law to Edward, and sister-in-law to Robert d'Artois, coming out of a convent, to which she had retired, interposed with so much spirit and address, that she engaged all parties to agree to a truce for a year, and might perhaps have brought about a peace if she had survived.

64 Edward invited into France a third time. In 1341, however, Edward's ambition was once more excited by the invitation of the count de Mountfort, who had possessed himself of the province of Brittany, and applied to Edward to second his claims. An offer of this kind entirely coincided with Edward's most sanguine desires. He was happy in the promised assistance of Mountfort, an active and valiant prince, closely united to him by interest, and thus opening to him an entrance into the heart of France. These flattering prospects, however, were for a while damped by the imprisonment of Mountfort; whose aims being discovered, he was besieged in the city of Nantz, and taken. But Jane of Flanders his wife soon made up for the loss of her husband. This lady courageously undertook to support the falling fortunes of her family. She assembled the inhabitants of Rennes, where she then resided; and carrying her infant son in her arms, deplored her misfortunes, and attempted to inspire the citizens with an affection for her cause. The inhabitants of Nantz instantly espoused her interests, and all the other fortresses of Brittany embraced the same resolution. The king of England was apprised of her efforts; and was intreated to send her succours with all possible expedition to the town of Hennebone, in which place she resolved to sustain the attacks of the enemy. Charles de Blois, Philip's general, anxious to make himself master of so important a fortress as Hennebone, and still more to take the countess a prisoner, sat down before the place with a large army, and conducted the siege with indefatigable industry. The defence was no less vigorous: several sallies were made by the garrison, in which the countess herself was still the most active, and led on to the assault. Observing one day that their whole army had quitted the camp to join in a general storm, she sallied out by a postern at the head of 300 horse, set fire to the enemy's tents and baggage, put their sutlers and servants to the sword, and occasioned such an alarm, that the French desisted from the assault, in order to cut off her communication with the town. Thus intercepted, she retired to Auray, where she continued five or six days; then returning at the head of 500 horse, she fought her way through one quarter of the French camp, and returned to her faithful citizens in triumph. But the besiegers had at length

France. length made several breaches in the walls; and it was apprehended that a general assault, which was hourly expected, would be fatal. A capitulation was therefore proposed, and a conference was already begun, when the countess, who had mounted on a high tower, and was looking towards the sea with great impatience, descried some ships at a distance. She immediately exclaimed that succours were arrived, and forbid any further capitulation. She was not disappointed in her wishes: the fleet she discerned carried a body of English gentlemen, with 6000 archers, whom Edward had prepared for the relief of Hennebone, but who had been long detained by contrary winds. They entered the harbour under the conduct of Sir Walter Manny, one of the most valiant commanders of his time. This relief served to keep up the declining spirits of the Bretons until the time appointed by the late truce with Edward was expired, on which he was at liberty to renew the war in greater form.

The succours under Sir Walter Manny were quickly followed by a more considerable reinforcement commanded by Robert of Artois, who made himself master of the city of Vannes soon after his arrival: but the Bretons soon recovered the city, and Robert was compelled to relinquish his prize after receiving a mortal wound. Edward himself, eager to revenge the death of his ally, soon landed at Morbain near Vannes with an army of 12,000 men. With this small number he undertook at once the siege of Vannes, Nantz, and Rennes: but by dividing his forces, he failed in every enterprise, and gave an opportunity to John duke of Normandy, the king of France's eldest son, to invest him in his camp. In this situation his provisions soon began to fail; and Edward, notwithstanding all his valour, would have been obliged to surrender, had he not by a train of artful negotiations, induced Philip to relinquish the advantage he had obtained, and consent to a truce of three years. This was accomplished by the mediation of the court of Rome; and the French monarch was soon made sensible of the partiality of that court, and the imprudence of the step he himself had taken. Edward soon found a pretence to renew the war, from the execution of some nobles of Brittany, who, he said, were partisans of Mountfort, and chose to look upon their punishment as an infraction of the treaty.

Philip now endeavoured to secure himself against the power of his rival by alliances, and by purchasing the city of Montpellier from the king of Majorca: but in the mean time, the English, under the command of the earl of Darby, had invaded Guicenne, twice defeated the French army commanded by the count de Lisle, and made themselves masters of a great number of towns. Philip, by reason of the exhausted state of his treasury, was for some time incapable of making any opposition. To recruit his finances, he was obliged to lay a duty on salt; which gave such offence to his subjects as had almost excited a rebellion. When these discontents were assuaged, however, he soon raised an army of 100,000 men, whose courage was further raised by the presence of the dukes of Normandy and Burgundy. The English general was therefore compelled to stand upon the defensive. One fortress after another was surrendered to the French: till at length nothing appeared but a total extinction of the power

of England upon the continent. In this situation, *France.* Edward resolved to bring relief in person to his distressed subjects and allies; and accordingly embarked in 1346 at Southampton, on board a fleet of near 1000 sail, of all dimensions. He carried with him, besides all the chief nobility of England, his eldest son the prince of Wales (afterwards surnamed the *Black Prince*); a youth of about 15 years old, and already remarkable both for understanding and valour above his age. His ⁶⁵ He lands army consisted of 4000 men at arms, 10,000 archers, with an ar- my in Nor- 10,000 Welsh infantry, and 6000 Irish; all which he mandy. landed safely at La Hogue, a port in Normandy, which country he determined to make the seat of the war.

The intelligence of Edward's landing, and the devastation caused by his troops, who dispersed themselves over the whole face of the country, soon spread universal consternation through the French court. The rich city of Caen was taken and plundered by the English without mercy; the villages and towns, even up to Paris, shared the same fate; and the French had no other resource but by breaking down their bridges, to attempt putting a stop to the invader's career. In the mean time, Philip was not idle in making preparations to repress the enemy. He had stationed one of his generals, Godemar de Faye, with an army on the opposite side of the river Somme, over which Edward was to pass; while he himself, at the head of 120,000 fighting men, advanced to give the English battle. Edward, thus unexpectedly exposed to the danger of being inclosed and starved in an enemy's country, published a reward to any that should bring him intelligence of a passage over the river Somme. This was discovered by a peasant of the country named Gobin Agace; and Edward had just time to get his whole army over the river, when Philip appeared in his rear. Of the battle that ensued, in which the French were overthrown with great slaughter, an account is given under the article CRESSY.

Edward next laid siege to Calais, which was then ⁶⁶ Calais ta- defended by John di Vienne, an experienced command- ken. er, and supplied with every thing necessary for defence. It was at length taken, after a twelvemonth's siege, the defendant's having been reduced to the last extremity by famine and fatigue; for the consequences of which, see the article CALAIS.

From the very beginning of this unfortunate war, Philip had invariably showed himself desirous of peace, and the victory of Cressy rendered him still more so. Edward also, notwithstanding his successes, was unable to support the expences of the war any longer. The mediation of the court of Rome was therefore readily accepted, and a truce for three years concluded. At the same time, Philip met with some recompence for the losses he had sustained, by the acquisition of Dauphiny, which has ever since given the title of Dauphin to the eldest son of the king of France. It was obtained by the resignation of Humbert prince of Dauphiny; who, being disappointed in his hopes of marrying Joan, daughter of the duke of Bourbon, gave up his territories to Charles the grandson of Philip, who had married that lady, himself retiring into a convent. Soon after this event, the king himself, who had been some time a widower, was married to Blanch, the daughter of Philip count of Eyreux, and Jane queen of Navarre; and his son

France.

lip.

son John to the countess of Boulogne. But the happiness occasioned by these marriages was soon interrupted by the death of the king; who expired in the year 1350, the 57th of his age, and 23d of his reign.

On the death of Philip, his eldest son John took possession of the kingdom; but scarcely was he seated on the throne, when he disgusted his nobility by an unseasonable act of severity. Robert de Brienne, count of Eu and Guisnes, had been taken prisoner by the king of England at Caen; and under pretence of negotiating his ransom, had passed several times between France and England; but being accused of a treasonable correspondence with Edward, he was by order of his sovereign suddenly arrested, condemned, and beheaded, without any form of trial. At his death, it is said, that he confessed his treasonable practices; but this has not been authenticated by any historian of credit. Having been constable of France, the sword, the badge of his office, was delivered to Charles de la Carda: but his fate was equally unfortunate with that of his predecessor, being soon after assassinated by Charles king of Navarre, surnamed *The Wicked*. This prince, celebrated for his personal qualifications, but detested for his crimes, was the son-in-law of John himself. He had demanded the duchy of Angouleme of the king; but as the latter had thought proper to bestow it upon Carda, he had taken the effectual method of revenging himself by assassinating his rival. John did not fail to show a proper resentment; but such was the weakness of his government, that the king of Navarre set him at defiance, and would not even condescend to the ceremony of asking pardon until John had sent him his second son as an hostage for his personal security. To these offences the king of Navarre added another still more atrocious, viz. that of aspiring to the crown of France itself; to which he pretended a right derived from his mother, being grandson by the female side to Louis the Boisterous. But his more immediate demands were the countries of Champagne and Brie. To obviate all difficulties on this head, however, John bestowed the duchy of Normandy on his eldest son Charles; and commanded him to seize the estates of the king of Navarre. On this the latter soon made his appearance at Paris; but John found himself obliged to appease his murmurs at the expence of no less than 100,000 crowns.

All this time the truce with England had been very ill observed on both sides; the French had possessed themselves of the port of St Jean d'Angeli; and the English had surpris'd the town of Guisnes. The rival houses of Mountfort and Blois still continued their animosities; while Edward continued to threaten war.—The king of Navarre went on with his intrigues; and even the dauphin was drawn into a confederacy against his father. John, however, being informed of their machinations, found means to defeat them effectually. The dauphin was reclaimed by pointing out to him the impropriety of his conduct, and the disadvantage which must unavoidably accrue to himself from the connections which he had formed. The king of Navarre was invited, with his principal adherents, to an entertainment, where they were unexpectedly arrested; the former being sent prisoner to the chateau Gailard, and several of the most obnoxious of the latter put to death. The rest of the conspirators, instead of

and con-
fined.

being dismayed by this check, immediately showed themselves in open rebellion; and finding themselves unable, without further assistance, to gain their point, they without delay invited over Edward from England.

That warlike and enterprising monarch had never lost sight of the object he had originally embraced; and on the expiration of the truce had sent his son, prince of Wales, and, from the colour of his armour, surnamed the *Black Prince*, with a fleet towards the coast of France. Young Edward had with this fleet entered the mouth of the river Garonne, burnt the towns and villages of Languedoc, and retired with the plunder into the country of Guienne. Edward himself, who had likewise passed over to the continent, wasted the country as far as St Omer; but the French king, notwithstanding all these provocations, determined to avoid a battle, and therefore prohibited his general, the constable of Bourbon, from coming to an engagement, though his army was much superior to that of the prince of Wales. With the flower of his troops, however, he pursued Edward from St Omer to Hesdin, where he defied him to a pitched battle; but the latter, without minding his bravadoes, continued his march to Calais, from whence he embarked for England.—After his departure, John called an assembly of the states at Paris, where he explained the distressed situation of his finances, and showed so fully the necessity of assisting him in the defence of the kingdom, that they consented to maintain an army of 30,000 men during the war. To supply the other exigencies of government, they revived the duty on salt, and added a variety of other imposts; but at the same time appointed a committee of their own number to take care that the money was solely appropriated to the public service.

The satisfaction which John received from these grants, and the suppression of some disturbances which happened about this time, was soon overcast by the news that the prince of Wales had marched with an army of 12,000 men from Bourdeaux; and, after ravaging the Agenois, Quercy, and the Limousin, had entered the province of Berry. The young warrior had penetrated into the heart of France with this trifling body of forces, in hopes of joining the duke of Lancaster in Guienne. But he soon found that his scheme was impracticable: the country before him was too well guarded to permit his advancing further; and all the bridges behind were broken down, which effectually barred a retreat. In this embarrassing situation, his perplexity was increased, by being informed, that the king of France was actually marching at the head of 60,000 men to intercept him. He at first thought of retreating; but soon finding it impossible, he determined calmly to await the approach of the enemy; and, notwithstanding the disparity of forces, to commit all to the hazard of a battle.

It was at a place called *Maupertuis*, near Poitiers, that both armies came in sight of each other. The French king might very easily have starved the English into any terms he thought proper to impose; but such was the impatient valour of the French nobility, and such their certainty of success, that it might have been equally fatal to attempt repressing their ardour to engage. In the mean time, while both armies were

France. drawn out, and expecting the signal to begin, they were stopped by the appearance of the cardinal Perigord, who attempted to be a mediator between them. However, John, who made himself sure of victory, would listen to no other terms than the restitution of Calais; with which the Black Prince refusing to comply, the onset was deferred till the next morning, for which both sides waited in anxious suspense.

During this interval, the young prince strengthened his post by new entrenchments; and placed 300 men in ambush, with as many archers, who were commanded to attack the enemy in flank during the heat of the engagement. Having taken these precautions, he ranged his army in three divisions: the van was commanded by the earl of Warwick, the rear by the earls of Salisbury and Suffolk, and the main body by himself. In like manner, the king of France arranged his forces in three divisions; the first commanded by the duke of Orleans; the second by the dauphin, attended by his younger brothers; while he himself led up the main body, seconded by his youngest and favourite son, then about 14 years of age. As the English were to be attacked only by marching up a long narrow lane, the French suffered greatly from their archers, who were posted on each side, behind the hedges. Nor were they in a better situation upon emerging from this danger, being met by the Black Prince himself at the head of a chosen body of troops, who made a furious onset upon their forces, already in great disorder. A dreadful overthrow ensued: those who were as yet in the lane recoiled upon their own forces; while the English troops who had been placed in ambush, took that opportunity to encrease the confusion, and confirm the victory. The dauphin and the duke of Orleans were among the first that fled. The king of France himself made the utmost efforts to retrieve, by his valour, what his rashness had forfeited: but his single courage was unable to stop that consternation which had now become general through his army; and his cavalry soon flying, he found himself exposed to the enemy's fury. At length, spent with fatigue, and despairing of success, he thought of yielding himself a prisoner; and frequently cried out, that he was ready to deliver himself to his cousin the prince of Wales. The honour of taking him, however, was reserved for a much more ignoble hand; he was seized by Dennis de Morbec, a knight of Arras, who had been obliged to fly his country for murder.

In April following, the prince conducted his royal prisoner through London, attended by an infinite concourse of people of all ranks and stations. His modesty upon this occasion was very remarkable: the king of France was clad in royal apparel, and mounted on a white steed distinguished by its size and beauty; while the prince himself rode by his side upon a mean little horse, and in very plain attire.

74 Miserable situation of France. This dreadful defeat, which happened in the year 1356, almost entirely ruined the French affairs; and the miseries which ensued from this cause were greatly augmented by intestine commotions. The dauphin, who had now assumed the government, was altogether unable to govern a turbulent and seditious people at such a crisis. An assembly of the states, which he called, took the opportunity to limit the power of the prince, impeach the former ministers, and demand the

liberty of the king of Navarre; the treasurer of the crown was murdered by one Marcel, a partizan of that worthless prince, who had filled the city of Paris with confusion by his intrigues. The assassin whom Marcel employed was dragged, by order of the dauphin, from an altar where he had taken refuge, and instantly put to death. The bishop of Paris resented the indignity done to the church; and Marcel avenged the fate of his adherent by murdering both the marshals, who had seized him in the presence of the dauphin; and so near him, that his clothes were stained with their blood. The prince indignantly asked him, if he was to be involved in the same destruction? when Marcel affected to provide for his safety by putting upon him a blue hood, the badge of the adherents of Navarre. The public disorders were now also augmented by the escape of the king of Navarre from confinement; and though the dauphin was even assured that he had administered a dose of poison to him, he was obliged still to pay him some appearance of regard. A scheme was even formed by the chiefs of the sedition to change the government, to vest all the power in the commons, and leave the king no more than an empty title; but though this was favourably received by the city of Paris, it was entirely rejected by the other cities of the kingdom. The dauphin was likewise recognised as regent by the states general, and the inhabitants of Picardy and Champagne took up arms in his cause.

In this disastrous state of affairs, the miseries of the people were heightened by a new and unexpected evil. The peasants, who had been all along oppressed by the nobles, were now treated in such a manner, that they rose in great numbers to revenge themselves; the castles of the nobility were rased to the ground, their wives and daughters ravished, and themselves put to the most cruel torments. At last they were obliged to arm in their own defence. The duke of Orleans cut off 10,000 of them in the neighbourhood of Paris; 12,000 were massacred by the king of Navarre; 9000, who had laid siege to the town of Meaux, where the dauphiness and three other ladies of the first rank resided, were routed and pursued with dreadful slaughter by an officer in the service of Edward. Amidst these confusions, Marcel, the seditious leader already mentioned, perished in a tumult of his own raising; and the most virtuous and prudent people of the nation supported the pretensions of the dauphin. His most dangerous enemy was the king of Navarre, who had allured to his standard numbers of those Norman and English adventurers who had followed Edward into France, and there been left to seek their fortunes; where they associated themselves under the name of the *Companions*.

By such a formidable competitor the dauphin was reduced almost to the last extremity, when his hopes were revived by an unexpected proposal from his rival, of peace upon equitable and moderate terms. Historians in general have ascribed this to the natural levity of the king of Navarre; but some have been of opinion, that he acted from prudential motives, and that he justly supposed it would be more easy to deal with the dauphin, who was his own kinsman, and humbled by so many misfortunes, than with an haughty and imperious conqueror like Edward.

On the the expiration of the truce in 1359, Edward again set sail for France, and anchored before Calais with

France.

France. with a fleet of 1100 sail, assumed the title of *King of France*, and augmented his army to 100,000 men. The dauphin, finding himself unable to withstand so great a power, was obliged to act on the defensive; choosing the city of Paris for his station, and allowing the English to ravage all the open country. Thus they were allowed to penetrate through Picardy into Champagne; but the city of Rheims, where Edward designed to have been crowned king of France, baffled their utmost efforts. From Champagne, therefore, which was already laid waste, the English monarch marched into Burgundy; pillaging Tonnerre, Gaillon, and Avalon. Burgundy was saved by the payment of 100,000 merks, and a like sum was paid for Nivernois. At last, after a long and destructive march, Edward arrived at the gates of Paris; but the prudence of the dauphin and citizens of that metropolis had rendered it impregnable to the attacks of famine as well as the assaults of an army. Thus the war went on till the year 1360, when the king of England was inclined to peace, as is said, by a dreadful tempest, to which his army was exposed while encamped in the fields round Chartres. His conduct, however, may more reasonably be derived from other motives. Notwithstanding all the victories he had gained, the French nation showed not the least favour to his claim of succession; the king of Navarre was a dangerous rival, and the caution of the dauphin in avoiding an engagement deprived him of the advantages he might expect from his valour and military skill. Thus conferences for a peace were opened at Bretigny in the Chartraine; and it was at last concluded on the following conditions, *viz.* That king John should pay for his ransom, at different periods, three millions of crowns of gold (about a million and an half Sterling): Edward should for ever renounce all claim to the kingdom of France; and should remain possessed of the territories of Poictou, Xaintonge, l'Aginois, Perigord, the Limousin, Quercy, Rouvergne, l'Angoumois, and other districts in that quarter, together with Calais, Guisnes, Montreuil, and the county of Ponthieu on the other side of France. Some other stipulations were made in favour of the allies of England, as a security for the execution of these conditions.

Upon John's return to his dominions, he found himself very ill able to ratify those terms peace that had been just concluded. He was without finances, at the head of an exhausted state; his soldiers without discipline, and his peasants without subordination. These had risen in great numbers; and one of the chiefs of their banditti assumed the title of *The Friend of God and the Terror of Man*. A citizen of Sens, named *John Counge*, also got himself, by means of his robberies, to be acknowledged king; and he soon caused as many calamities by his devastations, as the real king had brought on by his misfortunes. Such was the state of that wretched kingdom upon the return of its captive monarch: and yet such was his absurdity, that he immediately prepared for a croisade into the Holy Land, before he was well replaced on the throne. Had his exhausted subjects, been able to equip him for this chimerical project, it is probable he would have gone through with it; but their miseries were such, that they were even too poor to pay his ransom. This was a breach of treaty that John would not submit to;

and he was heard to express himself in a very noble manner upon the occasion; "Though (says he) good faith should be banished from the rest of the earth, yet she ought still to retain her habitation in the breast of kings." In consequence of this declaration, he actually returned to England once more; and yielded himself a prisoner, since he could not be honourably free. It is said by some, that his passion for the countess of Salisbury was the real cause of his journey: but we want at this time the foundations for such an injurious report. He was lodged in the Savoy, the palace where he had resided during his captivity; and soon after he closed a long and unfortunate reign, by his death, which happened in the year 1384, about the 56th year of his age.

Charles, surnamed *the Wise*, succeeded his father on the throne of France; and this monarch merely by the force of a finely conducted policy, and even though suffering some defeats, restored his country once more to tranquillity and power. He quelled and dissipated a set of banditti, who had associated themselves under the name of *Companions*, and who had long been a terror to the peaceable inhabitants. He had them inrolled into a body, and led them into the kingdom of Castile, against Peter, surnamed *the Cruel*, whom his subjects had dethroned, and who, by means of an alliance with the English, endeavoured to get himself reinstated upon the throne. In consequence of these alliances, the English and French again came to an engagement; their armies on the one side commanded by the Black Prince; on the other, by Henry of Tanstamarre, and Bertand du Guesclin, one of the most consummate generals and accomplished characters of the age in which he lived. However, the usual good fortune of the English prince prevailed; the French lost above 20,000 men, while only 4 knights and 40 private men on the side of the English were slain.

Nevertheless, these victories were attended with very few good effects. The English, by their frequent levies, had been quite exhausted, and were unable to continue an army in the field. Charles, on the other hand, cautiously forbore coming to any decisive engagement; but was contented to let his enemies waste their strength in attempts to plunder a fortified country. When they were retired, he then was sure to fall upon them, and possess himself of such places as they were not strong enough to defend. He first fell upon Ponthieu; the citizens of Abbeville opened their gates to him; those of St Valois, Rue, and Crotoy, imitated the example; and the whole country was, in a little time, reduced to total submission. The southern provinces were, in the same manner, invaded by his generals with equal success: while the Black Prince, destitute of supplies from England, and wasted by a cruel and consumptive disorder, was obliged to return to his native country, leaving his affairs in the south of France in a desperate condition.

In this exigence, the resentment of the king of England was excited to the utmost pitch; and he seemed resolved to take signal vengeance on his enemies on the continent. But the fortunate occasion was now elapsed; and all his succeeding designs were marked with ill success. The earl of Pembroke and his whole army were intercepted at sea, and taken prisoners by Henry king of Castile. Sir Robert Knolles, one of his

France. his generals on the continent, at the head of 30,000 men, and was defeated by Bertrand de Guesclin; while the duke of Lancaster, at the head of 25,000 men, had the mortification of seeing his troops diminished one half by flying parties, without ever coming to a battle.

At last, the English affairs were totally ruined by the death of the Black Prince and king Edward. On receiving this news, the armies of Charles attacked the English on all sides. One under the command of the duke of Burgundy, entered Artois; another entered Auvergne, under the command of the duke of Berry; that which acted in Guienne was commanded by the duke of Anjou; and the forces in Bretagne were under the constable Guesclin; the king himself had a powerful body of troops, that he might be able to repair any accident which should happen through the chance of war. The constable joined the duke of Burgundy, who found it difficult to oppose Sir Thomas Felton and the Seneschal of Bourdeaux. Soon after his arrival, the constable attacked and defeated them, making both the commanders prisoners of war. This victory was so well pursued, that, at the close of the campaign 1377, Bayonne and Bourdeaux, with the districts about them, and the fortrefs of Calais with its dependencies, were all the places left to the England on the continent.

83
Death of
Charles.

Thus Charles established once more the house of Valois on the throne of France, but did not long live to enjoy his good fortune. He died in the year 1379, at the age of 44, of the consequences of poison formerly given him by the king of Navarre, as has already been mentioned. The immediate operation of this poison had been suspended by the skill of a physician sent by the emperor Charles IV. He opened an issue in his arm, the running of which preserved his life; but the physician declared, that whenever it should dry up, the consequence would be fatal. Not long before his death, Charles had commenced a process against the king of Navarre for this crime. Several of the associates of the latter suffered on this occasion, and the king himself was deprived of his possessions in Normandy, as well as his lordship of Montpellier, which had been given him in lieu of the counties of Champagne and Brie, and the duchy of Burgundy which he had claimed. He did not long survive the death of the French monarch whom he destroyed. His death was singular and very terrible; for having been afflicted with the leprosy, he had been obliged to make use of some bandages dipped in sulphur and afterwards steeped in brandy. These took fire by the carelessness of a page, and the unfortunate prince was burnt to death.

84
And of the
king of Na-
varre.

85
Reign of
Charles VI.

Charles V. was succeeded by his son Charles VI. surnamed the *Well-beloved*, who at the time of his accession to the throne was only 12 years of age. The duke of Anjou, eldest brother to the late king, had been appointed guardian during the minority of the prince; but he being totally unfit for the office, and distinguished only for his rapacity and ambition, readily resigned his charge to the dukes of Burgundy and Bourbon, the former uncle to the king by his father's side, the later by his mother's. None of these tutors, however, proved faithful to the trust reposed in them. The duke of Anjou seized the plate and treasures of the

late king, in order to support his ambitious enterprises. At that time Joan, infamous for her profligacy, reigned in Naples. She had appointed one Charles Durazzo, who was her relation, to succeed her in the throne; but the inhuman wretch murdered his benefactress, who with her last breath revoked her grant of the kingdom to him, and bestowed it upon the duke of Anjou. His influence at the French court enabled him to waste the treasures of the kingdom in support of his pretensions; though he proved ultimately unsuccessful, his forces being constantly defeated and his designs frustrated by the superior skill of his adversary. The duke of Burgundy, instead of instructing his pupil in the ways of virtue, indulged him in every kind of vicious pleasure, hoping thereby to gain his favour afterwards. The citizens of Paris, oppressed by taxes, broke out into tumults, and were quelled with difficulty; while the mal-administration of Philip the duke of Burgundy soon involved the nation in hostilities with the Flemings. Philip invaded their country at the head of an army of 80,000 men, along with whom was the young king, accompanied by the principal nobility of France. The first operations of war were favourable to the Flemings; but they were at length totally defeated on the banks of the river Lis, where their leader, with 25,000 of his followers perished. This victory was followed by the submission of the whole country; but the satisfaction of the king at this event was disturbed by new seditions and revolts in the city of Paris, and other great towns of the kingdom. His return, however, at the head of a victorious army, soon reduced them to their duty, and several of the revolted cities were severely punished; at the same time that the death of the duke of Anjou having freed him from the immediate dependence on his tutors, he assumed the reins of government into his own hands in the year 1384.

France.

86
Flanders
invaded.

The genius which Charles began to display in his early years, raised the hopes of the nation; but these were soon overcast, and greater misfortunes than ever were now about to ensue. The young king, whose marriage began to be a subject of attention to the council, refused to comply with the forms in use among his predecessors, and insisted upon seeing the person designed for his consort. An interview was accordingly contrived betwixt him and Isabella daughter to the duke of Bavaria; where he fell in love with that princess, and afterwards married her. His administration was for some time prudent and vigorous. He conciliated the affections of his people by restoring their privileges, punishing their oppressors, and relieving them from the taxes which had been imposed in his minority. He reduced the Flemings to submit to the authority of his uncle the duke of Burgundy; detached 15,000 archers and 1500 men at arms to assist the Scots in their incursions into England; and in 1385 fitted out a prodigious armament against England. A vast fleet was assembled in the harbour of Sluys, and a very numerous army in the neighbourhood. According to some writers, the armament consisted of 1200 ships, 20,000 foot differently armed, 20,000 cavalry, and 20,000 cross-bow men. There was besides a vast wooden edifice or floating town, which was contrived for the protection of the soldiers when landed: but all these preparations were at last brought

87

France. brought to nothing through the obstinacy of the duke of Berry ; who, having been originally against this measure, carried on his part of the armament so slowly, that he did not arrive at Sluys till the middle of September, when the season was so far advanced, that no invasion was practicable. A storm that happened soon after, drove the greatest part of the fleet on shore, and beat the wooden edifice all to pieces ; the remains of which the king bestowed on the duke of Burgundy, to whom he gave also the port of Sluys, which was then very commodious, and of the utmost importance.

The destruction of the French fleet was only a prelude to calamities of a more extraordinary nature. The Sieur de Craon, a profligate nobleman, had been entrusted by the court of France with a considerable sum of money for the support of the duke of Anjou, at the time he was reduced to distress by his Italian expedition. This money he had dissipated at Venice ; but, by the credit of the duke of Orleans, the king's brother, he had obtained his pardon, and returned to court. Here he attempted to gratify his private resentment by the assassination of Oliver Clifton the constable, whom he suspected of having promoted his disgrace. This veteran hero was attacked, on his return from the hotel de St Pol, by a band of 20 ruffians against whom he defended himself with wonderful intrepidity, when at last he fell after receiving more than 50 wounds. Happily, however, he recovered notwithstanding his being mangled in this manner ; while the assassin to screen himself from vengeance, fled for protection to the duke of Brittany. The king demanded the assassin to be given up to him in chains, but the duke answered, that he knew nothing of him : to which the king giving no credit, marched with all his forces into his territories. When the army arrived at Mans, the king was seized with a slow fever ; but could not be prevailed upon to rest or take physic. On the 5th of August 1391, having marched all day in the heat of the sun, a miserable, ragged, wild-looking fellow, darted from behind a tree, and laying hold of the bridle of his horse, cried out, " Stop ! where are you going, king ? You are betrayed ; " and immediately withdrew again into the wood. The king passed on, not a little disturbed ; and soon after one of the pages, who rode behind and carried his lance, overcome with heat, fell asleep, and let it fall upon the helmet which was carried by the other. The king, hearing the noise, looked about : and perceiving the page lifting the lance, killed him immediately : then riding furiously with his sword drawn, he struck on every side of him, and at every person, till he broke his sword ; upon which one of his gentlemen leaped up behind him, and held his arm. He fell soon after, and lay as if he had been dead ; so that being taken up and bound in a waggon, he was carried back to Mans, where he lay two days in a lethargy, after which he came a little to himself, and expressed great concern at the blood he had shed in his delirium. The people, who had expressed the greatest concern for his distemper, were equally rejoiced at the news of his recovery ; but unfortunately it was soon discovered, that he no longer possessed that strength of judgment and understanding for which he had formerly been remarkable. Hence a regency became indispensably necessary ;

88
Is seized
with luna-
tic fits.

and the competition for it brought to light the characters of the queen and duke of Orleans, which had not hitherto been displayed to public view. The former of these was a most beautiful and accomplished princess ; but vindictive, violent, and intriguing ; insensible to natural affection, but easily accessible to flattery, and ready to yield to every impulse of lawless passion. The duke of Orleans was equally remarkable for his personal accomplishments, and had married Valentina daughter of the duke of Milan ; but his engagements with that princess did not prevent him from engaging in a number of licentious amours, and among the rest, as was supposed, with his sister-in-law Isabella. During the king's illness he openly aspired at the regency ; but his pretensions were over-ruled by the states, the administration of affairs being for the present conferred on the duke of Burgundy. In a few months indeed the health and understanding of the king seemed to be sufficiently restored ; but in the year 1393 it was again disturbed by an accident no less extraordinary than the former had been. An entertainment had been given in honour of the marriage of one of the queen's attendants. At this six masques entered the apartment, disguised like satyrs, in linen clothes covered with rosin, and while warm stuck over with down. These were the king and five of his lords. The duchess of Berri paid attention to the king though she did not know him, and engaged in conversation with him. In the meantime the duke of Orleans, ignorant of the consequence, out of diversion ran a lighted torch against one of them. His whole dress was instantly in a flame, and the fire was from him communicated to all the rest. The masques, notwithstanding the dreadful situation they were in, called out, " Save the king ; save the king ! " On which the duchess of Berri, recollecting that it must be him with whom she had engaged in conversation, wrapped him in her cloak, and preserved him from farther danger. Only one of the rest escaped by jumping into a cistern of water ; the other four perished in the flames. The terror which the king underwent by this accident instantly occasioned a relapse ; and he continued delirious at intervals as long as he lived. During this state of insanity he was intractable by every person except Valentina duchess of Orleans : who seemed to have as great an influence over him as her husband the duke had over the mind of the queen. So great was the power indeed which she had over the king in this deplorable state, that in those superstitious times it was supposed by many to be the effect of magic. Others, with more probability, ascribed it to her superior charms as a woman ; and this idea instantly produced her a number of enemies among her own sex. The duchess of Burgundy, particularly, by her hatred, and the quarrel between the two ladies, soon extended itself to their husbands. Amidst their dissensions, however, they did not entirely neglect the administration of public affairs ; they strove to conciliate the affection of the parliament by preserving the rights of the commons inviolate ; and they endeavoured to check and inordinate passion for gaming, which began to appear about this time, and to substitute manly and martial exercises in its place.

During the intervals of his reason, Charles frequently assumed the government into his own hands ; and as the war still continued with England, though in

An accident occasions a relapse in the king.

France. a languid manner, the French monarch, in one of these lucid intervals, had an interview with Richard king of England, in order to put an end to hostilities, of which both were equally weary. Still, however, their claims were so difficult to be adjusted, that they could do no more than conclude a truce for 25 years; during which space it was hoped that a lasting peace might take place. Richard gave up Cherbourg to Charles, and Brest to the duke of Brittany: a marriage was also concluded betwixt the king of England and Isabella the daughter of Charles, though the latter was then only seven years of age; but by reason of the tender age of the princess, this marriage was never consummated.

⁹¹
Interview
betwixt the
king of
France and
England.

During this unfortunate reign, France was still farther weakened by the succours sent to the Hungarians against the Turks. On this fatal expedition upwards of 1000 of the bravest and most experienced knights were sent under the conduct of John count of Nevers, eldest son of the duke of Burgundy; the count of Eu constable of France; John de Vienne admiral of France; and the count of Marche, a prince of the blood-royal; together with De Courcy, one of the best and most experienced captains in Christendom. The prudent counsels of this veteran, however, were not obeyed by the youthful warriors by whom he was accompanied. Attacking the enemy therefore rashly, and while heated with wine, they were all either killed or taken prisoners. Notwithstanding this disaster, however, assistance was sent in the year 1400 to Wenceslaus emperor of Germany; and the duke of Orleans, who commanded the army on this occasion, acquitted himself so well that he acquired the duchy of Luxemburg for himself, and left his ally satisfied: but while the friendship of France was thus courted by foreign powers, the kingdom itself was in the most miserable situation. The king's distemper seemed daily to gain ground; while the discordant interests of the contending parties kept the whole nation in a ferment. The most violent animosity took place betwixt the dukes of Orleans and Burgundy. The former, by means of his own interest with the queen, and the ascendancy his duchess had over the king, for some time got the better of his rival, and was made lieutenant general and governor of the kingdom; but having presumed on his power to levy new imposts on the people, and oppressing also the churchmen, whom in that superstitious age he ought by all means to have let alone, he was deprived of his authority, and obliged to yield to the duke of Burgundy. For some time, however, these powerful rivals were kept within some bounds by the mediation of the duke of Bourbon, who seems to have been the only grandee who maintained a pure and unspotted character; but by his death in 1404, the unhappy nation was left totally exposed to their relentless fury. In 1405, the queen and duke of Orleans again seized the administration; but were soon deprived of it by the unanimous voice of the people. During this period Charles and his children were neglected and abandoned to distress; but they were relieved by the duke of Burgundy on his obtaining the regency; and Isabella, with the duke of Orleans, was obliged to retire from Milan. A sudden return of the king's reason and understanding for a much longer time than usual, now deprived both parties of their power; and the ad-

ministration was vested in the queen and a council composed of princes of the blood.

The two rival dukes, thus prohibited from interfering in public affairs, exercised themselves in committing hostilities against the English, with whom the truce had been lately concluded. They were encouraged to this infraction of the treaty by the unsettled situation of the affairs of Henry IV.: but their attempts proving unsuccessful, the truce was renewed after obtaining restoration of the princess, who had been married to Richard II. as has been already mentioned. The failure of their enterprises produced a new scene of discord betwixt the dukes, who mutually threw the blame upon each other. By the intreaties of the duke of Berri they were apparently reconciled; but the duke of Burgundy pretended friendship only in order to take the more signal vengeance. To this he was now further inflamed by jealousy. Having hired a band of ruffins to execute his bloody purpose, the duke was one evening attacked by eighteen of them while attended only by two pages. A Norman gentleman whom the duke had deprived of an employment; headed the assassins, and in person attacked the duke. At the first blow he cut off his hand, at the second he struck him from his mule, and at the third put an end to his life. His wife Valentina was so concerned at his death, that she died soon after. The duke of Burgundy escaped to Flanders; and the whole nation was rent into two factions called the *Burgundians* and *Armagnacs*; the latter being the title of the party of the duke of Orleans, from Armagnac the father-in-law of that prince. A dreadful confusion ensued: the duke of Burgundy soon returned to France, and extorted a pardon from the unhappy king, who was now no longer able to resist him: and we may have some notion of the state of the kingdom in general from being told, that 2000 people perished in one tumult in the capital. The king himself was alternately the prisoner of each party, and alternately transferred the power from the one to the other as he happened to fall into their hands. This therefore was thought by Henry V. of England a favourable opportunity to recover from France those grants that had been formerly given up by treaty. But previously, to give his intended expedition the appearance of justice, he sent over ambassadors to Paris, offering a perpetual peace and alliance, on condition of being put in possession of all those provinces which had been ravished from the English during some former reigns, and of espousing Catharine, the French king's daughter, in marriage, with a suitable dowry. Though the French court was at that time extremely averse to war, yet the exorbitance of these demands could not be complied with; and Henry very probably made them in hopes of a denial. He therefore assembled a great fleet and army at Southampton; and having allured all the military men of the kingdom to attend him, from the hopes of conquest, he put to sea, and landed at Harfleur, at the head of an army of 6000 men at arms, and 24,000 foot, mostly archers.

⁹⁵
Invasion by
Henry V.
of Eng-
land.

His first operations were upon Harfleur: which being pressed hard, promised at a certain day to surrender, unless relieved before that time. The day arriving, and the garrison unmindful of their engagement, still resolving to defend the place, Henry ordered an assault

France.

assault to be made, took the town by storm, and put all the garrison to the sword. From thence, the victor advanced farther into the country, which had been already rendered desolate by factions, and which he now totally laid waste. But although the enemy made a feeble resistance, yet the climate seemed to fight against the English; a contagious dysentery carrying off three parts of Henry's army. In this situation he had recourse to an expedient common enough in that barbarous age, to inspire his troops with confidence in their general. He challenged the dauphin who commanded in the French army, to single combat, offering to stake his pretensions on the event. This challenge, as might naturally be expected, was rejected; and the French, though disagreeing internally, at last seemed to unite at the appearance of the common danger. A numerous army of 14,000 men at arms, and 40,000 foot, was by this time assembled under the command of count Albert, and was now placed to intercept Henry's weakened forces on their return. The English monarch, when it was too late, began to repent of his rash inroad into a country where disease and a powerful army every where threatened destruction; he therefore thought of retiring into Calais. In this retreat, which was at once both painful and dangerous, Henry took every precaution to inspire his troops with patience and perseverance; and showed them in his own person the brightest example of fortitude and resignation. He was continually harassed on his march by flying parties of the enemy; and whenever he attempted to pass the river Somme, across which his march lay, he saw troops on the other side ready to oppose his passage. However, he was so fortunate as to seize by surprise a passage near St Quintin, which had not been sufficiently guarded; and there he safely carried over his army.

96
Battle of
Agincourt.

But the enemy was still resolved to intercept his retreat: and after he had passed the small river of Tertois at Blangi, he was surprised to observe from the heights the whole French army drawn up in the plains of Agincourt; and so posted, that it was impossible for him to proceed on his march, without coming to an engagement. A battle accordingly took place, in which the English gained a victory, the most remarkable perhaps of any recorded in history; an account of which is given under the article AGINCOURT.

97
Henry
lands again
in Nor-
mandy.

This victory, gained on the 25th of October 1415, was however attended with no immediate effects. Henry still continued to retreat, after the battle of Agincourt, out of the kingdom: and carried his prisoners to Calais, and from thence to England. In 1517, he once more landed an army of 25,000 men in Normandy; and prepared to strike a decisive blow for the crown of France, to which the English monarchs had long made pretensions. That wretched country was now in a most deplorable situation. The whole kingdom appeared as one vast theatre of crimes, murders, injustice, and devastation. The duke of Orleans was assassinated by the duke of Burgundy: and the duke of Burgundy, in his turn, fell by the treachery of the dauphin. At the same time, the duke's son, desirous of revenging his father's death, entered into a secret treaty with the English; and a league was immediately concluded at Arras, between Henry and the young duke of Burgundy, in which the king pro-

VOL. VII.

France.

posed to revenge the murder of the late duke; and the son seemed to insist upon no farther stipulations. Henry, therefore, proceeded in his conquests without much opposition from any quarter. Several towns and provinces submitted on his approach; the city of Rouen was besieged and taken: Pontoise and Gisors he soon became master of. He even threatened Paris by the terror of his power, and obliged the court to remove to Troye. It was at this city that the duke of Burgundy, who had taken upon him the protection of the French king, met Henry in order to ratify that treaty which was formerly begun, and by which the crown of France was to be transferred to a stranger. The imbecility into which Charles had fallen, made him passive in this remarkable treaty; and Henry dictated the terms throughout the whole negociation. The principle articles of this treaty were, That Henry should espouse the princess Catharine; that king Charles should enjoy the title and dignity of king for life; but that Henry should be declared heir to the crown, and should be intrusted with the present administration of the government; that France and England should forever be united under one king, but should still retain their respective laws and privileges; that Henry should unite his arms with those of king Charles and the duke of Burgundy, to depress and subdue the dauphin and his partisans.

It was not long after this treaty, That Henry married the princess Catharine; after which he carried his father-in-law to Paris, and took a formal possession of that capital. There he obtained, from the estates of the kingdom, a ratification of the late compact; and then turned his arms with success against the adherents of the dauphin; who, in the mean time, wandered about a stranger in his own patrimony, and to his enemies successes only opposed fruitless expostulations.

98

cess Catha-
rine.

Henry's supplies were not provided in such plenty as to enable him to carry on the war, without returning in person to prevail upon his parliament for fresh succours; and, upon his arrival in England, though he found his subjects highly pleased with the splendor of his conquests, yet they seemed somewhat doubtful as to the advantage of them. A treaty which in its consequences was likely to transfer the seat of empire from England, was not much relished by the parliament. They therefore, upon various pretences, refused him a supply equal to his exigencies or his demands; but he was resolved on pursuing his schemes; and, joining to the supplies granted at home, the contributions levied on the conquered provinces, he was able once more to assemble an army of 28,000 men, and with these he landed safely at Calais.

In the mean time, the dauphin, a prince of great prudence and activity, omitted no opportunity of repairing his ruined situation, and to take the advantage of Henry's absence from France. He prevailed upon the regent of Scotland to send him a body of 8000 men from that kingdom; and with these and some few forces of his own, he attacked the duke of Clarence, who commanded the troops in Henry's absence, and gained a complete victory.

This was the first action which turned the tide of success against the English. But it was of short duration: for Henry soon after appearing with a consider-

3 G

able

France. able army, the dauphin fled at his approach; while many of the places which held out for the dauphin in the neighbourhood of Paris; surrendered to the conqueror. In this manner, while Henry was every where victorious, he fixed his residence at Paris; and while Charles had a small court, he was attended with a very magnificent one. On Whitsunday 1421, the two kings and their two queens with crowns on their heads dined together in public; Charles receiving apparent homage, but Henry commanding with absolute authority.

In the mean time, the dauphin was chased beyond the Loire, and almost totally dispossessed of all the northern provinces. He was even pursued into the south by the united arms of the English and Burgundians and threatened with total destruction. In this exigence, he found it necessary to spin out the war, and to evade all hazardous actions with a rival who had been long accustomed to victory. His prudence was every where remarkable; and after a train of long persecutions from fortune, he found her at length willing to declare in his favour, by the death of the king of England.

99
Death of
Henry and
Charles
VII.

Charles VI. died a short time after; and Charles VII. succeeded his father to a nominal throne. Nothing could be more deplorable than the situation of that monarch on assuming his title to the crown. The English were masters of almost all France; and Henry VI. though yet but an infant, was solemnly invested with regal power by legates from Paris. The duke of Bedford was at the head of a numerous army, in the heart of the kingdom ready to oppose every insurrection; while the duke of Burgundy, who had entered into a firm confederacy with him, still remained steadfast, and seconded his claims. Yet, notwithstanding these favourable appearances, Charles found means to break the leagues formed against him, and to bring back his subjects to their natural interests and their duty.

100
Desperate
situation of
Charl. VII.

However, his first attempts were totally destitute of success. Wherever he endeavoured to face the enemy he was overthrown, and he could scarcely rely on the friends next his person. His authority was insulted even by his own servants; advantage after advantage was gained against him: and a battle fought near Verneuil, in which he was totally defeated by the duke of Bedford, seemed to render his affairs altogether desperate. But from the impossibility of the English keeping the field without new supplies, Bedford was obliged to retire into England; and in the mean time, his vigilant enemy began to recover from his late consternation. Dumois, one of his generals, at the head of 1000 men, compelled the earl of Warwick to raise the siege of Montargis; and this advantage, slight as it was, began to make the French suppose that the English were not invincible.

101
The French
affairs re-
trieved by
the Maid
of Orleans.

But they soon had still greater reason to triumph in their change of fortune, and a new revolution was produced by means apparently the most unlikely to be attended with success. In the village of Domremi, near Vaucouleurs, on the borders of Lorraine, there lived a country girl, about 27 years of age, called *Joan de Arc*. This girl had been a servant at a small inn; and in that humble station had submitted to those hardy employments which fit the body for the fatigues of war. She was of an irreproachable life, and had hi-

thereto testified none of those enterprising qualities which displayed themselves soon after. She contentedly fulfilled the duties of her situation, and was remarkable only for her modesty and love of religion. But the miseries of her country seemed to have been one of the greatest objects of her compassion and regard. Her mind, inflamed by these objects, and brooding with melancholy steadfastness upon them, began to feel several impulses, which she was willing to mistake for the inspirations of heaven. Convinced of the reality of her own admonitions, she had recourse to one Baudricourt, governor of Vaucouleurs, and informed him of her destination by heaven to free her native country of its fierce invaders. Baudricourt treated her at first with neglect; but her importunities at length prevailed; and willing to make a trial of her pretensions, he gave her some attendants, who conducted her to the court, which at that time resided at Chinon.

The French court were probably sensible of the weakness of her pretensions; but they were willing to make use of every artifice to support their declining fortunes. It was therefore given out, that Joan was actually inspired; that she had been able to discover the king among the number of his courtiers although he had laid aside all the distinctions of his authority; that she had told him some secrets, which were only known to himself; and that she had demanded, and minutely described, a sword in the church of St Catharine de Fierbois, which she had never seen. In this manner, the minds of the vulgar being prepared for her appearance, she was armed cap-à-pee, and shown in that martial dress to the people. She was then brought before the doctors of the university; and they tinged with the credulity of the times, or willing to second the imposture, declared that she had actually received her commission from above.

When the preparations for her mission were completely blazoned, the next aim was to send her against the enemy. The English were at that time besieging the city of Orleans, the last resource of Charles, and every thing promised them a speedy surrender. Joan undertook to raise the siege; and to render herself still more remarkable, girded herself with the miraculous sword, of which she before had such extraordinary notices. Thus equipped, she ordered all the soldiers to confess themselves before they set out; she displayed in her hand a consecrated banner, and assured the troops of certain success. Such confidence on her side soon raised the spirits of the French army; and even the English, who pretended to despise her efforts, felt themselves secretly influenced with the terrors of her mission. A supply of provisions was to be conveyed into the town; Joan, at the head of some French troops, covered the embarkation, and entered Orleans at the head of the convoy, which she had safely protected. While she was leading her troops along, a dead silence and astonishment reigned among the English; and they regarded with religious awe that temerity, which they thought nothing but supernatural assistance could inspire. But they were soon roused from their state of amazement by a fall from the town; Joan led on the besieged, bearing the sacred standard in her hand, encouraging them with her words and actions, bringing them to the trenches, and overpowering the besiegers.

France.

France.

gers in their own redoubts. In the attack of one of the forts, she was wounded in the neck with an arrow; but instantly pulling out the weapon with her own hands, and getting the wound quickly dressed, she hastened back to head the troops, and to plant her victorious banner on the ramparts of the enemy. These successes continuing, the English found that it was impossible to resist troops animated by such superior energy; and Suffolk, who conducted the attack, thinking that it might prove extremely dangerous to remain any longer in the presence of such a courageous and victorious enemy, raised the siege, and retreated with all imaginable precaution.

From being attacked, the French now in turn became the aggressors. Charles formed a body of 6000 men, and sent them to besiege Jergeau, whither the English, commanded by the earl of Suffolk, had retired, with a detachment of his army. The city was taken; Suffolk yielded himself a prisoner; and Joan marched into the place in triumph at the head of the army. A battle was soon after fought near Patay, where the English were worsted, as before; and the generals Scales and Talbot were taken prisoners.

The raising of the siege of Orleans was one part of the maid's promise to the king of France; the crowning him at Rheims was the other. She now declared that it was time to complete that ceremony; and Charles, in pursuance of her advice, set out for Rheims at the head of 12,000 men. The towns thro' which he passed opened their gates to receive him; and Rheims sent him a deputation, with its keys, upon his approach. The ceremony of his coronation was there performed with the utmost solemnity; and the *Maid of Orleans* (for so she was now called) seeing the completion of her mission, desired leave to retire, alleging, that she had now accomplished the end of her calling. But her services had been so great, that the king could not think of parting with her; he pressed her to stay so earnestly, that she at length complied with his request.

A tide of successes followed the performance of this solemnity; Laon, Soissons, Chatteau-Thierri, Provins, and many other fortresses in that neighbourhood, submitted to him on the first summons. On the other hand, the English, discomfited and dispirited, fled on every quarter; not knowing whether to ascribe their misfortunes to the power of sorcery or to a celestial influence; but equally terrified at either. They now found themselves deprived of the conquests they had gained, in the same manner as the French had formerly submitted to their power. Their own divisions, both abroad and at home, unfitted them entirely for carrying on the war; and the duke of Bedford, notwithstanding all his prudence, saw himself divested of his strong-holds in the country, without being able to stop the enemy's progress. In order, therefore, to revive the declining state of his affairs, he resolved to have Henry crowned king at Paris, knowing that the natives would be allured to obedience by the splendor of the ceremony. In 1430, Henry was accordingly crowned, all the vassals that still continued under the English power, swearing fealty and homage. But it was now too late for the ceremonies of a coronation to give a turn to the affairs of the English; the generality of the kingdom had declared against them, and the

102
Henry VI.
of England
crowned
king of
France.

remainder only waited a convenient opportunity to follow the example.

An accident ensued soon after, which, though it promised to promote the English cause in France, in the end served to render it odious, and conduced to the total evacuation of that country. The duke of Burgundy, at the head of a powerful army, had laid siege to Compeign; and the Maid of Orleans had thrown herself into the place, contrary to the wishes of the governor, who did not desire the company of one whose authority would be greater than his own. The garrison, however, were rejoiced at her appearance, and believed themselves invincible under her protection. But their joy was of short duration; for Joan having the day after her arrival headed a sally, and twice driven the enemy from their intrenchments, she was at last obliged to retire, placing herself in the rear, to protect the retreat of her forces. But in the end attempting to follow her troops into the city, she found the gates shut, and the bridge drawn up by order of the governor, who is said to have long wished for an opportunity of delivering her up to the enemy.

Nothing could exceed the joy of the besiegers, in having taken a person who had been so long a terror to their arms. The service of *Te Deum* was publicly celebrated on this occasion; and it was hoped, that the capture of this extraordinary person would restore the English to their former victories and successes. The duke of Bedford was no sooner informed of her being taken, than he purchased her of the count Vendome, who had made her his prisoner, and ordered her to be committed to close confinement. The credulity of both nations was at that time so great, that nothing was too absurd to gain belief that coincided with their passions. As Joan but a little before, from her successes, was regarded as a saint, she was now, upon her captivity, considered as a sorceress, forsaken by the demon who had granted her a fallacious and temporary assistance. Accordingly it was resolved in council to send her to Rouen to be tried for witchcraft: and the bishop of Beauvais, a man wholly devoted to the English interest, presented a petition against her for that purpose. The university of Paris was so mean as to join in the same request. Several prelates, among whom the cardinal of Winchester was the only Englishman, were appointed as her judges. They held their court at Rouen, where Henry then resided; and the Maid, clothed in her former military apparel, but loaded with irons, was produced before this tribunal. Her behaviour there no way disgraced her former gallantry; she betrayed neither weakness nor womanish submission; but appealed to God and the pope for the truth of her former revelations. In the issue, she was found guilty of heresy and witchcraft; and sentenced to be burnt alive, the common punishment for such offences.

But previous to the infliction of this dreadful sentence upon her, they were resolved to make her abjure her former errors; and at length so far prevailed upon her, by terror and rigorous treatment, that her spirits were entirely broken by the hardships she was obliged to suffer. Her former visionary dreams began to vanish, and a gloomy distrust to take place of her late inspirations. She publicly declared herself willing to recant, and promised never more to give way to the

France.

103

Orleans
taken pri-
soner.

France.

vain delusions which had hitherto misled her, and imposed on the people. This was what her oppressors desired; and willing to show some appearance of mercy, they changed her sentence into perpetual imprisonment, and to be fed during life on bread and water. But the rage of her enemies was not yet satiated. Suspecting that the female dress, which she had consented to wear, was disagreeable to her, they purposely placed in her apartment a suit of mens apparel, and watched for the effect of their temptation upon her. Their cruel artifices prevailed. Joan, struck with the sight of a dress in which she had gained so much glory, immediately threw off her penitent's robes, and put on the forbidden garment. Her enemies caught her equipped in this manner; and her imprudence was considered as a relapse into her former transgressions. No recantation would suffice, and no pardon would be granted. She was condemned to be burnt alive in the market-place of Rouen; and this infamous sentence was accordingly executed with most brutal severity.

104
And cruelly put to death.

One of the first misfortunes which the English felt after this punishment, was the defection of the duke of Burgundy; who had for some time seen the error of his conduct, and wished to break an unnatural connection, that only served to involve his country in ruin. A treaty was therefore begun and concluded between him and Charles, in which the former agreed to assist him in driving the English out of France. This was a mortal blow to their cause; and such was its effects upon the populace of London when they were informed of it, that they killed several of the duke of Burgundy's subjects, who happened to be among them at that time. It might perhaps also have hastened the duke of Bedford's death, who died at Rouen a few days after the treaty was concluded; and the earl of Cambridge was appointed his successor to the regency of France.

105
Affairs of the English totally ruined,

From this period, the English affairs became totally irretrievable. The city of Paris returned once more to a sense of its duty. Lord Willoughby, who commanded it for the English, was contented to stipulate for the safe retreat of his troops to Normandy. Thus ground was continually, though slowly, gained by the French; and notwithstanding their fields were laid waste, and their towns depopulated, yet they found protection from the weakness and divisions of the English. At length both parties began to grow weary of a war, which, though carried on but feebly, was yet a burden greater than either could support. But the terms of peace insisted upon by both were so wide of each other, that no hopes of an accommodation could quickly be expected. A truce, therefore, for twenty-two months, was concluded in 1443, which left every thing on the present footing between the parties. No sooner was this agreed upon, than Charles employed himself with great industry and judgment in repairing those numberless ills to which his kingdom, from the continuance of wars both foreign and domestic, had so long been exposed. He established discipline among his troops, and justice among his governors. He revived agriculture, and repressed faction. Thus being prepared once more for taking the field, he took the first favourable occasion of breaking the truce; and Normandy was at the same time invaded by four powerful armies; one commanded by Charles himself,

France.

a second by the duke of Brittany, a third by the count of Alençon, and a fourth by the count Dunois. Every place opened its gates almost as soon as the French appeared before them. Rouen was the only one that promised to hold out a siege; but the inhabitants clamoured so loud for a surrender, that the duke of Somerset, who commanded the garrison, was obliged to capitulate. The battle, or rather the skirmish, of Fourmingsi, was the last stand which the English made in defence of their French dominions. However, they were put to the rout, and above a thousand were slain. All Normandy and Guienne, that had so long acknowledged subjection to England, were lost in the space of a year; and the English saw themselves entirely dispossessed of a country which for about three centuries they had considered as annexed to their native dominions. Calais alone remained of all their conquests; and this was but a small compensation for the blood and treasure which had been lavished in that country, and only served to gratify ambition with a transient applause.

Thus, in the year 1450, the power of the English in France was entirely destroyed; and Charles deservedly obtained the surname of *Victorious*, on account of the vigour he had shown in driving out the invaders of his country. His satisfaction, however, was now greatly diminished by domestic misfortunes. The daughter, forgetting the allegiance and filial duty he owed to his father, had already impeded his conquests by his seditious intrigues. He had used every endeavour to thwart the designs of his ministers, and it was supposed that he had destroyed Agnes Soreille his father's favourite mistress by poison. He had married Charlotte daughter to the duke of Savoy; which Charles had resented by a declaration of war against the duke, but had been persuaded to recall it in order to prosecute the war against Guienne, which made part of the dominions of the English. At last, weary of the disobedience of his son, he commanded him to be arrested; but Louis, informed of his design, withdrew to Franche Comte, and afterwards to Brabant; of which the duke of Burgundy (at this time sovereign of the country) was no sooner apprised, than he ordered him to be supplied with every necessary, and treated with all imaginable respect. He refused to see him, however, until he should obtain the approbation of his father; on which Louis, having in vain attempted to draw the duke into a participation of his crimes, employed himself in sowing dissension between his benefactor and his son the count of Charolois, at the very time that he himself was receiving a pension of 12,000 crowns annually from the father. Thus he at last destroyed the domestic peace of his benefactor, while his unnatural behaviour created continual suspicions in the mind of his father. Charles was repeatedly informed that his own domestics, along with his undutiful son, were in a conspiracy against his life. The miserable monarch, therefore, in continual fear of being poisoned, and having none in whom he could repose any confidence, obstinately refused for some days to take any nourishment; and when at last prevailed upon by the importunities of his attendants to do so, his stomach had become incapable of receiving food, so that he died for want of sustenance in the year 1461. His body, neglected by his unnatural son, was interred at the ex-

pence of Tanneui de Chastel, who had been his faithful companion.

On the death of Charles, his son Louis succeeded to the throne, to which he had so long aspired. He was reckoned one of the greatest politicians that ever existed; though his character was not on that account the more amiable; on the contrary, there are few princes whose history appears in a more detestable light. So destitute was he of natural affection, that he did not even attempt to conceal his joy at his father's death. He pretended much friendship for the count of Charolois, son to the duke of Burgundy, on account of the protection he had received at his father's court; and even conferred upon him a pension of 12,000 crowns annually: but all this show of affection soon degenerated into a mortal aversion on both sides. Some differences which took place between the courts of France and Castile produced an interview betwixt the two monarchs, Louis, and Henry surnamed the *Impotent*. They met at Mauleon on the confines of Navarre: but their negociations came to nothing, and they parted with a mutual contempt of each other: Henry despising the mean and sordid appearance of Louis, as he in his turn did the gaudy magnificence of Henry. In his negociations with the duke of Burgundy, Louis proved more successful; persuading him to restore some towns on the river Somme, which had been ceded by Charles VII. and by the possession of which the duke was in effect master of Picardy. This cession was opposed by the count of Charolois; but Louis, by corrupting John de Croy the duke's minister, obtained his end; and for the sum of 400,000 crowns the cities were delivered to him. By this transaction he effectually ensured the hatred of Charolois: and even in that very transaction the duplicity of Louis was eminently displayed; for though he had agreed to retain in those towns the officers appointed by the duke, he was no sooner in possession of them than he displaced them all, and nominated others in their stead.

108
Formidable
confederacy
against
Louis.

The duchy of Brittany was at this time governed by Francis, a weak but generous prince, and whose defect of capacity was supplied by the abilities of his ministers. Him Louis insulted in the most grievous manner; and as Francis found himself unable to oppose such a powerful adversary alone, he joined in a close alliance with the duke of Burgundy and the count of Charolois; the latter having been grievously offended with Louis, and even accused him of attempting his life. The conspiracy was joined by several of the principal French nobility, who had been oppressed by the king; and though the secret was confided to upwards of 500 persons, not one of them ever divulged it. Louis finding matters become very critical, marched with an army towards the capital, which the count of Charolois already insulted. A battle ensued, in which both princes exerted themselves to the utmost, though their valour was but ill seconded by the bravery of their troops. About 1500 perished on each side; but the count of Charolois remained master of the field of battle. Louis, however, after this engagement, entered the capital; where he endeavoured by every kind of concession he could think of, to conciliate the affection of his subjects; in which he succeeded so well, that though the army of insurgents

was soon augmented to more than 100,000 men, they were unable to make themselves masters of the city. At last a treaty was set on foot betwixt Louis and the count of Charolois; by which the latter obtained the towns which had been formerly ceded, with the districts of Boulogne, Guisne, Peronne, Moudidior, and Roye, as a perpetual inheritance for himself. By granting favours to the other confederates, the league was broken; and the moment that Louis found himself freed from danger, he protested against the whole treaty in presence of some confidential members of parliament, as contrary to the interests of the crown; and therefore waited the first favourable opportunity to crush one by one those who had been ready by their united efforts to destroy himself. The duke of Bourbon, one of the most able of the confederates, was gained over, by bestowing upon him in marriage Jane the natural daughter of Louis himself, with the dowry of Usson in Auvergne; together with Moras, Beaurepaire, and Cormillon in Dauphiny; while, by the discontent betwixt the dukes of Brittany and Normandy, he was enabled to secure the neutrality of the former, and to recover from the latter some territories which he had unwillingly ceded to him.

In 1467, Philip duke of Burgundy, from his amiable qualities surnamed *The Good*, died, and left his dominions to his son Charles count of Charolois. That fiery and impetuous prince, jealous of the growing power of France, and an implacable enemy of Louis, had entered into a secret treaty with Francis; but Louis had driven the Britons from the posts they occupied in Normandy before the duke of Burgundy could pass the Somme. The king, however, alarmed at the power of the confederates, concluded a peace with Brittany; and, confiding in his talents for negotiation, determined to have a personal interview with the duke of Burgundy.

This memorable interview took place in the year 1468; and Peronne, a city of Picardy, but belonging to the duke of Burgundy, was appointed as the place of rendezvous. To this place the politic Louis repaired with a slender train, and attended only by Cardinal Balue, the duke of Bourbon, and the count de St Pol, constable of France; seemingly without reflecting that he was entering an hostile city, where he might be confined for any length of time, or treated at the pleasure of the duke, who was his mortal enemy. Indeed he had not long been in the place when he began to see the error of his conduct; and by the daily concourse of Burgundian lords and other persons of rank, who were his avowed enemies, he became alarmed for his personal safety. His fear now suggested to him a worse measure than even the former; and he requested apartments in the castle, where it was in the power of his rival in a moment to make him a close prisoner. This event accordingly took place, and that through the arts and machinations of Louis himself. His design had been from the beginning to keep the duke of Burgundy constantly employed in domestic wars. For this purpose he had, before his interview with Charles, excited the inhabitants of Liege, who were subject to the duke of Burgundy, to revolt. It is most probable, that he did not imagine the effects of this treachery would so soon begin to appear. At the very time, however, that Louis was

in:

France.

in the castle of Peronne, the people of Liege revolted, seized the bishop and governor; and having massacred great numbers of the adherents of Charles, retired with the prisoners they had made to the capital. Charles was soon informed of this massacre, with the additional circumstance, that the ambassadors of Louis were seen animating the insurgents to their work of destruction. He then flew into a transport of rage; commanded the gates of the castle to be shut and strictly guarded; denouncing the severest vengeance on the perfidious monarch who had so often deceived him. Louis, however, though greatly, and no doubt very justly, alarmed, did not neglect to take the proper methods for securing himself. He distributed large sums of money among those officers to whom he imagined the duke was most inclined to pay any regard, and by splendid promises and presents endeavoured to allay the resentment of his other enemies. At last the resentment of Charles having subsided, he entered into a treaty with the king, and concluded it upon much the same terms as those which had been agreed upon before. His resentment, however, still manifested itself so far, that he insisted upon Louis being present at the punishment he inflicted upon the inhabitants of Liege for the massacre they had committed, and of which we have already taken notice. This was agreed to: the two princes formed the siege of the city in conjunction; and, notwithstanding the obstinate defence of the people, it was at last taken by storm, and the inhabitants massacred. It was not long, however, before the new alliance was dissolved. A confederacy against Louis, whom neither promises nor treaties could bind, was formed betwixt his own brother the duke of Normandy and the duke of Burgundy; but before their measures were ripe for execution, Louis had already commenced hostilities. The duke of Burgundy, as a peer of France, was summoned to parliament; and on his refusal, the constable St Pol made himself master of St Quintin. Several other cities were soon after reduced; and Baldwin, the natural brother of Charles, corrupted by Louis, deserted his cause; and the haughty spirit of the duke was thus at last obliged to condescend to solicit a peace. This, however, was of no long duration. Charles, encouraged by the success of Edward IV. of England his brother-in-law, began once more to league against Louis with the dukes of Brittany and of Guienne; the latter being the king's brother, formerly duke of Normandy, but who had exchanged that duchy for the territory of Guienne. But while the affairs of the confederates seemed to be in a prosperous way, their prospects were suddenly overcast by the death of the duke of Guienne, which was universally supposed to have been occasioned by poison, and Louis was as universally looked upon as the author. The abbot of St Joan d'Angeli was fixed upon as the immediate perpetrator of the deed: but on the day appointed for his trial he was found strangled in his cell; and this also was with great probability supposed to have been the deed of Louis, who after the death of his brother instantly seized on the territory of Guienne, and annexed it to the dominions of France.

112
A treaty
between
Louis and
Charles.

By this unheard of conduct of the French monarch, Charles was exasperated to such a degree, that he vowed the most dreadful vengeance against the unhappy

people of France, and threatened to sacrifice to the memory of the duke of Guienne every one who now fell into his hands. The citizens of Nefle were massacred without distinction of sex or age; Beauvais resisted his attacks; after which Charles wreaked his fury on other places. Having entered the country of Caux, he reduced the cities of Eu and St Valery, burnt Longueville, and wasted the whole country as far as Rouen. Louis, on the other hand, steady and constant in his designs, determined to dissolve the league between the duke of Brittany and Edward IV. of England. Accordingly he encamped with his army on the frontiers of Brittany; while the duke, not meeting with the assistance promised by Edward, was obliged to consent to a truce for a year; and the duke of Burgundy himself was obliged to follow his example, having committed such devastations as deprived him of all means of subsistence in the country, so that he could neither advance nor retreat. In a very little time, however, he again began to conspire with the king of England against Louis, and a powerful invasion was determined upon. Edward was to cross the sea with an army of 10,000 men, while Charles assembled all his forces to join him. The former was also to set up a claim to the crown of France, and at least to obtain the provinces of Normandy, and Guienne; the duke was to have Champagne with some adjacent districts; to free his dominions from homage; and neither party was to make peace without the consent of the other. It was supposed that the duke of Brittany would naturally accede to the confederacy; and the count de St Pol, constable of France, had engaged to deliver up the town of St Quintin and others which he occupied on the river Somme. Louis, however, still had the good fortune to avoid the storm. Charles, instead of advancing to the assistance of Edward, who had entered France at the head of 15,000 archers and 1500 men at arms, laid siege to the city of Nuiz on the Rhine; while the constable St Pol, instead of delivering up the towns as he had promised, deceived his allies, and enabled Louis to dissolve a confederacy, which, had it been vigorously maintained, might have involved him in the greatest difficulties. To procure the departure of Edward, however, he was obliged to consent to a tribute of 75,000 crowns, as well as to settle on the king himself 50,000 crowns for life: bestowing also the dauphin to the eldest daughter of the king of England. The duke of Burgundy exclaimed loudly against this treaty: But Edward persisted in his resolution; and it was accordingly executed at a place called *Pecquigny*, near Amiens; but in such a manner as showed the little confidence the two sovereigns reposed in each other. A grated barrier was erected in the middle of the bridge of Pecquigny, between the barriers of which only a man's arm could pass: the two princes appeared on the opposite sides of it; and having conferred privately, and confirmed the treaty between them, parted with many protestations of friendship; in which, probably, neither party was very sincere. A power was reserved by Edward, for the duke of Burgundy to accede to the treaty; but the latter haughtily replied, that he was able to support himself without the assistance of England; and that he would make no peace with Louis till three months after the return of Edward to his own country.

country. To this resolution he adhered ; but no sooner was the term expired, than he concluded a truce with Louis for nine years. The stipulations publicly agreed upon betwixt these two princes, consisted only in some articles for the mutual advantage of their subjects ; but privately they had signed others of a different nature. The constable St Pol having rendered himself obnoxious to all parties by his complicated treachery, fled to Mons in Hainault ; but the duke of Burgundy had already consented to deliver him up on condition of receiving his estates and moveables as the price of his treachery.

116
Charles engaged in a war with the Swifs.

Thus was Louis, without any other remarkable qualification than the mere arts of falsehood and duplicity, got rid of all his enemies except the duke of Burgundy, whose growing power rendered him a constant object of jealousy and terror. His own imprudence and rashness, however, soon proved his ruin. Having rashly engaged in a war with the Swifs, he was defeated in the first engagement with that martial nation, with the loss of his military chest and baggage, with his plate and jewels, supposed to be the richest in Europe. His disappointment on this occasion was so great, that he was seized with a severe sickness, from which he had hardly recovered, when he resumed his mad scheme of conquering the Swifs. Another battle ensued ; in which, after an obstinate dispute, Charles was defeated with the loss of 18,000 men, himself escaping with great difficulty. This disaster was followed by the defection of most of his allies : the duke of Lorraine recovered the city of Nancy, and great part of his dominions which Charles had seized ; while the latter, overwhelmed with shame and disappointment, spent his time in solitude and inactivity. From this he was at last roused by the misfortunes which fell upon him in such quick succession. He now invested the city of Nancy ; and in this, as well as in every other instance, he acted against the advice of his best officers ; and the consequences were still more fatal than before.— The duke of Lorraine advanced with a strong body of Germans to the relief of the city, while Charles had scarcely 4000 men to oppose him. His troops were therefore easily defeated, and himself, notwithstanding the most heroic efforts of valour, hurried away in the crowd. The count de Campobasso, an Italian nobleman, in whom he put a great deal of confidence, but who was in reality a traitor, had deserted with about 80 men in the beginning of the engagement. He left 12 or 15 men about the duke's person, with strict orders to assassinate him in the tumult ; and this order they punctually complied with ; the body of Charles being found two days after the battle, pierced with three wounds.

116
He is assassinated.

118
Conquest of Burgundy by Louis.

The news of Charles's death was received with the most unfeigned joy by Louis, whose sole object now was to unite the territories of the duke of Burgundy, to his own. This might be done in two ways ; one by a match between the dauphin and Mary the heiress of Burgundy ; the other, by marrying her to the duke of Angouleme, a prince of the royal blood of France, and on whom Mary had shown some inclination to bestow herself. The king, however, to whom duplicity and falsehood seem to have been absolutely necessary, chose a third method, more agreeable to his character. The match with the dauphin was attended with such

circumstances as rendered it evidently impracticable. The disparity of age was very great, the dauphin being only eight years old, and the princess twenty ; the Flemings were besides very much averse from submitting to a prince whose powerful resources would enable him to oppress their liberties : but, notwithstanding these insurmountable difficulties, Louis chose to insist upon the match, at the same time that he endeavoured to make himself master of her dominions by force of arms. He addressed circular letters to the principal cities of Burgundy ; representing, that the duchy had been given by king John to the male heirs of his son Philip ; and that now, when these were extinct by the death of Charles, the territory reverted of course to the crown. To render this argument more effectual, he corrupted the governors of some towns, seduced the inhabitants of others to rise against their governors ; whilst he himself, at the head of an army, prepared to enforce obedience from those who could not be worked upon by other methods. Thus the province of Burgundy was entirely reduced ; but Flanders could not be brought under subjection either by fair means, force, or fraud. In his conduct for this purpose, indeed, Louis displayed the most detestable, as well as the meanest, treachery and falsehood. To render Mary odious to her subjects, he negotiated with her ministers, and prevailed upon them to disclose to him some of the most important state secrets ; after which, he communicated their letters to the states of Flanders. This double treachery, however, did not at present answer his purpose. The two ministers whom he had betrayed, were indeed put to death without mercy, and that even in the presence of their sovereign ; but Mary herself was thus induced to bestow herself upon the emperor Maximilian ; and Louis had the mortification to find, that all his arts had contributed only to aggrandize a rival power, whom he had already sufficient cause to dread. To remedy this oversight, he entered into an alliance with Edward IV. of England, whom he had inspired with a jealousy of his brother Clarence, in order to prevent a match between that nobleman and the princess Mary, which had also been in agitation. Thus a peace was concluded between the two monarchs, to continue during the life of each, and for a year after.

The marriage of Mary with Maximilian effectually secured the independence of Flanders ; while the return of the prince of Orange to the party of that princess, extended the flames of war once more to the cities of Burgundy. The French were on the point of being totally expelled from that country, when Maximilian unexpectedly made proposals of peace. A truce was on this concluded between the two princes ; but without any term limited for its duration, or without any conditions stipulated in favour of the Burgundians ; so that the whole country was quickly after reduced by Louis.

The king now, freed from the apprehension of foreign enemies, turned his vindictive disposition against his own subjects ; over whom, under pretence of former rebellions, he exercised the most insupportable tyranny. The principal victim to his sanguinary disposition on this occasion was James d'Armagnac, duke of Nemours, one of the first noblemen in the kingdom, but who had formerly appeared a zealous confederate against

France.

119
Tyranny and cruelty of Louis.

France. against him in the league in which Edward and Charles were concerned. The unfortunate nobleman, knowing that vengeance was determined against him, fled to a fortress named *Carlat*, situated among the mountains of Auvergne. Here he was besieged by the seigneur de Beaujeu, who had married Anne the daughter of Louis. The place, however, was almost impregnable to any force; so that his enemies were obliged to make the most solemn promises of safety in order to induce him to surrender himself. By these he was at last persuaded to trust himself in the hands of the faithless tyrant; who no sooner had him in his power than he shut him up in the Bastile in an iron cage, and reprimanded the judges because they had released him from this close confinement during the time of his examination. The judges reluctantly condemned him to be beheaded: but the king's cruelty extended beyond the sentence; and he ordered the two young sons of the duke, though yet in early childhood, to be placed directly under the scaffold, that they might be covered with the blood of their father. Four thousand persons are supposed to have perished upon this occasion without any form of trial: and were it not for the concurrent testimony of the historians of that age, the inhumanities and barbarities of this monarch are scarce to be credited. By these he broke the spirits of the French nobility, and gradually extended the power of the crown beyond all bounds; so that at last it was limited only by the sovereign's pleasure. Amidst all the perfidy and cruelty, however, for which this monarch is so justly to be detested, we may on some occasions remark a kind of magnanimity and generosity, which we cannot but applaud. An instance of this was his supporting the house of Medici against pope Sextus, whom he obliged to desist from his attacks, and to recall his sentence which he had fulminated against them.

120
Burgundy
unsuccessfully
invaded by
Maximilian.

In 1479, the emperor Maximilian, who had lightly abandoned the duchy of Burgundy when he might have reduced it, now renewed his claims when it was no longer in his power to enforce them. After a variety of actions of lesser note, and the destruction of cities on both sides, a decisive battle was fought at Guinegate. Here the Flemings were routed; but as the French pursued with too great ardour, the infantry of the enemy rallied, and the battle was renewed with great slaughter on both sides. A more decisive advantage was afterwards gained by the capture of 80 Flemish vessels, which induced that commercial people to think of peace. In the mean time, however, Louis, after a life spent in continual deceit, hypocrisy, and cruelty, received warning of his approaching end by a fit of apoplexy with which he was seized in the year 1480. He lay speechless and motionless for two days; after which he recovered in some degree, but never completely regained his health and strength. His illness, however, neither prevented him from pursuing the schemes of his ambition, nor from using the same methods as before to attain them. He seized, without any pretence, the estates of the duke of Bourbon, the only nobleman in the kingdom whose power could give him any cause of suspicion; yet, notwithstanding his assiduity for the interest of the dauphin, he kept him a kind of prisoner in the castle of Amboise, permitting none but his own servants, or per-

sons of the meanest rank, to have access to him. He banished his own consort, the mother of the dauphin, to Savoy, and endeavoured to inspire the prince with aversion towards her. By the death of Charles, the titular king of Naples, and the last of the second house of Anjou, he became master of the county of Provence; but his satisfaction on this occasion was marred by a second stroke of apoplexy. Still, however, he revived, and, with his recovery, again began to pursue his ambitious intrigues. The death of Mary of Burgundy, who perished by a fall from her horse, inspired him with new views; and he betrothed his son to the infant daughter of the emperor. Thus he offended Edward IV. of England, whose eldest daughter Elizabeth had been previously contracted to the dauphin; and a war would have undoubtedly ensued, had it not been for the death of the king of England. This was followed in no long time after by that of Louis himself, who had in vain exhausted the skill of the physician, and wearied the clerical order with prayers and processions to avert the impending stroke. He expired in the year 1483, after a reign of 23 years; during which he was detested by his subjects, whom he had continually oppressed; and equally dreaded and hated by his neighbours, whom he had constantly deceived; notwithstanding which he obtained the title of *Most Christian* from his holiness which his successors have ever after retained.

France.

121
Death of
Louis XI.

Notwithstanding the dark character of this prince, it is undoubtedly to be allowed, that he laid the foundations of the future greatness of France. By his arts he deprived the common people of their liberty; depressed the power of the nobility, established a standing army, and even induced the states to render many taxes perpetual, which formerly were only temporary, in order to support the army which was to keep themselves in slavery. From this time the people were accustomed to submit entirely to the voice of their sovereign as their only legislator; and being always obedient in matters of the greatest consequence, they cheerfully contributed whatever sums were required to fulfil the king's pleasure.

Charles VIII. who succeeded his father Louis XI. in 1483, was only 14 years of age at the time of his father's death: but though he might, even at that age, have ascended the throne without any material violation of the laws of France, yet it was judged necessary to have a regent on account of the king's delicacy of constitution and want of education. Three competitors appeared as candidates for this important trust, viz. John duke of Bourbon, a prince of the blood, and who had, till the age of 60, maintained the most unblemished character; Louis duke of Orleans, presumptive heir to the crown, but who, from his being only 20 years old himself, seemed incapacitated on that account from undertaking such an important office: the third competitor was Anne, the eldest daughter of Louis, to whom the latter had in the last moments of his life committed the charge of the kingdom, with the title of governess. The claim of this lady was supported by the assembly of the states-general at Tours; and though she was only entered in the 22d year of her age, it appears that the office could not have been more properly bestowed. Being married to Peter of Bourbon, sire of Beaujeu;

her

France. her present title was *the Lady of Beaujeu*; but she appears to have acted entirely independent of her husband, who was but of a moderate capacity, and indeed had been recommended to her by Louis on account of his slender abilities, lest by any other match the house of Bourbon should be too much aggrandized. Her first step was to ingratiate herself with the people by some popular acts: among which one was to punish the instruments of her father's cruelties. One of these, named Oliver le Dain, who, from the station of a barber, had raised himself to the confidence and favour of the king, and had distinguished himself by the invention of new modes of torture, was publicly hanged. Another, named Jean Doyac, who by continual acts of violence and rapacity had oppressed the people, was condemned, after being whipped in all the open places or squares of Paris, to have one of his ears cut off, and his tongue pierced with a hot iron: after which he was conveyed to his native city of Montferrand, where he was again whipped, and his other ear cut off; after which his estates, as well as those of Oliver, were confiscated. Jacques Coitier, the physician of Louis, who had availed himself of the terror of death with which the king was strongly influenced, to extort great sums of money from him, was ordered to answer for the immense wealth he had acquired: but he averted the danger by paying a fine of 50,000 crowns.

Thus the lady de Beaujeu gained the affection of the people at large; and was equally successful, in gaining over those who were averse to her government. The duke of Bourbon was made constable, an office which he had long desired; but the duke of Orleans behaved in such a manner as to exclude all hopes of favour. Incensed at the determination of a trifling dispute at tennis against him by the lady Beaujeu, he exclaimed, that whoever had decided it in that manner "was a liar if a man, or a strumpet if a woman." After this furious declaration he fled to the castle of Beaujency, where, however, he was soon forced to surrender. He then applied to Henry VII. of England, who had newly ascended the throne of England; but that prince, naturally slow and cautious, did not pay much attention to his proposals; on which he next made his application to the court of Brittany. Here he was received with great marks of esteem, and began to entertain hopes of marrying the daughter of the duke: but being looked upon with a jealous eye by the nobility, they entered into secret negotiations with Anne, and even solicited her to invade the country. In these negotiations, however, they stipulated that only a certain number of troops should enter the province, and that no fortified place should remain in the hands of the French: which conditions were indeed agreed to by the regent, though she determined to keep them no longer than it answered her purpose. In pursuance of this resolution, Brittany was invaded at once by four armies, each of them superior to the stipulated number, who quickly made themselves masters of the most important places in the country; while the troops of the duke retired in disgust, leaving them to pursue their conquests as they pleased. Finding at last, however, that the entire subjection of their country was determined upon, the nobility began to exert themselves in defence of it; and, enflamed by the enthusiasm of liber-

17, they raised an army of 60,000 men. By these the French were compelled to abandon the siege of Nantz: but this proved only a transient gleam of success. Anne persevered in her design of completing the conquest of the country, and the state of Europe at that time favoured the design. Of all the European states, England alone was then capable of affording any effectual assistance; and the slow caution of Henry prevented him from giving the assistance which for his own interest he ought to have done. Thus the Bretons were left to defend themselves the best way they could; and having ventured a battle, they were entirely defeated, and most of their leaders taken prisoners. A small body of English, under the command of lord Woodville, who assisted them, were entirely cut in pieces. The duke soon after died by a fall from his horse, leaving his dominions to his daughter Anne, at that time only 13 years of age. A marriage was negotiated betwixt the princess and Maximilian king of the Romans, who had been married to Mary of Burgundy; but by reason of the poverty of that prince it was never completed. The lady Beaujeu, then finding that the absolute conquest of Brittany would still be a difficult matter, determined to conclude a marriage betwixt the young king of France and the duchess, though the former had already been married to Margaret of Austria, the daughter of Maximilian. This marriage indeed had not been consummated by reason of the tender age of the princess; but she had been sent to Paris for her education, and had for several years been treated as queen of France. In 1491, however, Margaret was sent back to her father: Anne of Brittany for a long time refused to violate the engagements into which she had entered; but at last, finding herself distressed on all sides, and incapable of resisting the numerous forces of France with which she was pressed, she reluctantly consented to the match, and the nuptials were celebrated the same year at Langeais in Touraine.

Maximilian, whose poverty had prevented him from giving any assistance to his bride, or even from coming to see her, enraged at the double disgrace he had suffered, began, when too late, to think of revenge. France was now threatened with an invasion from the united forces of Austria, Spain, and England. But this formidable confederacy was soon dissipated. Henry whose natural avarice had prevented him from giving the necessary assistance, was bought off with money: the immediate payment of 145,000 crowns, and the promise of 25,000 annually ever after, persuaded him to retire into his own country. Ferdinand king of Spain had the countries of Roussillon and Cerdagne restored to him; while Maximilian was gratified by the cession of part of Artois, which had been acquired by Louis XI.

The young king of France agreed to these terms the more readily, that he was impatient to undertake an expedition into Italy, in order to conquer the kingdom of Naples, to which he claimed a right. Most of his counsellors were against the expedition; but the king was inflexible, even though Ferdinand king of Naples offered to do homage for his kingdom, and pay him a tribute of 50,000 crowns a year. He appointed Peter duke of Bourbon regent in his absence; after which he set out on his expedition with very few troops

troops and very little money. By the way he fell ill of the small-pox, but in a short time recovered, and entering Italy with only 6000 horse and 12,000 foot, he was attended with the most surprising success, traversing the whole country in six weeks, and becoming master of the kingdom of Naples in less than a fortnight. Such extraordinary good fortune seemed miraculous; and he was reckoned an instrument raised up by God to destroy the execrable tyrants with which Italy was at that time infested. Had Charles made use of this prepossession in his favour, and acted up to the character generally given him, he might have raised his name as high as any hero of antiquity. His behaviour, however, was of a very different nature. He amused himself with feasts and shows; and leaving his power in the hands of favourites, they abandoned it to whoever would purchase titles, places, or authority, at the rates they imposed; and the whole force he proposed to leave in his new conquered dominions amounted to no more than 4000 men.

128
His death.

But while Charles was thus losing his time, a league was concluded against him at Venice; into which entered the pope, the emperor Maximilian, the archduke Philip, Ludovic Sforza, and the Venetians. The confederates assembled an army of 40,000 men, commanded by Francis marquis of Mantua; and they waited for the king in the valley of Farnova, in the duchy of Parma, into which he descended with 9000 men. On the 6th of July 1495 he attacked the allies; and, notwithstanding their great superiority, defeated them, with the loss of only 80 of his own men. Thus he got safe to France; but his Italian dominions were lost almost as soon as he departed. Some schemes were proposed for recovering these conquests; but they were never put in execution, and the king died of an apoplexy in 1498.

The premature death of this monarch, in the 28th year of his age, was supposed to have been owing to his irregular life, and particularly his attachment to women; which had for some time impaired his health, and brought on evident symptoms of his approaching dissolution. At last he relinquished his irregularities, and retired with the queen to the castle of Ambloise. Here in passing through a low door he struck his head with violence against the top. No unfavourable symptom appeared at the time; but soon afterwards, as he conversed with his confessor, and avowed his design of observing the nuptial fidelity he owed to the queen, he suddenly fell backwards in a fit of apoplexy. He recovered his voice three times, and uttered some expressions of devotion; but instantly relapsed, and in a short time expired, notwithstanding every assistance that could be given. He was greatly celebrated for his sweet temper and agreeable disposition, which procured him the surnames of the *Affable* and *Courteous*. Two of his domestics are said to have died of grief after his death, and his widow abandoned herself to the most pungent sorrow for *two days*.

By the death of Charles VIII. the throne of France passed from the direct line of the house of Valois, and Louis duke of Orleans succeeded to the throne. At the time of his accession he was in his 36th year, and had long been taught prudence in the school of adversity. During the administration of the Lady Beaujeu, he had been, as we have already observed, constantly in disgrace; and after his connections with the

France.

duke of Brittany, had spent a very considerable time in prison; and though afterwards set at liberty by Charles, he had never possessed any share of that monarch's confidence or favour. Towards the conclusion of that reign, he fell under the displeasure of the queen: and had afterwards continued at his castle of Blois till he was called from thence to the possession of the kingdom. He had been married in early life, and against his will, to Jane the youngest daughter of Louis XI. a princess of an amiable disposition, but deformed in her person, and supposed to be incapable of bearing children. Afterwards he entertained thoughts of having this marriage dissolved, and was supposed to possess the affection of the dutchess of Brittany before she became queen of France. After the death of her husband, that princess retired to Brittany, where she pretended to assume an independent sovereignty; but Louis having got his marriage with Jane dissolved by Pope Alexander VI. quickly after made proposals to the queen-dowager, which on her part were accepted without hesitation; though it was stipulated, that if she should have two sons, the younger should inherit the duchy of Brittany.

As Louis while duke of Orleans, had some pretensions to the kingdom of Naples, he instantly set about realizing them by conquest. On this accession, he found matters in that country much more favourable to his designs than formerly. The pope, Alexander VI. was very much in his interests, from the hopes of getting his son Cæsar Borgia provided for; he had conciliated the friendship of the Venetians by promising them a part of the Milanese; he concluded a truce with the archduke Philip; and renewed his alliances with the crowns of England, Scotland and Denmark. He then entered Italy with an army of 20,000 men; and being assisted by the Venetians, quickly conquered one part of the duchy, while they conquered the other, the duke himself being obliged to fly with his family to Inspruck. He then attacked Ferdinand of Spain with three armies at once, two to act by land, and one by sea; but none of these performing any thing remarkable, he was obliged to evacuate the kingdom of Naples in 1504.

In 1506, the people of Genoa revolted; drove out the nobility; chose eight tribunes; and declared Paul Nuova, a silk-dyer, their duke: after which, they expelled the French governor, and reduced a great part of the Riviera. This occasioned Louis's return into Italy; where, in 1507, he obliged the Genoese to surrender at discretion: and, in 1508, entered into the league of Cambray, with the other princes who at that time wanted to reduce the overgrown power of the Venetians. Pope Julius II. who had been the first contriver of this league, very soon repented of it: and declared, that if the Venetians would restore the cities of Faenza and Rimini, which had been unjustly taken from him, he would be contented. This was refused; and in 1509, the forces of the republic received such an entire defeat from Louis, that they agreed to restore not only the two cities demanded by pope Julius, but whatever else the allies required.

The pope now, instead of executing his treaties with his allies, made war on the king of France without the least provocation. Louis called an assembly of his clergy; where it was determined, that in some cases it was lawful to make war upon the pope; upon which

the

France. the king declared war against him, and committed the care of his army to the Marshal de Trivulce. He soon obliged the pope to retire into Ravenna; and in 1511, Gaston de Foix, duke of Nemours, gained a great victory at Ravenna, but was himself killed in the engagement. After his death the army disbanded for want of pay; and the French affairs in Italy, and every where else, fell into great confusion. They recovered the duchy of Milan, and lost it again in a few weeks. Henry VIII. of England invaded France, and took Terruene and Tournay; and the Swifs invaded Burgundy with an army of 25,000 men. In this desperate situation of affairs the queen died, and Louis put an end to the opposition of his most dangerous enemies by negociating marriages. To Ferdinand of Spain he offered his second daughter for either of his grandsons, Charles or Ferdinand; and to renounce, in favour of that marriage, his claims on Milan and Genoa. This proposal was accepted; and Louis himself married the princess Mary, sister to Henry VIII. of England. This marriage he did not long survive, but died on the 2d of January 1514; and was succeeded by Francis I. count of Angoulesme, and duke of Bretagne and Valois.

132
Defeated and taken prisoner.

The new king was no sooner seated on the throne, than he resolved on an expedition into Italy. In this he was at first successful, defeating the Swifs at Marignano, and reducing the duchy of Milan. In 1518, the emperor Maximilian dying, Francis was very ambitious of being his successor, and thereby restoring to France such a splendid title, which had been so long lost. But Maximilian, before his death, had exerted himself so much in favour of Charles V. of Spain, that Francis found it impossible to succeed; and from that time an irreconcilable hatred took place between the two monarchs. In 1521, this ill-will produced a war; which, however, might perhaps have been terminated, if Francis could have been prevailed upon to restore the town of Fontarabia, which had been taken by his admiral Bonivet: but this being refused, hostilities were renewed with greater vigour than ever; nor were they concluded till France was brought to the very brink of destruction. The war was continued with various success till the year 1524; when Francis having invaded Italy, and laid siege to Pavia, he was utterly defeated before that city, and taken prisoner on the 24th of February.

This disaster threw the whole kingdom into the utmost confusion. The Flemish troops made continual inroads; many thousand boors assembled in Alsace, in order to make an invasion from that quarter; Henry VIII. had assembled a great army, and threatened the kingdom on that side also; and a party was formed in the kingdom, in order to dispossess the duchess of the regency, and confer it on the duke de Vendosme. This prince, however, who, after the constable, was the head of the House of Bourbon, went on purpose to Lyons, where he assured the regent that he had no view but for her service, and that of his country; upon which she formed a council of the ablest men of the kingdom, and of this she made him president. The famous Andrew Doria failed with the French galleys to take on board the remainder of the French troops under the duke of Alva, whom he landed safely in France. Those who escaped out of the

Milanese also made their way back again as well as they could. Henry VIII. under the influence of cardinal Wolsey, resolved not to oppress the oppressed: he therefore assured the regent that she had nothing to fear from him; and at the same time advised her not to consent to any treaty by which France was to be dismembered. To the emperor, however, he used another language. He told him, that the time was now come when this puissant monarchy lay at their mercy; and therefore, that so favourable an opportunity should not be let slip: that, for his part, he should be content with Normandy, Guienne, and Gascony, and hoped the empire would make no scruple of owning him king of France: adding, that he expected the emperor would make a right use of his victory, by entering Guienne in person; in which case he was ready to bear half the expences of the war. He foresaw what fell out: the emperor was alarmed at these conditions, and did not care to have him for a neighbour; for which reason he agreed to a truce with the regent for six months. In Picardy the Flemings were repulsed; and the count de Guise, with the duke of Lorraine, had the good fortune, with a handful of troops, to defeat and cut to pieces the German peasants.

In the mean time, Francis was detained in captivity in Italy: but being wearied of his confinement in that country, and the princes of Italy beginning to cabal for his deliverance, he was carried to Madrid; where, on the 14th of January 1525, he signed a treaty, the principal articles of which were, That he should resign to the emperor the duchy of Burgundy in full sovereignty; that he should desist from the homage which the emperor owed him for Artois and Flanders; that he should renounce all claim to Naples, Milan, Asti, Tournay, Lisle, and Hesdin, &c.; that he should persuade Henry d'Albert to resign the kingdom of Navarre to the emperor, or at least should give him no assistance; that within 40 days he should restore the duke of Bourbon and all his party to their estates; that he should pay the king of England 500,000 crowns which the emperor owed him; that when the emperor went to Italy to receive the imperial crown, he should lend him 12 galleys, four large ships, and a land-army, or instead of it 200,000 crowns.

All these articles the king of France promised on the word and honour of a prince to execute; or, in case of non-performance to return prisoner into Spain. But notwithstanding these professions, Francis had already protested before certain notaries and witnesses in whom he could trust, that the treaty he was about to sign was against his will, and therefore null and void. On the 21st of February, the emperor thought fit to release him from his prison, in which he had been closely confined ever since his arrival in Spain; and after receiving the strongest assurances from his own mouth, that he would literally fulfil the terms of the treaty, sent him under a strong guard to the frontiers, where he was exchanged for his two eldest sons, who were to remain as hostages for his fidelity.

When the king returned to his dominions, his first care was to get himself absolved by the pope from the oaths he had taken; after which he entered into a league with the pontiff, the Venetians, the duke of Milan, and the king of England, for preserving the peace of Italy. In the month of June, he publicly

134
And break

France. received remonstrances from the States of Burgundy ; in which they told him, without ceremony, that by the treaty of Madrid he had done what he had no right to do, in breach of the laws and his coronation-oath ; adding, that if he persisted in his resolution of throwing them under a foreign yoke, they must appeal to the General States of the kingdom. At these remonstrances the viceroy of Naples and the Spanish ministers were present. They perceived the end which the king aimed at, and therefore expostulated with him in pretty warm terms. At last the viceroy told him, that he had now nothing left but to keep his royal word in returning to the castle of Madrid, as his predecessor John had done in a like case. To this the king replied, that king John acted rightly ; that he returned to a king who had treated him like a king ; but that at Madrid he had received such usage as would have been unbecoming to a gentleman : that he had often declared to the emperor's ministers, that the terms they extorted from him were unjust and impracticable : but that he was still willing to do all that was fit and reasonable ; and to ransom his sons at the rate of two millions of gold, in lieu of the duchy of Burgundy.

Hitherto the treaty for the tranquillity of Italy had been kept secret, in hopes that some mitigation of the treaty of Madrid would have been obtained ; but now it was judged expedient to publish it, though the viceroy of Naples and the Spanish lords were still at the French court ; and the emperor was to be admitted into it, provided he accepted the king's offer of two millions for the release of his children, and left the duke of Milan and other Italian princes in quiet possession of their dominions. It is the common misfortune of all leagues, that the powers who enter into them keep only their own particular interests in view, and thus defeat the general intention of the confederacy. This was the case here. The king's great point was to obtain his children upon the terms he had proposed ; and he was desirous of knowing what hopes there were of that, before he acted against the monarch who had them in his power. Thus the duke of Milan and the Pope were both sacrificed. The former was obliged to surrender to the duke of Bourbon, and the latter was surpris'd by the Colonnas ; both of which disasters would have been prevented if the French succours had entered Italy in time. See ITALY.

According to an agreement which had been made between Francis and Henry, their ambassadors went into Spain, attended each of them by a herald, in order to summon the emperor to accept the terms which had been offered him ; or, in case of a refusal, to declare war. It seems the emperor's answer was foreseen in the court of France ; and therefore the king had previously called together an assembly of the notables ; that is, persons of the several ranks of his people in whom he could confide. To them he proposed the great question, Whether he was bound to perform the treaty of Madrid ? or, Whether, if he did not perform it, he was obliged in honour to return to Spain ? To both these questions, the assembly answered in the negative ; they said, that Burgundy was united to the crown of France, and that he could not separate it by his own authority ; that his person also was the property of the public, of which therefore he could not dispose ; but for the two millions, which they looked

upon as a just equivalent, they undertook that it should be raised for his service. When the ambassadors delivered their propositions, Charles treated the English herald with respect, and the French one with contempt ; which produced a challenge from Francis to the emperor*. All differences, however, were at last adjusted ; and a treaty was concluded at Cambray, on the 5th of August 1528. By this treaty, instead of the possession, the emperor contented himself with reserving his rights to the duchy of Burgundy, and the two millions of crowns already mentioned. Of these he was to receive 1,200,000 in ready money : the prince's lands in Flanders belonging to the house of Bourbon, were to be delivered up ; these were valued at 400,000 more ; and the remaining 400,000 were to be paid by France in discharge of the emperor's debt to England. Francis was likewise to discharge the penalty of 500,000 crowns which the emperor had incurred, by not marrying his niece the princess Mary of England ; and to release a rich *fleur de lys* which had been many years before pawned by the house of Burgundy for 50,000 crowns. The town and castle of Hesdin were also yielded ; together with the sovereignty of Flanders and Artois, and all the king's pretensions in Italy. As for the allies of France, they were abandoned to the emperor's mercy, without the least stipulation in their favour ; and Francis himself protested against the validity of the treaty before he ratified it, as did also his attorney-general before he registered it in parliament ; but both of them with the greatest secrecy imaginable.

Nothing farther of much consequence happened during the remainder of the reign of Francis I. The war was soon renewed with Charles, who made an invasion into France, but with very bad success ; nor was peace fully established but by the death of Francis, which happened on the 3d of March, 1547. He was succeeded by his son Henry II. who ascended the throne the very day on which he was 29 years of age. In the beginning of his reign, an insurrection happened in Guienne, owing to the oppressive conduct of the officers who levied the salt tax. The king dispatched against the insurgents two bodies of troops ; one commanded by the duke of Aumale son to the duke of Guise, the other by the constable. The first behaved with the greatest moderation, and brought back the people to their duty without making many examples : the other behaved with the utmost haughtiness and cruelty ; and though the king afterwards remitted many of his punishments, yet from that time the constable became odious to the people, while the family of Guise were highly respected.

In 1548, the king began to execute the edicts which had been made against the Protestants with the utmost severity ; and, thinking even the clergy too mild in the prosecution of heresy, erected for that purpose a chamber composed of members of the parliament of Paris. At the queen's coronation, which happened this year, he caused a number of Protestants to be burned, and was himself present at the spectacle. He was, however, so much shocked, that he could never forget it ; but complained, as long as he lived, that, at certain times, it appeared before his eyes, and troubled his understanding.

In 1549, a peace being concluded with England, the king

king purchased Boulogne from the latter, for the sum of 400,000 crowns; one half to be paid on the day of restitution, and the other a few months after.— Scotland was included in the treaty, and the English restored some places they had taken there. This was the most advantageous peace that France had hitherto made with England; the vast arrears which were due to that crown being in effect remitted; and the pension which looked so like tribute, not being mentioned, was in fact extinguished. The earl of Warwick himself, who had concluded the peace, was so sensible of the disgrace suffered by his nation on this occasion, that he pretended to be sick, in order to avoid setting his hand to such a scandalous bargain.

This year, an edict was made to restrain the extravagant remittances which the clergy had been in use of making to the court of Rome, and for correcting some other abuses committed by the papal notaries.— With this edict pope Julius III. was highly displeased; and the following year (1550), war was declared by the king of France against the pope and the emperor. The pretence was, that Henry protected Octavio Farnese, duke of Parma, whom the pope was desirous of depriving of his dominions. In this war the king was threatened with the censures of the church, more especially when it was known that he had entered into an alliance with the Turks, and a Turkish fleet entered the Mediterranean, where they threatened the isle of Gozo, and made descents upon Sicily. Henry, however, strongly denied any such connection, and insisted that the emperor had given them sufficient provocation: but, be this as it will, the emperor soon found himself in such danger from these new enemies, that he could not support the pope as he intended, who on that account was obliged to sue for peace. After this, the king continued the war against the emperor with success; reducing the cities of Toul, Verdun, and Metz. He then entered the country of Alsace, and reduced all the fortresses between Hagenau and Wissemburg. He failed, however, in his attempt on Strasburg: and was soon after obliged by the German princes and the Swiss to desist from further conquests on that side. This war continued with very little interruption, and as little success on the part of the French, till the year 1557, when a peace was concluded; and soon after, the king was killed at a tournament, by one count de Montgomery, who was reckoned one of the strongest knights in France, and who had done all he could to avoid this encounter with the king.

Civil wars
with the
protestants.

The reign of his successor Francis II. was remarkable only for the persecution of the Protestants; which became so grievous, that they were obliged to take up arms in their own defence. This occasioned several civil wars, the first of which commenced in the reign of Charles IX. who succeeded to the throne in 1560. This first war continued till the year 1562, when a peace was concluded, by which the Protestants were to have a free pardon, and liberty of conscience. In 1565, the war broke out anew, and was continued with very little interruption till 1569, when peace was again concluded upon very advantageous terms for the Protestants. After this, king Charles, who had now taken the government into his hands, caressed the Protestants in an extraordinary manner. He invited to

court the admiral Coligni, who was the head of the Protestant party; and cajoled him so, that he was lulled into a perfect security, notwithstanding the many warnings given him by his friends, that the king's fair speeches were by no means to be trusted: but he had soon reason to repent his confidence. On the 22d of August 1571, as he was walking from the court to his lodgings, he received a shot from a window, which carried away the second finger of his right hand, and wounded him grievously in the left arm. This he himself ascribed to the malice of the duke of Guise, the head of the Catholic party. After dinner, however, the king went to pay him a visit, and amongst others made him this compliment; "You have received the wound, but it is I who suffer;" desiring at the same time, that he would order his friends to quarter about his house, and promising to hinder the Catholics from entering that quarter after it was dark. This satisfied the admiral of the king's sincerity; and hindered him from complying with the desires of his friends, who would have carried him away, and who were strong enough to have forced a passage out of Paris if they had attempted it.

In the evening, the queen mother, Katharine de Medicis, held a cabinet-council to fix the execution of the massacre of the Protestants, which had been long meditated. The persons of which this council was composed were, Henry duke of Anjou, the king's brother; Gonzagua duke of Nevers; Henry of Angoulesme, grand prior of France, and bastard brother of the king; the marshal de Tavannes; and Albert de Gondi, count de Rhetz. The direction of the whole was given to the duke of Guise, to whom the administration had been entirely confided during the former reign. The guards were appointed to be in arms, and the city-officers were to dispose the militia to execute the king's orders, of which the signal was the ringing of a bell near the Louvre. Some say, that when the hour approached, which was that of midnight, the king grew undetermined: that he expressed his horror at shedding so much blood, especially considering that the people whom he was going to destroy were his subjects, who had come to the capital at his command, and in confidence of his word; and particularly the admiral, whom he had detained so lately by his cares. The queen-mother, however, reproached him with his cowardice, and represented to him the great danger he was in from the Protestants; which at last induced him to consent. According to others, however, the king himself urged on the massacre; and when it was proposed to him to take off only a few of the heads, he cried out, "If any are to die, let there not be one left to reproach me with breach of faith."

As soon as the signal was given, a body of Swiss troops, of the Catholic religion, headed by the duke of Guise, the chevalier d'Angoulesme, accompanied by many persons of quality, attacked the admiral's house. Having forced open the doors, the foremost of the assassins rushed into his apartment; and one of them asked if he was Coligni? To this he answered that he was; adding, "Young man, respect these grey hairs:" to which the assassin replied by running him through the body with his sword. The duke of Guise and the chevalier, growing impatient below stairs, cried out to know

France.

142
Dreadful
massacre of
the Protec-
tants.

France. know if the business was done; and being told that it was, commanded that the body should be thrown out at the window. As soon as it fell on the ground, the chevalier, (or as some say) the duke of Guise, wiping the blood off the face, kicked it with his foot. The body was then abandoned to the fury of the populace; who after a series of indignities, dragged it to the common gallows, to which they chained it by the feet, the head being cut off and carried to the queen-mother; who, it is said, caused, it to be embalmed and sent to Rome. The king himself went to see the body hang upon the gibbet; where a fire being kindled under it, part was burnt, and the rest scorched. In the Louvre the gentlemen belonging to the king of Navarre and the princess of Condé were murdered under the king's eye. Two of them wounded, and pursued by the assassins, fled into the bed-chamber of the queen of Navarre, and jumped upon her bed, beseeching her to save their lives; and as she went to ask this favour of the queen-mother, two more, under the like circumstances, rushed into the room, and threw themselves at her feet. The queen-mother came to the window to enjoy these dreadful scenes; and the king, seeing the Protestants who lodged on the other side of the river, flying for their lives, called for his long gun, and fired upon them. In the space of three or four days, many thousands were destroyed in the city of Paris, by the most cruel deaths which malice itself could invent. Peter Ramus, professor of philosophy and mathematics, after being robbed of all he had, his belly being first ripped open, was thrown out of a window. This so much affected Dennis Lambin the king's professor, that, though a zealous Catholic, he died of terror. The first two days, the king denied it was done by his orders, and threw the whole blame on the house of Guise: but, on the 28th of August, he went to the parliament, avowed it, was complimented upon it, and directed a process against the admiral, by which he was stigmatized as a traitor. Two innocent gentlemen suffered as his accomplices in a pretended plot against the life of the king, in order to set the crown on the head of the prince of Condé. They were executed by torch light; and the king and the queen-mother (with the king of Navarre and the prince of Condé by force) were spectators of this horrid fact; and they also assisted at the jubilee to thank God for the execution of such an infamous design.

This massacre was not confined to the city of Paris alone. On the eve of St Bartholomew, orders had been sent to the governors of provinces to fall upon the Protestants themselves, and to let loose the people upon them; and though an edict was published before the end of the week, assuring them of the king's protection, and that he by no means designed to exterminate them because of their religion, yet private orders were sent of a nature directly contrary; in consequence of which the massacre, or (as, in allusion to the Sicilian vespers*, it was now styled) the *Matins of Paris*, were repeated in Meaux, Orleans, Troyes, Angers, Tholouze, Rouen, and Lyons; so that in the space of two months 30,000 Protestants were butchered. The next year Rochelle, the only strong fortress which the Protestants held in France, was besieged, but was not taken without the loss of 24,000 of the Catholics who besieged it. After this a pacification ensued on terms

*See Sicily.

favourable to the Protestants, but to which they never trusted.

This year the duke of Anjou was elected king of Poland, and soon after set out to take possession of his new kingdom. The king accompanied him to the frontiers of the kingdom; but during the journey was seized with a slow fever, which from the beginning had a very dangerous appearance. He lingered for some time under the most terrible agonies both of body and mind; and at last died on the 30th of May 1572, having lived 24 years, and reigned 13. It is said, that after the dreadful massacre abovementioned, this prince had a fierceness in his looks and a colour in his cheeks which he never had before. He slept little, and never found. He waked frequently in agonies, and had soft music to compose him again to rest.

During the first years of the reign of Henry III. who succeeded his brother Charles, the war with the Protestants was carried on with different success on the part of the Catholics. In 1575, a peace was concluded, called by way of eminence the *Edict of Pacification*. It consisted of no fewer than 63 articles; the substance of which was, that liberty of conscience, and the public exercise of religion were granted to the reformed without any other restriction than that they should not preach within two leagues of Paris or any other part where the court was: Party chambers were erected in every parliament, to consist of equal numbers of Catholics and Protestants, before whom all judgments were to be tried: The judgments against the admiral, and, in general, all who had fallen in the war or been executed, were reversed; and eight cautionary towns were given to the Protestants.

This edict gave occasion to the Guises to form an association in defence, as was pretended, of the Catholic religion, afterwards known by the name of the *Catholic League*. In this league though the king was mentioned with respect, he could not help seeing that it struck at the very root of his authority: for, as the Protestants had already their chiefs, so the Catholics were, for the future, to depend entirely upon the chief of the league; and were, by the very words of it, to execute whatever he commanded, for the good of the cause, against any, without exception of persons. The king, to avoid the bad effects of this, by the advice of his council declared himself head of the league; and of consequence recommenced the war against the Protestants, which was not extinguished as long as he lived.

The faction of the duke of Guise, in the mean time, took a resolution of supporting Charles cardinal of Bourbon, a weak old man, as presumptive heir of the crown. In 1584 they entered into a league with Spain, and took up arms against the king: and tho' peace was concluded the same year, yet in 1587 they again proceeded to such extremities, that the king was forced to fly from Paris. Another reconciliation was soon after effected; but it is generally believed that the king from this time resolved on the destruction of Guise. Accordingly, finding that this nobleman still behaved towards him with his usual insolence, the king caused him to be stabbed, as he was coming into his presence, by his guards, on the 23d of December 1587. The king himself did not long survive him; being stabbed by one James Clement, a Jacobine

cobine monk, on the first of August 1588. His wound at first was not thought mortal: but his frequent swooning quickly discovered his danger; and he died next morning, in the 39th year of his age, and 16th of his reign.

Before the king's death, he nominated Henry Bourbon king of Navarre for his successor on the throne of France; but as he was a Protestant, or at least one who greatly favoured their cause, he was at first owned by very few except those of the Protestant party. He met with the most violent opposition from the members of the Catholic league; and was often reduced to such straits, that he went to people's houses under colour of visits, when in reality he had not a dinner in his own. By his activity and perseverance, however, he was at last acknowledged throughout the whole kingdom, to which his abjuration of the Protestant religion contributed not a little. As the king of Spain had laid claim to the crown of France, Henry no sooner found himself in a fair way of being firmly seated on the throne, than he formally declared war against that kingdom; in which he at last proved successful, and in 1597 entered upon the quiet possession of his kingdom.

Edict of
Nantes.

149
The king
proposes to
new-model
the Euro-
pean
powers.

The king's first care was to put an end to the religious disputes which had so long distracted the kingdom. For this purpose, he granted the famous edict, dated at Nantes, April 13. 1598. It re-established, in a most solid and effectual manner, all the favours that had ever been granted to the reformed by other princes; adding some which had not been thought of before, particularly the allowing them a free admission to all employments of trust, profit, and honour; the establishing chambers in which the members of the two religions were equal; and the permitting their children to be educated without constraint in any of the universities. Soon after, he concluded peace with Spain upon very advantageous terms. This gave him an opportunity of restoring order and justice throughout his dominions; of repairing all the ravages occasioned by the civil war; and abolishing all those innovations which had been made, either to the prejudice of the prerogatives of the crown or the welfare of the people. His schemes of reformation, indeed, he intended to have carried beyond the boundaries of France. If we may believe the duke of Sully, he had in view no less a design than the new modelling of all Europe. He imagined that the European powers might be formed into a kind of Christian republic, by rendering them as nearly as possible of equal strength; and that this republic might be maintained in perpetual peace, by bringing all their differences to be decided before a senate of wise, disinterested, and able judges: and then he thought it would be no difficult matter to overturn the Ottoman empire. The number of these powers was to be 15; viz. the Papacy; the empire of Germany; France; Spain; Hungary; Great Britain; Bohemia; Lombardy, Poland; Sweden; Denmark; the republic of Venice; the States-General; the Swiss Cantons; and the Italian commonwealth, which was to comprehend the states of Florence, Genoa, Lucca, Modena, Parma, Mantua, and Monaco. In order to render the states equal, the empire was to be given to duke of Bavaria; the kingdom of Naples to the pope; that of

Sicily to the Venetians: Milan to the duke of Savoy, who, by this acquisition, was to become king of Lombardy; the Austrian Low Countries were to be added to the Dutch republic; Franche Compté, Alsace, and the country of Trent, were to be given to the Swiss. With a view, it is now thought, of executing this grand project, but under pretence of reducing the exorbitant power of the house of Austria, Henry made immense preparations both by sea and land; but if he really had such a design, he was prevented by death from attempting to execute it. He was stabbed in his coach by one Ravilliac, on the 12th of May 1608.

France.

150
He is mur-
dered.

On the death of Henry IV. the queen-mother assumed the regency. Ravilliac was executed, after suffering horrid tortures. It is said that he made a confession, which was so written by the person who took it down, that not one word of it could ever be read, and thus his instigators and accomplices could never be discovered. The regency, during the minority of Louis XIII. was only remarkable for cabals and intrigues of the courtiers. In 1617, the king assumed the government himself, banished the queen-mother to Blois, caused her favourite marshal d'Ancre to be killed, and chose for his minister the famous cardinal Richlieu. In 1620, a new war broke out between the Catholics and Protestants, which was carried on with the greatest fury on both sides; and we may judge of the spirit which actuated both parties, by what happened at Negreplisse, a town in Quercy. This place was besieged by the king's troops, and it was resolved to make an example of the inhabitants. The latter, however, absolutely refused to surrender upon any terms. They defended themselves, therefore, most desperately; and the city being at last taken by storm, they were all massacred, without respect of rank, sex, or age, except ten men. When these were brought into the king's presence, he told them they did not deserve mercy: they answered, that they would not receive it; that the only favour they asked, was to be hanged on trees in their own gardens; which was granted, and the place reduced to ashes. Both parties soon became weary of such a destructive war; and a peace was concluded in 1621, by which the edict of Nantes was confirmed. This treaty, however, was of no long duration. A new war broke out which lasted till the year 1628, when the edict of Nantes was again confirmed; only the Protestants were deprived of all their cautionary towns, and consequently of the power of defending themselves in time to come. This put an end to the civil wars on account of religion in France. Historians say, that in these wars above a million of men lost their lives; that 150,000,000 livres were spent in carrying them on; and that 9 cities, 400 villages, 2000 churches, 2000 monasteries, and 10,000 houses, were burnt or otherwise destroyed during their continuance. The next year, the king was attacked with a slow fever which nothing could allay, an extreme depression of spirits, and prodigious swelling in his stomach and belly. The year after, however, he recovered to the great disappointment of his mother, who had been in hopes of regaining her power. She was arrested: but found means to escape into Flanders, where she remained during the rest of this reign. Richlieu, by a masterly train of politics, though himself was next to an enthusiast for popery, supported the

152
Louis XIV.

Louis XIV. surnamed *le Grand*, succeeded to the throne when he was only five years of age. During his minority, the kingdom was torn in pieces under the administration of his mother Anne of Austria, by the factions of the great, and the divisions between the court and parliament, for the most trifling causes, and upon the most despicable principles. The prince of Condé shined like a blazing star; sometimes a patriot, sometimes a courtier, and sometimes a rebel. He was opposed by the celebrated Turenne, who from a Protestant had turned Papist. The nation of France was involved at once in civil and domestic wars; but the queen-mother having made choice of cardinal Mazarine for her first minister, he found means to turn the arms even of Cromwell against the Spaniards, and to divide the domestic enemies of the court so effectually among themselves, that when Louis assumed the reins of government into his own hands, he found himself the most absolute monarch that had ever sat upon the throne of France. He had the good fortune, on the death of Mazarine, to put the domestic administration of his affairs into the hands of Colbert, who formed new systems for the glory, commerce, and manufactures of France, all which he carried to a surprising height. The king himself, ignorant and vain, was blind to every patriotic duty of a king, promoting the interests of his subjects only that they might the better answer the purposes of his greatness; and by his ambition he embroiled himself with all his neighbours, and wantonly rendered Germany a dismal scene of devastation. By his impolitic and unjust revocation of the edict of Nantes in the year 1685, with the dragooning* the protestants that followed it, he obliged them to take shelter in England, Holland, and different parts of Germany, where they established the silk manufactories, to the great prejudice of their own country. He was so blinded by flattery, that he arrogated to himself the divine honours paid to the pagan emperors of Rome. He made and broke treaties for his convenience; and in the end he raised against himself a confederacy of almost all the other princes of Europe; at the head of which was king William III. of England. He was so well served, that he made head for some years against this alliance; and France seemed to have attained the highest pitch of military glory, under the conduct of those renowned generals Condé and Turenne. (See UNITED PROVINCES.) At length, having provoked the English by his repeated infidelities, their arms under the duke of Marlborough, and those of the Austrians under prince Eugene, rendered the latter part of Louis's life as miserable as the beginning of it was splendid. His reign, from the year 1702 to 1711, was one continued series of defeats and calamities; and he had the mortification of seeing those places taken from him, which, in the former part of his reign, were acquired at the expence of many thousand lives. (See BRITAIN, n^o 342, &c.)—Just as he was reduced, old as he was, to the desperate resolution of collecting his people and dying at their head, he was saved by the English Tory ministry de-

* See Dragooning.

serting the cause, withdrawing from their allies, and concluding the peace of Utrecht in 1713. See BRITAIN, n^o 371, &c.

The last years of Louis XIV. were also embittered by domestic calamities; which, added to those he had already endured of a public nature, impressed him with a deep melancholy. He had been for some time afflicted with a fistula: which, though successfully cut, ever afterwards effected his health. The year before the peace, his only son, the duke of Burgundy, died, together with the duchess and their eldest son; and the only remaining child was left at the point of death. The king himself survived till the month of September 1715; but on the 14th of that month expired, leaving the kingdom to his great grandson Louis, then a minor.

By the last will of Louis he had devolved the regency, during the minority of the young king, upon a council, at the head of which was the duke of Orleans. That noblemen, however, disgusted with a disposition which gave him only a casting vote, appealed to the parliament of Paris, who set aside the will of the late king, and declared him sole regent. His first acts were extremely popular, and gave the most favourable ideas of his government and character. He restored to the parliament the right which had been taken from them of remonstrating against the edicts of the crown, and compelled those who had enriched themselves during the calamities of the former reign to restore their wealth. He also took every method to efface the calamities occasioned by the unsuccessful wars in which his predecessor had engaged: promoted commerce and agriculture; and, by a close alliance with Great Britain and the United Provinces, seemed to lay the foundation of a lasting tranquillity. This happy prospect, however, was soon overcast by the intrigues of Alberoni the Spanish minister, who had formed a design of recovering Sardinia from the emperor, Sicily from the duke of Savoy, and of establishing the Pretender on the throne of Britain. To accomplish these purposes, he negotiated with the Ottoman Porte, Peter the Great of Russia, and Charles XII. of Sweden; the Turks intending to resume the war against the emperor; the two latter to invade Great Britain. But as long as the duke of Orleans retained the administration of France, he found it impossible to bring his schemes to bear. To remove him, therefore, he fomented divisions in the kingdom. An insurrection took place in Brittany; and Alberoni sent small parties in disguise into the country, in order to support the insurgents, and even laid plots to seize the regent himself. All of a sudden, however, the Spanish minister found himself disappointed in every one of his schemes. His partisans in France were put to death; the king of Sweden was killed at Frederickshall in Norway; the Czar, intent on making new regulations, could not be persuaded to make war upon Britain; and the Turks refused to engage in a war with the emperor, from whom they had lately suffered so much. The cardinal, nevertheless, continued his intrigues; which quickly produced a war betwixt Spain on the one part, and France and Britain on the other. The Spaniards, unable to resist the union of two such formidable powers, were soon reduced to the necessity of suing for peace; and the terms were dictated

France.

153
Louis XV.

154
Administration of the duke of Orleans.

France. tated by the regent of France; and of these the dismission of Alberoni the Spanish minister was one. A double marriage was now set on foot: the duke of Orleans gave his own daughter, Mademoiselle Montpensier, to Don Lewis prince of Asturias, while the Infanta of Spain was betrothed to her cousin, the king of France. From this time the house of Bourbon continued united; both princes being convinced, that it was their interest not to waste their strength in wars against each other.

155 Destructive project of John Law. The spirit of conquest having now in a great measure subsided, and that of commerce taken place throughout the world in general, France became the scene of as remarkable a project in the commercial way as ever was known in any country. One John Law, a Scotsman, having been obliged to fly from his own country for murder, laid the plan of a company which might by its notes pay off the debt of the nation, and reimburse itself by the profits. Law had wandered through various parts of Europe, and had successively endeavoured to engross the attention of various courts. The proposal was made to Victor Amadeus king of Sicily; but he dismissed Law with a reply, that "he was not rich enough to ruin himself: but in France it was looked upon in a more favourable light; the nation being at this time involved in a debt of 200 millions, and the regent, as well as the people in general, very fond of embarking in new schemes. The bank, thus established, proceeded at first with some degree of caution; but having by degrees extended their credit to more than 80 times their real stock, they soon became unable to answer the demands made upon them; so that the company was dissolved the very same year in which it had been instituted. The confusion into which the kingdom was thrown by this fatal scheme, required the utmost exertions of the regent to put a stop to it; and scarcely was this accomplished, when the king in 1723, took the government into his own hands. The duke then became minister; but did not long enjoy this post. His irregularities had broken his constitution, and brought on a number of maladies, under which he in a short time sunk, and was succeeded in his administration by the duke of Bourbon Conde. The king, as we have already remarked, had been married, when very young, to the Infanta of Spain, though by reason of his tender years the marriage had never been completed. The princess, however, had been brought to Paris, and for some time treated as queen of France; but as Louis grew up, it was easy to see that he had contracted an inveterate hatred against the intended partner of his bed. The minister, therefore, at last consented that the princess should be sent back; an affront so much resented by the queen her mother, that it had almost produced a war betwixt the two nations.

156 The king takes the government into his own hands. The dissolution of the marriage of Louis was the last act of Conde's administration; and the procuring of a new match was the first act of his successor Cardinal Fleury. The princess pitched upon was the daughter of Stanislaus Leszczinski, king of Poland, who had been deposed by Charles XII. of Sweden. The princess was destitute of personal charms, but of an amiable disposition; and though it is probable that she never possessed the love of her husband, her excellent qualities could not but extort his esteem; and the

France. birth of a prince soon after their marriage removed all the fears of the people concerning the succession.

France. Cardinal Fleury continued the pacific schemes pursued by his predecessors; though they were somewhat interrupted by the war which took place in the year 1733. Notwithstanding the connection betwixt that monarch and the French nation, however, Fleury was so parsimonious in his assistance, that only 1500 soldiers were sent to relieve Dantzic, where Stanislaus himself resided, and who at that time was besieged by the Russians. This pitiful reinforcement was soon overwhelmed by a multitude of Russians; and Stanislaus was at last obliged to renounce all thoughts of the crown of Poland, though he was permitted to retain the title of king: and that this title might not be merely nominal, the king of France consented to bestow upon him the duchies of Bar and Lorraine; so that, after the death of Stanislaus, these territories were indissolubly united to the dominions of France. Fleury steadily pursued his pacific plans, and the disputes between Spain and England in 1737 very little affected the peace of that kingdom; and it must be remembered to his praise, that instead of fomenting the quarrels betwixt the neighbouring potentates, he laboured incessantly to keep them at peace. He reconciled the Genoese and Corsicans, who were at war; and his mediation was accepted by the Ottoman Porte, who at that time carried on a successful war with the emperor of Germany, but made peace with him at the intercession of the cardinal. All his endeavours to preserve the general peace, however, proved at last ineffectual. The death of the emperor Charles VI. in 1740, the last prince of the house of Austria, set all Europe in a flame. The emperor's eldest daughter, Maria Theresa, claimed the Austrian succession, which comprehended the kingdoms of Hungary and Bohemia, the duchy of Silesia, Austrian Suabia, Upper and Lower Austria, Styria, Carinthia, Carniola; the four forest towns; Burgaw; Brisgaw; the Low Countries; Friuli; Tyrol; the duchy of Milan; and the duchies of Parma and Placentia. Among the many competitors who pretended a right to share, or wholly to inherit these extensive dominions, the king of France was one. But as he wished not to awaken the jealousy of the European princes by preferring directly his own pretensions, he chose rather to support those of Frederic III. who laid claim to the duchy of Silesia. This brought on the war of 1740; and of which an account is given under the articles BRITAIN and PRUSSIA. It was terminated in 1748 by the treaty of Aix-la-Chapelle; but to this Louis, who secretly meditated a severe revenge against Britain, only consented, that he might have time to recruit his fleet and put himself somewhat more upon an equality with that formidable power. But while he meditated great exploits of this kind, the internal tranquillity of the kingdom was disturbed by violent disputes betwixt the clergy and parliaments of France. In the reign of Louis XIV. there had been violent contests betwixt the Jansenists and Jesuits concerning free-will and other obscure points of theology; and the opinions of the Jansenists had been declared heretical by the celebrated papal bull named *Unigenitus*; the reception of which was enforced by the king, in opposition to the parliaments, the archbishop of Paris, and the body of the people.

France.

people. The archbishop, with 15 other prelates, protested against it as an infringement of the rights of the Gallican church, of the laws of the realm, and an insult on the rights of the people themselves. The duke of Orleans favoured the bull by inducing the bishops to submit to it; but at the same time stopped a persecution which was going on against its opponents. Thus matters passed over till the conclusion of the peace; a short time after which the jealousy of the clergy was awakened by an attempt of the minister of state to inquire into the wealth of individuals of their order. To prevent this, they revived the contest about the bull Unigenitus; and it was resolved, that confessional notes should be obtained of dying persons; that these notes should be signed by priests who maintained the authority of the bull; and that, without such notes, no person could obtain a viaticum, or extreme unction. On this occasion the new archbishop of Paris, and the parliament of that city, took opposite sides; the latter imprisoning such of the clergy as refused to administer the sacraments excepting in the circumstances abovementioned. Other parliaments followed the example of that of Paris; and a war was instantly kindled betwixt the civil and ecclesiastical departments of the state. In this dispute the king interfered, forbade the parliaments to take cognizance of ecclesiastical proceedings, and commanded them to suspend all prosecutions relative to the refusal of the sacraments: but instead of acquiescing, the parliament presented new remonstrances, refused to attend any other business, and resolved that they could not obey this injunction without violating their duty as well as their oath. They cited the bishop of Orleans before their tribunal, and ordered all writings, in which its jurisdiction was disputed, to be burnt by the executioner. By the assistance of the military, they enforced the administration of the sacraments to the sick, and ceased to distribute that justice to the subject for which they had been originally instituted. The king, enraged at their obstinacy, arrested and imprisoned four of the members who had been most obstinate, and banished the remainder to Bourges, Poitiers, and Auvergne; while, to prevent any impediment from taking place in the administration of justice by their absence, he issued letters patent, by which a royal chamber for the prosecution of civil and criminal suits was instituted. The counsellors refused to plead before these new courts; and the king, finding at last that the whole nation was about to fall into a state of anarchy, thought proper to recall the parliament. The banished members entered Paris amidst the acclamations of the inhabitants; and the archbishop, who still continued to encourage the priests in refusing the sacraments, was banished to his seat at Conflans; the bishop of Orleans and Troyes were in like manner banished, and a calm for the present restored to the kingdom.

160
Parliament
of Paris banished.

161
New disputes
betwixt the
king and
parliament

The tranquillity thus established was of no long duration. In the year 1756, the parliament again fell under the displeasure of the king by their imprudent persecution of those who adhered to the bull Unigenitus. They proceeded so far in this opposition as to refuse to register certain taxes absolutely necessary for the carrying on of the war. By this Louis was so provoked, that he suppressed the fourth and fifth chambers of inquests, the members of which had distin-

guished themselves by their opposition to his will. He commanded the bull Unigenitus to be respected, and prohibited the secular judges from ordering the administration of the sacraments. On this 15 counsellors of the great chamber resigned their offices, and 124 members of the different parliaments followed their example; and the most grievous discontents took place throughout the kingdom. An attempt was made by a fanatic, named *Damien*, to assassinate him; and the king was actually wounded, though slightly, between the ribs, in the presence of his son and in the midst of his guards. The assassin was put to the most exquisite tortures; in the midst of which he persisted, in the most obstinate manner, to declare that he had no intention to kill the king; but that his design was only to wound him, that God might touch his heart, and incline him to restore peace to his dominions, &c. These expressions, which undoubtedly indicated insanity, had no effect on his merciless judges, who consigned him to one of the most horrid deaths the ingenuity or cruelty of man could invent. This attempt, however, seems to have had some effect upon the king, as he soon after banished the archbishop of Paris, who had been recalled, and accommodated matters with his parliament once more.

The unfortunate event of the war of 1755 had brought the nation to the brink of ruin, when Louis implored the assistance of Spain; and on this occasion the celebrated *Family Compact* was signed; by which, with the single exception of the American trade, the subjects of France and Spain are naturalized in both kingdoms, and the enemy of the one sovereign is invariably to be looked upon as the enemy of the other. At this time, however, the assistance of Spain availed very little; both powers were reduced to the lowest ebb, and the arms of Britain were triumphant in every quarter of the globe. See the article BRITAIN.

The peace concluded at Paris in the year 1763, though it freed the nation from a most destructive and bloody war, did not restore its internal tranquillity. The parliament, eager to pursue the victory they had formerly gained over their religious enemies, now directed their efforts against the Jesuits, who had obtained and enforced the bull Unigenitus. That once powerful order, however, was now on the brink of destruction. A general detestation of its members had taken place throughout the whole world. A conspiracy formed by them against the king of Portugal, and from which he narrowly escaped, had roused the indignation of Europe, and this was still farther inflamed by some fraudulent practices of which they had been guilty in France. Le Valette, the chief of their missionaries at Martinico, had, ever since the peace of Aix-la-Chapelle, carried on a very extensive commerce, insomuch that he even aspired at monopolizing the whole West-India trade when the war with Britain commenced in 1755. Leonay and Gouffre, merchants at Marseilles, in expectation of receiving merchandize to the value of two millions from him, had accepted of bills drawn by the Jesuits to the amount of a million and an half. Unhappily they were disappointed by the vast numbers of captures made by the British; in consequence of which they were obliged to apply to the Society of Jesuits at large; but they, either ignorant of their true interest, or too slow in giving assistance,

167
Death of
Louis XV.
168
Reign of
Louis XVI.

The new king Louis XVI. grandson to the former, ascended the throne in the year 1774, in the 20th year of his age: and to secure himself against the disease which had proved fatal to his predecessor, submitted to inoculation, with several others of the royal family. Their quick and easy recovery contributed much to extend that practice throughout the kingdom, and to remove the prejudices, which had been entertained against it.

The king had no sooner regained his health, than he applied himself diligently to extinguish the differences which had taken place betwixt his predecessor and the people. He removed those from their employments who had given cause of complaint by their arbitrary and oppressive conduct; and he conciliated the affection of his subjects by removing the new parliaments and recalling the old ones.

But though the prudence of Louis had suggested to him these compliances, he endeavoured still to preserve pure and entire the royal authority. He explained his intentions by a speech in the great chamber of parliament. "The step that he had taken to ensure the tranquillity and happiness of his subjects, ought not (he observed) to invalidate his own authority; and he hoped from the zeal and attachment of the present assembly, an example of submission to the rest of his subjects. Their repeated resistance to the commands of his grandfather had compelled that monarch to maintain his prerogative by their banishment; and they were now recalled, in the expectation that they would quietly exercise their functions, and display their gratitude by their obedience." He concluded with declaring that it was his desire to bury in oblivion all past grievances; that he should ever behold with extreme disapprobation whatever might tend to create divisions and disturb the general tranquillity; and that his chancellor would read his ordinance to the assembly, from which they might be assured he would not suffer the smallest deviation to be made." That ordinance was conceived in the most explicit terms, and was immediately registered by the king's command. The articles of it limited within very narrow bounds the pretensions of the parliament of Paris: The members were forbidden to look upon themselves as one body with the other parliaments of the kingdom, or to take any step, or assume any title, that might tend towards, or imply, such an union; they were enjoined never to relinquish the administration of public justice, except in cases of absolute necessity, for which the first president was to be responsible to the king; and it was added, that on their disobedience the Grand Council might replace the parliament, without any new edict for the purpose. They were still, however, permitted to enjoy the right of remonstrating before the registering of any edicts or letters patent which they might conceive injurious to the welfare of the people, provided they preserved in their representations the respect due to the throne. But these remonstrances were not to be repeated; and the parliament, if they proved ineffectual, were to register the edict objected to within a month at farthest from the first day of its

being published: They were forbidden to issue any arrests which might excite trouble, or in any manner retard the execution of the king's ordinances; and they were assured by the king himself, at the conclusion of this code for their future conduct, that as long as they adhered to the bounds prescribed, they might depend upon his countenance and protection. In short, the terms on which Louis consented to re-establish the parliaments were such, that they were reduced to mere cyphers, and the word of the king still continued to be the only law in the kingdom. The archbishop of Paris, who had likewise presumed to raise some commotions with regard to the bull Unigenitus, was obliged to submit; and severely threatened if he should afterwards interfere in such a cause.

The final conquest of the Corsicans, who provoked by the oppression of their governors, had once more attempted to regain their former liberty, was the first event of importance which took place after this restoration of tranquillity: but the kingdom was yet filled with disorder from other causes. A scarcity of corn happening to take place just at the time that some regulations had been made by M. Turgot the new financier, the populace rose in great bodies, and committed such outrages, that a military force became absolutely necessary to quell them; and it was not till upwards of 500 of these miserable wretches were destroyed that they could be reduced. The king, however, by his prudent and vigorous conduct on this occasion, soon put a stop to all riots, and eminently displayed his clemency as well as prudence in the methods he took for the restoration of the public tranquillity.

The humanity of Louis was next shown in an edict which he caused to be registered in parliament, sentencing the deserters from his army in future to work as slaves on the public roads, instead of punishing them as formerly with death; and with equal attention to the general welfare of his subjects, he seized the moment of peace to fulfil those promises of economy which on his accession he had given to his people. Various regulations took place in consequence; particularly the suppression of the Mousquetaires and some other corps, which being adapted more to the parade of guarding the royal person than any real military service, were supported at a great expence, without any adequate return of benefit to the state.

Particular attention was also paid to the state of the marine; and the appointment of M. de Sartine in 1776 to that department did honour to the penetration of the sovereign. That minister, fruitful in resources, and unwearied in his application, was incessantly engaged in augmenting the naval strength of his country; and the various preparations that filled the ports and docks created no small uneasiness to the British court.

The next appointment made by the king was equally happy, and in one respect singular and unprecedented. M. Turgot, though possessed of integrity and industry, had not been able to command the public confidence. On this retreat, M. Clugny, intendant general of Bourdeaux, had been elevated to the vacant post; but he dying in a very short space, M. Taboureaud des Reaux was appointed his successor; and the king soon after associated with him in the management of the

Appointment of M
Necker to the direction of the
finances.

France: the finances M. Necker, by birth a Swiss, and by religion a Protestant. That gentleman, in the preceding reign, had been chosen to adjust some differences between the East India company and the crown; and had discharged his trust in a manner which gained the approbation of both parties. Possessed of distinguished abilities, his appointment would have excited no surprize, had it not been contrary to the constant policy of France, which had carefully excluded the aliens of her country and faith from the control of her revenue. It now stood forward as a new instance of enlargement of mind and liberality of sentiment; and will to posterity mark the prominent features of the reign of Louis XVI.

172
The French privately assist the Americans in their contest with Britain;

Although the French monarch was of a pacific disposition, and not destitute of generosity of sentiment; yet his own and the public exultation had been openly and constantly proportioned to the success of the Americans in their contest with Britain: the princes of the blood and the chief nobility were eager to embark in support of the cause of freedom; and the prudence of the king and his most confidential ministers alone restrained their ardour. The fatal events of the former war were still impressed on the mind of Louis; and he could not readily consent to expose his infant marine in a contest with a nation who had so frequently asserted the dominion of the seas, and so lately broken the united strength of the house of Bourbon. At the same time, he was sensible that the opportunity of humbling those haughty islanders should not be entirely neglected, and that some advantages should be taken of the present commotions in America. Two agents from the United States, Silas Deane and Dr Benjamin Franklin, had successively arrived at Paris; and though all audience was denied them in a public capacity, still they were privately encouraged to hope that France only waited the proper opportunity to vindicate in arms the independence of America. In the mean while, the American cruizers were hospitably received into the French ports; artillery and all kinds of warlike stores were freely sold or liberally granted to the distress of the colonists; and French officers and engineers, with the connivance of government, entered into their service.

Some changes were about this time introduced into the different departments of state. The conduct of M. Necker in the finances had been attended with universal approbation; and M. Taboureau des Reaux, his colleague, had resigned his situation, but still retained the dignity of counsellor of state. To afford full scope to the genius of M. Necker, Louis determined no longer to clog him with an associate; but, with the title of Director-general of the Finances, submitted to him the entire management of the funds and revenue of France. In the ensuing year, the count de St Germain, secretary at war, died; and the prince de Montbarey, who had already filled an inferior situation in that department, was now appointed to succeed him.

In the mean time, Louis's negotiations with foreign courts were not neglected. He concluded a new treaty of alliance with Switzerland: vigilantly observed the motions of the different princes of Germany on the death of the elector of Bavaria; and when closely questioned by the English ambassador Lord Stormont, respecting the various warlike preparations which were

diligently continued through the kingdom, he replied, That at a time when the seas were covered with English fleets and American cruizers, and when such armies were sent to the New World as had never before appeared there, it became prudent for him also to arm for the security of the colonies and the protection of the commerce of France. The king was not ignorant at the same time, that the remonstrances of Great Britain, and the importunities of the agents of the United States, would soon compel him to adopt some decisive line of conduct. This was hastened by a new event disastrous to Britain; the failure of general Burgoyne's expedition, and the capture of his army. The news of that event was received at Paris with unbounded exultation. M. Sartine, the marine superintendent, was eager to measure the naval strength of France with that of Great Britain; the queen, who had long seconded the applications of the American agents, now espoused their cause with fresh ardour; and the pacific inclinations of Louis being overborne by the suggestions of his ministers and the influence of his queen, it was at length determined openly to acknowledge the independence of the United States.

Dr Franklin and Silas Deane, who had hitherto acted as private agents, were now acknowledged as public ambassadors from those states to the court of Versailles; and a treaty of amity and commerce was signed between the two powers in the month of February 1778. The duke of Noailles, ambassador to the court of London, was in the month of March instructed to acquaint that court with the above treaty. At the same time he declared, that the contracting parties had paid great attention not to stipulate any exclusive advantages in favour of France, and that the United States had reserved the liberty of treating with every nation whatever on the same footing of equality and reciprocity. But this stipulation was treated by the British with contempt; and the recal of Lord Stormont, their ambassador at Versailles, was the signal for the commencement of hostilities.—The events produced by this war are related under the articles AMERICA, BRITAIN, and INDOSTAN. Here our chief business is with domestic transactions, the measures of the cabinet, and the internal economy of the state.

In the year 1780, new changes in the French ministry took place. M. Bertin had resigned the office of secretary of state; the prince de Montbarey had retired from the post of secretary at war, and was succeeded by the marquis de Segur. But the most important removal was that of M. Sartine, who had for several years presided over the marine department, and whose unwearied application and ability had raised the naval power of France to a height that astonished Europe; but his colleagues in the cabinet loudly accused a profusion, which would have diverted into one channel the whole resources of the kingdom; and his retreat opened a road to the ambition of the marquis de Castries, who was appointed to supply his place.

This year, the king fixed on the anniversary of his birth-day to render it memorable by a new instance of humanity; and he abolished for ever the inhuman custom of *putting the question*, as it was called, by torture; a custom which had been so established by the practice of ages, that it seemed to be an inseparable part of the

France.

173
And at last openly acknowledge the independence of the United States.

174
Removal of M. de Sartine.

France.

the constitution of the courts of Justice in France. At the same time to defray the charges of war, he continued to diminish his own expenditure; and sacrificing his magnificence to the ease of his subjects, dismissed at once above 400 officers belonging to his court.

Unhappily, however, the popular discontents were excited next year by the dismissal of their favourite minister M. Necker. He had conceived the arduous but popular project of supporting a war by loans without taxes; and the rigid economy which he had introduced into all the departments of the royal household, and the various resources that presented themselves to his fertile genius, had supported him amidst the difficulties that attended this system. But his austerity of temper had not rendered him equally acceptable to the sovereign and his subjects; and the repeated reforms he had recommended were represented as inconsistent with the dignity of the crown: he was therefore in 1781 dismissed from his office of comptroller-general; and M. Joli de Fleuri, counsellor of state, was appointed to that important department. The defeat of the count de Grasse happened next year, and impressed the kingdom with general grief and consternation. Immense preparations were, however, made for the operations of 1783; and in conjunction with the courts of Madrid and the Hague, Louis was determined this year to make the most powerful efforts to bring the war to a conclusion. But in the midst of these preparations, the voice of peace was again heard; and Louis was induced to listen to the proffered mediation of the two first potentates in Europe, the emperor of Germany and the empress of Russia. The count de Vergennes, who still occupied the post of secretary of foreign affairs, was appointed to treat with Mr Fitzherbert the British minister at Brussels; but who had lately proceeded to Paris to conduct this important negotiation. The way was already smoothed for the restoration of the public tranquillity, by provisional articles signed at the conclusion of the last year between the States of America and Great Britain, and which were to constitute a treaty of peace finally to be concluded when that between France and Great Britain took place. Preliminary articles were accordingly agreed upon and signed at Versailles: these were soon after succeeded by a definitive treaty; and France, throughout her extensive dominions, beheld peace once more established. Though the late war had been attended by the most brilliant success, and the independence of America seemed to strike deep at the source of her rival's power, yet France herself had not been entirely free from inconvenience. The retreat of M. Necker had, as we have already observed, diminished the public confidence; three different persons who had since transiently occupied his post, increased the jealousies of the people; and the failure of the celebrated Caisse d'Escompte completed the universal consternation.

176
Peace con-
cluded.

177
Of the
Caisse
d'Escompte

That bank had been established in the year 1776. The plan of it was formed by a company of private adventurers, and its capital was fixed at L.500,000 Sterling. The professed design of the Company was to discount bills at short dates, at the rate of four *per cent. per annum*: but as this interest could never be an equivalent for the capital sunk by the proprietors, they were entrusted with the additional power of issuing notes to the amount of their capital, which, as they

France.

were capable at any time of being converted into specie, might be often voluntarily taken by their customers from mere convenience. The reputation of the bank soon caused its stock to sell above par; and its credit was still at the highest, when to the astonishment of the nation it suddenly stopped payment on the 2d of October 1783. The cause assigned was an uncommon scarcity of specie: But the public suspected that the failure arose from a loan secretly made to government; and what confirmed the suspicion was, that government about the same time stopped payment of the bills drawn upon them by their army in America.

Whatever was the cause of this event, the king was prevailed on to extend his protection to the company. By four successive edicts the banks in Paris were ordered to receive the notes of the Caisse d'Escompte as currency; and a lottery with a stock of one million Sterling, redeemable in eight years, being established, the tickets were made purchasable in notes of the Caisse d'Escompte. By these expedients the public confidence in that bank was revived, its business increased, and its stock rose to above double the original subscription; the bills from America were at the same time put in a train of payment, and public credit was restored throughout the kingdom. Some compensation also for the expences that had been incurred during the late war, was drawn from a treaty with the United States of America. These engaged to reimburse France in the sum of 18 million of livres, which had been advanced in the hour of their distress; and Louis consented to receive the money, as more convenient to the States, in the space of 12 years, by 12 equal and annual payments.

The general peace was soon after followed by a particular treaty between France and Holland, which was effected with great address by the Count de Vergennes. It included all the principles which can serve to cement in the closest union distinct nations under distinct governments; and by which they may mutually participate, in peace or in war, of good or of evil; and in all cases administer the most perfect, aid, counsel, and succour to each other. It also prescribed, if their united good offices for the preservation of peace should prove ineffectual, the assistance they were to afford each other by sea and land. France was to furnish Holland with 10,000 effective infantry, 2000 cavalry, with 12 ships of the line and 6 frigates. Their High Mightinesses, on the other side, in case of a marine war, or that France should be attacked by sea, were to contribute to her defence six ships of the line and three frigates; and in case of an attack on the territory of France, the States-general were to have the option of furnishing their land contingent either in money or troops, at the estimate of 5000 infantry and 1000 cavalry. Further, if the stipulated succours should be insufficient for the defence of the party attacked, or for procuring a proper peace, they engaged to assist each other with all their forces, if necessary; it being however agreed that the contingent of troops to be furnished by the States-general should not exceed 20,000 infantry and 4000 cavalry. It was further added, that neither of the contracting powers should disarm, or make or receive proposals of peace or truce, without the consent of the other: they promised also not to contract any future alliance or engagement what-

Treaty be-
tween
France and
Holland.

ever,

France. ever, directly or indirectly, contrary to the present treaty; and on any treaties or negociations being proposed which might prove detrimental to their joint interest, they pledged their faith to give notice to each other of such proposals as soon as made.

Thus was Holland now converted into the firm ally of that power against whose encroaching spirit she had formerly armed the most powerful kingdoms in Europe; while France having asserted the independence of America against Great-Britain, and having converted an ancient and formidable foe into an useful friend, seemed to have attained an influence over the nations of the earth that she had never before been possessed of.

179
Consequence to France from her interference between Britain and her colonies.

But however exalted her present situation might appear, the seeds of future commotion were already apparent to an attentive observer. The applause that had attended the parliament of Paris in their struggles with the late king might be considered as the first dawn of freedom; the language of that assembly had boldly inculcated to their countrymen their natural rights, and taught them to look with a less enraptured eye on the lustre that encompassed the throne. The war in America had contributed to enlarge the political ideas of the French: they had on that occasion stood forth as the champions of liberty, in opposition to regal power; and the officers who had acted on that conspicuous theatre, accustomed to think and speak without restraint, on their return imparted to the provinces of France the flame of freedom which had been kindled in the wilds of America. From that moment the French, instead of silently acquiescing under the edicts of their sovereign, canvassed each action with bold and rigid impartiality; while the attachment of the army, which has ever been considered as the sole foundation of despotism, gave way to the noble enthusiasm of liberty.

180
Appointment and measures of M. de Calonne.

We have already noticed the public dissatisfaction that had attended the dismissal of M. Necker; his transient successor, M. de Flenry, had retired from the management of the finances in 1783, and the more transient administration of M. d'Ormesson had expired in the same year that gave it birth. On his retreat, M. de Calonne, who had successively filled with acknowledged reputation the office of intendant of Mentz, and afterwards of the provinces of Flanders and Artois, was nominated to the post of comptroller-general. This gentleman, flexible and insinuating, eloquent in conversation and polished in his manners, fertile in resources and liberal in the disposal of the public money, soon rendered himself acceptable to the sovereign. But he did not enter upon his new and arduous station favoured by the breath of popularity: he was reported to be more able than consistent, and not to have tempered the ardour of his spirit by the severity of deep research; and the people, amidst repeated loans, regretted that severe simplicity which had characterised the administration of M. Necker.

It was the bold and judicious measures of Calonne, however, that restored credit to the Caisse d'Escompte, which had stopped payment a few weeks before his accession. His next measure in 1784, the establishment of the Caisse d'Amortissement or sinking fund, was intitled to a still higher degree of applause. The plan of that fund was simple and moderate: It was to pay annually by government, into the hands of a board set

France. apart for that purpose, the entire interest of the national debts, whether in stock or annuities, together with an additional sum of L. 120,000. The annuities that would be extinguished every year were estimated at L. 50,000; and in that proportion, the sum set apart for the redemption of the national debt would annually increase. The operation of this new fund was limited to the term of 25 years; and during that term the annual receipt of the Caisse d'Amortissement is declared unalterable, and incapable of being diverted to any other object.

The principal measure of the next year was the establishment of a new East India Company, the constitutions of which have been already detailed in a preceding volume of this work, under the article COMPANY; see Vol. V. p. 247, 248: A measure not equally commendable with the preceding, and which did not fail to excite violent complaints. The time, however, was now approaching, when the necessities of the state would compel him to measures still more unpopular, and destined to undergo a severer scrutiny. Although peace had been re-established throughout Europe for three years, yet the finances of France seemed scarce affected by this interval of tranquillity, and it was found requisite to close every year with a loan. The public expenditure of 1785 might probably seem to sanction this measure. It had been thought proper to fortify Cherbourg upon a large and magnificent scale; the claim of the emperor to the navigation of the Scheldt, had obliged the French to increase their land forces, either to form a respectable neutrality, or to assist effectually their Dutch allies; and the marquis de Castries, fond of war and profuse in his designs, had not suffered the navy, which M. Sartine had surrendered into his hands, to decline during the interval of peace. The treaty of commerce concluded in the year 1786 with Great Britain was a new source of discontent. Though regarded by the English manufacturers as far from advantageous, it excited in France still louder murmurs. It was represented as likely to extinguish those infant establishments, which were yet unable to vie with the manufactures of England that had attained to maturity; and the market that it held out for the wines and oils of France was passed over in silence, while the distress of the artisan was painted in the most striking colours. But when the edict for registering the loan at the conclusion of the last year, and which amounted to the sum of three millions three hundred and thirty thousand pounds, was presented to the parliament of Paris, the murmurs of the people, through the remonstrances of the assembly, assumed a more legal and formidable aspect. The king, however, signified to the select deputation that were commissioned to convey to him their remonstrances, that he expected to be obeyed without farther delay. The ceremony of the registering accordingly took place on the next day; but it was accompanied with a resolution, importing, "that public economy was the only genuine source of abundant revenue, the only means of providing for the necessities of the state, and restoring that credit which borrowing had reduced to the brink of ruin."

The king was no sooner informed of this step, than he commanded the attendance of the grand deputation of parliament; when he erased from their records the

France.

the resolution that had been adopted; and observed, that though it was his pleasure that the parliament should communicate, by its respectful representations, whatever might concern the good of the public, yet he never would allow them so far to abuse his clemency as to erect themselves into the censors of his government. At the same time, more strongly to mark his displeasure at their expostulations, he superseded one of their officers, who had appeared most active in forwarding the obnoxious resolution.

M. de Calonne, however, though gratified by the approbation of his sovereign, could not but feel himself deeply mortified by the opposition of the parliament. His attempts to conciliate that assembly had proved ineffectual; and he experienced their inflexible aversion at the critical juncture when their acquiescence might have proved of the most essential service. An anxious inquiry into the state of the public finances had convinced him that the expenditure by far exceeded the revenue. In this situation, to impose new taxes was impracticable; to continue the method of borrowing was ruinous; to have recourse only to economical reforms, would be found totally inadequate; and he hesitated not to declare, that it would be wholly impossible to place the finances on a solid basis, but by the reformation of whatever was vicious in the constitution of the state.

To give weight to this reform, M. de Calonne was sensible that something more was necessary than the royal authority; he perceived that the parliament was neither a fit instrument for introducing a new order into public affairs, nor would submit to be a passive machine for sanctioning the plans of a minister, even if those plans were the emanations of perfect wisdom. Though originally a body of lawyers, indebted for their appointments to the king, there was not an attribute of genuine legislative assembly but what they seemed desirous to engross for themselves; and they had been supported in their pretensions by the plaudits of the people, who were sensible that there was no other body in the nation that could plead their cause against royal or ministerial oppression. To suppress, therefore, the only power of control that remained, and to render the government more arbitrary, was deemed too perilous a measure: yet to leave the parliament in the full possession of their influence, an influence that the minister was convinced would be exerted against him, was at once to render his whole system abortive.

In this dilemma, the only expedient that suggested itself was to have recourse to some other assembly, more dignified and solemn in its character, and which should in a greater degree consist of members from the various orders of the state and the different provinces of the kingdom. This promised to be a popular measure; it implied a deference to the people at large, and might be expected to prove highly acceptable. But the true and legitimate assembly of the nation, the states-general, had not met since the year 1614; nor could the minister flatter himself with the hope of obtaining the royal assent to a meeting which a despotic sovereign could not but regard with secret jealousy. Another assembly had occasionally been substituted in the room of the states-general: this was distinguished by the title of the *Notables*; and consisted of a num-

ber of persons from all parts of the kingdom, chiefly selected from the higher orders of the state, and nominated by the king himself. This assembly had been convened by Henry IV. again by Louis XIII. and was now once more summoned by the authority of the present monarch.

The writs for calling them together were dated on the 29th of December 1786; and they were addressed to seven princes of the blood, nine dukes and peers of France, eight field-marschals, twenty-two nobles, eight counsellors of state, four masters of requests, eleven archbishops and bishops, thirty-seven of the heads of the law, twelve deputies of the *pays d'etats*, the lieutenant civil, and twenty-five magistrates of the different towns of the kingdom. The number of members was 144; and the 29th of January 1787 was the period appointed for their meeting.

Upon the arrival of the notables at Paris, however, the minister found himself yet unprepared to submit his system to their inspection, and postponed the opening of the council to the 7th of February. A second delay to the 14th of the same month was occasioned by the indisposition of M. de Calonne himself and that of the count de Vergennes president of the council of finance and first secretary of state; and a third procrastination was the necessary result of the death of the count on the day previous to that fixed for the opening of the meeting. He was succeeded in the department of foreign affairs by the count de Montmorin, a nobleman of unblemished character. But his loss at this critical juncture was severely felt by M. de Calonne; he alone, of all the ministers, having entered with warmth and sincerity into the plans of the comptroller-general. The chevalier de Mirosmesnil, keeper of the seals, was avowedly the rival and enemy of that statesman. The marshal de Castries, secretary for the marine department, was personally attached to M. Necker; and the baron de Breteuil, secretary for the household, was the creature of the queen, and deeply engaged in what was called the Austrian system.

It was under these difficulties that M. de Calonne, on the 22d of February, first met the assembly of the Notables, and opened his long expected plan. He began by stating, that the public expenditure had for centuries past exceeded the revenue, and that a very considerable deficiency had of course existed; that the Mississippi scheme of 1720 had by no means, as might have been expected, restored the balance; and that under the economical administration of cardinal Fleury the deficit still existed; that the progress of this derangement under the last reign had been extreme; the deficiency amounting to three millions sterling at the appointment of the abbé Terray; who, however, reduced it to one million six hundred and seventy-five thousand pounds; it decreased a little under the short administration that followed, but rose again in consequence of the war, under the administration of M. Necker; and at his own accession to the office, it was three millions three hundred and thirty thousand pounds.

In order to remedy this growing evil, M. Calonne recommended a territorial impost, in the nature of the English land-tax, from which no rank or order of men were to be exempted; and an enquiry into the possessions

France.

France. possessions of the clergy, which, hitherto had been deemed sacred from their proportion of the public burdens; the various branches of internal taxation were also to undergo a strict examination; and a considerable resource was presented in mortgaging the demesne lands of the crown.

The very necessity for these reforms was combated with a degree of boldness and force of reasoning that could not fail of deeply impressing the assembly; and instead of meeting with a ready acquiescence, the comptroller-general was now launched into the boundless ocean of political controversy. M. Necker, previous to his retirement, had published his *Compte rendu au Roi*, in which France was represented as possessing a clear surplus of 425,000 pounds sterling: this performance had been read with avidity, and probably contributed to estrange from the author the royal countenance; but the credit of it was ably vindicated by M. de Brienne, archbishop of Thoulouse.

183
Opposed by Mirabeau and the bishop of Thoulouse; M. de Calonne met with a still more formidable adversary in the count de Mirabeau. This extraordinary man, restless in his disposition, licentious in his morals, but bold, penetrating, and enterprising, had occasionally visited every court in Europe. He had been admitted at one time to the confidence of the minister; and had been directed, though in no ostensible character, to observe at Berlin the disposition of the successor of the great Frederic: in this capacity, he was frequently exposed to neglect and disappointment; his letters were often left unanswered; disgust succeeded to admiration; and he who had entered the Prussian court the intimate friend, returned to Paris the avowed enemy, of M. de Calonne: while the archbishop arraigned the understanding, the count impeached the integrity, of the comptroller-general.

184
And by the principal nobility, clergy, and magistrates. The eloquence of M. de Calonne, however, might have successfully vindicated his system and reputation, against the calculations of Brienne, and the invectives of Mirabeau; but he could not support himself against the influence of the three great bodies of the nation. The ancient nobility and the clergy had ever been free from all public assessments; and had the evil gone no farther, it might have been still perhaps borne with patience; but through the shameful custom of selling patents of nobility, such crowds of new noblesse started up, that every province in the kingdom was filled with them. The first object with those who had acquired fortunes rapidly, was to purchase a patent; which, besides gratifying their vanity, afforded an exemption to them and their posterity from contributing proportionably to the exigences of the state; the magistracies likewise throughout the kingdom, enjoyed their share of these exemptions; so that the whole weight of the taxes fell on those who were least able to bear them.

The minister's design, then, of equalising the public burdens, and by rendering the taxes general diminishing the load borne by the lower and most useful classes of people, though undoubtedly great and patriotic, at once united against him the nobility, the clergy, and the magistracy; and the event was such as might be expected: the intrigues of those three bodies raised against him so loud a clamour, that, finding it impossible to stem the torrent, he not only resigned his

VOL. VII.

place on the 12th of April, but soon after retired to England from the storm of persecution.

In the midst of these transactions at home, Louis's attention was also called to the state of affairs in the republic of Holland, his new and close ally. The prince of Orange had been stripped of all authority by the aristocratic party; and, retiring from the Hague, maintained the shadow of a court at Nimeguen. His brother-in-law, however, the new king of Prussia, exerted his endeavours to promote the interest of the stadtholder; and having offered, in concert with France, to undertake the arduous task of composing the differences which distracted the republic, the proposal was received with apparent cordiality by the court of Versailles. At the same time it could scarce be expected that France would become the instrument of restoring the prince of Orange to that share of power which he had before occupied, and thus abandon one of the longest and most favourite objects of her policy, the establishing a supreme and permanent controul in the affairs of Holland. In fact, the conditions which were framed by the Louvestein faction, as the basis of reconciliation, were such as plainly indicated their design to reduce the influence and authority of the stadtholder within very narrow limits. On his renouncing the right of filling up the occasional vacancies in the town-senates, he was to be restored to the nominal office of captain-general: but he was to be restrained from marching the troops into, or out of any province, without leave from the respective provinces concerned; and he was also to subscribe to a resolution passed some time before by the senate of Amsterdam, that the command should at all times be revocable at the pleasure of the states. Had the prince acquiesced in these preliminaries, France would have completely attained the object of her long negotiations, and by means of the Louvestein faction have acquired the ascendancy that she had repeatedly sought in the councils of Holland. But under the difficulties that surrounded him, the prince of Orange was admirably supported and assisted by the genius, the spirit, and the abilities of his consort: she firmly rejected every measure tending to abridge any rights that had been attached to the office of stadtholder; and M. de Rayneval, the French negociator, having in vain endeavoured to overcome her resolution, broke off the correspondence between the Hague and Nimeguen, and returned to Paris about the middle of January 1787.

The events that ensued will be found detailed under a subsequent article. It is only necessary to observe in this place, that the republican party were totally disappointed in their hopes from France. The court of Versailles had indeed long trusted to the natural strength of the republican party, and had been assiduous during the whole summer in endeavouring to second them by every species of succours that could be privately afforded. Crowds of French officers arrived daily in Holland; and either received commissions in the service of the states, or acted as volunteers in their troops. Several hundreds of tried and experienced soldiers were selected from different regiments; and being furnished with money for their journey, and assurances of future favour, were dispatched in small parties to join the troops, and help to discipline the burghers

France.

185

186
Disturbances in Holland.

187
Attempts of the French to support the republican party.

France. burghers and volunteers. A considerable corps of engineers were also directed to proceed silently and in disguise towards Amsterdam, and to assist in strengthening the works of that city. These aids, which might have proved effectual had the contest been confined to the states of Holland and the stadtholder, were overwhelmed in the rapid invasion of the Prussians; and the court of Berlin had taken its measures with so much celerity, and the situation of the republicans was already become so desperate, that it was doubtful whether their affairs could be restored by any assistance that France was capable of immediately administering. Yet on Great Britain fitting out a strong squadron of men of war at Portsmouth to give confidence to the operations of the king of Prussia, the court of Versailles also sent orders to equip 16 sail of the line at Brest, and recalled a small squadron which had been commissioned on a summer's cruise on the coast of Portugal. But in these preparations Louis seemed rather to regard his own dignity, than to be actuated by any hopes of effectually relieving his allies. All opposition in Holland might be already considered as extinguished. The states assembled at the Hague had officially notified to the court of Versailles, that the disputes between them and the stadtholder were now happily terminated; and as the circumstances which gave occasion for their application to that court no longer existed, so the succours which they had then requested would now be unnecessary.

Under these circumstances, France could only wish to extricate herself from her present difficulty with honour. She therefore readily listened to a memorial from the British minister at Paris; who proposed, in order to preserve the good understanding between the two crowns, that all warlike preparations should be discontinued, and that the navies of both kingdoms should be again reduced to the footing of a peace establishment. This was gladly acceded to by the court of Versailles; and that harmony which had been transiently interrupted between the two nations was restored.

181
Domestic
concerns of
France.

Though the French king could not but sensibly feel the mortification of thus relinquishing the ascendancy which he had attained in the councils of Holland, the state of his own domestic concerns and the internal situation of his kingdom furnished matter for more serious reflection. The dismissal of M. de Calonne had left France without a minister, and almost without a system; and though the king bore the opposition of the Notables with admirable temper, yet the disappointment that he had experienced sunk deep into his mind. Without obtaining any relief for his most urgent necessities, he perceived too late that he had opened a path to the restoration of the ancient constitution of France, which had been undermined by the crafty Louis XI. and had been nearly extinguished by the daring and sanguinary counsels of Richlieu under Louis XIII. The Notables had indeed demeaned themselves with respect and moderation, but at the same time they had not been deficient in firmness. The appointment of the archbishop of Thoulouse, the vigorous adversary of M. de Calonne, to the office of comptroller-general, probably contributed to preserve the appearance of good humour in that assembly; yet

189
Assembly
of the No-
tables dis-
solved.

the proposed territorial impost, or general land tax, which was an object so ardently coveted by the court, was rejected. Louis, therefore, deprived of any farther hope of rendering the convention subservient to his embarrassments, determined to dissolve the assembly; which he accordingly did, with a very moderate and conciliatory speech to the members on their dismissal.

Thus disappointed of the advantage which he had flattered himself he would have drawn from the acquiescence of the Notables, the king was obliged now to recur to the usual mode of raising money by the royal edicts: among the measures proposed for which purpose were the doubling the poll-tax, the re-establishment of the third twentieth, and a stamp-duty. But the whole was strongly disapproved by the parliament of Paris; and that assembly, in the most positive terms, refused to register the edict. Louis was obliged to apply, as the last resort, to his absolute authority; and, by holding what is called a *bed of justice*, compelled them to enroll the impost.

The parliament, though defeated, were far from subdued; and on the day after the king had held his bed of justice, they entered a formal protest against the edict; declaring, "that it had been registered against their approbation and consent, by the king's express command; that it neither ought nor should have any force; and that the first person who should presume to attempt to carry it into execution, should be adjudged a traitor, and condemned to the gallies." This spirited declaration left the king no other alternative, than either proceeding to extremities in support of his authority, or relinquishing for ever after the power of raising money upon any occasion without the consent of the parliament. Painful as every appearance of violence must have proved to the mild disposition of Louis, he could not consent to surrender, without a struggle, that authority which had been so long exercised by his predecessors. Since the commencement of the present discontents, the capital had been gradually filled with considerable bodies of troops; and about a week after the parliament had entered the protest, an officer of the French guards, with a party of soldiers, went at break of day to the house of each individual member, to signify to him the king's command, that he should immediately get into his carriage, and proceed to Troyes, a city of Champagne, about 70 miles from Paris, without writing or speaking to any person out of his own house before his departure. These orders were served at the same instant; and before the citizens of Paris were acquainted with the transaction, their magistrates were already on the road to their place of banishment.

Previous to their removal, however, they had presented a remonstrance on the late measures of government, and the alarming state of public affairs. In stating their opinion on taxes, they declared, that neither the parliaments, nor any other authority, excepting that of the three estates of the kingdom collectively assembled, could warrant the laying of any permanent tax upon the people; and they strongly enforced the renewal of those national assemblies, which had rendered the reign of Charlemagne so great and illustrious.

This requisition of the parliaments to re-establish the

France.

the national council, or states-general, was the more honourable, as the former assemblies must have sunk under the influence of the latter, and returned to their original condition of mere registers and courts of law. The confidence and attachment of the people of consequence rose in proportion to this instance of disinterestedness; their murmurs were openly expressed in the streets of the capital, and the general dissatisfaction was augmented by the stop that was put to public business by the exile of the parliament.

The cabinet at the same time was apparently weak, disunited, and fluctuating; and continual changes took place in every department of the state. Louis, averse to rigorous counsels, wished to allay the growing discontent by every concession that was consistent with his dignity; but it was generally believed, that the queen strongly dissuaded him from any step that might tend to the diminution of the royal authority. The influence of that princess in the cabinet was undoubtedly great: but the popularity which once had accompanied her was no more: and some imputations of private levity, which had been rumoured through the capital, were far from rendering her acceptable to the majority of the people; while the count d'Artois, the king's brother, who had expressed himself in the most unguarded terms against the conduct of the parliament, stood exposed to all the consequences of popular hatred.

Nor was it only in the capital that the flame of liberty once more burst forth; it blazed with equal strength in the provincial parliaments. Among various instances of this nature, the parliament of Grenoble passed a decree against *lettres de cachet*, the most odious engine of arbitrary power; and declared the execution of them within their jurisdiction, by any person, and under whatever authority, to be a capital crime.

The king had endeavoured to soothe the Parisians by new regulations of œconomy, and by continual retrenchments in his household: but these instances of attention, which once would have been received with the loudest acclamations, were now disregarded under their affliction for the absence of their parliament. His majesty, therefore, in order to regain the affections of his subjects, consented to restore that assembly; abandoning at the same time the stamp-duty and the territorial impost, which had been the sources of dispute. These measures were, however, insufficient to establish harmony between the court and the parliament. The necessities of the state still continued; nor could the deficiency of the revenue be supplied but by extraordinary resources, or a long course of rigid frugality. About the middle of November 1787, in a full meeting of the parliament, attended by all the princes of the blood, and the peers of France, the king entered the assembly, and proposed two edicts for their approbation: one was for a new loan of 450 millions, near 19 millions sterling: the other was for the re-establishment of the Protestants in all their ancient civil rights; a measure which had long been warmly recommended by the parliament, and which was probably now introduced to procure a better reception to the loan.

On this occasion, the king delivered himself in a speech of uncommon length, filled with professions of regard for the people, but at the same time strongly expressive of the obedience he expected to his edicts.

Louis probably imagined, that the dread of that banishment from which the members had been so lately recalled, would have ensured the acquiescence of the assembly; but no sooner was permission announced for every member to deliver his sentiment, than he was convinced that their spirits remained totally unsubdued. An animated debate took place, and was continued for nine hours; when the king, wearied by perpetual opposition, and chagrined at some freedoms used in their debates, suddenly rose, and commanded the edict to be registered without further delay. This measure was most unexpectedly opposed by the duke of Orleans first prince of the blood; who, considering it as an infringement of the rights of parliament, protested against the whole proceedings of the day as being thereby null and void. Though Louis could not conceal his astonishment and displeasure at this decisive step, he contented himself with repeating his orders; and immediately after quitting the assembly, retired to Versailles. On the king's departure, the parliament confirmed the protest of the duke of Orleans; and declared, that as their deliberations had been interrupted, they considered the whole business of that day as of no effect.

It was not to be supposed that Louis would suffer so bold an attack upon his power with impunity. Accordingly a letter was next day delivered to the duke of Orleans, commanding him to retire to Villars Cotterel, one of his seats about 15 leagues from Paris, and to receive no company there except his own family; at the same time the Abbe Sabatier and M. Freteau, both members of the parliament, and who had distinguished themselves in the debate, were seized under the authority of *lettres de cachet*, and conveyed, the first to the castle of Mont St Michael in Normandy, the last to a prison in Picardy. This act of despotism did not fail immediately to rouse the feelings of the parliament. On the following day they waited on the king, and expressed their astonishment and concern that a prince of the blood royal had been exiled, and two of their members imprisoned, for having declared in his presence what their duty and consciences dictated; and at a time when his majesty had announced that he came to take the sense of the assembly by a plurality of voices. The answer of the king was reserved, forbidding, and unsatisfactory; and tended to increase the resentment of the parliament. At the same time it did not prevent them from attending to the exigencies of the state; and convinced of the emergency, they consented to register the loan for 450 millions of livres, which had been the source of this unfortunate difference. This concession contributed to soften the mind of the king, and the sentence of the two magistrates was in consequence changed from imprisonment to exile; M. Freteau being sent to one of his country seats, and the Abbe Sabatier to a convent of Benedictines.

The parliament, however, was not to be soothed by that measure to give up the points against which they had originally remonstrated. In a petition conceived with freedom, and couched in the most animated language, they boldly reprobated the late acts of arbitrary violence, and demanded the entire liberation of the persons against whom they had been exerted. We have already noticed the fluctuating counsels of the court of

Verfailles ; and that Louis, as often as he was left to purfue his own inclinations, adopted meafures of reconciliation. On the prefent occafion, in the beginning of the year 1788, he recalled the duke of Orleans to court, who foon after obtained leave to retire to England ; and he permitted the return of the Abbe de Sabatiere and M. Freteau to the capital.

197
New re-
monftran-
ces.

The parliament however had not confined their demands to the liberation of thefe gentlemen ; but had alfo echoed the remonftrances of the parliament of Grenoble, and had loudly inveighed againft the execution of *lettres de cachet*. Thefe repeated remonftrances, mingled with personal reflections, feconded moft probably the fuggeltions of the queen, and Louis was once more infligated to meafures of feverity. Mef. d'Efpremevil and Monfambert, whofe bold and pointed harangues had preffed moft clofely on the royal dignity, were doomed to experience its immediate refentment. While a body of armed troops furrrounded the hotel in which the parliament were convened, Colonel Degout entered the affembly, and fecured the perfons of the obnoxious members, who were inflantly conducted to different prifons. This new inflance of arbitrary violence occafioned a remonftrance from parliament, which in boldnefs far exceeded all the former representations of that affembly. They declared they were now more ftrongly confirmed, by every proceeding, of the entire innovation which was aimed at in the conftitution. "But, fire," added they, "the French nation will never adopt the defpotic meafures to which you are advised, and whofe effects alarm the moft faithful of your magiftrates: we fhall not repeat the unfortunate circumftances which afflict us ; we fhall only represent to you with refpectful firmnefs, that the fundamental laws of the kingdom *muft* not be trampled upon, and that *your authority can only be efteemed fo long as it is tempered with juftice.*"

198
Affembly
of the No-
tables.

Language fo pointed and decifive, and which afferted the controlling power of the laws above the regal authority, could not fail of ferioufly alarming the king ; and with a view to diminifh the influence of parliament, it was determined again to convene the Notables. Accordingly, about the beginning of May, Louis appeared in that affembly ; and after complaining of the exceffes in which the parliament of Paris had indulged themfelves, and which had drawn down his reluctant indignation on a few of the members, he declared his refolution, inftead of annihilating them as a body, to recal them to their duty and obedience by a falutary reform. M. de la Moignon, as keeper of the feals, then explained his majefty's pleafure to eftablifh a *cour pleniere* or fupreme affembly, to be compofed of princes of the blood, peers of the realm, great officers of the crown, the clergy, marefchals of France, governors of provinces, knights of different orders, a deputation of one member from every parliament, and two members from the chambers of council, and to be fummoned as often as the public emergency, in the royal opinion, fhould render it requifite.

199
Oppofition
to the
king's pro-
pofals.

If the affembly of the Notables liftened in filent deference to the project of their fovereign, the parliament of Paris received it with every fymptom of averfion. That body ftrongly protefted againft the eftablifhment of any other tribunal ; and declared their final refolution not to affift at any deliberations in the fupreme

France.

affembly which his majefty prepared to inflitute. A more unexpected mortification occurred to the king in the oppofition of feveral peers of the realm : thefe expreffed their regret at beholding the fundamental principles of the conftitution violated ; and while they were lavish in their profeltions of attachment to the perfon of their fovereign, concluded with apologifing for not entering on thofe functions affigned them in the plenary court, as being inconfiftent with the true interefts of his majefty, which were infeparable from thofe of the nation.

The flame quickly fpread throughout the more diftant provinces ; at Rennes in Brittany, and Grenoble in Dauphiné, the people broke out into acts of the moft daring outrage. In the latter city feveral hundreds of the inhabitants perifhed in a conflict with the military ; they yet maintained their ground againft the regulars ; and the commanding officer, at the intreaties of the firft prefident, readily withdrew his troops from a conteft into which he had entered with reluctance. The different parliaments of the kingdom at the fame time expreffed their feelings in the moft glowing language ; and ftrongly urged the neceffity of calling together the fates-general, the lawful council of the kingdom, as the only means of reftoring the public tranquillity.

Louis now plainly faw, that a compliance with the public wifhes for the re-eftablifhment of the States-general was abfolutely neceffary, in order to avoid the calamities of a civil war which impended upon his refufal. In that event he muft have expected to have encountered the majority of the people, animated by the exhortations and example of their magiftrates: the peers of the realm had expreffed the ftrongeft difapprobation of his meafures ; nor could he even depend any longer on the fupport of the princes of the blood : but what afforded moft ferious matter of alarm was the fpirit lately difplayed among the military, who, during the difturbances of the provinces, had reluctantly been brought to draw their fwords againft their countrymen ; and many of whofe officers, fo recently engaged in eftablifhing the freedom of America, publicly declared their abhorrence of defpotifm.

It was not, however, till after many a painful ftruggle that Louis could refolve to reftore an affembly, whofe influence muft naturally overfhadow that of the crown, and whofe jurifdiction would confine within narrow limits the boundlefs power he had inherited from his predeceffor. In the two preceding reigns, the fates-general had been wholly difcontinued ; and though the queen-regent, during the troubles that attended the minority of Louis XIV. frequently expreffed her intention of calling them together, fhe was constantly diffuaded by the representations of Mazarin. It is probable, that the prefent monarch ftill flattered himfelf with the hopes of being able to allure the members of that affembly to the fide of the court ; and having employed them to eftablifh fome degree of regularity in the finances, and to curb the fpirit of the parliaments, that he would again have difmiffed them to obfcurity.

Under thefe impreffions an arret was iffued in Auguft, fixing the meeting of the fates-general to the firft of May in the enfuing year ; and every ftep was taken to fecure the favourable opinion of the public during

ral.

France.

during the interval. New arrangements took place in the administration; and M. Necker, whom the confidence of the people had long followed, was again introduced into the management of the finances; the torture, which by a former edict had been restricted in part, was now entirely abolished; every person accused was allowed the assistance of counsel, and permitted to avail himself of any point of law; and it was decreed, that in future sentence of death should not be passed on any person, unless the party accused should be pronounced guilty by a majority at least of three judges.

The time appointed for the convention of the states-general was now approaching; and the means of assembling them formed a matter of difficult deliberation in the cabinet. The last meeting, in 1614, had been convened by application to the bailiwicks. But this mode was liable to several strong objections; the bailiwicks had been increased in number and jurisdiction, several provinces having since that period been united to France; and the numbers and quality of the members were no less an object of serious attention: it was not till the close of the year, therefore, that the proposal of M. Necker was adopted, which fixed the number of deputies at 1000 and upwards, and ordained that the representatives of the third estate or commons should equal in number those of the nobility and clergy united.

The eyes of all Europe were now turned on the states-general; but the moment of that assembly's meeting was far from auspicious: The minds of the French had long been agitated by various rumours; the unanimity that had been expected from the different orders of the states was extinguished by the jarring pretensions of each; and their mutual jealousies were attributed by the suspicions of the people to the intrigues of the court, who were supposed already to repent of the hasty assent which had been extorted. A dearth that pervaded the kingdom increased the general discontent; and the people, pressed by hunger, and inflamed by resentment, were ripe for revolt. The sovereign also, equally impatient of the obstacles he continually encountered, could not conceal his chagrin; while the influence of the queen in the cabinet was again established, and was attended by the immediate removal of M. Necker. The dismissal of that minister, so long the favourite of the public, was the signal of open insurrection, the Parisians assembled in myriads; the guards refused to oppose and stain their arms with the blood of their fellow-citizens; the count d'Artois and the most obnoxious of the nobility, thought themselves happy in eluding by flight the fury of the insurgents; and in a moment a revolution was accomplished, the most remarkable perhaps of any recorded in history.

But that we may not take up room with an imperfect or dubious narration, we must defer giving any detail of particulars till some future opportunity, when the tide of innovation and reform now prevailing in that kingdom shall have subsided, and the government in one shape or another have attained a footing that promises to be durable. The objects of the revolution are many and arduous; and it is impossible to say, whether we may have yet to record their entire consummation; or to recount a new train of events

tending to shake the *republican* fabric, and to restore the influence and the splendor of *royalty*, though the sceptre of *despotism* should be swayed no more. In short, it is wished to have an opportunity, not only of detailing the progress, but of surveying the final issue, of the event in question. Such an opportunity may perhaps be afforded by the time we arrive at the article *REVOLUTION*, where there will be occasion to advert to the principal events which under that denomination have formed eras in the history of different nations, and when of course this great æra in the annals of France will claim a share of attention proportioned to its magnitude and importance.

The air in France is pure, healthy, and temperate. The kingdom is so happily seated in the middle of the temperate zone, that some make it equal to Italy, with regard to the delightfulness of the landscapes, and the fertility of the soil: however, it is certainly much more healthful. The soil produces corn, wine, oil, and flax, in great abundance; and they have very large manufactures of linen, woollen, silk, and lace. They have a foreign trade to Spain, Italy, Turkey, and to the East and West Indies. They themselves reckon that the number of the inhabitants is 20,000,000. The kingdom is watered by a great number of rivers; of which the four principal are, the Loire, the Seine, the Rhone, and the Garonne or Gironde. The monarchy was absolute before the late revolution; and the subjects were extremely devoted to their prince even under the greatest acts of oppression. The parliaments, for a long series of years past, had little or no share in the government; and their business was confined to the passing and registering the arrets or laws which the king was pleased to send them: however, they did not always pay a blind obedience to the king, and we have had frequent instances of their making a noble stand. In civil causes these parliaments were the last resort, provided the court did not interpose. That of Paris was the most considerable, where the king used often to come in person to see his royal acts recorded. It consisted of the dukes and peers of France (when dukes and peers existed), besides the ordinary members, who purchased their places; and they only took cognizance of causes belonging to the crown. The revenues of the crown arose from the *taille* or land-tax, and the aids which proceed from the customs and duties on all merchandize, except salt, the tax upon which commodity is called the *gabelles**: besides these, there were other taxes; as, the capitation or poll-tax; the tenths of all estates, offices, and employments; besides the 15th penny, from which neither the nobility nor clergy were exempted. Add to these, the tenths and free-gifts of the clergy, who were allowed to tax themselves; and, lastly, crown-rents, fines, and forfeitures, which brought in a considerable sum. All these are said to have amounted to 15,000,000 Sterling a-year. But the king had other resources and ways of raising money, whenever necessity obliged him. The army, in time of peace, is said to consist of 200,000 men, and in time of war of 400,000; among whom are many Swiss, Germans, Scots, Irish, Swedes, and Danes. There was till lately no religion allowed in France but the Roman Catholic, ever since the revocation of the edict of Nantz in 1685; though they are not so devoted to the pope as other nations of that communion,

France.

nor had they ever any inquisition among them. The Roman Catholic is still the established religion; but with ample toleration to the Protestants, who are now even not excluded from places of the highest trust in the state.

Ile of FRANCE, a province of France, so called, because it was formerly bounded by the river Seine, Marne, Oise, Aisne, and Ourque. It comprehends, besides Paris, the Beauvoisis, the Valois, the county of Senlis, the Vexin, the Hurepois, the Gatinois, the Multien, the Goele, and the Mentois. Paris is the capital.

FRANCESCA (Peter), an eminent Florentine painter of night-pieces and battles, was employed to paint the Vatican. He also painted portraits, and wrote on arithmetic and geometry. He died in 1458.

FRANCFORT *on the MAIN*, an Imperial and Hanseatic town of Franconia in Germany, where the emperors were formerly elected. It is a handsome, strong, and rich place, and has a great deal of commerce. Here the golden bull is preserved, which is the original of the fundamental laws of the empire. It is seated in a fine fertile plain; and well fortified with a double ditch, bastions, redoubts, and ravelins. The streets are remarkably wide, and the houses handsomely built. It has great conveniency for carrying on an extensive trade with the other parts of Germany, by means of the navigable river which runs throughout it. The suburbs is called *Saxon hausen*, and joined to the town by a stone bridge built over the Main. E. Long. 8. 40, N. Lat 49. 55.

FRANCFORT, *on the Oder*, a rich and handsome town of Germany, in the middle Marche of Brandenburg, formerly imperial, but now subject to the king of Prussia. E. Long. 15. 0. N. 52. 20.

FRANCHE-COMTE, a province of France, bounded on the south and west by Champagne and Burgundy; on the north by Lorraine; and to the east by the earldom of Mumplegard, and Switzerland. It is in length from north to south about 30 leagues; in breadth about 20. It is partly flat and partly hilly. The flat country is fruitful in grain, wine, hemp, and pasture; and the hilly country abounds in cattle, producing also some wine and corn, copper, lead, iron, and silver ores, mineral waters, and quarries of stone, marble, and alabaster.

FRANCHISE, in law. *Franchise* and *liberty* are used as synonymous terms; and their definition is, "a royal privilege or branch of the king's prerogative, subsisting in the hands of a subject." Being therefore derived from the crown, they must arise from the king's grant; or, in some cases, may be held by prescription, which, as had been frequently said, presupposes a grant. The kinds of them are various, and almost infinite. We shall here briefly touch upon some of the principal; premising only, that they may be vested in either natural persons or bodies-politic; in one man, or in many; but the same identical franchise, that has before been granted to one, cannot be bestowed on another, for that would prejudice the former grant.

To be a county-palatine, is a franchise vested in a number of persons. It is likewise a franchise for a number of persons to be incorporated and subsist as a body-politic; with a power to maintain perpetual succession, and do other corporate acts: and each indivi-

dual member of such corporation is also said to have a franchise or freedom. Other franchises are, to hold a court-leet: to have a manor or lordship; or, at least, to have a lordship paramount: to have waifs, wrecks, estrays, treasure-trove, royal fish, forfeitures, and deodands: to have a court of one's own, or liberty, of holding pleas and trying causes: to have the cognizance of pleas; which is a still greater liberty, being an exclusive right, so that no other court shall try causes arising within that jurisdiction: to have a bailiwick, or liberty exempt from the sheriff of the county; wherein the grantee only, and his officers, are to execute all process: to have a fair or market; with the right of taking toll, either there or at any other public places, as at bridges, wharfs, or the like; which tolls must have a reasonable cause of commencement (as in consideration of repairs, or the like), else the franchise is illegal and void: or lastly, to have a forest, chase, park, warren, or fishery, endowed with privileges of royalty. See CHASE, FOREST, &c.

FRANCHISE is also used for an asylum or sanctuary, where people are secure of their persons, &c. Churches and monasteries in Spain are franchises for criminals; so were they anciently in England, till they were abused to such a degree that there was a necessity for abolishing the custom. One of the most remarkable capitulars made by Charlemagne in his palace of Heristal in 779, was that relating to the franchises of churches. The right of franchise was held so sacred, that even the less religious kings observed it to a degree of scrupulousness; but to such excess in time was it carried, that Charlemagne resolved to reduce it. Accordingly he forbade any provision being carried to criminals retired into churches for refuge.

FRANCHISE *of Quarters*, is a certain space or district at Rome, wherein are the houses of the ambassadors of the princes of Europe; and where such as retire cannot be arrested or seized by the sbirri or serjeants, nor persecuted at law. The people of Rome look on this as an old usurpation and a scandalous privilege, which ambassadors, out of a jealousy of their power, carried to a great length in the 15th century, by enlarging insensibly the dependencies of their palaces or houses, within which the right of franchise was anciently confined. Several of the popes, Julius III. Pius XIV. Gregory XIII. and Sixtus V. published bulls and ordinances against this abuse; which had rescued so considerable a part of the city from their authority, and rendered it a retreat for the most abandoned persons. At length Innocent XI. expressly refused to receive any more ambassadors but such as would make a formal renunciation of the franchise of quarters.

FRANCIA (Francesco), a celebrated Bolognese painter, born in 1350. He was first a goldsmith or jeweller, afterwards a graver of coins and medals; but applying at last to painting, obtained great reputation by his works, particularly by a piece of St Sebastian, whom he had drawn bound to a tree with his hands tied over his head. He pined himself into a consumption, by despairing to equal Raphael; and died in 1518.

FRANCIS I. king of France, the rival of the emperor Charles V. and the restorer of learning and politeness in France. See (*History* of) FRANCE.

FRANCIS (Philip), a very ingenious writer, of Irish

Franchise
|
Francis.

Plate CIII.

Franciscans.

extraction, if not born in that kingdom. His father was a dignified clergyman in Ireland, being dean of some cathedral; and our author, his son, was also bred to the church, and had a doctor's degree conferred on him. He was more distinguished as a translator than as an original writer. His versions of Horace and Demosthenes have been justly valued: the former is accompanied with notes, and is perhaps as complete and useful a work of its kind as hath yet appeared. He was also a considerable political writer; and in the beginning of the present reign is supposed to have been employed by the government: for which service, he was promoted to the rectory of Barrow in Suffolk, and to the chaplainship of Chelsea hospital. He was also the author of two tragedies, Eugenia, and Constantia; but, as a dramatic writer, not very successful. He died at Bath in March 1773; leaving a son, who was then one of the supreme council at Bengal.

FRANCISCANS, in ecclesiastical history, are religious of the order of St Francis, founded by him in the year 1209. Francis was the son of a merchant of Assisi, in the province of Umbria, who, having led a dissolute life, was reclaimed by a fit of sickness, and afterwards fell into an extravagant kind of devotion, that looked less like religion than alienation of mind. Soon after this, viz. in the year 1208, hearing the passage repeated, Matt. x. 9. 10. in which Christ addresses his apostles, *Provide neither gold, nor silver, &c.* he was led to consider a voluntary and absolute poverty as the essence of the gospel, and to prescribe this poverty as a sacred rule both to himself and to the few that followed him. This new society, which appeared to Innocent III. extremely adapted to the present state of the church, and proper to restore its declining credit, was solemnly approved and confirmed by Honorius III. in 1223, and had made a considerable progress before the death of its founder in 1226. Francis, through an excessive humility, would not suffer the monks of his order to be called *fratres*, i. e. brethren or friars, but *fraterculi*, i. e. little brethren, or friars-minor, by which denomination they still continue to be distinguished. They are also called *grey friars*, on account of the colour of their clothing, and *cordeliers*, &c. The Franciscans and Dominicans were zealous and active friends to the papal hierarchy, and, in return, were distinguished by peculiar privileges and honourable employments. The Franciscans, in particular, were invested with the treasure of ample and extensive indulgences; the distribution of which was committed to them by the popes, as a means of subsistence, and a rich indemnification for their voluntary poverty. In consequence of this grant, the rule of the founder, which absolutely prohibited both personal and collective property, for that neither the individual nor the community were to possess either fund, revenue, or any worldly goods, was considered as too strict and severe, and dispensed with soon after his death. In 1231, Gregory IX. published an interpretation of this rule, mitigating its rigour; which was farther confirmed by Innocent IV. in 1245, and by Alexander IV. in 1247. These milder alterations were zealously opposed by a branch of the Franciscans called the *spiritual*; and their complaints were regarded by Nicholas III. who, in 1279, published a famous constitution, confirming the

rule of St Francis, and containing an elaborate explanation of the maxims it recommended, and the duties it prescribed. In 1287, Matthew of Aqua Sparta, being elected general of the order, discouraged the ancient discipline of the Franciscans, and indulged his monks in abandoning even the appearance of poverty; and this conduct inflamed the indignation of the spiritual or austere Franciscans; so that from the year 1290, seditions and schisms arose in an order that had been so famous for its pretended disinterestedness and humility. Such was the enthusiastic phrenzy of the Franciscans, that they impiously maintained, that the founder of their order was a second Christ, in all respects similar to the first; and that their institution and discipline were the true gospel of Jesus. Accordingly, Albizi, a Franciscan of Pisa, published a book in 1383, with the applause of his order, intitled, *The Book of the Conformities of St Francis with Jesus Christ*. In the beginning of this century, the whole Franciscan order was divided into two parties; the one, embracing the severe discipline and absolute poverty of St Francis, were called *spirituals*; and the other, who insisted on mitigating the austere injunctions of their founder, were denominated *brethren of the community*. These wore long, loose, and good habits, with large hoods; the former were clad in a strait, coarse, and short dress, pretending that this dress was enjoined by St Francis, and that no power on earth had a right to alter it. Neither the moderation of Clement V. nor the violence of John XXII. could appease the tumult occasioned by these two parties: however, their rage subsided from the year 1329. In 1368 these two parties were formed into two large bodies, comprehending the whole Franciscan order, which subsist to this day; viz. the *conventual brethren*, and the *brethren of the observance or observation*, from whom sprung the capuchins and recollects. The general opinion is, that the Franciscans came into England in the year 1224, and had their first house at Canterbury, and their second at London; but there is no certain account of their being there till king Henry VII. built two or three houses for them at the dissolution of the monasteries, the conventual Franciscans had about 55 houses, which were under seven custodies or wardenships; viz. those of London, York, Cambridge, Bristol, Oxford, Newcastle, and Worcester.

FRANCONIA, a circle of the German empire, lying between Bohemia on the east, and the electorate of Mentz on the west. Its capital is Nuremberg; and from this country the Franks, who conquered and gave name to the kingdom of France, are said to have come.

FRANGULA, in botany. See RHAMNUS.

FRANK LANGUAGE, *Lingua Franca*, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts and ports of the Levant, composed of Italian, Spanish, French, Vulgar Greek, and other languages.

FRANK, or *Franc*, an ancient coin, either of gold or silver, struck and current in France. The value of the gold Frank was something more than that of the gold crown; the silver Frank was a third of the gold one: this coin has been long out of use, tho' the term is still retained as the name of a money of account; in which sense it is equivalent to the livre, or 20 sols.

Franciscans
||
Frank.

Frank

FRANK, or *Franc*, meaning literally *free* from charges and impositions, or exempt from public taxes, has various significations in the ancient English customs.

FRANK *Almoigne*, (*libera eleemosyna*), or "free alms;" a tenure of a spiritual nature, whereby a religious corporation, aggregate or sole, holdeth lands of the donor to them and their successors for ever. The service which they were bound to render for these lands was not certainly defined: but only in general to pray for the souls of the donor and his heirs, dead or alive; and therefore they did no fealty (which is incident to all other services but this), because this divine service was of an higher and more exalted nature. This is the tenure by which almost all the ancient monasteries and religious houses held their lands; and by which the parochial clergy, and very many ecclesiastical and eleemosynary foundations, hold them at this day; the nature of the service being upon the reformation altered and made conformable to the purer doctrines of the church of England. It was an old Saxon tenure; and continued under the Norman revolution, through the great respect that was shown to religion and religious men in ancient times. This is also the reason that tenants in frankalmoign were discharged of all other services except the *trinoda necessitas*, of repairing the highways, building castles, and repelling invasions; just as the druids, among the ancient Britons, had *omnium rerum immunitatem*. And even at present this is a tenure of a very different nature from all others; being not in the least feudal, but merely spiritual. For, if the service be neglected, the law gives no remedy by distress, or otherwise, to the lord of whom the lands are holden; but merely a complaint to the ordinary or visitor to correct it.

FRANK-*Chafe* is defined to be a liberty of free chace, whereby persons that have lands within the compass of the same, are prohibited to cut down any wood, &c. out of the view of the forester.

FRANK-*Fee*, signifies the same thing as holding lands and tenements in fee-simple; that is, to any person and his heirs, and not by such a service as is required by ancient demesne, but is pleaded at common law. See FEE.

FRANK-*Law*, a word applied to the free and common law of the land, or the benefit a person has by it.

He that for any offence loseth this frank-law, incurs these inconveniences, viz. He may not be permitted to serve on juries, nor used as an evidence to the truth; and if he has any thing to do in the king's court, he must not approach it in person, but appoint his attorney; his lands, goods, and chattels, shall be seized into the king's hands; and his lands be estreated, his trees rooted up, and his body committed to custody.

FRANK-*Marriage*, in law, is where tenements are given by one man to another, together with a wife, who is the daughter or cousin to the donor, to hold in frank-marriage. By such gift, though nothing but the word *frank-marriage* is expressed, the donees shall have the tenements to them, and the heirs of their two bodies begotten; that this, they are tenants in special tail. For this one word, *frank-marriage*, denotes, *ex vi termini*, not only an inheritance, like the word *frankalmoigne*, but likewise limits that inheritance; supply-

I

ing not only words of descent, but of procreation also. Such donees in frank-marriage are liable to no service but fealty; for a rent reserved therein is void until the fourth degree of consanguinity be past between the issues of the donor and donee.

FRANK-*Pledge*, in law, signifies a pledge or surety for the behaviour of freemen.

According to the ancient custom of England, for the preservation of the public peace, every free-born man, at the age of fourteen, except religious persons, clerks, knights, and their eldest sons, was obliged to give security for his truth and behaviour towards the king and his subjects, or else be imprisoned. Accordingly, a certain number of neighbours became interchangeably bound for each other, to see each person of their pledge forth coming at all times, or to answer for the offence of any one gone away; so that whenever any person offended, it was presently inquired in what pledge he was, and there the persons bound either produced the offender in 31 days, or made satisfaction for his offence.

FRANK-*Tenement*. See TENURE.

FRANKED LETTERS. The privilege of letters coming free of postage to and from members of parliament was claimed by the English house of commons in 1660, when the first legal settlement of the present post office was made; but afterwards dropped, upon a private assurance from the crown, that this privilege should be allowed the members. And accordingly a warrant was constantly issued to the post master-general, directing the allowance thereof to the extent of two ounces in weight: till at length it was expressly confirmed by 4 Geo. III. c. 14. which adds many new regulations, rendered necessary by the great abuses crept into the practice of franking; whereby the annual amount of franked letters had increased from L. 23,600 in the year 1715, to L. 170,700 in the year 1763. Further regulations have since taken place; in particular, franks must be dated (the month written at length), and put into the office the same day; notwithstanding which, the revenue still loses by this privilege above L. 80,000 *per annum*.

FRANKEN (Franciscus), commonly called *Old Frank*, a famous Flemish painter, supposed to have been born about the year 1544; but though his works are well known, very few of the circumstances of his life have been transmitted to posterity. This master painted historical subjects from the Old and New Testaments; and was remarkable for introducing a great number of figures into his compositions, which he had the address to group very distinctly. Vandyck often commended his works, and thought them worthy of a place in any collection.

FRANKEN (Franciscus), distinguished by the name of *Young Frank*, was the son of the former, born in the year 1580. He was instructed by his father; whose style he adopted so closely, that their works are frequently mistaken. When he found himself sufficiently skilled at home, he travelled into Italy for improvement in colouring; and, on his return, his works were much coveted. The most capital performance of this painter are, a scriptural performance in the church of Notre-dame at Antwerp; and an excellent picture, in a small size, of Solomon's idolatry. Young Frank died in 1642.

FRANK-

Frank.

Frankendal ||
Franks. FRANKENDAL, a strong town of Germany, in the dominions of the Elector Palatine. It was taken by the Spaniards in 1623, by the Swedes in 1632, and burnt by the French in 1688. E. Long. 8. 29. N. Lat. 49. 28.

FRANKENIA, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is quinquefid, and funnel-shaped; the petals five; the stigma sexpartite; the capsule unilocular and trivalvular.

FRANKINCENSE. See INCENSE.

FRANKLIN (Dr Benjamin). See APPENDIX.

FRANKLIN (Thomas), D. D. chaplain in ordinary to his Britannic majesty, was the son of Richard Franklin, well known as the printer of an anti-ministerial paper called *The Craftsman*; in the conducting of which he received great assistance from Lord Bolingbroke, Mr Pulteney, and other excellent writers, who then opposed Sir Robert Walpole's measures. By the advice of the second of these gentlemen, young Franklin was devoted to the church, with a promise of being provided for by the patriot; who afterwards forgot his undertaking, and then entirely neglected him. He was educated at Westminster-school; from whence he went to the university of Cambridge, where he became fellow of Trinity College, and was some time Greek professor. In Dec. 1758, he was instituted vicar of Ware and Thundridge; which, with the lectureship of St Paul, Covent-Garden, and a chapel in Queen-street, were all the preferments he held till he obtained the rectory of Brasted in Kent. This gentleman was possessed of no inconsiderable share of learning and poetical abilities, and was long a favourite in the literary world. His translations of Phalaris, Sophocles, and Lucian, equally evince his learning and his genius, as they are not more distinguished for fidelity in the version, than congeniality with the spirit of the admirable originals. Dr Franklin, like Mr Foote, suffered a translation from the French to be printed in his name; but the Orestes and Electra are supposed to be all that were really by him. It was a translation of Voltaire's works, to which also Dr Smollet's name appears. His own dramatic compositions, of which the principal are the tragedies of The Earl of Warwick and Matilda, are universally known, and deservedly esteemed by the public; so that his death, which happened March 15, 1784, may be considered as a loss to the republic of letters.

FRANKS, FRANCS, FRANKIS, or FRANQUIS, a name which the Turks, Arabs, Greeks, &c. give to all the people of the western parts of Europe. The appellation is commonly supposed to have had its rise in Asia, at the time of the croisades; when the French made the most considerable figure among the croisades: from which time the Turks, Saracens, Greeks, Abyssinians, &c. used it as a common term for all the Christians of Europe; and called Europe itself *Frankistan*. The Arabs and Mahometans, says M. d'Herbelot, apply the term *Franks* not only to the French (to whom the name originally belonged), but also to the Latins and Europeans in general.

But F. Goar, in his notes on Condinus, cap. 5. n. 43. furnishes another origin of the appellation *Franks*, of greater antiquity than the former. He observes, that

VOL. VII.

the Greeks at first confined the name to the *Franci*, i. e. the German nations, who had settled themselves in France or Gaul; but afterwards they gave the same name to the Apulians and Calabrians, after they had been conquered by the Normans; and at length the name was farther extended to all the Latins.

In this sense is the word used by several Greek writers; as Comnenus, &c. who, to distinguish the French, call them the *western Franks*. Du-Cange adds, that about the time of Charlemagne, they distinguished eastern France, western France, Latin or Roman France, and German France, which was the ancient France, afterwards called *Franconia*.

FRASCATI, or FRESCATI. See FRESCATI.

FRASERSBURGH, a small sea-port town in the county of Aberdeen, situated in a cheap and populous country, on the point of land called *Kinnaird's Head*, which is the southern extremity of the Murray firth. It has a small good harbour, made and kept up at a considerable expence by the proprietor and the town, and well adapted for building of small vessels. According to the tide, there are 11 to 15 feet water within the harbour, and 20 feet immediately without at spring-tides: without is a tolerable road for shipping, in a bay nearly a league in length and half a league in depth, with good anchorage in a sandy bottom. Vessels of about 200 tons burden enter the harbour at present. Frasersburgh contains about 1000 inhabitants, and is well situated for trade with the east coast of Europe. The town has lately advanced considerably, and requires only encouragement to render it a port of some consequence on the coast of Scotland. At present it carries on a small trade to the east sea, several manufactories are forming in its neighbourhood, and the port is well adapted for building of small vessels.

FRATERNAL, something belonging to the relation of brother.

FRATERNAL Affection is the love and attachment subsisting among, or due to one another by, children of the same family.

Though all mankind sprung from the same head, and are bound to cultivate a mutual good-will to each other; yet this duty is not so obvious and striking as that which is incumbent on those who belong to the same family. Nothing can approach nearer to self-love than fraternal affection: and there is but a short remove from our own concerns and happiness, to theirs who come from the same stock, and are partakers of the same blood. Nothing, therefore, can be more horrible than discord and animosity among members so allied; and nothing so beautiful as harmony and love.

This relation is formed by nature, not by choice; and though it has many things in common with, yet it is prior to, the obligations of friendship: consequently nature and reason dictate that there should be a peculiar affection between brethren. We are not obliged, however, to make a brother or sister an intimate or bosom friend in preference to one who is not akin. Diversity of temper, and want of suitable qualifications, may render it unsafe and improper. But where friendship and fraternity meet in the same persons, such a conjunction adds a lustre to the relation.

Among brethren, an hearty benevolence, an ardent concern for each other's welfare, a readiness to serve

3 L

and

Frascati

||
Fraternal

Fraternity and promote it, are the peculiar offices of this relation; and though friends are to have their share, yet the claim of kindred is first and ordinarily strongest. "Necessaria præsidia vitæ debentur iis maxime (says Cicero), quos ante dixi (*i. e.* propinquis); vita autem, victusque communis, concilia, sermones, &c. in amicitiiis vigent maxime." *De Officiis.*

FRATERNITY, BROTHERHOOD, the relation or union of brothers, friends, partners, associates, &c.

FRATERNITY, in a civil sense, is used for a guild, association, or society of persons, united into a body, for some common interest or advantage. See **COMPANY** and **GUILD**.

FRATERNITY, in the Roman Catholic countries, signifies a society for the improvement of devotion. Of these there are several sorts: as, 1. The fraternity of the rosary, founded by St Dominic. It is divided into two branches, called the *common rosary*, and the *perpetual rosary*; the former of whom are obliged to confess and communicate every first Sunday in the month, and the latter to repeat the rosary continually. 2. The fraternity of the scapulary, whom the blessed Virgin, according to the sabbatine bull of Pope John XXII. has promised to deliver out of hell the first Sunday after their death. 3. The fraternity of St Francis's girdle are clothed with a sack of grey colour, which they tie with a cord; and in processions walk barefooted, carrying in their hands a wooden cross. 4. That of St Austin's leathern girdle, comprehends a great many devotees. Italy, Spain, and Portugal, are the countries where one sees the greatest number of these fraternities, some of which assume the name of *arch-fraternities*. Pope Clement VII. instituted the arch-fraternity of charity, which distributes bread every Sunday among the poor, and gives portions to 40 poor girls on the feast of St Jerom their patron. The fraternity of death, buries such dead as are abandoned by their relations, and causes masses to be celebrated for them.

FRATRES ARVALES. See **ARVALES**.

FRATRIAGE, the partition among brothers, or coheirs, coming to the same inheritance or succession.

FRATRICELLI, in ecclesiastical history, an enthusiastic sect of Franciscans, which rose in Italy, and particularly in the marquisate of Ancona, about the year 1294. The word is an Italian diminutive, signifying *fraterculi*, or "little brothers;" and was here used as a term of derision, as they were most of them apostate monks, whom the Italians call *fratelli*, or *fratricelli*. For this reason the term *fratricelli*, as a nick-name, was given to many other sects, as the Catharists, the Waldenses, &c. however different in their opinions and in their conduct. But this denomination applied to the austere part of the Franciscans was considered as honourable. See **FRANCISCANS**.

The founders were P. Mauro, and P. de Fossombroni, who having obtained of pope Celestin V. a permission to live in solitude, after the manner of hermits, and to observe the rule of St Francis in all its rigour, several idle vagabond monks joined them, who, living after their own fancies, and making all perfection to consist in poverty, were soon condemned by pope Boniface VIII. and his successor, and the inquisitors ordered to proceed against them as heretics: which commission they executed with their usual barbarity.

Upon this, retiring into Sicily, Peter John Oliva de Serignan had no sooner published his Comment on the Apocalypse, than they adopted his errors. They held the Romish church to be Babylon, and proposed to establish another far more perfect one. They were condemned afresh by pope John XXII. In consequence of whose cruelty they regarded him as the true antichrist; but several of them returning into Germany, were sheltered by Lewis, duke of Bavaria, the emperor.

There are authentic records, from which it appears, that no less than 2000 persons were burnt by the inquisition, from the year 1318 to the time of Innocent VI. for their inflexible attachment to the poverty of St Francis. The severities against them were again revived towards the close of the 15th century by pope Nicolas V. and his successors. However, all the persecutions which this sect endured were not sufficient to extinguish it; for it subsisted until the times of the reformation in Germany, when its remaining votaries adopted the cause and embraced the doctrine and discipline of Luther. And this has led Popish writers to charge the Fratricelli with many enormities, some of which are recounted by M. Bayle, art. *Fratricelli*.

The Fratricelli had divers other denominations: they were called *fratricelli*, according to some, because they lived in community, in imitation of the primitive Christians, or rather through the humility of the founder of the Franciscan order, to which the Fratricelli originally belonged; *dulcini*, from one of their doctors; *Bizochi*, *Beguins*, and *Beghardi*.

FRATRICIDE, the crime of murdering one's brother. See **PARRICIDE**.

FRAUD, in law, signifies deceit in grants, or conveyances of lands, &c. or in bargains and sales of goods, &c. to the damage of another person.

A fraudulent conveyance of lands or goods to deceive creditors, as to creditors is void in law. And a fraudulent conveyance in order to defraud purchasers, is also to such purchasers void; and the persons justifying or putting off such grants as good, shall forfeit a year's value of the lands, and the full value of the goods and chattels, and shall likewise be imprisoned. See **CHEATING**.

FRAUSTADT, a town of Silesia, on the frontiers of Poland, remarkable for a battle gained by the Swedes over the Saxons in 1706. E. Long. 15. 50. N. Lat. 51. 45.

FRAXINELLA, in botany. See **DICTAMNUS**.—It is remarkable of this odorous plant, that, when in full blossom, the air which surrounds it in a still night, may be inflamed by the approach of a lighted candle. Dr Watson doubts whether this inflammability proceeds from an inflammable air which is exhaled by the plant, or from some of the finer parts of the essential oil of the plant being dissolved in the common atmospheric air. The latter is the most probable supposition; for were it the pure inflammable air, as Mr Cavallo observes, it would, on account of its small specific gravity, leave the plant as soon as it was produced. Common air acquires the property of becoming inflammable, by being transmitted through several essential oils.

FRAXINUS, the **ASH**: A genus of the diœcia order, belonging to the polygamia class of plants; and in the natural method ranking under the 44th order, *Sepiaria*.

Fratricide
||
Fraxinus.

Fray

Freats.

Sepiaria. There is no hermaphrodite calyx, or it is quadripartite; and there is either no corolla, or it is tetrapetalous: there are two stamina; one pistil; one lanceolated seed; and the pistil of the female is lanceolated. There are six species; of which the most useful is the common ash, which is so well known, that it needs no description. If a wood of these trees is rightly managed, it will turn greatly to the advantage of the owner: for, by the underwood, which will be fit to cut every eight or ten years, there will be a continual income, more than sufficient to pay the rent of the ground and all other charges; and still there will be a stock preserved for timber, which in a few years will be worth 40s. or 50s. per tree. This tree flourishes best in groves, but grows very well in rich soil in open fields. It bears transplanting and lopping. In the north of England they lop the tops of these trees to feed the cattle in autumn when the grass is on the decline; the cattle peeling off the bark as food. The wood hath the singular property of being nearly as good when young as when old. It is hard and tough, and is much used to make the tools employed in husbandry. The ashes of the wood afford very good potash. The bark is used in tanning calfskin. A slight infusion of it appears of a pale yellowish colour when viewed betwixt the eye and the light; but when looked down upon, or placed betwixt the eye and an opaque object, appears blue. This blueness is destroyed by the addition of an acid, but recovered by alkalies. The seeds are acrid and bitter. In the church-yard of Lochaber in Scotland, Dr Walker measured the trunk of a dead ash tree, which at five feet from the surface of the ground was 58 feet in circumference.—Horses, cows, sheep, and goats eat it; but it spoils the milk of cows, so that it should not be planted in dairy farms.

FRAY literally signifies to fret; as cloth or stuff does by rubbing, or over-much wearing.

Among hunters a deer is said to fray his head, when he rubs it against a tree, to cause the skins of his new horns to come off.

FREA, or FRIGGA, the wife of Odin, was, next to him, the most revered divinity among the Heathen Saxons, Danes, and other northern nations. As Odin was believed to be the father, Frea was esteemed the mother of all the other gods. In the most ancient times, Frea was the same with the goddesses Herthus, or Earth, who was so devoutly worshipped by the Angli and other German nations. But when Odin, the conqueror of the north, usurped the honours due only to the true Odin, his wife Frea usurped those which had been formerly paid to mother Earth. She was worshipped as the goddess of love and pleasure, who bestowed on her votaries a variety of delights, particularly happy marriages and easy child-births. To Frea the sixth day of the week was consecrated, which still bears her name.

FREAM, a name given by farmers to ploughed land worn out of heart, and laid fallow till it recover.

FREATS, or FREITS, a term used in Scotland for *ill omens*, and sometimes denoting accidents supernaturally unlucky. King James VI. in his *Dæmonologie*, MS. pen. Edit. B. 1. ch. III. p. 13. "But I pray you forget not likewise to tell what are the Devill's rudimentis? E. His rudimentis I call first in generall

all that quhilk is called vulgairlie the virtu of woode, herbe, and staine; quhilk is used by unlawful charmis without natural causis. As lykeways all kynd of prattiques, *freitis*, or utherlyk extraordinair actions, quhilk cannot abyde the trew twiche of naturall reason." It occurs again in the same sense in p. 14. marg. note; and in p. 41. speaking of Sorcerers: "And in generall that naime was gevin thaim for using of sic chairmis and *freitis*, as that craft teachis thaim."

FRECKLES, LENTIGINES, spots of a yellowish colour, of the bigness of a lentile-seed, scattered over the face, neck, and hands. Freckles are either natural, or proceeding accidentally from the jaundice or the action of the sun upon the part. Heat, or a sudden change of the weather, will often cause the skin to appear of a darker colour than natural; and thereby produce what is called *tan*, *sunburn*, and *morphew*, which seem to differ only in degree; and usually disappear in winter.

Persons of a fine complexion, and such whose hair is red, are the most subject to freckles, especially in those parts which they expose to the air.

To remove freckles, put juice of lemons in a glass-vial, and, mixing it with sugar and borax finely powdered, let it digest eight days, and then use it. Homberg proposes bullock's gall mixed with alum, and, after the alum has precipitated, exposed three or four months to the sun in a close vial, as one of the best remedies known for the removing of freckles.

FREDBERG, a rich, strong, and fine town of Germany, in Misnia, remarkable for its mines, and for being the burying place of the princes of the house of Saxony. It is a delightful place, seated on the river Multa. E. Long. 13. 40. N. Lat. 51. 2.

FREDERICA, a town of North America, in Georgia, seated at the mouth of the river Alatomaha, lately built and fortified by general Oglethorpe. The island it stands upon is called *St Simons's*; and is about 13 miles in length and 4 in breadth. W. Long. 81. 35. N. Lat. 31. 0.

FREDEKICK II. the Great, of Prussia, one of the greatest warriors the present age has produced, was the son of Frederick William then hereditary prince of Brandenburg, and Maria Dorothea, a princess of the house of Brunswick. He was born in 1712, the year before his father Frederick I. mounted the throne of Prussia. The latter was so far from being a patron of literature, that he regarded nothing but what related to the military art; and most of his generals, whatever their merits in their own line might be, scarce knew how to sign their names. So great indeed was the ignorance of the monarch himself that he banished from his dominions a philosopher of the name of *Wolf*, merely because he maintained the doctrine of pre-established harmony; upon which a theologian named *Lange* asserted, that on such principles his majesty's grenadiers were not culpable when they deserted, it being only the necessary consequence of the impulse their machine had received from their Creator. His son was of a disposition the very reverse of his father. Being put from his birth under the care of Val de Recoule a French lady of great merit and understanding, he acquired, in his early years not only a taste for literature in general, but a predilection for the French language, which was not obliterated throughout his whole life.

Freckles

Frederic.

Frederick. It is not to be supposed that a prince of the disposition abovementioned, would suffer his son to be long engaged in literary pursuits. At seven years of age, young Frederick was taken out of the hands of Madame de Recoule, and put under the care of military tutors. General Count de Finkestein, an old warrior, was appointed his governor; his sub-governor was Colonel de Kalkstein, an officer renowned for his courage and experience; he was taught mathematics and fortification by Major Senning; Han de Jendun, a Frenchman, instructed him in other branches of knowledge; and a cadet of the name of *Kenzel*, taught him his exercise. At eight years of age he was furnished with a small arsenal stored with all sorts of arms proportioned to his age and strength, of which his father left him absolute master. In a short time he was named captain and chief of the corps of cadets; and the young prince performed every day, in miniature, with his little soldiers, all the evolutions with which his father exercised his giants. At last he received the command of a company in his father's regiment famous throughout all Europe, and which was composed of men of whom scarce one was short of seven French feet.

Born, however, with a taste for the arts, he devoted to their cultivation every moment he could escape the vigilance of his guardians. He was more particularly fond of poetry and music, and when he could find a moment's leisure, he read French authors; or played on the flute; but his father, as often as he surprised him playing or reading, broke his flute and threw his books into the fire. The prince, chagrined at such injurious treatment, and having a great desire to visit Germany, England, France, and Italy, desired permission to travel. This, however, his father would not allow, but permitted him to accompany himself in the little journeys he made from time to time into Germany; and, in 1728, took him to Dresden to see the king of Poland. By these little expeditions the desire of the prince to visit other countries was only the more inflamed, so that at last he formed a design of setting out without his father's knowledge. The design was intrusted to two of the prince's young friends named *Kat* and *Keit*; money was borrowed for the occasion, and the day of their departure fixed, when unluckily the whole project was discovered. The old king, implacable in his resentment, and considering his son as a deserter, determined to put him to death. He was shut up in the fortress of Custrin; and it was with the utmost difficulty that the Count de Seckendorf, sent for the purpose by the emperor Charles VI. was able to alter the king's resolution. Certain vengeance, however, was determined on both the intended associates in Frederick's journey. *Keit* escaped the danger by flying into Holland; but *Kat* had not that good fortune. The king first directed that he should be tried by a court-martial; but as they, contrary to his expectation, only sentenced the criminal to perpetual imprisonment, the revengeful monarch by an unheard of exercise of the royal prerogative caused him to be beheaded. The execution was performed under the windows of the prince royal, whose head was held towards the scaffold by four grenadiers; but no sooner did he approach the window and see his friend in the hands of the executioner, than he stretched out his arms towards him, crying out "Kat!

Kat!" and instantly fainted away. During the remainder of his life he considered capital punishments with a great degree of horror, and they were rare throughout the Prussian dominions while he continued to reign. When the emperor had succeeded in preventing the execution of Frederick, the king remarked, that "Austria would one day see what a serpent she had nourished in her bosom." The royal prisoner remained a year at Custrin; during which time his father wished that he should learn the maxims of government and finance. For this purpose M. de Munchow, president of the chamber of domains and finances, was ordered to make him assist at all their assemblies, to consider him as a simple counsellor, to treat him as such, and make him work like others. The young counsellor, however, though he assisted at their meetings, did not trouble himself with reading acts or copying decrees. Instead of this, he amused himself sometimes with reading French Pamphlets, and at others with drawing caricaturas of the president or members of the assembly. M. Munchow himself was likewise very favourable to the prince at this time, by furnishing him books and other articles of amusement, notwithstanding the express prohibition of his father; though in this he certainly ran a great risk; for the old king, who set but a very light value on human life, would undoubtedly have put him to death had he received intelligence of his complaisance.

Frederick, after passing the time abovementioned in confinement, was recalled to Berlin, on pretence of being present at the celebration of his eldest sister's marriage with the hereditary prince of Bareith; but the true reason was, that the king had now prepared a match for the prince himself. This was the princess Elizabeth Christina of Brunswick, niece to the empress. Frederick, who was not only totally indifferent to the fair sex in general, but particularly prejudiced against this princess, made some objections; his father, however, overcame all obstacles with "his usual arguments (says the author of the life of Frederick), viz. his cane, and a few kicks."

The coldness which Frederick at this time showed for the fair sex, appears not to have been natural; for as early as the year 1723, though then only in the 11th year of his age, he is said to have fallen in love with the princess Anne, daughter of George II. Even at this early period he entered into vows to refuse every other but her for his consort; nor were these ever broken, as far as depended on himself. The marriage perhaps would have taken place, had it not been for some differences which arose between the courts of Prussia and Hanover about a few acres of meadow-land, and two or three Hanoverians enlisted by the Prussian recruiters. It is supposed also, that it was intended at one time to marry him to Maria Theresa of Austria; but, as in that case it would have been necessary to change his religion, Frederick derived from thence a plausible pretence for refusing the match. The princess whom he espoused had a large share of beauty; and, what was still better, an excellent heart: but Frederick is said to have suffered so much in his former amours, that certain natural and unsurmountable impediments remained to the completing of his marriage with any woman. Scarcely therefore was he in bed with his young spouse, when a cry of *Fire!* was raised by his friends.

Frederick. friends. Frederick got up to see where the conflagration was: but finding it to be a false alarm, he sent messengers to compose the princess; but neither that night, nor any other, did he think proper to disturb her rest.

On occasion of this marriage, Frederick received from his father the county of Rupin. He resided in the capital of this county, named also *Rupin*, for some time; but afterwards chose Rheinsberg for his place of abode. This is a little town built in the sands, on the confines of Mecklenburg, and at that time containing only 1000 inhabitants; but it was soon greatly improved by Frederick. Having put over the great gate of the castle, however, the following inscription, *FREDERICO TRANQUILLITATEM COLENTI*, his father was displeased with it, and therefore hurried him from his peaceful retreat into the noise and tumult of war. At this time the succession to the crown of Poland had kindled a general war throughout Europe, and the king of Prussia was to send 10,000 auxiliaries to the imperial army, then commanded by prince Eugene. The king conducted his troops in person, and resolved to take this opportunity of giving his son an idea of war. At this time, however, he learnt but little; and only saw, as he himself expresses it, the shadow of the great Eugene. That consummate general, nevertheless, did not overlook his merit; but predicted that he would one day be a great captain. Frederick having gone to reconnoitre the lines at Philipsburg, in his return through a very open wood, was exposed to the cannon of the lines, which thundered incessantly. The balls broke a number of branches on every side of him: notwithstanding which, he never caused his horse move quicker; nor did his hand which held the bridle ever alter its motion even for a moment. He continued to converse quietly with the generals who attended him, and never showed the smallest sign of apprehension. Being one night at supper with field-marshal Grumkow, the conversation turned on the young prince Eugene who died on the Rhine; and he was asked whether that prince would ever have become a great man? Frederick decided in the negative, on account of young Eugene's not having known at any period of his life how to choose a friend who dared to tell him the truth.

During this campaign the health of the old king was so much impaired, that he was obliged to leave the army; and Frederick, on his return, was for some time intrusted with signing all the orders in his father's name. On the king's recovery the prince was sent to Stetten, under the care of the prince of Dessau, that he might see the fortifications of that town. He was afterwards permitted to go to Konigsberg to see the unfortunate Stanislaus, who had taken refuge in that place, and who was no less remarkable for his philosophy and constancy than for his misfortunes. With him Frederick remained for some weeks, and contracted a friendship which was not dissolved but by the death of Stanislaus. At last he was allowed to return to his peaceful mansion at Rheinsberg, where he remained till the death of his father. In this place his time was occupied alternately by the study of the sciences, the cultivation of the arts, and the pleasures of friendship. Philosophy, history, politics, the military art, poetry and music, agreeably suc-

ceeded each other, and had each its stated period. The prince passed the greatest part of the day in his library; and the remainder in the society of a select company of agreeable and learned men. The principal of these were Chasot, a French officer; Kayferling, a gentleman of Courland, on whom the prince bestowed the name of *Casarion*; Jordan, a French refugee; and Knobelsdorf, director of the buildings and gardens; but who could converse on all the arts of designing with as much taste as judgement.—In these meetings, gaiety generally presided; there were generals to speak of war, musicians to form concerts, and excellent painters to decorate the apartments. Whilst Knobelsdorf was executing landscapes and laying out the gardens, Pefne was immortalizing himself by his cielings, and du Buisson by his pictures of flowers. The two Grauns composed excellent music, or directed the orchestra; and Benda, one of the first violins of Europe, accompanied the prince who played extremely well on the flute. The morning was usually dedicated to study; gaiety and agreeable conversation prevailed at every repast; and every evening there was a little concert. In this retreat Frederick conceived that ardent passion for military glory and the aggrandisement of his kingdom for which he became at last so remarkable; and here he is supposed to have formed the most sublime and daring projects. He was fired with a desire of imitating the celebrated heroes of antiquity, of whom he read in the ancient authors, and for which he set apart some hours every day. Amongst the works which he read almost every year, were Herodotus, Thucydides, Xenophon, Plutarch, Tacitus, Sallust, Livy, Quintus Curtius, Cornelius Nepos, Valerius Maximus, Polybius, Cæsar Vegetius, &c. He never spoke but with enthusiasm of the great warriors of Greece and Rome; and when seated on the throne, thought he could never distinguish an able soldier in a more honourable manner than by conferring on him a Roman surname. Hence he distinguished, by the name of *Quintus Icilius*, M. Guichard who had written some treatises on the military art of the ancients; giving him at the same time a free battalion. This name of *Quintus Icilius* was retained by M. Guichard as long as he lived.

In his pursuit of glory Frederick found that it was not improper to cultivate the friendship of celebrated poets, philosophers, and others of the literary class; for which purpose he flattered, commended, and complimented all the most celebrated literati of Europe at that time. “The philosophers (says the author of his life) answered him as a mad lover writes to his mistress. They wrote to him that he was a great poet, a great philosopher, the *Solomon* of the north. All these hyperboles were printed; and Solomon was not sorry for it, though he had too much understanding to believe in them. Wolf, Rollin, Gravesande, Maupertuis, Algarotti, Voltaire, were honoured with his correspondence. The last especially, accustomed to offer up incense to the idol of the day were it transported from the dunghill to the altar, did not fail to exalt as the first man of the universe, a prince who was in expectancy of the throne, and who assured him that he was the greatest philosopher of the age and the first poet in the world.”

That Frederick might keep up his character with the literati, or perhaps from a real predilection for his principles,

Frederick. principles, he patronised the Apology of Wolf, and had his principal treatises translated into French. He even prevailed upon his father to relax a little in favour of that philosopher. A commission of reformed and Lutheran theologians was appointed in 1736, to examine into the tenets of that unfortunate philosopher. Wolf was declared innocent, and a letter was sent to him at Marpourg containing an invitation to return; but the philosopher did not think proper to make his appearance till the year 1740, when his protector was seated on the throne.

During his residence at Rheinsburg, Frederick composed his refutation of the principles of Machiavel, under the title of *Anti-Machiavel*; of which he sent the manuscript to Voltaire to correct, and to get printed.

The old king, now almost worn out with infirmity, saw with regret the predilection his son entertained for men of letters; and, in his peevish fits, often threatened the whole society with confinement in the fortress of Spandau. These threats frequently occasioned a violent alarm among the joyous company at Rheinsberg, which it required all the eloquence of Frederick to quiet. Their apprehensions on this account, however, were soon removed. At the commencement of the year 1740, the king's disorder increased to a great degree, and in the month of May his case became desperate. He lived, however, till the 31st of that month, when he expired, and left the throne to his son Frederick II.

The acquisition of a kingdom did not abate Frederick's passion for literature, though to this he was now obliged to superadd the qualities and labours of a great king. A consideration of his transactions in this character falls under the article PRUSSIA, to which we refer: these, indeed, so totally engrossed the remaining part of his life, that little more remains to be said under this article, than to relate some anecdotes by which we may be in some measure able to trace the character of this great and singular personage.

It has already been mentioned, that in the early part of his life, Frederick had conceived a great inclination to travel. This passion seems not to have been extinguished by the splendor of his new situation; for having, soon after his accession, gone into Prussia and Westphalia to receive the homage of the inhabitants, he formed a resolution of proceeding *incognito* as far as Paris. Being discovered at Strasbourg, however, he laid aside the design of proceeding to Paris, and went to see his states in Lower Germany. Here he wrote the celebrated Voltaire, that he should come *incognito* to visit him at Brussels; but being seized with an indisposition in the little palace of Meuse, two leagues from Cleves, he wrote again to that philosopher, informing him that he expected he should make the first advances. The following curious account is given by him of his reception, &c. "The only guard I found at the gate was one soldier. The privy-counsellor, Bambonet, was cooling his heels in the court: he had large ruffles of dirty linen; a hat full of holes; and an old magisterial peruke, one end of which descended as low as his pockets, and the other scarcely reached his shoulder. I was conducted into his majesty's apartment, where there was nothing but bare walls. I perceived in a cabinet, by the glimmering of a taper, a truckle bed, two feet and an half wide, on which lay a little

man muffled up in a night gown of coarse blue cloth. Frederick. This was the king, in a strong perspiration, and even trembling under a wretched blanket in a violent fit of the ague. I bowed to him; and began by feeling his pulse, as if I had been his first physician. The fit over, he dressed himself and sat down to table. Algarotti, Kayserling, Maupertuis, the king's minister to the States General, and myself, were of the party; where we conversed profoundly on the immortality of the soul, on liberty, and the androgynes of Plato."

This rigid œconomy, and contempt of every luxury with regard to his own person, was maintained by Frederick as long as he lived. The following account, taken likewise from Voltaire, will give an idea of his manner of living. "He rose at five in the morning in summer, and six in winter. A lacquey came to light his fire, and dress and shave him; and indeed he almost wholly dressed himself. His room was not inelegant. A rich balustrade of silver, ornamented with little cupids, seemed to inclose an alcove bed, the curtains of which were visible; but behind them, instead of a bed, there was a library: the king slept on a truckle bed with a slight mattress concealed behind a screen. Marcus Aurelius and Julian, those apostles of Stoicism, did not sleep in a more homely manner. At seven his prime minister arrived with a great bundle of papers under his arm. This prime minister was no other than a clerk who had formerly been a soldier and valet de chambre. To him the secretaries sent all their dispatches, and he brought extracts of them, to which the king wrote answers in two words on the margin: and thus the affairs of the whole kingdom were expedited in an hour. Towards eleven the king put on his boots, reviewed his regiment of guards in the garden, and at the same hour the colonels were following his example in their respective provinces. The princes his brothers, the general officers, and one or two chamberlains, dined at his table; which was as good as it could be in a country where there is neither game, tolerable butcher's meat, nor a pullet, and where the very wheat is brought from Magdebourg. After the repast he retired alone into his cabinet, where he made verses till five or six o'clock. Then came a young man named D'Arget, formerly secretary to Valory the French envoy, who read to him. A little concert began at seven, in which the king played on the flute with as much skill as the first performer; and pieces of his composition were frequently executed. Supper was served in a little hall, the singular and striking ornament of which was a picture the design of which he had given to Pefne, one of our best colourists. It was a fine picture of Priapus. These repasts were not in general the less philosophic on that account. Never did men converse in any part of the world with so much liberty respecting all the superstitions of mankind, and never were they treated with more pleasantry and contempt. God was respected; but none of those who had deceived men in his name were spared. Neither women nor priests ever entered the palace. In a word, Frederick lived without a court, without counsel, and without religious worship."

As Frederick had espoused his princess entirely contrary to his inclination, it was imagined that on his accession to the throne he would embrace the opportunity of setting himself free from engagements so disagreeable.

Frederick. able to himself. The queen was not without suspicions of this kind, insomuch that she was on the point of fainting away when he made his first visit to her. To the surprize of all parties, however, he made her a very affectionate speech, apologizing for his indifference, and inviting her to participate with him the throne of which she was so worthy. In the first year of his reign he restored the academy of sciences at Berlin which had been founded in 1700; but he soon became disgusted with its members, whom he endeavoured at all times to ridicule rather than encourage. His war with the queen of Hungary, however, which took place almost immediately after his accession, for some time prevented him from taking such an active part in literary matters as he was naturally inclined to do. After the peace, being at liberty to follow his inclination, he gave full scope to his passion for literature; and in the interval betwixt the conclusion of the first war and beginning of that of 1756, he composed most of the works which are now ascribed to him. At this time he wrote his *History of my own Time*, afterwards announced among his posthumous works. In writing history he acquired a taste for historians; and justly gave the preference to the ancients, the most celebrated of whose works he perused every year. Voltaire was his principal literary correspondent, whom he invited to reside with him. Afraid of losing his liberty, however, that philosopher hesitated, excused himself, and entered into pecuniary treaties, first for himself, and afterwards for his niece Madam Dennis, whom he wished to accompany him. At last he was determined by seeing a poem from Frederick to M. D'Arnaud, in which the latter was compared to the rising, and Voltaire to the setting, sun. By this Voltaire was so much piqued, that he set out for Berlin without delay, and arrived there in June 1750. He was received in the most magnificent and affectionate manner, and for some time his situation was very agreeable: but the disputes and rivalry which took place betwixt him and Maupertuis soon threw every thing into confusion. In these the king interfered in such a manner as was certainly below his dignity; and he often exercised himself in making a jest of the other men of letters in a way exceedingly disgusting, and which induced many of them to leave him. The squabbles with Voltaire were sometimes very diverting; an account of some of which is given under the article VOLTAIRE. They ended at last in a final quarrel with that wit, and his departure from the kingdom. The restless disposition of Frederick showed itself after his departure, by his attempts to provoke the literati who remained at his court to quarrel with him as Voltaire had been accustomed to do. But they were of too passive a disposition to gratify him in this respect, choosing rather to suffer the most mortifying strokes of raillery, or to leave the kingdom altogether, than to contend with him. This proved so uneasy to the king, that he one day exclaimed. "Shall we have no more quarrels then?" The breaking out of the war in 1756, however, put a stop to this diversion, and afforded him as many enemies as he could wish. The exploits he performed during the seven years which this unequal contest lasted, are almost incredible*; and it is amazing how the fortitude and resolution of any person could enable him to sustain the difficulties which during this period he had

Frederick. to encounter. In one fatal moment, indeed, even, the resolution of Frederick was on the point of giving way. This happened after the battle of Colin, when his affairs seemed altogether desperate, before they were retrieved by the victory at Rosbach. At this time he wrote to his sister at Bareith, that he was on the point of putting an end to his own life; but as this resolution did not extinguish in him the love of glory, he wished to have it said that he made verses on the brink of the grave. With this view he wrote a long poetical epistle to the marquis d'Argens, in which he communicated to him his design, and bade him farewell.

Happily, at last, the king's affairs took a better turn, and such desperate thoughts were laid aside. His constitution, however, was irreparably injured by the excessive fatigues he had sustained. Soon after the conclusion of the peace, his body began to bend, and his head to incline to the right side: by degrees he became very infirm; he was tormented with the gout, and subject to frequent indigestions. All his distempers, however, were borne with invincible patience; and, till a very short time before his death, he never ceased to attend his reviews, or visit the different provinces of his dominions. He has been known to review his troops, and gallop through all the ranks, as if he felt no pain, notwithstanding that an abscess which had broken out upon him, and approached to a suppuration, frequently, upon such occasions, touched the saddle. In August 1785 he impaired his health still farther by assisting at a review, where he was exposed without even a cloak to a heavy rain for four or five hours. On his return to Potsdam he was seized with a fever; and, for the first time, became unable to assist at the military exercises of Potsdam, which take place in September. His malady, however, did not prevent him from dictating the disposition of these exercises during the three days they lasted, and he always gave the word in presence of his generals and the foreigners of distinction then at Potsdam. About the end of autumn the fever left him, but was succeeded by a violent cough; and he continued free from the gout which had usually attacked him at this season. He was greatly weakened by the cough, which prevented him from sleeping; but this did not in the least interrupt him in the execution of business. Every morning, at four or five o'clock, he ordered the three cabinet secretaries to enter his apartment, where he dictated answers to their papers. It was not till after the dispatch of all his affairs that he saw a surgeon, or sometimes a physician, though he had a bad opinion of the physicians in general, whom he consulted on his distemper. In the evening he amused himself from five to eight with some of his society; and after that hour he passed the remainder of the time before he went to rest, in hearing some ancient authors read to him; and thus he continued to employ himself till the very day before he died. On the 17th and 18th of May 1786, he was unable to assist at the ordinary reviews, but still he hoped to be present at those of Silesia. He several times attempted to mount his horse to go to the parade at Potsdam; but finding his powers insufficient, he was obliged to return, after having proceeded a few paces. He made other attempts, but with as little success; and at last his disorder terminated in a dropsy. Being now no longer able to remain in bed, he sat day and night in

* See Prussia.

Frederick. an arm chair with springs which could be moved at pleasure. For near a month before his death the swelling of his feet gave him violent pain, so that he wished an incision to be made; but the surgeon refused to perform the operation, suspecting that it might hasten his death. Nature, however, accomplished his desires; his right leg opened, and discharged such a quantity of matter, that he was greatly relieved; and those unacquainted with the medical art began to entertain hopes of his recovery. The physicians, however, were of a very different opinion; and the event justified their apprehensions. On the 16th of August 1786 his throat began to rattle violently, and his attendants expected every moment that he would breathe his last. In this situation his three secretaries entered the room for the dispatch of business as usual. Even then Frederick made an effort to collect his force, giving them a sign to wait, as if he would speak with them in a short time. This, however, was the last he could make: for he soon after fell into a stupor; though from this he recovered so far as to be able to speak. In the evening he asked what o'clock it was? and on being answered that it was nine, he said, "Well then I am going to rest." His respiration and voice became gradually more feeble; and he expired on Thursday at 19 minutes after two in the morning, without any convulsion or symptom of pain.

This great monarch was of the middle size, had large blue eyes and a piercing look. He spoke German incorrectly, and in a very rough manner; but talked French very fluently, and his voice was then mild and agreeable. His constitution was naturally feeble, but he had greatly improved it by his activity and laborious life. He had the art of relieving every one from that embarrassment which frequently occurred in accosting such a celebrated monarch; and it seems probable that he himself considered on what he should say to any illustrious person who happened to come to his court. His universal knowledge enabled him to converse on all subjects; and thus he talked of war with military men, of verses with the poet, of agriculture with the farmer, jurisprudence with the lawyer, commerce with the merchant, and politics with the Englishman. He had a very retentive memory; was fond of solitude and gardening; and likewise took great pleasure in dogs, of which animals he constantly kept a number about him, giving them little balls covered with leather to play with. In company, he was fond of asking questions and jesting; in which last he proceeded such lengths as undoubtedly were unbecoming in a superior towards his inferiors, who would not have failed to resent such jokes from persons more on an equality with them. In military affairs he was excessively severe, not to say cruel; of which the following anecdote may serve as an instance. In the first war of Silesia, wishing to make some alterations in his camp during the night, he forbade every person, under pain of death, to keep, after a certain hour, a fire or other light in his tent. He himself went the rounds; and in passing the tent of a captain Zeitern he perceived a light. Entering the tent, he found the captain sealing a letter to his wife, for whom he had a great affection. "What are you doing there?" (says the king :) "Do you not know the order?" The captain fell on his knees and asked pardon, but did not attempt to make any excuse. "Sit down (says Frede-

rick), and add a few words I am going to dictate to you." Zeitern obeyed; and the king dictated, "Tomorrow I shall perish on a scaffold." The unfortunate man wrote them, and next day was executed. In matters of domestic legislation, he was more arbitrary than just; of which we have a notable example in the famous case of Arnold the miller. The man had refused to pay the rent of the mill he possessed, on pretence that the stream which turned it had been diverted into a fish-pond. This was evidently a frivolous excuse; because the water which ran into the pond also ran out of it into the same channel as before, so that nothing could be lost except what evaporated from the surface of the fish-pond. The judges therefore gave sentence against the miller; but the king not only reversed their sentence, but disgraced them. For this he was celebrated through all the news-papers in Europe; and yet he was in the wrong, and afterwards even acknowledged himself to have been so: but, notwithstanding he knew his error, he not only made no reparation to the parties he had injured, but allowed them to lie in prison at Spandau all his lifetime, so that they were not released till the commencement of the present reign. He entertained certain and almost unaccountable prejudices against certain places and persons, which neither conduct nor merit could eradicate. One of these unfortunate places was Westphalia, on which he never conferred any bounty; and one day a native of that country, a man of great merit, being proposed to him for a place, he refused, saying, "He is a Westphalian; he is good for nothing." Voltaire accuses him of ingratitude to the Count de Seckendorf; who, as we have already seen, saved his life, and against whom he afterwards conceived the most implacable hatred. His indifference towards those who afforded him the most essential service, was evident: when a robust butcher prevented him from falling, horse and all, over a precipice, where both would have undoubtedly been killed; the king, sensible of the assistance that had been afforded him, turned about, and saying, "Thank you, friend," rode off without ever inquiring farther about the person who had just preserved him from destruction.

With regard to the literary merits of this monarch, we certainly cannot pronounce them extraordinary. Voltaire boasts of having corrected his works, and others of having furnished him with materials for his history. He has been accused of borrowing whole hemistichs of poetry from Voltaire, Boileau, Rousseau, and others; nor does the charge appear to be at all void of foundation. Such of his verses as appear to have undergone no correction, are very indifferent, nor indeed can we pronounce any of his poetic works to be of the first rate. In the former part of his life he entertained a great partiality for the French learning and language: but as he advanced in years, he entirely lost this predilection, and inclined much more to favour the English and Germans. Towards the end of his life, indeed, he affected a contempt for the French, without whom it is said he would scarce ever have made any figure except in the military line.

FREDERICKSBURG, in Virginia. See APPENDIX.

FREDERICKSBURG, a fort and colony of Brandenburg, on the gold-coast of Guinea, in Africa, near Cape Three-points, and about 75 miles from

Frederick- Cape Coast. It mounts 46 pieces of cannon on four
shall batteries; and formerly belonged to the Prussians,
Free-Stone. || but is now subject to Denmark. W. Long. 1. 15.
N. Lat. 4. 30.

FREDERICKSHALL, or FREDERICKSTADT, a strong town of Norway, in the prefecture of Agerhuys, where Charles XII. king of Sweden was killed by a musket-ball in 1718, when he was besieging this town. It is seated on the coast of the Catagate, in E. Long. 10. 45. N. Lat. 59. 2.

FREDERICKSODE, a town of Denmark, in Jutland, taken by the Swedes in 1657, but now subject to Denmark. It is seated near the sea, in E. Long. 10. 0. N. Lat. 55. 42.

FREDERICKSTADT, a town of Denmark, in South Jutland, built in 1621. It is seated on the river Eyder, in E. Long. 9. 23. N. Lat. 55. 32.

FREDERICKSTADT, a town of Norway, in the province of Agerhuys, seated on a bay of the sea, near the frontiers of Sweden, in E. Long. 11. 6. N. Lat. 59. 12.

FREE, in a general sense, is used in opposition to whatever is constrained or necessitated. When applied to things endowed with understanding, it more peculiarly relates to the liberty of the will.

FREE-BENCH, signifies that estate in copy-hold which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor.

In regard to this free-bench, different manors have different customs: and in the manor of east and west Enbourne in the county of Berks, and in other parts of England, there is a custom, that when a copyhold tenant dies, the widow shall have her free-bench in all the deceased husband's lands, *dum sola & casta fuerit*, "whilst she lives single and chaste;" but if she is found to be guilty of incontinency, she shall forfeit her estate. Nevertheless, upon her coming into the court of the manor riding backwards on a black ram, with his tail in her hand, rehearsing a certain form of words, the steward is bound by custom to restore her to her free-bench. The words are,

Here I am,
Riding on a black Ram,
Like a whore as I am;
And for my crincum crancum
Have lost my bincum bancum,
And for my tail's game
Have done this worldly shame:

Therefore, pray Mr Steward, let me have my land again.

FREE or Imperial Cities in Germany, are those not subject to any particular prince; but governed, like republics, by their own magistrates.

There were free cities, (*liberae civitates*), even under the ancient Roman empire: such were those to whom the emperor, by the advice or consent of the senate, gave the privilege of appointing their own magistrates, and governing themselves by their own laws. See CITY.

FREE Fishery. See Free FISHERY.

FREE Warren. See WARREN.

FREE-Mason. See MASON.

FREE-Stone, a whitish stone, dug up in many parts of Britain, that works like alabaster, but is more hard and durable; being of excellent use in build-

ing, &c. It is a kind of the grit stone, but finer sanded and smoother; and is called *free*, from its being of such a constitution as to cut freely in any direction. Free-Stone
||
Freehold.

The qualities of the several kinds of free-stones used in the different parts of Europe are very different. They all agree in this general property indeed, that they are softer while in the quarry, than when they have been some time exposed to the air: but even this general property differs greatly in degree. They have a sort of grey free-stone in use at Paris (of which we do not yet seem to have met with any in this country), which has the abovementioned quality in so great a degree, that the expence of working it is in a great measure saved.

This stone lies every-where on the south-side of the river Seine, and is of a coarse and large grit. It is so soft when newly taken out of the strata, that they fashion it very conveniently with a sort of broad ax, and form as many stones for building in this manner in an hour, as an equal number of our people do in a day or two. Though this stone is as soft as dry clay when first taken up, it is found to harden so considerably in the air, that it becomes more than equal to the ordinary free-stone.

The Portland stone of the finest kind, which is white, and of a close grit, is very fit for hewing and carving; but it will neither resist water nor fire, which is a very singular instance in so dense a stone; while the free-stone of Kent, which is less beautiful to the eye, and is of a greyish colour, and considerably close, though of a larger grain, resists the air and water very well. The free-stone of Derbyshire, on the other hand, is so brittle as to be unfit for any fine working; and so coarse and open in its texture, that it lets water through: yet it bears the fire extremely well, and is fit for ovens, hearths, &c.

FREEBOOTER, or FLIBUSTER, a name given to the pirates who scour the American seas, particularly such as make war against the Spaniards. See BUCA-NEER.

FREEDOM, in general, the state or quality of being free. See LIBERTY.

FREEDOM of a Corporation, the right of enjoying all the privileges and immunities belonging to it. See CORPORATION.

The freedom of cities, and other corporations, in Britain, is regularly obtained by serving an apprenticeship; but it is also purchased with money, and sometimes conferred by way of compliment.

FREEDOM of Conscience. See TOLERATION.

FREEDOM of the Will, that power or faculty of the mind, whereby it is capable of acting or not acting, choosing or rejecting whatever it judges proper †. Of † See *Meta-*
this every man must be sensible, who finds in himself *physics*.
a power to begin or forbear, continue or end several actions, barely by a thought or preference of the mind.

FREEHOLD, FRANK TENEMENT, (*liberum tenementum*), is land, or tenement, which a man holds in *fee-simple*, *fee-tail*, or for term of life. See FEE and TAIL.

Freehold is of two kinds, in *deed* and in *law*.

The first is the real possession of land or tene-

Freehold ||
Freezing. ment in fee, fee tail, or for life: the other is the right a man has to such land or tenement before his entry or seizure.

A freehold, by the common law, cannot commence *in futuro*; but it must take effect presently, either in possession, reversion, or remainder. Whatever is part of the freehold goes to the heir; and things fixed thereto may not be taken in distress for rent, or in execution, &c. No man shall be disseised of his freehold by stat. Magna Charta, cap. 29. but by judgment of his peers, or according to the laws of the land: nor shall any distrain freeholders to answer for their freehold, in any thing concerning the same, without the king's writ. Freehold estates, of certain value, are required by statutes to qualify jurors, electors of the knights of the shire in parliament, &c.

FREEHOLD is likewise extended to such offices as a man holds in fee, or for life.

FREEHOLD is also sometimes taken in opposition to villenage.

Lambard observes, that land, in the Saxons time, was distinguished into *bockland*, i. e. holden by book or writing; and *folkland*, held without writing. The former, he says, was held on far better condition, and by the better sort of tenants, as noblemen and gentlemen; being such as we now call *freehold*: the latter was mostly in possession of peasants; being the same with what we now call *at the will of the lord*.

In the ancient laws of Scotland, freeholders are called *milites*, "knights." In Reg. Judicial. it is expressed, that he who holds land upon an execution of a statute merchant, until he hath satisfied the debt, *tenet ut liberum tenementum sibi et assignatis suis*; and the same of a tenant *per eligit*: the meaning of which seems to be, not that such tenants are freeholders, but as freeholders for the time, till they have received profits to the value of their debt.

FREETHINKER. See DEIST.

FREEZE, FRIEZE, or *Frize*, in commerce. See FRIZE.

FREEZE, in architecture, that part of the entablature of columns, between the architrave and cornice.

The freeze is properly a large flat face, or member, separating the architrave from the cornice.

The ancients called it *zoophorus*, (*ζωοφορος*), because it was usually enriched with figures of animals; and our denomination *freeze* has a like origin, being formed of the Latin *phrygio*, "an embroiderer," because it is commonly adorned with sculptures in basso-relievo, imitating embroidery.

FREEZING, in philosophy, the same with congelation. See CONGELATION, FROST, and ICE.

FREEZING Rain, or *Raining Ice*, a very uncommon kind of shower, which fell in the west of England, in December 1672; whereof we have divers accounts in the Philosophical Transactions.

This rain, as soon as it touched any thing above ground, as a bough or the like, immediately settled into ice; and by multiplying and enlarging the icicles, broke all down with its weight. The rain that fell on the snow immediately froze into ice, without sinking in the snow at all.

It made an incredible destruction of trees, beyond any thing in all history. "Had it concluded with

some gust of wind (says a gentleman on the spot), it might have been of terrible consequence. I weighed the sprig of an ash tree, of just three-quarters of a pound; the ice on which weighed 16 pounds. Some were frightened with the noise in the air; till they discerned it was the clatter of icy boughs, dashed against each other." Dr Beale observes, that there was no considerable frost observed on the ground during the whole; whence he concludes, that a frost may be very intense and dangerous on the tops of some hills and plains; while in other places it keeps at two, three, or four feet distance above the ground, rivers, lakes, &c. and may wander about very furious in some places, and remits in others not far off. The frost was followed by glowing heats, and a wonderful forwardness of flowers and fruits.

FREIGHT, in navigation and commerce, the hire of a ship, or a part thereof, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant, for the hire and use of a vessel. See *Maritime LAWS*.

FREIND (John), a most learned English physician and writer in the 18th century, was born at Croton, Northamptonshire, in 1675. In 1696, he published, in conjunction with Mr P. Foulkes, an edition of two Greek orations, one of Æschines against Ctesiphon, and the other of Demosthenes *de Corona*, with a new Latin version. In 1699, he wrote a letter to Dr Sloane concerning an *Hydrocephalus*, published in the Philosophical transactions: and another letter in Latin to the same gentleman, *De spasms rarior. historia*, printed in the same transactions. In 1708, his *Emmenologia* appeared; which gained him great reputation. In 1704, he was chosen professor of chemistry in the university of Oxford. In 1705, he attended the earl of Peterborough to Spain, as physician to the army there; and upon his return in 1707, published an account of the earl's expedition and conduct. In 1709, he published his *Chemical Lectures*. In 1712, he attended the duke of Ormond in Flanders, as his physician. In 1716, he was admitted a fellow of the college of physicians in London. This year he published the first and third books of Hippocrates *De morbis popularibus*, with a Commentary on Fevers, written by himself. He sat a member of the borough of Launceston in Cornwall in 1722, where he distinguished himself by his opposition to the administration. March 1722, he was committed to the tower on a charge of high-treason: and while he was under confinement, he wrote a Latin epistle to Dr Mead, *De quibusdam variolarum generibus*; and began his *History of Physic*, the first part of which was published in 1725, and the second in 1726. Upon the accession of George II. to the throne, he was appointed physician in ordinary to the queen, who showed the utmost regard and esteem for him. He died at London in 1728. His works were published together in Latin at London, 1733, in folio, and dedicated to the queen.

FREINSEMIUS, a learned and elegant author, born at Ulm in 1608. He made Supplements to Livy, Tacitus, and Q. Curtius, in 60 books, printed at Strasburg in 1654. He wrote likewise notes upon Q. Curtius, Florus, Tacitus, and some other Latin authors; and died in 1660.

French,

FREITS. See FREATS.

FRENCH, in general, something belonging to France: thus we say, the French language, French customs, polity, &c.

The French language, as it now stands, is no original or mother language, but a medley of several. Those that prevail most, and which are, as it were, the basis thereof, are, 1. The Celtic; whether that were a particular language itself, or whether it were only a dialect of the Gothic, as spoke in the west and north. 2. The Latin, which the Romans carried with them into Gaul, when they made the conquest thereof. And, 3. The Teutonic, or that dialect of the Teutonic spoke by the Franks, when they passed the Rhine, and established themselves in Gaul. Of these three languages, in the space of about thirteen hundred years, was the present French formed, such as it is now found. Its progress was very slow; and both the Italian and Spanish were regular languages long before the French.

Pasquier observes, it was under Philip de Valois, that the French tongue first began to be polished; and that, in the register of the chamber of accounts of that time, there is a purity seen almost equal to that of the present age. However, the French was still a very imperfect language till the reign of Francis I. the custom of speaking Latin at the bar, and of writing the public acts and instruments of the courts of justice in that language, had made them overlook the French, their own language. Add, that the preceding ages had been remarkable for their ignorance, which was owing, in good measure, to the long and calamitous wars which France had been engaged in: whence the French noblesse deemed it a kind of merit not to know any thing; and the generals regarded little whether or no they wrote and talked politely, provided they could but fight well.

But Francis I. who was the restorer of learning, and the father of the learned, changed the face of things; and after his time, Henry Stevens printed his book, *De la Precellence du Language François*. The change was become very conspicuous at the end of the 16th century; and under Henry IV. Amyot, Coeffeteau, and Malherbe, contributed towards bringing it to its perfection; which the Cardinal De Richelieu completed, by the establishment of the French academy; an assembly, wherein the most distinguished persons of the church, the sword, and the gown, have been members. Nor did the long reign of Louis XIV. contribute a little to the improvement of the language: the personal qualities of that prince, and his taste for the fine arts, and that of the princes of the blood, rendered his court the politest in Europe. Wit and magnificence seemed to vie; and his generals might have disputed with the Greeks, Romans, &c. the glory of writing well, if they could not that of fighting. From court, the elegance and purity of the language soon spread itself into the provinces; and now there is scarce any body there who does not write and speak good French.

One of the characters of the French language is, to be natural and easy. The words are ranged in it much in the same order as the ideas in our minds; in which it differs exceedingly from the Greek and Latin, where the inversion of the natural order of words is reputed a

beauty. Indeed the Hebrew surpasses even the French in this point; but then it comes short of it in copiousness and variety.

French,
Frescati.

It must be added, however, that as to the analogy of grammar, and the simplicity wherewith the moods of verbs are formed, the English has the advantage not only over the French, but over all the known languages in the world; but then the turns, the expressions, and the idioms, of the English, are sometimes so quaint and extraordinary, that it loses a good deal of the advantage which its grammatical simplicity gives it over the rest.

The French has but few compound words; wherein it differs widely from the Greek, High Dutch, and English. This the French authors own a great disadvantage in their language; the Greek and Dutch deriving a great part of their force and energy from the composition of words, and frequently expressing that in one sounding word, which the French cannot express but by a periphrasis. The diminutives in the French are as few as the compounds; the greatest part of those remaining in use having lost their diminutive signification; but what distinguish the French most, are its justness, purity, accuracy, and flexibility.

French is the most universal and extensive language in Europe. The policy of states and courts has rendered it necessary for the ministers of princes, and their officers, &c. and the taste for arts and sciences has had the same effect with regard to the learned. In Germany, and elsewhere, the princesses and persons of distinction value themselves on understanding French; and in several courts of Europe, French is almost as much known as the language of the country.

FRESCATI, or FRASCATI, a small town, situated on the brow of a hill, about twelve miles to the eastward of Rome. It derives its name from the coolness of the air, and *fresh* verdure of the fields around. It is built on the ruins of the ancient Tusculum; and the Tusculan villa where Cicero wrote his famous questions is at a place now called *Grotta Ferrata*, about two miles distant. E. Long. 11. 43. N. Lat. 41. 48. There is a very fine prospect from this town into the neighbouring country, which abounds with the seats of cardinals and other nobility. It is the see of a bishop, who is one of the six senior cardinals, and is surrounded by some of the most beautiful villas in Italy; the principal of which are the villa Aldrobandini, belonging to prince Pamfili; the villa Taberna, belonging to prince Borghese; and villa Ludovisi, to the family of Colonna. The villa Aidobrandini, called also *Belvedere* from its beautiful prospect, is the most remarkable, on account of its fine situation, extensive gardens, airy terraces, its grottos, cascades, and waterworks. Over a saloon, near the grand cascade, is the following inscription:

*Huc ego migravi musis comitatus Apollo;
Hic Delphi, hic Helicon, hic mihi Delos erit.*

The walls are adorned with a representation of Apollo and the muses, and some of that god's adventures are painted in fresco by Domenichino. The villa Taberna is one of the finest and best furnished of any in the neighbourhood of Rome. From this you ascend thro' gardens to Monte Dracone, another palace on a more lofty situation, belonging also to that prince, and deriving its name from the arms of his family. From

Fresco. hence you may see Rome, and the whole extent of the plain: it has a noble ascent, with a broad paved walk; and among other curiosities there is a hall adorned with the pictures of a vast number of eminent men for learning and arms. The gardens, laid out by Vignola, contain three miles in compass; and have many delightful walks, with curious water-works. Near this place are the monks of Camaldoli and the capuchins; and higher up are the ruins of the ancient Tusculum. Ascending towards the plain, two miles on the right-hand, you find the famous abbey of Grotta Ferrata, belonging to the monks of St Basil, and situated on the ruins of Cicero's house. The virgin Mary of the great altar is an ancient Greek picture; in the chapel the pictures of St Nilus and St Bartholomew the abbot, are by Annibal Caracci; and all the paintings in fresco of this chapel are by Domenichino. Villa Ludovisia has a charming walk going up to it, where you see the ruins of Lucullus's palace. The house is small; but the gardens are large, embellished with a great variety of walks and fountains, and a beautiful cascade.

FRESCO, a method of painting in relief on walls, so as to endure the weather. It is performed with water-colours on fresh plaster, or on a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar, and drying along with it, becomes very durable. The Italians, from whom we borrow the term, call it *fresco*; because it is frequently used for walls, alcoves, and other buildings in the *open air*. Vitruvius, lib. vii. cap. 4. calls it *udo testorio*.

Painting in fresco is very ancient, having been practised in the earliest ages of Greece and Rome. It is chiefly performed on walls and vaults, newly plastered with lime and sand; but the plaster is only to be laid, in proportion as the painting goes on; no more being to be done at once than the painter can dispatch in a day, while it dries. Before he begins to paint, a cartoon or design is usually made on paper, to be calked, and transferred to the wall, about half an hour after the plaster is applied.

The ancients painted on stucco; and we may remark in Vitruvius what infinite care they took in making the incrustation or plastering of their buildings to render them beautiful and lasting; though the modern painters find a plaster made of lime and sand preferable to it; both as it does not dry so hastily, and as being a little brownish, it is fitter to lay colours on, than a ground so white as stucco.

In this kind of painting, all the compound and artificial colours, and almost all the minerals, are set aside, and scarce any thing is used but earths; which are capable of preserving their colour, defending it from the burning of the lime, and resisting its salt, which Vitruvius calls its bitterness.

For the work to come out in all its beauty, the colours must be laid on quick, while the plaster is yet moist; nor should they ever be retouched, dry, with colours mixed up with the white of an egg, or size, or gum, as some workmen do; because such colours grow blackish; nor do any preserve themselves, but only such as were laid on hastily at first.

The colours used are white made of lime flaked long before, and white marble dust; ochre, both red and

yellow; verditer; lapis lazuli; smalt; black chalk, &c. All which are only ground, and worked up with water; and most of them grow brighter and brighter as the fresco dries.

The brushes and pencils for this work ought to be long and soft, otherwise they will rake and raise the painting. The colours should be full, and flowing from the brush; and the design perfect: for in this work you cannot alter or add upon any colour.

FRESH-WATER, is that not tinged or impregnated with salt or saline particles, enough to be discoverable by the sense. Such generally is that of springs, rains, wells, lakes, &c.

The dulcifying or making of salt water fresh is a secret that has been long sought with great attention. For an account of the principal attempts that have been made with this view, see *Sea-WATER*.

FRESH Wind signifies strong, but not violent; hence when the gale increases, it is said to freshen.

FRESHES, in sea-language, denotes the impetuosity of an ebb tide, increased by heavy rains, and flowing out into the sea, often discolouring it a considerable distance, and forming a line that separates the two colours, and which may be distinctly perceived for a great length along the coast.

FRESHES, a local term signifying annual inundations, from the rivers being swollen by the melted snows and other fresh waters from the uplands, as is the Nile, &c. from periodical or tropical rains. As a sailor's term, it is opposed to marine or salt-water floodings, tides, &c. The word is of common use in America, where the inundations so called are of great service. They bring down the soil to the intervals below, and form a fine mould, producing corn, grain, and herbage, in the most luxuriant plenty. They also afford another benefit, in regard to many rivers in America, *viz.* in equalizing the surface of the stream (where rapid falls, or cascades, obstruct the navigation), so that rafts of timber and other gross produce are then floated down to the sea-ports in great quantities.

FRESNOY (Charles Alphonse du), an excellent poet and painter, was born at Paris in 1611. He was instructed there by Perrier and Simon Vouet in painting: but he did not long adhere to Vouet's manner of colouring; for as soon as he fixed himself at Rome, he made the works of Titian the models for his imitation. He was, however, more celebrated as a poet than as a painter; and gave more attention to the theory than to the practice of the pencil. Accordingly, he is better known by his incomparable poem *De arte graphica*, than by his performances on the canvas: and on this poem he bestowed so much pains, that he died in 1665, before it was published. It was printed afterwards with a French prose translation and notes by M. de Piles; and was translated into English by Mr Dryden, who prefixed to it an original preface containing a parallel between painting and poetry.

FRET, or **FRETTE**, in architecture, a kind of knot or ornament, consisting of two lists or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth.

FRET, in heraldry, a bearing composed of six bars, crossed and variously interlaced. Some call it the *true-lover's knot*. See **HERALDRY**.

Friburg.

Friburg
||
Friction.

FRET, in music, signifies a kind of stop on some instruments, particularly bass-voils and lutes. Frets consist of strings tied round the neck of the instrument at certain distances, within which such and such notes are to be found.

FRET-Work, that adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but it is mostly practised in roofs, which are fretted over with plaster work.

FRETTS, in mineralogy, a term used by miners to express the worn side of the banks of the rivers in mine-countries, where they search for the shoad stones or grewts washed down from the hills, in order from thence to trace out the running of the shoad up to the mine.

FRETTS, *Freats*, or *Freits*. See **FREATS**.

FRIABLE, among naturalists, an appellation given to bodies that are easily crumbled to pieces: such are pumice and all calcined stones.

FRIAR, or **FRIER**, by the Latins called *frater*, the Italians *fra*, and the French *frere*, that is, *brother*: a term common to the monks of all orders; founded on this, that there is a kind of fraternity or brotherhood presumed between the several religious persons of the same convent or monastery.

Friars are generally distinguished into these four principal branches, *viz.* 1. Minors, grey friars, or franciscans. 2. Augustines. 3. Dominicans, or black friars. 4. White friars or carmelites. From these four the rest of the orders descend. See **FRANCISCANS**, **AUGUSTINES**, &c.

FRIAR, in a more peculiar sense, is restrained to such monks as are not priests; for those in orders are usually dignified with the appellation of *father*.

FRIARS *Observant* (*fratres observantes*), were a branch of the Franciscans; thus called, because not combined together in any cloister, convent, or corporation, as the conventuals are; but only agreed among themselves to observe the rules of their order, and that more strictly than the conventuals did, from whom they separated themselves out of a singularity of zeal, living in certain places of their own choosing.

FRIBURG, a large town of Germany, and capital of Brisgaw; remarkable for the steeple of the great church, which, next to that of Strasburg, is the finest in Germany; and for its university. The inhabitants are famous for polishing crystal and precious stones. It has been several times taken and retaken; particularly by the French in 1744, who demolished the fortifications. It is seated on the river Triser, ten miles east of Brisach, and 30 south of Strasburgh. E. Long. 7. 57. N. Lat. 48. 4.

FRIBURG, a town of Swisserland, and capital of the canton of the same name, seated on the river Sane, in E. Long. 7. 5. N. Lat. 46. 50. Its situation is most singular and picturesque: "It stands partly in a small plain, partly on bold acclivities on a ridge of rugged rocks, half encircled by the river Sane; and is so entirely concealed by the circumjacent hills, that the traveller scarcely catches the smallest glimpse, until he bursts upon a view of the whole town from the overhanging eminence. The fortifications, which consist of high stone-walls and towers, inclose a circumference of about four miles; within which space the eye comprehends a singular mixture

of houses, rocks, thickets, and meadows, varying instantly from wild to agreeable, from the bustle of a town to the solitude of the deepest retirement. The Sane winds in such a serpentine manner as to form in its course, within the space of two miles, five obtuse angles, between which the intervening parts of the current are parallel to each other. On all sides the descent to the town is extremely steep: in one place the streets even pass over the roofs of the houses. Many of the edifices are raised in regular gradation like the seats of an amphitheatre; and many overhang the edge of a precipice in such a manner, that on looking down, a weak head would be apt to turn giddy. But the most extraordinary point of view is from the Pont-neuf. To the north-west, part of the town stands boldly on the sides and the piked back of an abrupt ridge; and from east to west a semicircle of high perpendicular rocks is seen, whose base is washed and undermined by the winding Sane, and whose tops and sides are thinly scattered with shrubs and underwood. On the highest point of the rocks, and on the very edge of the precipice, appears, half-hanging in the air, the gate of the town called *Bourgillon*: a stranger standing on the bridge would compare it to Laputa, or the Flying Island in *Guilliver's Travels*: and would not conceive it to be accessible but by means of a cord and pulleys. The houses, constructed with a grey sand-stone, are neat and well built; and the public edifices, particularly the cathedral, are extremely elegant. The inhabitants are Roman Catholics, as are those of the whole canton. The bishop of Lausanne, called here the bishop of Friburg, resides in this city. He is appointed by the pope, usually at the recommendation of the French court; and his revenues, including a small pension from France, and from the abbey of Hauterive, of which he was abbot, amount to about L. 400 *per annum*. His diocese extends over the whole canton, and part of that of Soleure. In all his acts and deeds he signs himself bishop and count of Lausanne, and prince of the German empire. The sovereign power resides in the great council of two hundred; comprising the two advocates, the chancellor, the grand sautier, the senate or little council of twenty-four, the sixty, from which body are chosen the bannerets and principal magistrates, and the remaining hundred and twelve members, who are simply denominated burghers."

FRIBURG (the canton of), and one of the 13 republics of Switzerland. It is surrounded on all sides by the canton of Bern. The land is fertile in corn, fruits, and pastures; and it is said the canton can send 18,000 men into the field. This canton is entirely catholic.

FRICASSEE, a dish or mess hastily dressed in a frying-pan, and seasoned with butter, oil, or the like. The word is French, formed of the Latin *frixatura*, "frying." Others will have fricassée formed in imitation of the noise made by butter, or other fat, when melted in the pan. We say a fricassée of pullets, of rabbits, of tench, of tripe, of frogs, of eggs, of peas, &c.

FRICENTI, an episcopal town of Italy, in the kingdom of Naples, and in the farther principato, near the river Tripalto, in E. Long. 14. 13. N. Lat. 40. 59.

FRICITION, the act of rubbing or grating the surface of one body against that of another, called also

Friction. also *attrition*. The phenomena arising upon the friction of divers bodies, under different circumstances, are very numerous and considerable. Mr Hawksbee gives us a number of experiments of this kind; particularly of the attrition or friction of glass, under various circumstances, the result of which was, that it yielded light and became electrical. All bodies by friction are brought to conceive heat; many of them to emit light; particularly a cat's back, sugar, beaten sulphur, mercury, sea-water, gold, copper, &c. but above all, diamonds, which, when briskly rubbed against glass, gold, or the like, yield a light equal to that of a live coal when blowed by the bellows. See ELECTRICS and ELECTRICITY.

FRICITION, in mechanics, denotes the resistance a moving body meets with from the surface on which it moves. Friction arises from the roughness or asperity of the surface of the body moved on, and that of the body moving: for such surfaces consisting alternately of eminences and cavities, either the eminences of the one must be raised over those of the other, or they must be both broke and worn off; but neither can happen without motion, nor can motion be produced without a force impressed. Hence, the force applied to move the body is either wholly or partly spent on this effect; and consequently there arises a resistance or friction, which will be greater, *ceteris paribus*, as the eminences are the greater and the substance the harder: and as the body, by continual friction, becomes more and more polished, the friction diminishes. See MECHANICS.

FRICITION, in medicine and surgery, denotes the act of rubbing a diseased part with oils, unguents, or other matters, in order to ease, relieve, and cure it. Frictions are much used of late in venereal cases. They prefer the applying of mercury externally by way of friction, to that of giving it internally, to raise a salivation.

There are also frictions with the flesh-brush, a linen cloth, or the hand only. These frictions are a sort of exercise which contributes greatly to health; as they excite and stir up the natural warmth, divert defluxions, promote perspiration, open the pores of the skin, and carry off stagnant humours.

The flesh-brush (Dr Cheyne observes) is an exercise extremely useful for promoting a full and free perspiration and circulation. Every body knows the effect of currying horses; that it makes them sleek, gay, lively, and active; so as even to be judged equivalent to half the feeding. This it can no otherwise effect, but by assisting nature to throw off the recrements of the juices, which stop the free circulation, and, by constant friction, irritation, and stimulation, to bring the blood and spirits to the parts most distant from the seat of heat and motion; and so plump up the superficial muscles. And the same effect it would have in other creatures, and man himself, if managed in the same manner, and with the same care and regularity. Persons, therefore, of weak nerves and sedentary lives, would do well to supply the want of other exercise with spending half an hour, morning and night, in currying and rubbing their whole body, especially their limbs, with a flesh-brush. But this means of health is most advantageously used when the *primæ viæ* are most empty.

FRIDAY, the sixth day of the week; so named of *Freya*, a Saxon deity. By the Romans it was called *dies Veneris*. See FREA.

Good FRIDAY. See *GOOD Friday*.

FRIDBURG, an imperial town of Germany, in Wetteravia. It is seated on a mountain, in E. Long. 8. 50. N. Lat. 50. 14. It was formerly much more considerable than at present.

FRIDSTOL, mentioned, in ancient writers, among the immunities granted to churches, signifies a seat, chair, or place of peace and security, where criminals might find safety and protection: of these there were many in England; but the most famous were that at Beverly, and that in St Peter's church at York, granted by charter of king Henry I.

FRIENDLY ISLANDS, a cluster of islands in the Pacific Ocean, so named by Captain Cook in the year 1773, on account of the friendship which appeared to subsist among the inhabitants, and from their courteous behaviour to strangers. Abel Jansen Tasman, an eminent Dutch navigator, first touched here in 1643, and gave names to the principal islands. Captain Cook laboriously explored the whole cluster, which he found to consist of more than 60. The three islands which Tasman saw he named *New Amsterdam*, *Rotterdam*, and *Middleburgh*. The first is the largest, and extends about 21 miles from east to west, and about 13 from north to south. These islands are inhabited by a race of Indians, who cultivate the earth with great industry. The island of Amsterdam is intersected by straight and pleasant roads, with fruit-trees on each side, which provide shade from the scorching heat of the sun. The chief islands are Annamooka, Tongataboo (the residence of the sovereign and the chiefs), Lefooga, and Eooa. Lefooga is about 7 miles long, and in some places not above two or three broad. It is in many respects superior to Annamooka. The plantations are both more numerous and more extensive; and inclosed by fences which, running parallel to each other, form fine spacious public roads, which would appear beautiful in countries where rural conveniences have been carried to the greatest perfection. They are, in general, highly cultivated, and well-stocked with the several roots and fruits which these islands produce; and Captain Cook endeavoured to add to their number by planting Indian corn, and the seeds of melons, pumpkins, and the like. Eooa, when viewed from the ship at anchor, formed one of the most beautiful prospects in nature, and very different from the others of the Friendly Isles; which being low and perfectly level, exhibit nothing to the eye but the trees which cover them: whereas here, the land rising gently to a considerable height, presents us with an extensive prospect, where groves of trees are only interspersed at irregular distances, in beautiful disorder, and all the rest is covered with grass, except near the shores, where it is entirely covered with fruit and other trees; amongst which are the habitations of the natives. In order to have a view of as great a part of the island as possible, Captain Cook and some of his officers walked up to the highest point of the island. From this place they had a view of almost the whole island, which consisted of beautiful meadows of prodigious extent, adorned with tufts of trees, and intermixed with plantations. 'While I was surveying this delightful pro-

Friday

Islands.

Friendly
Islands.

prospect (says Captain Cook), I could not help flattering myself with the pleasing idea that some future navigator may, from the same station, behold these meadows stocked with cattle, brought to these islands by the ships of England; and that the completion of this single benevolent purpose, independent of all other considerations, would sufficiently mark to posterity, that our voyages had not been useless to the general interests of humanity. 'The next morning,' says our benevolent commander, 'I planted a pine-apple, and sowed the seeds of melons and other vegetables in Taofa's plantation. I had indeed some encouragement to flatter myself that my endeavours of this kind also would not be fruitless; as I had this day a dish of turnips served up at my dinner, which was the produce of seeds I left here in my former voyage.'

The natives of these islands seldom exceed the common stature; but are very strong and well made, especially as to their limbs. They are generally broad about the shoulders; and though the muscular disposition of the men, which seems a consequence of much action, rather conveys the appearance of strength than of beauty, there are several to be seen who are really handsome. The women are not so much distinguished from the men by their features as by their general form, which is for the most part destitute of that strong fleshy firmness that appears in the latter. Tho' the features of some are so delicate, as not only to be a true index of their sex, but to lay claim to a considerable share of beauty and expression, for the bodies and limbs of most of the females are well proportioned; and some absolutely perfect models of a beautiful figure. But the most remarkable distinction in the women, is the uncommon smallness and delicacy of their fingers, which may be put in competition with the finest in Europe. The general colour is a cast deeper than the copper brown; but several of the men and women have a true olive complexion; and some of the last are even a great deal fairer. Their countenances very remarkably express the abundant mildness or good-nature which they possess; and are entirely free from that savage keenness which marks nations in a barbarous state. They are frank, cheerful, and good-natured.

There are, upon the whole, few natural defects or deformities to be found amongst these people. The most common is the tetter or ring-worm, that seems to affect almost one half of them, and leaves whitish serpentine marks every where behind it; but this is of less consequence than another which is very frequent, and appears on every part of the body. Captain Cook had the mortification to learn that all the care he took, when he first visited these islands, to prevent the venereal disease from being communicated to the inhabitants, had proved ineffectual. What is extraordinary, they do not seem to regard it much; and as there appeared few signs of its destroying effects, probably the climate, and the way of living of these people, greatly abate its virulence. There are two other complaints frequent amongst them; one of which is an indolent firm swelling, that affects the legs and arms, and increases them to an extraordinary size in their whole length. The other is a tumor of the same sort in the testicles, which sometimes exceeds the size of the two fists. But in other respects they may be considered as uncommonly healthy.

Friendly
Islands.

Their hair is in general straight, thick, and strong, though a few have it bushy or frizzled. The natural colour is black; but the greatest part of the men, and some of the women, have it stained of a brown or purple colour, and a few of an orange cast. They wear it variously cut. Some have it cut off on one side of the head only; others have it entirely cut off except a single lock; the women in general wear it short. The men have their beards cut short; and both men and women strip the hair from the arm-pits. The men are stained from about the middle of the belly to about half way down the thighs with a deep blue colour. The women have only a few small lines or spots thus imprinted on the inside of their hands. Their kings, as a mark of distinction, are exempted from this custom.

The men are all circumcised, or rather supercised, as the operation consists in cutting off only a small piece of the foreskin at the upper part; which by that means is rendered incapable ever after of covering the glans. This is all they aim at, as they say the operation is practised from a notion of cleanliness.

The dress of both men and women are the same; and consists of a piece of cloth or matting (but mostly the former) about two yards wide and two and a half long; at least so long as to go once and a half round the waist, to which it is confined by a girdle or cord. It is double before, and hangs down like a petticoat, as low as the middle of the leg. The upper part of the garment above the girdle is plaited into several folds; so that, when unfolded, there is cloth sufficient to draw up and wrap round the shoulders; which is very seldom done. The inferior sort are satisfied with small pieces; and very often wear nothing but a covering made of leaves of plants, or the maro, which is a narrow piece of cloth or matting like a sash. This they pass between the thighs and wrap round the waist; but the use of it is chiefly confined to the men. The ornaments worn by both sexes are necklaces, made of the fruits of the pandanus, and various sweet-smelling flowers, which go under the general name of *kabulla*. Others are composed of small shells, the wing and leg bones of birds, shark's teeth, and other things; all which hang loose upon the breast; rings of tortoise shells on the fingers; and a number of these joined together as bracelets on the wrists. The lobes of the ears (though most frequently only one) are sometimes perforated with two holes, in which they wear cylindrical bits of ivory about three inches long.

Cleanliness induces them to bathe in the ponds, which seem to serve for no other purpose. They are sensible that salt water hurts their skin; and when necessity obliges them to bathe in the sea, they commonly have some cocoa-nut shells filled with fresh water poured over them to wash it off. People of superior rank use cocoa-nut oil, which improves the appearance of the skin very much.

The employment of the women is of the easy kind, and, for the most part, such as may be executed in the house. The manufacturing their cloth is wholly consigned to their care; as is also that of their mats, which are esteemed both for their texture and their beauty. There are many other articles of less note that employ the spare time of their females; as combs, of which they make vast numbers, and little baskets with small beads;

Friendly
Islands.

beads; but all finished with such neatness and taste in the disposition of the various parts, that a stranger cannot help admiring their assiduity and dexterity.

The province allotted to the men, as might be expected, is far more laborious and extensive than that of the women. Agriculture, architecture, boat-building, fishing, and other things that relate to navigation, are the objects of their care. Cultivated roots and fruits being their principal support, this requires their constant attention to agriculture, which they pursue very diligently, and seem to have brought almost to as great perfection as circumstances will permit. In planting the plantains and yams, they observe so much exactness, that, which ever way you look, the rows present themselves regular and complete. The cocoa-nut and bread-fruit trees are scattered about without any order, and seem to give them no trouble after they have attained a certain height.

The houses of the lower people are poor huts, and very small; those of the better sort are larger and more comfortable. The dimensions of one of a middling size are about 30 feet long, 20 broad, and 12 high. Their house is, properly speaking, a thatched roof or shed, supported by posts and rafters, disposed in a very judicious manner. The floor is raised with earth smoothed, and covered with strong thick matting, and kept very clean. A thick strong mat, about two and a half or three feet broad, bent into the form of a semicircle, and set upon its edge, with the ends touching the side of the house, in shape resembling the fender of a fire hearth, incloses a place for the master and mistress of the family to sleep in. The rest of the family sleep upon the floor, wherever they please to lie down; the unmarried men and women apart from each other: Or if the family be large, there are small huts adjoining, to which the servants retire in the night; so that privacy is as much observed here as one could expect. The clothes that they wear in the day serve for their covering in the night. Their whole furniture consists of a bowl or two, in which they make kava; a few gourds; cocoa-nut shells; and some small wooden stools, which serve them for pillows.

They display much ingenuity in the building of their canoes, as well as in the navigating them.

The only tools which they use to construct them, which are very dexterously made, are hatchets, or rather thick adzes, of a smooth black stone that abounds at Toofoa; augres, made of shark's teeth, fixed on small handles, and rasps of a rough skin of a fish, fastened on flat pieces of wood, thinner on one side, which also have handles. The cordage is made from the fibres of the cocoa-nut husk, which, though not more than nine or ten inches long, they plait, about the size of a quill, or less, to any length that they please, and roll it up in balls, from which the larger ropes are made by twisting several of these together. The lines that they fish with are as strong and even as the best cord we make, resembling it almost in every respect. Their other fishing implements are large and small hooks made of pearl-shell. Their weapons are clubs of different sorts (in the ornamenting of which they spend much time), spears, and darts. They have also bows and arrows; but these seemed to be designed only for amusement, such as shooting at birds, and

not for military purposes. The stools are about two feet long, but only four or five inches high, and near four broad, bending downward in the middle, with four strong legs, and circular feet; the whole made of one piece of black or brown wood, neatly polished, and sometimes inlaid with bits of ivory.

Yams, plantains, and cocoa-nuts, compose the greatest part of their vegetable diet. Of their animal food, the chief articles are, hogs, fowls, fish, and all sorts of shell fish; but the lower people eat rats. The two first vegetable articles, with bread-fruit, are what may be called the basis of their food, at different times of the year, with fish and shell-fish; for hogs, fowls, and turtle, seem only to be occasional dainties, reserved for their chiefs. Their food is generally dressed by baking, and they have the art of making, from different kinds of fruit, several dishes which most of us esteem very good. The generality of them lay their victuals upon the first leaf they meet with, however dirty it may be; but when food is served up to their chiefs, it is commonly laid upon green plantain leaves. The women are not excluded from eating with the men; but there are certain ranks or orders amongst them that can neither eat nor drink together. This distinction begins with the king; but where it ends could not be learnt. They seem to have no set time for meals. They go to bed as soon as it is dark, and rise with the dawn in the morning.

Their private diversions are chiefly singing, dancing, and music, performed by the women. The dancing of the men has a thousand different motions with the hands, to which we are entire strangers; and they are performed with an ease and grace which are not to be described but by those who have seen them.

Whether their marriages be made lasting by any kind of solemn contract, our voyagers could not determine with precision; but it appeared that the bulk of the people satisfied themselves with one wife. The chiefs, however, have commonly several women; tho' it appeared as if one only was looked upon as the mistress of the family.

When any person of consequence dies, his body is washed and decorated by some woman or women, who are appointed on the occasion; and these women are not, by their customs, to touch any food with their hands for many months afterwards; and it is remarkable, that the length of the time they are thus proscribed, is the greater in proportion to the rank of the chief they had washed.

The concern of these people for the dead is most extraordinary. They beat their teeth with stones, strike a shark's tooth into the head until the blood flows in streams, and thrust spears into the inner part of the thigh, into their sides below the arm-pits, and through the cheeks into the mouth. All these operations convey an idea of such rigorous discipline, as must require either an uncommon degree of affection, or the grossest superstition to exact. It should be observed, however, that the more painful operations are only practised on account of the death of those most nearly connected.

Their long and general mourning proves, that they consider death as a very great evil. And this is confirmed by a very odd custom which they practice to avert it. They suppose that the Deity will accept

Friendly
Islands.

Friendly
Islands.

of the little finger, as a sort of sacrifice efficacious enough to procure the recovery of their health. They cut it off with one of their stone hatchets. There appeared scarcely one in ten of them who was not thus mutilated in one or both hands. According to Captain King, it is common also for the inferior people to cut off a joint of their little finger on account of the sickness of the chiefs to whom they belong.

They seem to have little conception of future punishment. They believe, however, that they are justly punished upon earth; and consequently use every method to render their divinities propitious. The supreme Author of all things they call *Kallafootonga*; who, they say, is a female residing in the sky, and directing the thunder, wind, rain, and in general all the changes of weather. They believe that when she is angry with them, the productions of the earth are blasted; that many things are destroyed by lightning; and that they themselves are afflicted with sickness and death as well as their hogs and other animals. When this anger abates, they suppose that every thing is restored to its natural order. They also admit a plurality of deities, though all inferior to *Kallafootonga*. They have less absurd sentiments about the immateriality and the immortality of the soul. They call it *life*, the living principle; or what is more agreeable to their notions of it, *Otooa*; that is, a divinity or invisible being.

Of the nature of their government no more is known than the general outline. According to the information received, the power of the king is unlimited, and the life and property of the subject are at his disposal; and instances enough were seen to prove that the lower order of people have no property, nor safety for their persons, but at the will of the chiefs to whom they respectively belong. When any one wants to speak with the king or chief, he advances and sits down before him with his legs across; which is a posture to which they are so much accustomed, that any other mode of sitting is disagreeable to them. To speak to the king standing would be accounted here as a striking mark of rudeness.

Though some of the more potent chiefs may vie with the king in point of actual possessions, they fall very short in rank and in certain marks of respect, which the collective body have agreed to pay the monarch. It is a particular privilege annexed to his sovereignty, not to be punctured nor circumcised, as all his subjects are. Whenever he walks out, every one whom he meets must sit down till he has passed. No one is allowed to be over his head; on the contrary all must come under his feet; for there cannot be a greater outward mark of submission than that which is paid to the sovereign and other great people of these islands by their inferiors. The method is this; the person who is to pay obeisance squats down before the chief, and bows the head to the sole of his foot: which, when he sits, is so placed that it cannot easily be come at, and having tapped or touched it with the under and upper side of the fingers of both hands, he rises up and retires. The hands, after this application of them to the chief's feet, are in some cases rendered useless for a time: for until they be washed, they must not touch any kind of food. When the hands are in this state, they call it *taboo rema*. *Taboo*, in general,

VOL. VII.

signifies "forbidden," and *rema* is their word for "hand." Their great men are fond of a singular piece of luxury; which is, to have women sit beside them all night, and beat on different parts of their body until they go to sleep; after which they relax a little of their labour, unless they appear likely to awake; in which case they redouble their drumming until they are again fast asleep.

FRIENDSHIP may be defined, a mutual attachment subsisting between two persons; and arising not merely from the general principle of benevolence, from emotions of gratitude for favours received, from views of interest, nor from instinctive affection or animal passion, but from an opinion entertained by each of them that the other is adorned with some amiable or respectable qualities.

The object of the general principle of benevolence is *mankind*, not any particular individual. Gratitude regards the person from whom he who feels its emotions has received a favour, whether that person be a virtuous or a vicious, a respectable or a contemptible, character: it prompts the person obliged to make a suitable return to his benefactor, but not to enter into any particular intimacy with him, merely on account of the favours which he has received. Many connections are formed, and dignified with the name of *friendship*, upon no other principle but the sordid hope which one or perhaps each of the parties entertains of accomplishing some selfish purpose through the assistance of the other; but such a connection is so base in its nature, and so transitory in its duration, as to render it unnecessary for us to spend time in demonstrating it to be unworthy of the name of friendship. The instinctive affection which a parent entertains for his child, as well as that which the child feels for his parent, seem intended by nature to form an union between the persons thus related to each other: but the union between parents and children, when supported by no other principle but instinct, is different from friendship; it extends no farther than to cause the parent to provide for his child during his helpless years, and the child to look up to his parent for protection and support. We need not mention that appetite which is the foundation of love, and is the provision which nature has made for the continuation of our species. This appetite alone, and unassisted by some nobler principle, cannot give rise to any connection worthy of an honourable name.

After excluding these principles, we can refer the origin of friendship only to "an opinion entertained by each of the parties between whom it subsists, that the other is adorned with some amiable or respectable qualities." A connection founded on different principles we cannot honour with the names of friendship; but that which flows from that pure source must be noble and virtuous. When two persons of virtue and abilities contemplate each the other's character and conduct, they cannot but view them with complacency and esteem. Habits and actions displaying prudence, fortitude, moderation, integrity, benevolence, and piety naturally command the approbation of the impartial spectator, and even affect him with delight. But as we are disposed to revisit a landscape, the beauties of which we have contemplated with rapture, and read with frequent delight a poem in which genius has

3 N.

faith-

Friendship. faithfully delineated some of the most enchanting scenes or the most interesting events in nature; so we also become desirous to enjoy frequent opportunities of contemplating a character distinguished for eminent abilities and illustrious virtues. The society of such a person is preferred to his who is disgraced by the opposite qualities. Hence, whenever men of truly respectable characters enjoy opportunities of mutual intercourse, an attachment naturally takes place between them; entirely disinterested, and founded solely on the approbation with which the one cannot avoid regarding the conduct of the other. The esteem which the one is thus induced to entertain for the other will lead them to seek frequent opportunities of enjoying each other's society, mutually to ask and listen to advice, to trust their most secret and important purposes to each other's confidence, and to be no less concerned each of them for the other's interest and honour than for his own. This, and this alone, is genuine friendship, founded on virtue, and on that approbation which virtue never fails to command; it is a natural consequence of intercourse between virtuous men. Where it is once established, it cannot die while those virtues to which it owes its origin continue to adorn the persons between whom it subsists.

3
Circumstances favourable to the rise and continuance of friendship.

But, perhaps, such a pure and sublime attachment can scarce be expected to exist among beings of so mixed and imperfect a character as mankind. The wise man of the ancient Stoics, or the Christian who faithfully obeys the precepts and follows the steps of his Saviour, might be capable of it; but, unfortunately, humanity never reaches such perfection. Virtue and vice are so blended together in every human character, that while none is so worthless as to excite no other sentiment but abhorrence, there is scarce any so uniformly virtuous as to command unvaried esteem or admiration. Even the purest and most disinterested of those friendships which prevail among men, owe their origin to other meaner principles, as well as to that which has been mentioned as the principle of genuine friendship. There are certain circumstances favourable, and others adverse, to the formation and continuance of friendship. These making amends as it were, for the imperfection of human virtue and human knowledge, lead men to overlook each others faults and follies, and to unite in the bonds of friendship; a friendship which though less solid, less generous, and less lasting, than that which we have above described, is yet attended with effects favourable to the happiness of individuals, and to the interests of society in general.

Equality of age is favourable to friendship. Infancy, manhood, and old age differ so considerably from each other, in their views, passions, and pursuits, that the *man* will seldom be disposed to associate with the *boy* or the *youth*, in preference to one who has had equal experience in the world with himself; and the *old man* will generally wish for the company of some ancient friend with whom he may speak of the days of former years."

They who also cultivate the *same trade or profession*, enjoy opportunities favourable to the formation of friendship. Being engaged among the same objects, and acquiring skill in the same arts, their knowledge, their sentiments, and habits, are nearly the same; they cannot avoid frequent intercourse with each other; they naturally enter into each other's prejudices and views,

and therefore cannot but take pleasure in each other's conversation and society. Physicians, lawyers, and divines, form each of them a distinct body; and the members of each of these bodies associate with one another more readily than with men of a different profession. It is related by Swift or Addison, that, in the beginning of the present century, there was a particular coffee-house in London which clergymen used to frequent, and that a son of the church scarce ever ventured to show his head in any other. In the days of Dryden, poets, and all who pretended to poetical genius or taste, resorted to *Will's* as to another Parnassus, to sip cups of coffee, and now and then perhaps to drink of some more inspiring liquor, instead of the waters of the fountain Hippocrene.

Equality of rank and fortune is also favourable to friendship. Seldom will a man of fortune be able to gain the sincere friendship of any of his dependants. Though he treat them with the most obliging condescension, and load them with favours; yet still, either the sense of dependence, or resentment for imaginary injuries, or impatience of the debt of gratitude, or some other similar reason, will be likely to prevent them from regarding him with cordial affection. Servants are but rarely faithful even to the most indulgent master; Shakespeare's old Adam is a very amiable but a very uncommon character. Indeed you may as soon expect to find the virtues and the generous courage of the chevalier Bayard among our military men of the present age, as to find an old Adam among the present race of servants. It is no less vain for the poor man to hope to acquire a sincere friend among his superiors in rank and fortune. The superior is generally disposed to exact such profound deference, such gratitude, such respect, even from the inferior whom he admits into his intimacy, that the equal amicable intercourse of friendship can scarce ever take place between them. Among the letters of the younger Pliny; we are pleased to find many monuments of the goodness of his heart. A number of his epistles addressed to friends in meaner circumstances, appear to have been accompanied with very considerable presents, which by his opulence he was well enabled to bestow. But he takes care to let those humble friends know the weight of the obligations which he conferred, and the vastness of the debt of gratitude which they owed to him, in such plain, nay even indelicate terms, that though they might receive his favours with gratitude and regard him as their benefactor, yet they could never regard him as a man with whom they might cultivate the free easy intercourse of friendship. Some one or other of Greek writers mentions a singular instance of cordial friendship subsisting between two persons in unequal circumstances. One of them dying before the other, and leaving a wife and daughter to whom he had no fortune nor even means of subsistence to bequeath, enjoined his rich friend, in his will, to take the charge of them on himself, and to support them in a liberal manner; nor did he intreat this from his humanity, but demanded it from his friendship. He had made a sure provision for his family. His rich friend delayed not to comply with his dying injunction. He readily took upon himself the charge of the wife and daughter of his deceased friend, treated them with kindness, and at last divided his whole fortune equally

Friendship. equally between his own only daughter and the child of his friend. This is an agreeable instance of the power of friendship: but such instances are not to be expected to occur frequently in ordinary life, any more than the stoic virtue of Cato, or the modest piety of a Nelson.

Similarity of taste and temper will generally be found favourable to friendship. Two peevish men, indeed, will not long endure each other's company with much satisfaction; but two persons of mild humane dispositions will naturally take delight in each other's society and conversation. They who are charmed with the bustle of a gay and active life, avoid the haunts of the indolent and contemplative, and join hand in hand to climb the heights of ambition, or tread the round of amusement and dissipation. Those whom taste leads to cultivate the elegant objects of literature amid the sweets of a rural retirement, to wander thro' the grove, or recline on the brink of some romantic rill, and peruse the pages of one of those geniuses who have shown themselves able to enlighten the understanding, and to kindle the glow of generous sentiment in the breast:—those children of taste frequently associate in their elegant pursuits. We are pleased to read the correspondence of Pliny and Tacitus, of Locke and Molineux, of Swift and Pope. We rejoice to find, that notwithstanding the rivalry of learning and genius, taste and philosophy have a natural tendency to promote benevolence and friendship among their votaries. The bustle of the world must be acknowledged to be generally unfavourable to friendship. When the heart is occupied with the sordid objects of ambition, or avarice, or gay dissipation, there is no room left for the pure and generous sentiments of friendship. Interests often interfere, competitions and jealousies arise, fatal to all the sweets of social intercourse. It is in an active life that virtue shines with the most brilliant lustre; but seldom, alas! does pure virtue appear in the scenes of active life. How beautifully does the character of Atticus shine amid the characters of his illustrious cotemporaries! *ut Luna inter minores ignes!* Sylla, Cæsar, Cicero, Brutus, Antony, and Augustus, were eminent for their abilities and virtues; but being engaged in the bustling pursuits of ambition, they seem to have been strangers to the calm and elegant happiness which Atticus enjoyed. Though those of them who were cotemporaries could not avoid perceiving and admiring each other's merits, yet never did cordial friendship subsist between them. Even Cicero who could so well define the duties and describe the happiness of friendship, yet appears to have but seldom enjoyed its delights. But Atticus, who constantly declined entering the scenes of public life, experienced such happiness in a private condition, as must have been more than an ample reward to him for shunning all the splendid pursuits of ambition. He was the disinterested friend of all those eminent men, and enjoyed their esteem and friendship. So upright was his character, so amiable his manners, that they who were mortal enemies to each other, yet agreed in cultivating at the same time the friendship of Atticus. None of them appear to have hated him on account of his attachment to their enemies: and while he was the friend of Cicero and Octavius, he was at the same time the protector of the wife of Antony. Perhaps

the virtue of such a character may be regarded as problematical. It may be alleged, that while such inveterate dissensions arose among his friends, the neutrality which he preserved was inconsistent with integrity. He has indeed been rashly branded by some writers as an avaricious time-serving man. But no evidence appears to justify their assertions; on the contrary, the most respectable testimony, the nicest scrutiny, exhibit his character in those amiable colours in which we have chosen to view it. Atticus is indeed no ordinary character. The general principles of human nature, and the examples which most frequently occur in the world, naturally suggest a suspicion, that had he been a man of genuine integrity, he must have observed a different tenor of conduct. But there is one circumstance which tends to strengthen considerably the respectable testimony of his cotemporaries in his behalf. In Cato, in Epictetus, in the philosopher who, while suffering under all the violence of an acute distemper, maintained to Pompey that pain was no evil, we have instances of the tenets of philosophy opposing and repressing the principles of nature. We know how often religious enthusiasm has produced the same effects. But Atticus was the votary of the mild and elegant philosophy of Epicurus; which, though there appears to have been a palpable inconsistency between its principles and the superstructure raised upon them, was yet in its general tendency not unfriendly to virtue, and recommended to its votaries that calm and innocent mode of life which Atticus cultivated. There is no small resemblance between the character of Atticus and that of Epicurus, the founder of this philosophy. The same tenets seem to have produced the same effects on both; and we will venture to pronounce so high an encomium on the Epicurean philosophy, as to assert, that it chiefly contributed to form the character of this amiable Roman.

We know not if we may venture to affirm, that friendships are most naturally contracted among persons of the same sex. We believe they often are. If similarity of taste, of sentiments, of manners, be favourable to friendship, this cannot but happen. The distinction which nature has established between the two sexes, the new distinctions which are introduced by the different views with which their education is conducted, and the different duties which they are called to perform in life, have all a tendency to dispose men and women to enter into habits of intimacy with persons of their own sex rather than with the other. Young girls have their peculiar amusements, as boys have theirs; they knit and sew together, consult each other concerning their dress, and associate at their idle hours. Young men, in the same manner, prefer the society of their equals of the same sex till such times as their hearts begin to feel the impulse of a new passion. This soft passion, indeed, causes the youth to prefer the company of his favourite maid to that of his dearest companion; and it perhaps causes the virgin to view her female companions with a jealous eye, while she fears that their charms may win the heart of the youth whose fond regard she herself wishes to engage. But the fears, the jealousies, the timidity, nay even the fondness of love, are incompatible with friendship. Though the lover and his mistress be dear to each other, yet the free confidence of

§
Sex.

Friendship. friendship cannot take place between them. They dare not yet venture to trust to each other all the secrets of their hearts. But if their mutual wishes be crowned by marriage; then, indeed, as their interests become the same, if the transports of love are not succeeded by the calm delights and the free confidence of friendship, they must be unhappy. The marriage state is peculiarly favourable to friendship. Persons whose relations to each other are more remote, will often find circumstances concurring to induce them to cultivate a friendly intercourse with each other. But here indifference is almost impossible. It is absolutely requisite, in order that they may not render each other miserable, that the husband and the wife be united in the bonds of friendship. This seems even to be one of the great laws of nature, by means of which provision is made for the happiness and the preservation of society. But though the wife and the husband be particularly attached to each other by the ties of friendship no less than by those of love, yet their mutual affection will not detach them from the rest of the world; their relations to the society around them will still remain; the husband will still cultivate the intimacy of those of his own sex, and the wife will still choose female in preference to male friends. Upon even a superficial view of life, we find reason to declare without hesitation, that acquaintance and intimacy most naturally take place among persons of the same sex. The husband and the wife are more than friends; they are *one bone and one flesh*. It has been sometimes slightly insinuated, and sometimes more openly asserted, by people who have but carelessly viewed the phenomena of social life, or have been disposed to cavil against the fair sex, that women are incapable of sincerity or constancy in friendship with each other. But it seems unnecessary to offer a serious refutation of this cavil. Neither is the general character of the female sex so inferior to that of the male, nor are their circumstances so very different from ours as to render them totally incapable of those virtues which are necessary to establish and support mutual friendship. They are in general possessed of more exquisite sensibility, nicer delicacy of taste, and a juster sense of propriety, than we: nor are they destitute of generosity, fidelity, and firmness. But such qualities are peculiarly favourable to friendship: they communicate a certain charm to the manners of the person who is adorned with them; they render the heart susceptible of generous disinterested attachment; and they elevate the soul above levity, insincerity, and meanness. Competitions and jealousies must no doubt arise now and then even among the most amiable of the female sex, as well as among us. These will preclude or destroy friendship. But the rivalry of beauty, of dress, of fashion, is not oftener fatal to friendship among the fair sex, than the contests of pride, avarice, vanity, and ambition, among their haughty lords. If friendship be ranked among the virtues, it is not less a female than a male virtue.

5
Relations
of consan-
guinity.

The delightful intercourse and intimacy of friendship may be naturally expected to subsist not only between the husband and the wife, but among all who are connected by any of the relations of consanguinity. The power of instinct does not always continue to unite the parent and the child. Its offices are of a

temporary nature; but when these are performed, it ceases to operate. During the infancy, the childhood, and even the youth, of his son or daughter, the parent watches over them with fond affection, and labours with anxious assiduity to promote their welfare, for no other reason but because the yearnings of paternal affection draw him towards them. But as they advance farther in life, and become able to care for themselves, it has been so ordered by the wisdom of nature, that the attachment of the parent almost dies away, unless the grateful affection and the merit of his children afford him reason to rejoice over them and bless them. How shocking, how miserable, the condition of that family, whose members are not united by the mutual esteem and confidence of friendship! where the parent views his children with jealousy, shame, indignation, or sorrow; and the children anxiously avoid the society of their parents! Their interests are so nearly connected; they have so many occasions for acting in concert, and must live so long together; that we may almost venture to affirm, that the parent and the child, like the husband and the wife, must be either friends or enemies. But the ties of nature, the influence of habit, sentiments, and circumstances, all concur to form between them the sacred connection of friendship. Brothers and sisters, the children of the same parents, and for a while members of the same family, may be expected to regard each other through life with kindness and esteem; and these we would rather choose to attribute to a rational attachment, founded on certain principles, than to a blind instinctive affection.

These are a few of the distinctions and relations in society which appear most favourable to friendship.— Were we to descend to minuter particulars, we might enumerate all the varieties of taste, of temper, and of circumstances, by which mankind are distinguished from one another, and distributed into particular classes. But this would be too tedious, and does not appear necessary.

As friendship is an attachment which takes place between certain human characters when placed in certain circumstances, there must therefore be laws for supporting the attachment and regulating the intercourse of friendship. Mutual esteem is the basis on which true friendship is established; and the intercourse of friendship ought surely to be connected in such a manner that this foundation be not injured. Friendship must diminish neither our benevolence nor prudence: it must not seduce us from an honest attention to our private interest, nor contract our social affections.

Sincerity may be considered as the first law of friendship. Artifice and hypocrisy are inimical to all social intercourse. Between the deceitful and the honest, friendship can never subsist. For a while, the one may impose on the other; unsuspecting integrity may not be able to see through the mask under which the hideous features of selfish cunning are veiled; but the deceitful friend must ever be a stranger to the delightful sentiments of genuine friendship. To enjoy these, your virtues must be sincere, your affection for the person whom you call your friend unfeigned: in communicating to each other your sentiments, in offering and listening to mutual advice, in joining to prosecute the same designs, or share in the same amusements, candid

6
Laws of
friendship.

Friendship. candid sincerity must still be observed between you. Attempt not to persuade each other, that your mutual affection is more ardent, or your mutual esteem more profound, than it really is. If the sentiments or opinions which the one expresses appear to the other improper or ill founded, let not a false delicacy prevent him from declaring his reasons against them; let him not applaud where, if he were sincere, he must blame. Join not even your friend in an undertaking which you secretly dislike, or an amusement insufferably disagreeable to you. You cannot, consistently with sincerity and candour: and you will soon begin to think the blessings of friendship too dear, when bought at the price of such sacrifices.

But though sincerity is to be faithfully observed in the intercourse of friendship; yet the harshness of contradiction must be carefully avoided. Those obliging manners which are so agreeable in an acquaintance or casual companion, are still more so in a friend. If they are necessary to recommend the advantages of social intercourse in general to the members society, they are no less necessary to communicate a charm to the intercourse of friendship. People often think themselves intitled to behave to those whom they call their friends, and whose interests they profess to regard as their own, with harshness, negligence, and indiscreet familiarity; but nothing can be more fatal to friendship. It is a well known maxim, established by general and uniform experience, that *too much familiarity occasions mutual contempt*. And indeed how can it be otherwise? Mild obliging manners are understood as the natural genuine expressions of kindness and affection: boisterous rudeness, petulance, and neglect, are naturally considered as expressive of opposite sentiments. But if friendship assume the tone, the carriage, and the language of enmity or indifference, it must soon lose all its native charms and advantages. Let the friend, as well as the casual companion, when he finds reason to disapprove of the sentiments and conduct, or to dissent from the opinions of his friend, express himself in the gentlest terms, with honesty and sincerity, but without carelessness or harshness. Let no frequency of intercourse nor union of interests ever tempt to careless or contemptuous familiarity. Stiff and unmeaning ceremony may be banished; but ease, and delicacy, and respectful deference, and obliging attention, must supply its room. Much of the unhappiness of the marriage state, and much of the mutual uneasiness which arises among those who are related by the endearing ties of consanguinity, is occasioned by the parties who are thus closely connected, thinking it unnecessary to observe the ordinary rules of good breeding in their mutual intercourse. Even kindness puts on a disgusting garb, and assumes an harsh aspect. But mutual kindness cannot there long subsist. Home, which ought to be a sanctuary to shelter from the anxieties and ills of life, a little paradise where those pure and innocent pleasures might be enjoyed which afford the most genuine happiness, and which are not to be tasted in the bustle of the busy and the dissipation of the gay world;—home thus becomes a place of torment, which is never entered but with pain and unwillingness; and from which the son, the daughter, the husband, and the wife, eagerly seize every opportunity to escape.

Mutual confidence is the very soul of friendship. If Friendship. friendship be rightly defined to be a mutual affection founded on mutual esteem, those who are united in the bonds of friendship cannot but repose mutual confidence in each other. Am I conscious of none but generous worthy sentiments, and none but upright honest intentions? I readily disclose all the secrets of my soul to him whom I regard as capable only of similar designs and similar sentiments. But it may be asked, how far the confidence of friendship ought to be carried? Must I reveal to my friend all my sentiments, opinions, and designs? Must I communicate to one friend the secrets which have been intrusted to me by another? Or must I rather observe the most suspicious caution in my intercourse with my friends, remembering that he who is now my friend may one day become my enemy? It seems most prudent to observe a medium between suspicious caution and unlimited confidence. Were human virtue perfect, and were there no instances of friends ever becoming enemies, those who regard each other with friendly affection might very reasonably be required to set no bounds to their mutual confidence. But as this is far from being the case, different measures are to be observed. Contract no friendships, if you think it necessary to treat a friend with the same reserve as an enemy. Yet venture not to disclose to your friend all the foolish or evil designs which the wantonness of imagination may seduce you to form. When you feel the emotions of pride, of vanity, or of any evil passion, if you are able to repress them by the strength of reason and conscience, it seems unnecessary for you to tell the struggle, or to boast of the victory. If, at any former period of life, you have been so unfortunate as to commit actions which you cannot now recollect without shame and contrition, there can be no reason why you may not, as far as possible, bury the remembrance of them in your own breast. In short, not to become tedious by descending to minute particulars, the laws of friendship do not require friends to unbosom themselves to each other any farther than is necessary—to give them just ideas of each other's character and temper,—to enable them to be serviceable to each other in the prosecution of honest designs,—and to afford each of them proper opportunities of exciting the other to virtue and wisdom, and of interposing his influence to preserve him from vice and folly. Whatever is necessary for any of these purposes ought to be mutually communicated; whatever is not, may be concealed without violating the laws of friendship. As mutual esteem is the foundation of friendship, and as human friendships are not always lasting, you ought not to pour into the ear of your friend all the impertinences which you may happen to conceive, nor even all the projects which may float in your imagination: but as much of the felicity of friendship arises from the mutual confidence to which it affords room, call not any man your friend in whose presence you find it proper to observe the same suspicious caution as if he were your enemy. The ancients, who talked of friendship with enthusiasm as one of the most elevated among the virtues, required still a closer union and a more disinterested attachment among friends than we dare venture to insist upon. The mutual duties which they have described as incumbent on friends, appear somewhat

Friendship: what extravagant. Among other things, some of them have gone so far as to require a degree of mutual confidence which would soon destroy all confidence, and could not fail to counteract all the purposes of friendship: they have required one friend to communicate to another, not only all his own thoughts and purposes, but even those secrets which have been confided to his honour by any other friend. But the evil consequences which should result are easily to be foreseen. Perhaps, like Atticus, you enjoy the friendship of men who are mutual enemies; and by communicating the secrets of the one to the other, you will then become the betrayer of both. Or, though not absolutely enemies, yet those who are *your* friends may happen not to be in habits of friendship with each other; and they may then perhaps not scruple to divulge those secrets of one another which you have imprudently blabbed to them. Indeed, might we suppose all mankind absolutely faultless, and not liable to moral imperfection, we need not fear these bad consequences from unbounded confidence in our friends. But friendship would in such a state of society be unknown; just as in the golden age of the poets there are supposed to have been no distinctions of property. We cannot here forbear dropping an observation, which will readily be acknowledged as just by all who have any tolerable knowledge of the morality of the philosophers of ancient Greece. All their doctrines and precepts appear calculated for a different order of beings than mankind. They glanced carelessly at the phenomena of the moral world; and gleaning a few facts, immediately set themselves to erect systems. From these, however wild and theoretical, they then pretended to deduce laws for the regulation of human conduct; and their rules are generally such as might be expected from the means which they appear to have employed in order to arrive at them. An apology has however been offered for some of them, which in our opinion, could occur only to superficial observers of human life. It has been alledged in behalf of the Stoics, that their system indeed required more exalted virtue than human nature is capable of attaining; but that, notwithstanding this, it could not fail to produce the happiest effects on the manners and sentiments of its votaries. Instances, too, have been produced in support of this assertion; a Cato, an Epictetus, an Antoninus. When we contemplate a model of perfection beyond what we can hope to reach, say the advocates of the Stoic philosophy, though we despair of attaining, yet we are prompted to aspire after it. Now, the most natural way of reasoning here seems to lead to a very different conclusion. If an object is set before me which I must not hope to obtain, I am unwilling to waste my time and exhaust my vigour in the pursuit of it: bid me ascend an inaccessible height, I view the vale below with new fondness. Philosophy, as well as superstition and enthusiasm might in a few instances triumph over the principles of nature; but was it always equally powerful? Were all the disciples of Zeno Catos or Epictetuses? Have all the monks and anchorites of the Romish church been holy as the founders of their orders? No: the Greek philosophers who infested Rome, and taught those *whimsical* doctrines which we hear frequently dignified with the name of *sublime*, were singularly corrupted and licentious in their manners.

Friendship. If those of the *regular* clergy of the church of Rome have been always more pure, they have been cruelly calumniated. Ask, then, only what I am capable of performing: if you demand what is above my strength, I sit still in indolence. In its general tendency, the Stoic philosophy was favourable rather to vice than to virtue.

But we have not yet exhausted all the duties of friendship. We have inculcated sincerity, and mutual respect and obligingness of manners: we have also endeavoured to ascertain, what degree of mutual confidence ought to take place between friends. But an important question still remains to be considered: how far is an *union of interests* to take place between friends? Am I to study the interest of my friend in preference to my own? May I lawfully injure others, in order to serve him? Here, too, we must consider the circumstances and the strength of human nature; and let us beware of imposing burdens too heavy to be borne. The greater and more perfect the union which reigns in society, the greater will be its strength and happiness; the closer the union of friends, the more advantages will each of them derive from their union. Where other ties besides those of friendship concur to unite two individuals, their interests will be more closely conjoined than if they were connected by the ties of friendship alone. The order of nature seems here to be,—the husband and wife—the parent and child—brothers and sisters, the offspring of the same parents—friends, connected by the ties of friendship alone. And, if we may presume to guess at the intentions of the Author of nature from what we behold in his works and read in his word, the closest union in society ought to be that between the husband and the wife; their interests are altogether the same; they ought mutually to forego convenience and gratification for each other's sake. The interests of parents and children are somewhat less closely connected; much is due from the one to the other, but somewhat less than in the former relation; their interests may sometimes be separate, but never ought to be opposite. Next come brethren, and other more distant relations; and next, the friend. In these cases, where we suppose the attachment of friendship to operate together with the ties of nature, we perceive that interests are variously united, and various duties are due; scarce in any of them does it appear that the interests of the two can become entirely one. Still less can that be expected to happen, where the ties of friendship act not in concert with those of nature. We give up, therefore, all those romantic notions, which some have so earnestly insisted on, of requiring the friend to consider his friend as himself. We cannot expect any two individuals to possess precisely the same degree of knowledge, to entertain exactly the same sentiments, or to stand in circumstances precisely similar. But till this happen, the interests of two can never be precisely the same. And we will not, therefore, require the friend actually to prefer his friend to himself; nay, we will even allow him to prefer himself to his friend; convinced that such is the design of nature, and that by presuming to counteract the principles of nature we will be able to serve no useful purpose. But as far as the first principles of human action and the institutions of society permit, we may reasonably require of friends, that they mutually endeavour

Friendship. your to contribute each to the other's interest. You will not desert your own family, nor neglect what is absolutely necessary for your own preservation, in order that you may serve a friend. It is not requisite that you be either a Damon or a Pythias. Away with what is romantic; but scruple not to submit to what is natural and reasonable. When your friend needs your direction and advice, freely and honestly give it: does he need more than advice; your active exertions in his behalf? the laws of friendship require you not to refuse them. Is it necessary for him to receive still more substantial assistance? You may even be expected to aid him with your fortune. But remember, that even the amiable principle of benevolence must be subject to the directions of prudence: if incapable of taking care of ourselves, we cannot be expected to contribute to the good of others: society would not be favourable to the happiness of the human race, if every individual studied the general interest so far as to neglect his own. We are not born to be citizens of the world; but Europeans or Americans, Englishmen or Scotchmen. Let every one, then, seek the interest and happiness of his friends with whom he is connected by the laws of friendship alone, in subordination to his own particular interest and happiness, and to the interest and happiness of those with whom he is connected by the ties of nature and the general institutions of society. Engage not in the service of your friend, nor lavish your fortune in his behalf, if by that means you are likely to injure either yourself or your family. Still less will you think it requisite to carry your friendship to such romantic excess as to commit crimes in the service of your friend. The ancients, whose ideas of the nature and duties of friendship were romantic and extravagant, have, some of them, required that a friend should hesitate at no action, however atrociously wicked, by which he can be useful to his friend. Have I been guilty of theft or murder, or any other heinous violation of the laws of morality or the institutions of society: when I am brought to justice for my crime, if you, being my friend, are appointed to sit as my judge, the laws of friendship, say those admirable masters of morality, require that you pronounce me innocent, though convinced of my guilt. But we need not declaim against the absurdity of enjoining such base deeds as duties of friendship. The idea of a connection, the laws of which are inimical to the order of society, must strike with horror every person who thinks of it. Such a connection is the union of a knot of villains, conspiring against the peace, nay even the existence of society.

7
General view of the advantages of friendship.
 Such we apprehend to be the nature of rational friendship; such the circumstances in the order of nature and of society which are most favourable to this union; and such the duties, by the performance of which it may be maintained. When founded on these principles, and regulated by these laws, friendship is truly virtuous, and cannot but be highly beneficial to the individuals between whom it subsists, and to the interest of society in general. How delightful to have some person of an amiable and virtuous character in whom you can confide; who will join with you in the prosecution of virtuous designs, or will be ready to call you back when you heedlessly stray into the paths of vice and folly! who will administer to you honest,

upright advice; will rejoice in your prosperity, will glory over your virtues, and will be ready to console and relieve you when sinking under the pressure of distress! Must not your connection with such a person be favourable to your virtue, your interest, and your happiness? When we survey any sublime or beautiful scene in nature, we wish for some person of congenial taste and feelings to participate with us in the noble enjoyment which the prospect affords; when we read any fine piece of composition, the pleasure which we receive from it is more exquisite if others join with us in applauding it. The landscape which we have often surveyed, the poem which we have often read, please us anew, with all the charms of novelty, when we have an opportunity of pointing out their beauties to some person to whom they have been hitherto unknown. Friendship communicates new charms and a more delicate relish to all our most refined and elegant pleasures. It enlivens our joys, it soothes and alleviates our sorrows. What Cicero has said of polite letters and philosophy, may be with still stronger propriety said of friendship. In every condition of life the influence of virtuous friendship is favourable to our welfare and our happiness; in prosperity, in adversity; in the silence and tranquillity of retirement, as well as amid the hurry of business; in the bosom of your family, and when surrounded by your nearest connections, no less than when removed to a strange country. Indeed, whatever advantages society bestows above what are to be enjoyed in a savage state, not less numerous nor less important are those which we may derive from uniting in the bonds of friendship, rather than living in a state of enmity or indifference.

8
Mistakes in forming friendships, and consequent inconstancy.
 But though friendship, when founded on mutual esteem, and regulated by the laws of prudence, benevolence, and honesty, be productive of so many happy effects; yet many instances occur in the world, in which connections dignified with the name of friendship are unfavourable both to the virtue and the happiness of those between whom they subsist. When men associate from views of convenience; when their union is hastily formed without a knowledge of each other's temper and character; when they are drawn together by accident, as when they happen to agree in the pursuits of the same interests or pleasures; when the young and the gay resort together to the haunts of dissipation, and the covetous and ambitious find it convenient to toil in concert for riches and power: on all such occasions, the connection which is formed and dignified with the name of friendship is unworthy of that honourable appellation. It is not virtuous; it is productive of no happy effects, and is quickly dissolved. He, therefore, who is not incapable of virtuous friendship, and is desirous of enjoying its advantages, must carefully consider the nature of the connection which he wishes to form, gain a thorough acquaintance with the character of the person whose esteem and affection he wishes to acquire, and attend to those rules by the observance of which true friendship may be maintained.

9
Relation illustrating the power of friendship over the human heart.
 Many instances are related, which show what power it is possible for friendship to acquire over the human heart. We need not here repeat the well-known story of Damon and Pythias, whose generous friendship afforded a spectacle which softened even the savage heart of heart.

Friendship

Friendship. of Dionysius. It is known to every school-boy; and, after the affected narrative of Valerius Maximus, has been studiously detailed and commented on by almost every succeeding story-teller or moralist. Addison, in one of his Spectators, gives a beautiful little relation, we know not upon what authority, which finely illustrates the power both of friendship and love. Two male negroes, in one of the West-India islands, nearly of the same age, and eminent among their fellows in slavery for gracefulness of figure, strength, agility, and dexterity, were also distinguished for their mutual friendship and for their common attachment to a young female negro, who was generally esteemed the most beautiful of her complexion in the whole island. The young female appeared to be equally pleased with both her lovers; and was willing to accept either of them for a husband, provided they could agree between themselves which of them should yield to the pretensions of the other. But here lay the difficulty; for while neither would treacherously supplant, neither of them was willing to yield to his friend. The two youths, therefore, long suffered the severest affliction, while their hearts were torn between love and friendship. At length, when they were no longer able to endure the agony of such a contest, being still unable to repress their passion for their lovely countrywoman, and incapable of violating the laws of friendship,—on a certain day, they both, in company with the object of their ill-fated love, retired into a wood adjoining to the scene of their labours. There, after fondly embracing the maid, calling her by a thousand endearing names, and lamenting their own unhappy fate, they stabbed a knife into her breast; which, while still reeking with her blood, was by each of them in his turn plunged into his own. Her cries reached the people who were at work in the next field: some of them hastening to the spot, found her expiring, and the two youths already dead beside her.

We have introduced this little narrative as a striking instance of the noble effects which naturally result from genuine friendship. Here we see it superior to the force of the most violent of passions. Had the elevated souls of those negro youths been refined and enlightened by culture and education in the principles of morality and true religion, we may reasonably suppose that their friendship would have triumphed over their love, without prompting them to the rash and desperate deed which they committed.

10
Friendship
not incon-
sistent with
the spirit of
Christiani-
ty.

Friendship, thus amiable in its character, thus beneficial in its influence and effects, the theme of unbounded panegyric to the philosophers and moralists of every age, has been said by some respectable modern writers to be inconsistent with the spirit of that holy religion which we profess, and which we regard as the revelation of heaven. General benevolence is frequently inculcated through the gospel: Jesus often earnestly intreated his disciples, “to love one another;” and directed them in what manner to display their mutual love, by telling them, that “whatsoever things they could reasonably wish to receive from others, the same ought they to do them.” The writers of the epistles often enlarge on the topics of charity and brotherly love. But private friendship is no where recommended in the code of Christianity. Nay, it is so inconsistent with that universal benevolence which

the gospel enjoins, that where the one is recommended and enforced, the other may be understood to be tacitly forbidden. But can that religion be true, or can it be favourable to the happiness of its votaries, which is inimical, nay which is even not friendly to virtuous friendship? Such are the suggestions of Lord Shaftesbury and Soame Jenyns on this head.

We must grant them, that the system of morals or religion which discourages a connection so noble in its origin, so amiable in its character, and so beneficial in its influence, as virtuous friendship, is rather unfavourable to the happiness and virtue of its votaries. But we must consider the genius of Christianity with more careful attention, before we suffer ourselves to be persuaded that friendship is inconsistent with it. Universal benevolence is, indeed, inculcated in the gospel: we are required to love our neighbours as ourselves; and our Saviour seems to insinuate, in the story of the humane Samaritan, that we ought to regard as neighbours all our brethren of the human race, however separated from us by any of the distinctions of society. But it would be unfair to conclude from this that the great author of the gospel meant to abolish the order of social life or to oppose the ties of nature. These may still be respected, though the laws of this benevolence be obeyed. The parent is not required to desert his child, in order that he may assist or relieve his neighbour; nor the child to leave his parent to perish under the infirmities of old age, while he hastes to lend assistance to a stranger. The gospel was not intended to dissolve communities, or to abrogate the distinctions of rank. In Jesus the end of the ceremonial law was accomplished: by him, therefore, that burthen of types and ceremonies with which the Jews had been loaded was taken away. But he who abolished the ceremonial law declared, that the obligations of the moral law should be more permanent than heaven or earth: The duties which it enjoyed were still to be religiously discharged: The precepts of the Gospel were to illustrate and enforce, not to contradict, the institutions of the moral law. The relative duties of parents and children were still to be performed; though men were directed not to confine all their sentiments of benevolence to domestic relations. Jesus, in his conduct, did not set himself to oppose the order of society. In various parts of the New Testament all the social duties are defined and enforced; the mutual duties of parents and children, of husbands and wives, and of masters and servants. The submission of all the members of a community to that power which is vested with the authority of the whole, is also strictly enjoined in the gospel. Jesus, when in his last moments he recommended his mother to the protection of his beloved disciple, chose to ask *him* to consider *her* as a parent; and directed *her* to expect from *him* the respect and kindness of a son. These facts and observations teach us in what sense to understand that universal benevolence which is inculcated in the gospel. Though we are to love all mankind; yet it is not necessary that all the individuals of the human race share our affection alike. Were we powerful, and wise, and benevolent, as the Deity, such extensive benevolence might be required of us: But our sphere of action and observation is narrow; we cannot extend our acquaintance or influence beyond a very limited circle. Were we to en-
deavour

Friendship. deavour to be equally useful to all mankind, we should become incapable of being useful to any individual. We cannot become citizens of the world in the sense in which some philosophers have affected to call themselves such, without becoming outcasts from every particular society. A son, a brother, a countryman, a stranger, lie around you, each in circumstances of extreme distress; you pity their misfortunes, and would gladly administer relief: but such is your benevolence, that you feel precisely the same degree of compassion for each of them; you cannot determine to whom you should first stretch out an helping hand; and you therefore stand like that venerable ass of the schoolmen, whose tantalizing situation between two bundles of hay has been so long celebrated and lamented by metaphysicians; and saffer son, and brother, and countryman, and stranger, to perish, without relieving any of them by your kind offices. It is therefore the design of the gospel, that we should submit to the laws of nature, and comply with the institutions of society. First, attend to self-preservation; next perform the duties of a wife or husband,—a parent,—a child,—a brother,—a citizen,—an individual of the human race. You will do well, indeed, to regard all mankind with benevolence; but your benevolence will be unavailing to the objects of it, if you overlook the distinctions of nature and those institutions which support the union of social life.

But if the spirit of Christianity be not inimical to the institutions and relations of society, neither can it be unfavourable to friendship. If that benevolence which the gospel enjoins, admit of any modifications, why not of that particular modification which constitutes private friendship? It is not indeed, directly enjoined; but neither is it forbidden. It is perfectly consistent with the general tendency and spirit of the gospel system: being favourable to the interests of society, it cannot but be agreeable to our holy religion.

But it is recommended by no direct precept, say those who would represent Christianity as inimical to it; while it has been the favourite theme of the philosophers and moralists of the heathen world.

But why should friendship be recommended by means different from those which the gospel employs for the purpose? Make yourself well acquainted with that admirable system which you so earnestly oppose; you will find that even the duties of private friendship are better explained and more powerfully enforced in the gospel, than by all the heathen philosophers and poets from Hesiod to Plutarch. The gospel makes a distinction between the virtuous and the vicious; it represents one character as more amiable and respectable than another. As it distinguishes between virtue and vice, between piety and impiety; so its great object is to deter us from vice, and to encourage us to the practice of virtue. It cannot be supposed, then, that the gospel will direct us to associate indifferently with virtuous and profligate characters. It does not. It directs us to seek improvement, by associating with those whom we have reason to esteem. It directs those who are incorrigibly wicked to be expelled from society. What is this but to command us to enter into habits of intimacy wherever there is ground for mutual esteem? But this is the only basis of genuine friendship. When all the means which lead to a certain

VOL. VII.

end are laid before you, and when you are particularly directed by some high authority to employ those means; though the end which you thus attain be not pointed out, yet the commanding you to employ such a series of means, is evidently the same as if you were directed to accomplish the purpose to which they tend. Thus, though the precepts of Christianity do not directly enjoin private friendship; yet they have a direct tendency to form those exalted characters who alone are capable of true friendship; they inculcate those virtues which naturally give rise to this generous attachment, and are absolutely necessary to support it where it is formed; they inculcate benevolence by the most effectual motives, and admit of modifications of that benevolence, correspondent to the relations and institutions of society: And therefore they may considered in as strong and direct terms, as if it had been expressly said, "Cultivate private friendship." Besides, friendship is rather an *accident* of society, a natural consequence of our character as moral and social beings; than a relation to be regulated and defined by institutions.

This union, so natural between virtuous persons, has been countenanced by the example of the Author of our religion; to whose life, no less than to his doctrines and precepts, we will do well to look for a standard by which we may regulate our conduct. We allude to two remarkable instances which occur in the evangelical history; and with the recital of which, as stated in all their striking circumstances by a very elegant writer*, we shall conclude the present article.

"The evangelist, in relating the miracle which Christ performed at Bethany by restoring a person to life who had lain some days in the grave, introduces his narrative by emphatically observing, that 'Jesus loved Lazarus;' intimating, it should seem, that the sentiments which Christ entertained of Lazarus were a distinct and peculiar species of that general benevolence with which he was actuated towards all mankind. Agreeably to this explication of the sacred historian's meaning, when the sisters of Lazarus sent to acquaint Jesus with the state in which their brother lay, they did not even mention his name; but pointing him out by a more honourable and equally notorious designation, the terms of their message were, 'Behold! he whom thou lovest is sick!' Accordingly, when he informs his disciples of the notice he had thus received, his expression is, 'Our friend Lazarus sleepeth.' Now that Christ did not upon this occasion use the word *friend* in its loose undistinguished acceptation, but in a restrained and strictly appropriated sense, is not only manifest from this plain account of the fact itself, but appears farther evident from the sequel. For as he was advancing to the grave, accompanied with the relations of the deceased, he discovered the same emotions of grief as swelled the bosoms of those with whom Lazarus had been most intimately connected; and sympathizing with their common sorrow, he melted into tears. This circumstance was too remarkable to escape particular observation: and it drew from the spectators, what one would think it must necessarily draw from every reader, this natural and obvious reflection, 'Behold! how he loved him!'

"But in the concluding catastrophe of our Saviour's life, he gave a still more decisive proof that sentiments

Friendship.

II
Friendship countenanced by our Saviour's example.

* W. Melmoth, Esq; in the concluding note to his *Translation of Cicero's Lælius.*

Friendship, of the strongest personal attachment and friendship were not unworthy of being admitted into his sacred bosom: they were too deeply, indeed, impressed, to be extinguished even by the most excruciating torments. In those dreadful moments, observing among the afflicted witnesses of his painful and ignominious sufferings, that faithful follower who is described by the historian as 'the disciple whom he loved;' he distinguished him by the most convincing instance of superior confidence, esteem, and affection, that ever was exhibited to the admiration of mankind. For, under circumstances of the most agonizing torments, when it might be thought impossible for human nature to retain any other sensibility but that of its own inexpressible sufferings, he recommended to the care and protection of this his tried and approved friend, in terms of peculiar regard and endearment, the most tender and sacred object of his private affections. But no language can represent this pathetic and affecting scene with a force and energy equal to the sublime simplicity of the Evangelist's own narrative: 'Now there stood by the cross of Jesus, his mother and his mother's sister, and Mary Magdalene. When Jesus saw his mother and the disciple (standing) by, whom he loved; he saith to his mother, Behold thy son! then he saith to the disciple, Behold thy mother! And from that hour that disciple took her to his own home.'

"It may safely be asserted, that among all those memorable examples of friendship, which have been celebrated with the highest encomiums by the ancients, there cannot be produced a single instance in which the most distinguishing features of exalted amity are so strongly displayed as in the foregoing relation. The only one, perhaps, that bears even a faint similitude to it, is that famous transaction † recorded by a Greek author, which passed between Eudamidas and Aretheus. But when the very different circumstances attending the respective examples are duly considered, it must be acknowledged, that the former rises as much above the latter in the proof it exhibits of sublime friendship, as it does in the dignity of the characters concerned.

"Upon the whole, then, it appears, that the divine Founder of the Christian religion, as well by his own example as by the spirit of his moral doctrine, has not only encouraged but consecrated friendship."

PRIESLAND, one of the united provinces of the Low Countries. It is bounded on the east by the river Lauvers, which parts it from the lordship of Groningen, on the south by Overijssel, on the west by the Zuider-Zee, and on the north by the German ocean. It is 30 miles from the north to south, and 28 from east to west. The land is very fertile in corn and pasture; the horses are large, and the cows and sheep prolific. It is divided into three parts; Westergo to the west, Ostergo to the east, and Sevenwalden to the south. The islands of Sheling, Ameland, and other small ones, are dependent on this province. The principal towns are Lewarden the capital, Franeker, Dockum, Harlingen, and Staveren.

FRIESLAND (East), a province of Germany, in the circle of Westphalia, lying near the German ocean. It is bounded on the south by the bishopric of Munster, on the east by the county of Oldenburg, on the west by the province of Groningen, and on the north by

the sea, being about 50 miles in length, and 30 in breadth. It belongs to Prussia, and was formerly called the *county of Embden*. It is a very fertile country, and feeds a great number of cattle; but it was greatly damaged by an inundation in 1717, and the repair of the dykes cost an immense sum. The principal towns are Norden, Leer, Effens, Whitmunde, and Aurick. Embden was an imperial city, and the principal place in the country; but now belongs also to the king of Prussia, who bought it of the Dutch.

FRIGATE, in sea affairs, a ship of war usually of two decks, light built, designed for swift sailing. When it hath but one deck, and consequently is of a smaller size, they call her a light frigate.

Frigates mount from 20 to 44 guns, and are esteemed excellent cruisers. The name was formerly known only in the Mediterranean, and applied to a long kind of vessel navigated in that sea with sails and oars. The English were the first who appeared on the ocean with these ships, and equipped them for war as well as for commerce.

FRIGATE-built, denotes the disposition of the decks of such merchant ships as have a descent of four or five steps from the quarter-deck and fore-castle into the waist, in contradistinction to those whose decks are on a continued line for the whole length of the ship, which are called *galley-built*.

FRIGATOON, a Venetian vessel, commonly used in the Adriatic, built with a square stern, and without any fore-mast, having only a main-mast, mizen-mast, and bow-sprit.

FRIGHT, or TERROR, a sudden and violent degree of fear. See FEAR.

Sudden fear is frequently productive of very remarkable effects upon the human system. Of this many instances occur in medical writings.—In general, the effects of terror are a contraction of the small vessels and a repulsion of the blood in the large and internal ones; hence proceed a suppression of perspiration, a general oppression, trembling, and anguish of the heart, and lungs overcharged with blood.

Frights often occasion incurable diseases, as epilepsy, stupor, madness, &c. In acute diseases, they have evidently killed many, by the agitation into which they have thrown the spirits, already too much disordered. We have also accounts of persons absolutely killed by terrors when in perfect health at the time of receiving the shock from them: people ordered to be executed, but with private orders for a reprieve, have expired at the block without a wound.—Out of many instances of the fatal effects of fear recorded in writers, the following is selected as one of the most singular. "George Grochantzy, a Poland, who had enlisted as a soldier in the service of the king of Prussia, deserted during the last war. A small party was sent in pursuit of him; and when he least expected it, they surprised him singing and dancing among a company of peasants, who were got together in an inn and were making merry. This event, so sudden and unforeseen, and at the same time so dreadful in its consequences, struck him in such a manner, that, giving a great cry, he became at once altogether stupid and insensible, and was seized without the least resistance. They carried him away to Glocau, where he was brought before the council of war, and received sentence as

Frigate
|
Fright.

† Already recited in this article, p. 466, col. 2.

Fright. a deserter. He suffered himself to be led and disposed of at the will of those about him, without uttering a word, or giving the least sign that he knew what had happened or would happen to him. He remained immovable as a statue wherever he was placed, and was wholly passive with respect to all that was done to him or about him. During all the time that he was in custody, he neither eat, nor drank, nor slept, nor had any evacuation. Some of his comrades were sent to see him; after that he was visited by some officers of his corps and by some priests; but he still continued in the same state, without discovering the least signs of sensibility. Promises intreaties, and threatenings, were equally ineffectual. The physicians who were consulted upon his case were of opinion, that he was in a state of hopeless idiocy. It was at first suspected, that those appearances were feigned; but these suspicions necessarily gave way, when it was known that he took no sustenance, and that the involuntary functions of nature were in a great measure suspended. After some time they knocked off his fetters and left him at liberty to go whither he would. He received his liberty with the same insensibility that he had showed upon other occasions: he remained fixed and immovable; his eyes turned wildly here and there without taking cognizance of any object, and the muscles of his face were fallen and fixed like those of a dead body. Being left to himself, he passed 20 days in this condition, without eating, drinking, or any evacuation, and died on the 20th day. He had been sometimes heard to fetch deep sighs; and once he rushed with great violence on a soldier, who had a mug of liquor in his hand, forced the mug from him, and having drank the liquor with great eagerness, let the mug drop to the ground.

When a person is affected with terror, the principal endeavour should be to restore the circulation to its due order, to promote perspiration, and to allay the agitation of the patient. For these purposes he may drink a little warm liquor, as camomile-tea, &c. the feet and legs may be put into warm water, the legs rubbed, and the camomile-tea repeated every six or eight minutes; and when the skin is warm, and there is a tendency to perspiration, sleep may be promoted by a gentle opiate.

But frights have been known not only to cause, but also to cure, diseases. Mr Boyle * mentions agues, gout, and sciatica, cured by this means.

To turn from the serious to the ludicrous effects of fear, the following instance of the latter sort, quoted from a French author by Mr Andrews in his volume of Anecdotes, shows upon what slight occasions this passion may be sometimes excited in a very high degree, even in persons the most unlikely to entertain such a guest. "Charles Gustavus (the successor of Christina of Sweden) was besieging Prague, when a boor of most extraordinary visage desired admittance to his tent; and being allowed entrance, offered, by way of amusing the king, to devour a whole hog of one hundred weight in his presence. The old general Konigsmarc, who stood by the king's side, and who, soldier as he was, had not got rid of the prejudices of his childhood, hinted to his royal master that the peasant ought to be burnt as a forcerer. 'Sir,' said the fellow, irritated at the remark, 'if

your majesty will but make that old gentleman take off his sword and his spurs, I will eat him immediately before I begin the hog.' General Konigsmarc (who had, at the head of a body of Swedes, performed wonders against the Austrians, and who was looked upon as one of the bravest men of the age) could not stand this proposal, especially as it was accompanied by a most hideous and preternatural expansion of the frightful peasant's jaws. Without uttering a word, the veteran suddenly turned round, ran out of the court, and thought not himself safe until he had arrived at his quarters; where he remained above 24 hours locked up securely, before he had got rid of the panic which had so severely affected him."

Fear (Dr Beattie † observes) should not rise higher than to make us attentive and cautious; when it gains an ascendancy in the mind, it becomes an insupportable tyranny, and renders life a burden. The object of fear is evil; and to be exempt from fear, or at least not enslaved to it, gives dignity to our nature, and invigorates all our faculties. Yet there are evils which we ought to fear. Those that arise from ourselves, or which it is in our power to prevent, it would be madness to despise, and audacity not to guard against. External evils which we cannot prevent, or could not avoid without a breach of duty, it is manly and honourable to bear with fortitude. Insensibility to danger is not fortitude, no more than the incapacity of feeling pain can be called patience; and to expose ourselves unnecessarily to evil is worse than folly, and very blameable presumption. It is commonly called fool-hardiness; that is, such a degree of hardiness or boldness as none but fools are capable of. See the article FORTITUDE.

FRIGID (*frigidus*), in a general sense, denotes the quality of being cold. It is frequently applied to a jejune style, that is unanimated by any ornaments, and consequently without any force or vigour.

FRIGID Zone. See ZONE.

FRIGIDITY, in medicine, the same with IMPOTENCE.

FRIGORIFIC, in physiology, small particles of matter, which, according to Gassendus and others, being actually and essentially cold, and penetrating other bodies, produce in them that quality which we call cold. See COLD.

FRILAZIN, the name of a class or rank of people among the Anglo-Saxons, consisting of those who had been slaves, but had either purchased, or by some other means obtained, their liberty. Though these were in reality free men, they were not considered as of the same rank and dignity with those who had been born free, but were still in a more ignoble and dependent condition, either on their former masters or on some new patrons. This custom the Anglo-Saxons seem to have derived from their ancestors in Germany, among whom those who had been made free did not differ much in point of dignity or importance in the state from those who continued in servitude. This distinction between those who have been made free and those who enjoy freedom by descent from a long race of free men, still prevails in many parts of Germany; and particularly in the original seats of the Anglo-Saxons. Many of the inhabitants of towns and cities in England, in this period, seem to have been of this class of men,

Frill.
Fringilla.

who were in a kind of middle state between slaves and freemen.

FRILL, in falconry. When a hawk trembles or shivers, they say she frills.

Plate
CCIII.

FRINGILLA, in ornithology, a genus belonging to the order of passerines. The bill is conical, straight, and sharp-pointed. There are no less than 108 species comprehended under this genus, distinguished principally by varieties in their colour. The following are the most noted.

1. The *carduelis*, or GOLDFINCH, with the quill-feathers red forwards, and the outermost without any spots; the two outermost are white in the middle, as the rest are at the point. The young bird before it moults is grey on the head; and hence it is termed by the bird-catchers a *grey-pate*. There is a variety of goldfinches called by the London bird-catchers a *cheverel*, from the manner in which it concludes its jerk. It is distinguished from the common sort by a white streak, or by two, sometimes three white spots under the throat. Their note is very sweet; and they are much esteemed on that account, as well as for their great docility. Towards winter, they assemble in flocks; and feed on seeds of different kinds, particularly those of the thistle. It is fond of orchards, and frequently builds in an apple or pear-tree: its nest is very elegantly formed of fine moss, liverworts, and bents, on the outside; lined first with wool and hair, and then with the gossin or cotton of the fallow. It lays five white eggs, marked with deep purple spots on the upper end; and has two broods in the year. When kept in cages, they are commonly fed much on hemp-seed, which they eat freely, but which is said to make them grow black, and lose both their red and yellow. The goldfinch is a long-lived bird, often attaining the age of 20 years.—This species is plenty throughout Europe; it is also met with both in Asia and Africa, but less common.

2. The *caelebs*, or CHAFFINCH, hath black limbs, and the wings white on both sides; the three first feathers of the tail are without spots, but two of the chief are obliquely spotted. It has its name from its delighting in chaff. This species entertains agreeably with its song very early in the year, but towards the latter end of summer assumes a chirping note: both sexes continue in Britain the whole year. What is very singular in Sweden, the females quit that country in September, migrating in flocks into Holland, leaving their mates behind: in the spring they return. In Hampshire Mr White has observed something of this kind; vast flocks of females with scarcely any males among them. Their nest is almost as elegantly constructed as that of the goldfinch, and of much the same materials, only the inside has the addition of some large feathers. They lay four or five eggs of a dull white colour, tinged and spotted with deep purple. They are caught in plenty in flight-time; but their nests are rarely found, though they build in hedges and trees of all sorts. They make their nests of moss and wool, or any thing they can gather up; and have young ones thrice a-year. They are seldom bred from the nest, as being a bird not apt to learn another's song, nor to whistle; so that it is best to leave the old ones to bring them up. The Essex finches are generally allowed to be the best sort, both for length of

song and variety, ending with several notes that are very pretty. It is an hardy bird, and will live almost upon any seeds, none coming amiss to him. He is seldom subject to disease, but will be very lousy if not sprinkled with wine two or three times a-month.

3. The *montifringilla*, or BRAMBLING, has a yellow bill tipped with black; the head, hind part of the neck, and back, are black; the throat, fore part of the neck, and breast, pale rufous orange; lower part of the breast and belly white; the quill feathers brown, with yellowish edges; the tail a little forked: the legs grey. This species migrates into England at certain seasons, but does not build there. It is frequently found among chaffinches, and sometimes comes in vast flocks. They are also seen at certain times in vast clouds in France, insomuch that the ground has been quite covered with their dung, and more than 600 dozen were killed each night. They are said to be particularly fond of beech mast, but will also eat seeds of various other kinds. Their flesh is eaten by many, but is apt to prove bitter. They are said to breed about Luxemburg, making the nest on the tall fir-trees, composed of long moss without, and lined with wool and feathers within: the eggs are four or five in number, yellowish, and spotted: and the young are fledged at the end of May. This species is found more or less throughout Europe; and is common in the pine forests of Russia and Siberia, but those of the last are darker in colour and less in size.

4. The *domestica*, or SPARROW, hath the prime feathers of the wings and tail brown, the body variegated with grey and black, and a single white streak on the wings. These well-known birds are proverbially fallacious, and have three broods in a year. They are every where common about houses, where they build in every place they can find admittance; under the roof, corner of the brick-work, or in holes of the wall. They make a slovenly nest; generally a little hay ill put together, but lined well with feathers; where they lay five or six eggs of a reddish white colour spotted with brown. They will sometimes build in the neighbouring trees, in which case they take more pains with the nest: and not unfrequently they expel the martins from theirs, to save the trouble of constructing one of their own. The sparrow, from frequenting only habitations and parts adjacent, may be said to be chiefly fed from human industry; for in spite of every precaution, it will partake with the pigeons, poultry, &c. in the food thrown out to them, grain of all kinds being most agreeable to its taste; though it will eat refuse from the kitchen of most kinds. It is a familiar but crafty bird, and will not so easily come into a snare as many others. In autumn they often collect into flocks, and roost in numbers on the neighbouring trees, when they may be shot by dozens, or at night caught in great numbers by a bat fowling-net. The flesh is accounted tolerable by many. The sparrow has no song, only a chirp or two frequently repeated, and far from agreeable. This species is spread every where throughout Europe; and is also met with in Egypt, Senegal, Syria, and other parts of Africa and Asia.

5. The *spinus*, or SISKIN, hath the prime feather of the wings yellow in the middle, and the four first chief tail-feathers without spots; but they are yellow at the base,

Fringilla.

Fringilla.

base, and black at the points. Mr Willoughby tells us, that this is a song-bird: that in Suffex it is called the *barley-bird*, because it comes to them in barley-feed time. We are informed that it visits Britain at very uncertain times, like the gros beak, &c. It is to be met with in the bird-shops in London; and being rather a scarce bird, sells at a higher price than the merit of its song deserves: it is known there by the name of the *aberdavine*. It is a very tame and docile species; and is often kept and paired with the canary-bird, with which it breeds freely. The bird-catchers have a notion of its coming out of Russia. Dr Kramer informs us, that this bird conceals its nest with great art; and though there are infinite numbers of young birds in the woods on the banks of the Danube, which seem just to have taken flight, yet no one could discover it.

6. The *linota*, or LINNET, has the bottom of the breast of a fine blood-red, which heightens as the spring advances. These birds are much esteemed for their song. They feed on seeds of different kinds, which they peel before they eat; the seed of the linum or flax is their favourite food; from whence the name of the linnet tribe. They breed among furze and white thorn: the outside of their nest is made with moss and bents, and lined with wool and hair. They lay five whitish eggs, spotted like those of the goldfinch.

7. The *cannabina*, or GREATER RED-POLE, is rather less than the common linnet, and has a blood-coloured spot on the forehead, and the breast of the male is tinged with a fine rose-colour. It is a common fraud in the bird-shops in London, when a male-bird is distinguished from the female by a red-breast, as in the case of this bird, to stain or paint the feathers, so that the deceit is not easily discovered, without at least close inspection. These birds are frequent on the British coasts; and are often taken in flight-time near London: it is a familiar bird; and is cheerful in five minutes after it is caught.

8. The *linaria*, or LESSER RED-POLE, is about half the size of the last, and a rich spot of purplish red on the forehead: the breast is of the same colour, but less bright. The female is less lively in colour; has no red on the breast; and the spot on the forehead is of a saffron hue. This species is common enough in England; and lays four or five eggs of a pale bluish green, thickly sprinkled near the blunt end with small reddish spots. Mr Pennant mentions an instance of this bird being so tenacious of her nest, as to suffer herself to be taken off by the hand; and that when released she would not forsake it. This species is known about London by the name of *stone redpole*. Linnæus, Kramer, and others, mention its being very fond of the seeds of alder. Whole flocks of them, mixed with the fishkin, frequent places where alders grow, for the sake of picking the catkins: they generally hang like the titmouse, with the back downwards; and in this state are so intent on their work, that they may be entangled one after another by dozens, by means of a twig smeared with birdlime fastened to the end of a fishing rod or other long pole. This species seems to be in plenty throughout Europe, from the extreme parts of Russia on the one hand to Italy on the other. Is very common in Greenland, and was also met with

by late voyagers at Aoonalashka. In America it is likewise well known. Hence it seems to be a bird common to the whole of the northern part of the globe without exception.

Fringilla.

9. The *montium*, or TWITE, is about the size of a linnet. It has the feathers of the upper part of the body dusky; those on the head edged with ash-colour, the others with brownish red: the rump is pale crimson; the wings and tail are dusky, the tips of the greater coverts and secondaries whitish; the legs pale brown. The female wants the red mark on the rump. Twites are taken in the flight-season near London along with other linnets. It is probable that the name has been taken from their twittering note, having no music in it; and indeed the bird-catchers will tell at some distance whether there be any twites mixed among linnets merely from this circumstance. The twite is supposed to breed in the more northern parts of Britain.

10. The *amandava*, or AMADUVADE BIRD, is about the size of a wren. The colour of the bill is of a dull red; all the upper parts are brown, with a mixture of red; the under the same, but paler, the middle of the belly darkest; all the feathers of the upper wing-coverts, breast, and sides, have a spot of white at the tip; the quills are of a grey brown; the tail is black; and the legs are of a pale yellowish white. It inhabits Bengal, Java, Malacca, and other parts of Asia.

11. The *Senegala*, or SENEGAL FINCH, is a species very little bigger than a wren. The bill is reddish, edged all round with brown; and beneath the under mandible a line of brown quite to the tip; the same also is seen on the ridge of the upper mandible: the upper parts of the body are of a vinaceous red colour; the lower parts, with the thighs and under tail-coverts, of a greenish brown; the hind part of the head and neck, the back, scapulars, and wing coverts, are brown; the tail is black; and the legs are pale grey. It inhabits Bengal; and, with the former species, feeds on millet. This affords the natives an easy method of catching them: they have no more to do than to support a large hollowed gourd, the bottom uppermost, on a stick, with a string leading to some covered place, and strewing under it some millet; the little birds, hastening in numbers to pick it up, are caught beneath the trap, by the stick being pulled away by the observer at a distance. The females are said to sing nearly as well as the males. They are familiar birds; and when once used to the climate, will frequently live five or six years in a cage. They have been bred in Holland by the fanciers of birds.

12. The *canaria*, or CANARY-BIRD, hath a whitish body and bill, with the prime feathers of the wings and tail greenish. It was originally peculiar to those isles to which it owes its name; the same that were known to the ancients by the addition of the *Fortunate*. Though the ancients celebrate the isle of Canaria for the multitude of birds, they have not mentioned any in particular. It is probable, then, that the species was not introduced into Europe till after the second discovery of these isles, which was between the 13th and 14th centuries. We are uncertain when it first made its appearance in that quarter of the globe. Belon, who wrote in 1555, is silent in respect to these birds: Gesner is the first who mentions them; and Al-drovand

Frippery
||
Frit.

drovand speaks of them as rarities, observing that they were very dear on account of the difficulty attending the bringing them from so distant a country, and that they were purchased by people of rank alone. They are still found on the same spot to which we were first indebted for the production of such charming songsters; but they are now become so numerous in our own country, that we are under no necessity of crossing the ocean for them.—The Canary-bird will prove fertile with the siskin and goldfinch; but in this case the produce, for the most part, proves sterile: the pairs succeed best when the hen-bird is the Canary, and the cock of the opposite species. It will also prove prolific with the linnet, yellow-hammer, chaffinch, and even the house sparrow; but the male Canary-bird will not assimilate with the female of these birds; the hen must be ever of the Canary species, and the young of these mostly prove male birds.—This bird is said by some to live 10 or 15 years; by others, as far as 18.

FRIPPERY, a French term sometimes used in our language to signify the trade or traffic of old second-hand clothes and goods. The word is also used for the place where such sort of commerce is carried on, and even for the commodities themselves. The company of frippers, or fripperers, at Paris, are a regular corporation, of an ancient standing, and make a considerable figure in that city.

FRISII, FRISEI, FRISIONES, and FRISONES, (anc. geog.), a people of Germany, so called either from their ardent love of freedom, or from the fresh and unbroken lands they occupied, contradistinguished from the old lands. Tacitus divides them, from their extent of power and territory, into the Majores, situated on the coast between the Rhine and the Ems; and into the Minores, occupying the parts about the lakes lying between the channels of the Rhine.

FRIT, or FRITT, in the glass manufacture, is the matter or ingredients whereof glass is to be made, when they have been calcined or baked in a furnace.

A salt drawn from the ashes of the plant kali or from fern, or other plants mixed with sand or flint, and baked together, makes an opaque mass called by glass-men *frit*; probably from the Italian *frittare*, to fry; or because the frit, when melted, runs into lumps, like fritters, called by the Italians *fritelli*.

Frit, by the ancients, was called *ammonitrum*, of *αμμων*, sand, and *νιτρον*, nitre; under which name it is described by Pliny thus: Fine sand from the Volturian sea, mixed with three times the quantity of nitre, and melted, makes a mass called *ammonitrum*; which being rebaked makes pure glass.

Frit, Neri observes, is only the calx of the materials which make glass; which though they might be melted, and glass be made, without thus calcining them, yet it would take up much more time. This calcining, or making of frit, serves to mix and incorporate the materials together, and to evaporate all the superfluous humidity. The frit, once made, is readily fused, and turned into glass.

There are three kinds of frits. The first, crystal frit, or that for crystal metal, is made with salt of pulverine and sand. The second, and ordinary frit, is made of the bare ashes of pulverine or barilla, without extracting the salt from them. This makes the ordinary white or crystal metal. The third is frit for green

glasses, made of common ashes, without any preparation. This last frit will require ten or twelve hours baking.

The materials in each are to be finely powdered, washed, and searced; then equally mixed, and frequently stirred together in the melting pot. For the rest see GLASS, and CRYSTAL.

FRITH, in its most usual acceptation, signifies the mouth or opening of a river into the sea; such are the Frith of Forth or of Edinburgh, the Frith of Clyde, Moray Frith, &c.

FRITILLARIA, FRITILLARY: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 10th order, *Coronariae*. The corolla is hexapetalous and campanulated, with a nectariferous cavity above the heel in each petal; the stamina are as long as the corolla. There are five species, all of them bulbous-rooted flowery perennials, producing annual stalks from about one foot to a yard or more high, terminated by large, bell-shaped, liliaceous flowers, of a great variety of colours. They are all propagated by offsets, which they furnish abundantly from the sides of their roots, and which may be separated every second or third year; they are hardy plants, and will thrive in any of the common borders.

FRIULI, a province of Italy, subject to Venice, and bounded by Carinthia in Germany on the north, by Carniola on the east, by the Gulph of Venice on the south, and by the Bellunese and Feltrin on the west.

FRIZE, or FRIEZE, in architecture, a part of the entablature of columns, more usually written and pronounced *freeze*. See FREEZE.

FRIZE, or FREEZE, in commerce, a kind of woollen cloth or stuff for winter wear, being frized or knapt on one side; whence, in all probability, it derives its name.

Of frizes, some are crossed, others not crossed: the former are chiefly of English manufacture, the latter of Irish.

FRIZING of CLOTH, a term in the woollen manufactory, applied to the forming of the nap of cloth or stuff into a number of little hard burrs or prominences, covering almost the whole ground thereof.

Some clothes are only frized on the back side, as black cloths; others on the right side, as coloured and mixed cloths, rateens, bays, friezes, &c.

Frizing may be performed two ways. One with the hand, that is, by means of two workmen, who conduct a kind of plank that serves for a frizing instrument. The other way is by a mill, worked either by water or a horse, or sometimes by men. This latter is esteemed the better way of frizing, by reason the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly. The structure of this useful machine is as follows:

The three principal parts are the frizer or crisper, the frizing table, and the drawer or beam. The two first are two equal planks or boards, each about 10 feet long and 15 inches broad; differing only in this, that the frizing table is lined or covered with a kind of coarse woollen stuff, of a rough sturdy knap; and the frizer is incrustated with a kind of cement composed of glue, gum-arabic, and a yellow sand, with a little aqua-vitæ, or urine. The beam, or drawer, thus called,

Frit
||
Frizing.

Frizing
|
Frobisher.

ed, because it draws the stuff from between the frizer and the frizing-table, is a wooden roller, beset all over with little, fine, short points or ends of wire, like those of cards used in carding of wool.

The disposition and use of the machine is thus. The table stands immoveable, and bears or sustains the cloth to be frized, which is laid with that side uppermost on which the nap is to be raised: over the table is placed the frizer, at such a distance from it as to give room for the stuff to be passed between them: so that the frizer, having a very slow semicircular motion, meeting the long hairs or naps of the cloth, twists, and rolls them into little knobs or burrs; while, at the same time, the drawer, which is continually turning, draws away the stuff from under the frizer, and winds it over its own points.

All that the workman has to do while the machine is a-going, is to stretch the stuff on the table as fast as the drawer takes it off, and from time to time to take off the stuff from the points of the drawer.

The design of having the frizing-table lined with stuff of a short, stiff, stubby nap, is that it may detain the cloth between the table and the frizer long enough for the grain to be formed, that the drawer may not take it away too readily, which must otherwise be the case as it is not held by any thing at the other end. It were unnecessary to say any thing particular of the manner of frizing stuffs with the hand, it being the aim of the workmen to imitate, as near as they can with their wooden instrument, the slow, equable, and circular motion of the machine: it needs only be added, that their frizer is but about two feet long and one broad; and that to form the nap more easily, they moisten the surface of the stuff lightly, with water mingled with whites of eggs or honey.

FROBENIUS (John), a famous and learned printer in the 16th century, was born at Hamelburgh in Franconia, and settled at Basil. He had before studied in that university, where he acquired the reputation of being uncommonly learned; and now setting up a printing-house in that city, was the first of the German printers who brought that admirable art to any degree of perfection. Being a man of great probity and piety, as well as skill, he was particularly choice in the authors he printed; and would never, for the sake of profit, suffer libels, or any thing that might hurt the reputation of another, to go through his press. The great character of this printer was the principal motive which induced Erasmus to reside at Basil, in order to have his own works printed by him. A great number of valuable authors were printed by Frobenius, with great care and accuracy; among which were the works of St Jerome, Augustine, and Erasmus. He designed to have printed the Greek Fathers; but died in 1527, before he could execute his design. Erasmus wrote his epitaph in Greek and Latin.

John Frobenius left a son, named *Jerome Frobenius*, and a daughter married to Nicholas Episcopus; who, joining in partnership, continued Frobenius's printing-house with reputation, and printed correct editions of the Greek Fathers.

FROBISHER, or FORBISHER (Sir Martin), an excellent navigator and sea-officer in the 16th century, was born near Doncaster in Yorkshire, and was from

his youth brought up to navigation. He was the first Englishman who attempted to find a north-west passage to China, and in 1576 he sailed with two barks and a pinnace in order to attempt that passage. In this voyage he discovered a cape, to which he gave the name of *Queen Elizabeth's Foreland*, and the next day discovered a strait to which he gave his own name. This voyage proving unsuccessful, he attempted the same passage in 1577; but discovering some ore in an island, and his commission directing him in this voyage only to search for ore, and to leave the farther discovery of the north-west to another time, he returned to England. He sailed again, with 15 ships and a great number of adventurers, to form a settlement: but being obstructed by the ice, and driven out to sea by a violent storm, they, after encountering many difficulties, returned home, without making any settlement, but brought a large quantity of ore.—He afterwards commanded the *Aid* in Sir Francis Drake's expedition to the West Indies, in which St Domingo in Hispaniola, Carthagena, and Santa Justina, in Florida, were taken and sacked. In 1588, he bravely exerted himself in defence of his country against the Spanish armada, when he commanded the *Triumph*, one of the largest ships in that service; and, as a reward for his distinguished bravery, received the honour of knighthood from the lord high-admiral at sea. He afterwards commanded a squadron which was ordered to cruise on the Spanish coast; and in 1592 took two valuable ships and a rich carrack. In 1594 he was sent to the assistance of Henry IV. king of France against a body of the Leaguers and Spaniards, who had strongly entrenched themselves at Croyzon near Brest; but in an assault upon that fort, on the 7th of November, Sir Martin was unfortunately wounded with a ball, of which he died soon after he had brought back the fleet to Plymouth, and was buried in that town.

FROBISHER'S Straits, lie a little to the northward of Cape Farewell in West Greenland, and were discovered by Sir Martin Frobisher. W. Long. 48. 16. N. Lat. 63. 12.

FRODSHAM, a town of Cheshire in England, 162 miles from London, is noted for its ancient castle. It has a stone-bridge over the river Weaver near its conflux with the Mersey, and a harbour for ships of good burden. By the late inland navigation, it has communication with the rivers Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Westmoreland, Stafford, Warwick, Leicester, Oxford, Worcester, &c.

FROG, in zoology. See RANA.

Bull-FROG. See RANA.

FROG-Fish of Surinam, a very singular animal, of which a figure is given by Mr Edwards, *Hist. of Birds*, Vol. I. There is no specimen in the British museum, nor in any private collection, except that of Dr Fothergill. It was brought from Surinam in South America.—Frogs, both in Asia and Africa, according to Merian, change gradually from Fishes to frogs, as those in Europe; but after many years revert again into fishes, though the manner of their change has never been investigated. In Surinam these fishes are called *jakjés*. They are cartilaginous, of a substance like the mustela,

Frobisher
||
Frog.

Frome,
Fronde-
scentia.

mustela, and exquisite food: they are formed with regular vertebræ, and small bones all over the body divided into equal parts; are first darkish, and then grey: their scales make a beautiful appearance. Whether this animal is, in its perfect state, a species of frog with a tail, or a kind of water-lizard, Mr Edwards does not pretend to determine; but observes, that when its size is considered, if it should be deemed a tadpole at first produced from spawn, and in its progress towards a frog, such an animal, when full grown, if it bears the same proportion to its tadpole as those in Europe do, must be of enormous size; for our full grown frogs exceed the tadpoles at least 50 times. See a reduced figure on Plate CCIII.

FROME, a river that rises from several springs in the Western parts of Dorsetshire in England, the principal of which is near Evershot; and directing its course almost due west, passes under Frampton-bridge, washes the town of Dorchester, and falls into a bay of the English Channel called *Poolhaven*, near Wareham.

FROME-Selwood, a town of Somersetshire in England, 105 miles from London. It is the chief town of this part of the country, which was anciently one great forest called *Selwoodshire*; and in the latter end of the last century, in those called *Frome-Woodlands*, there was a considerable gang of money-coiners or clippers, of whom many were taken and executed, and their covert laid open. Though the town is bigger than some cities, yet it has only one church; but it has six or seven meeting-houses of Protestant dissenters. The inhabitants are reckoned about 13,000, whose chief manufactory is broad-cloth. About 50 years ago, more wire cards for carding the wool for the spinners were made at this place than in all England besides, which was for the most part supplied with them from hence; for here were no less than 20 master card-makers, one of whom employed 400 men, women, and children, in that manufactory at one time; so that even children of 7 or 8 years of age could earn half-a-crown a-week. The river here, which abounds with trout, cels, &c. rises in the woodlands; and runs under its stone-bridge towards Bath, on the east side of which it falls into the Avon. This town has been a long time noted for its fine beer, which they keep to a great age, and is generally preferred by the gentry to the wines of France and Portugal. It was governed formerly by a bailiff, and now by two constables of the hundreds of Frome, chosen at the court-leet of the lord of the manor.

FRONDESCENTIA, from *frons*, "a leaf;" the precise time of the year and month in which each species of plants unfolds its leaves.

All plants produce new leaves every year; but all do not renew them at the same time. Among woody plants, the elder, and most of the honey-suckles; among perennial herbs, crocus and tulip, are the first that push or expand their leaves. The time of sowing the seeds decides with respect to annuals. The oak and ash are constantly the latest in pushing their leaves: the greatest number unfold them in spring; the mosses and firs in winter. These striking differences with respect to so capital a circumstance in plants as that of unfolding their leaves, seem to indicate that each species of plants has a temperature proper or pe-

culiar to itself, and requires a certain degree of heat to extricate the leaves from their buds, and produce the appearance in question.

This temperature, however, is not so fixed or constant as it may appear to a superficial observer. Among plants of the same species, there are some more early than others; whether that circumstance depends, as it most commonly does, on the nature of the plants, or is owing to differences in heat, exposure, and soil. In general, it may be affirmed, that small and young trees are always earlier than larger or old ones.

The pushing of the leaves is likewise accelerated or retarded according to the temperature of the season; that is, according as the sun is sooner or later in dispensing that certain degree of heat which is suitable to each species.

FRONT, the forehead, or that part of the face above the eye-brows. The word is formed of the Latin *frons*; and that from the Greek *φρονεω* "to think, perceive;" of *φρονεω* *mens*, "the mind, thought." Martinius, to make out this etymology, observes, that from the forehead of a person we perceive what he is, what he is capable of, and what he thinks of.

FRONT, is also used where several persons or things are ranged side by side, and show their front or fore-parts.

FRONT, in architecture, denotes the principal face or side of a building, or that presented to their chief aspect or view.

FRONTAL, in architecture, a little fronton or pediment, sometimes placed over a small door or window.

FRONTAL, *Frontlet*, or *Brow-band*, is also used in speaking of the Jewish ceremonies. This frontal consists of four several pieces of vellum, on each whereof is written some text of scripture. They are all laid on a piece of a black calf's leather with thongs to tie it by. The Jews apply the leather with the vellum on their foreheads in the synagogue, and tie it round the head with the thongs.

FRONTIER, the border, confine, or extreme, of a kingdom or province, which the enemies find in front when they would enter the same. Thus we say, a frontier town, frontier province, &c. Frontiers were anciently called *marches*.

The word is derived from the French *frontiere*, and that from the Latin *frontaria*; as being a kind of front opposed to the enemy. Skinner derives *frontier* from *front*; inasmuch as the frontier is the exterior and most advanced part of a state, as the front is that of the face of a man.

FRONTIGNIAC WINE, is so called from a town of Languedoc in France, situated 16 miles south-west of Montpellier, remarkable for producing it.

FRONTINUS (Sextus Julius), an ancient Roman writer, was of consular dignity, and flourished under the emperors Vespasian, Titus, Domitian, Nerva, and Trajan. He commanded the Roman armies in Britain; was made city-prætor when Vespasian and Titus were consuls; and Nerva made him curator of the aqueducts, which occasioned his writing *De aquæductibus urbis Romæ*. He wrote four books upon the Greek and Roman art of war; a piece *De re agraria*, and another *De limitibus*. These have been often separately

piece
||
Frost.

Frost.

ly reprinted ; but were all collected together in a neat edition at Amsterdam in 1661, with notes by Robertus Keuchenius. He died under Trajan.

FRONTISPIECE, in architecture, the principal face of a fine building. The word is formed of the Latin *frontispicium*, q. d. *frontis hominis inspectio*.—Hence also, by a figure, we say, the frontispiece of a book ; meaning an ornament with an engraven title on the first page.

FRONTLET. See FRONTAL.

FRONTO (Marcus Cornelius), was chosen for his eloquence to instruct the emperor Marcus Aurelius and Lucius Verus in rhetoric ; in recompence of which he was promoted to the consulate, and a statue was erected to his honour. He taught Marcus Aurelius not only eloquence, but the duty of kings, and excellent morals. Some say he wrote against the Christians. A sect was formed of those who looked upon him as a model of perfect eloquence, and these were called *Frontoniani*. The Civilians, whose names were *Fronto*, mentioned in the pandects, were probably descended from him.

FROST, in physiology, such a state of the atmosphere as occasions the congelation or freezing of water and other fluids. See CONGELATION.

Under the articles COLD, CONGELATION, EVAPORATION, FLUIDITY, &c, it is shown, that water and other fluids are capable of containing the element of fire or heat in two very different states. In the one, they seem to imbibe the fire in such a manner, that it eludes all the methods by which we are accustomed to observe it, either by our sensation of feeling, or the thermometer ; in the other, it manifests itself obviously to our senses, either by the touch, the thermometer, or the emission of light.

In the first of these states, we call the body *cold* ; and are apt to say that this coldness is occasioned by the *absence* of heat. But this manner of expressing ourselves is certainly improper ; for even those fluids which are coldest to the touch contain a vast deal of heat. Thus vapour, which is colder to the touch than the water from which it was raised, contains an immense quantity of fire, even more than sufficient to heat it red hot. The like may be said of common salt, and snow, or ice. If a quantity of each of these substances is separately reduced to the degree of 28 or 30 of Fahrenheit's thermometer, upon mixing them together, the heat which would have raised the thermometer to the degree abovementioned, now enters into the substance of them in such a manner that the mercury falls down to 0.—Here an excessive degree of cold is produced, and yet we are sure that the substances contain the very same quantity of heat that they formerly did : nay, they will even seem exceedingly cold, when they most certainly contain a great deal more heat than they originally did ; for they absorb it from all bodies around them ; and if a small vessel full of water is put in the middle of such a mixture, it will in a short time be full of ice.

It appears, therefore, that our senses, even when assisted by thermometers, can only judge of the state in which the element of fire is with relation to the bodies around us, without regard to the quantity contained in them. Thus, if heat flows from any part of our body into any substance actually in contact with it, the

sensation of cold is excited, and we call that substance *cold* ; but if it flows from any substance into our body, the sensation of heat is excited, and we call that substance *hot*, without regard to the absolute quantity contained in either case. See HEAT.

Of all known substances, the atmosphere either absorbs or throws out heat with the most remarkable facility : and in one or other of these states it always is with respect to the surface of the earth, and such bodies as are placed on or near it ; for these, properly speaking, have no temperature of their own, but are entirely regulated by that of the atmosphere.—When the air has been for some time absorbing the heat from terrestrial bodies, a frost must be the undoubted consequence, for the same reason that water freezes in a vessel put into a freezing mixture ; and were this absorption to continue for a length of time, the whole earth would be converted into a frozen mass. There are, however, certain powers in nature, by which this effect is always prevented ; and the most violent frost we can imagine, must always as it were defeat its own purposes, and end in a thaw. To understand this subject, we must observe,

1. In that state of the atmosphere which we denominate frost, there is a most intimate union between the air and the water it contains ; and therefore frosty weather, except in very high latitudes, is generally clear.

2. When such an union takes place, either in winter or summer, we observe the atmosphere also inclined to absorb heat, and consequently to frost. Thus in clear settled weather, even in summer, though the day may be excessively hot by reason of the continued sunshine, yet the mornings and evenings are remarkably cold, and sometimes even disagreeably so.

3. The air being therefore always ready in the time of frost or in clear weather, to absorb heat from every substance which comes into contact with it, it follows that it must also absorb part of that which belongs to the vapours contained in it.

4. Though vapour is capable of becoming much colder than water without being frozen, yet by a continued absorption it must at last part with its latent heat, *i. e.* that which essentially constitutes it vapour ; and without which it is no longer vapour, but water or ice. No sooner, therefore, does the frost arrive at a certain pitch, than the vapours, every where dispersed through the air, give out their latent heat ; the atmosphere then becomes clouded ; the frost either totally goes off, or becomes milder by reason of the great quantity of heat discharged into the air ; and the vapours descend in rain, hail, or snow, according to the particular disposition of the atmosphere at the time.

5. Even in the polar regions, where it may be thought that the frost must increase beyond measure, there are also natural means for preventing its running to extremes. The principal cause here is, the mixture of a great quantity of vapours from the more temperate regions of the globe with the air in those dreary climates. It is well known, that aqueous vapour always flies from a warm to a colder place. For this reason, the vapours raised by the sun in the more temperate regions of the earth, must continually travel northward and southward in great quantities. Thus

Frost. they furnish materials for those immense quantities of snow and ice which are to be found in the neighbourhood of the poles, and which we cannot imagine the weak influence of the sun in these parts capable of raising. It is impossible that a quantity of vapour can be mixed with frosty air, without communicating a great deal of heat to it; and thus there are often thaws of considerable duration even in those climates where, from the little influence of the sun, we should suppose the frost would be perpetual.

6. We may now account with some probability for the uncertain duration of frosts. In England they are seldom of a long continuance; because the vapours raised from the sea with which that island is surrounded, perpetually mix with the air over the island, and prevent a long duration of the frost. For the same reason, frosts are never of such long duration in maritime places on the continent as in the inland ones. There is nothing, however, more uncertain than the motion of the vapours with which the air is constantly filled; and therefore it is impossible to prognosticate the duration of a frost with any degree of certainty. In general, we may always be certain, that if a quantity of vapour is accumulated in any place, no intense frost can subsist in that place for any length of time; and by whatever causes the vapours are driven from place to place, by the same causes the frosts are regulated throughout the whole world. See THAW, VAPOUR, &c.

The effects of frost in several different countries, are enumerated under the article CONGELATION. In the northern parts of the world, even solid bodies are liable to be affected by frost. Timber is often apparently frozen, and rendered exceedingly difficult to saw. Marble, chalk, and other less solid terrestrial concretions, will be shattered by strong and durable frosts. Metals are contracted by frost: thus, an iron tube, 12 feet long, upon being exposed to the air in a frosty night, lost two lines of its length. On the contrary, frost swells or dilates water near one-tenth of its bulk. Mr Boyle made several experiments with metalline vessels, exceedingly thick and strong; which being filled with water, close stopped, and exposed to the cold, burst by the expansion of the frozen fluid within them. Trees are frequently destroyed by frost, as if burnt up by the most excessive heat; and in very strong frosts, walnut-trees, ashes, and even oaks, are sometimes split and cleft, so as to be seen through, and this with a terrible noise, like the explosion of fire-arms.

Frost naturally proceeds from the upper parts of bodies downwards: but how deep it will reach in earth or water, is not easily known; because this depth may vary with the degree of coldness in the air, by a longer or shorter duration of the frost, the texture of the earth, the nature of the juices wherewith it is impregnated, the constitution of its more internal parts as to heat and cold, the nature of its effluvia, &c. Mr Boyle, in order to ascertain this depth, after four nights of hard frost, dug in an orchard, where the ground was level and bare, and found the frost had scarce reached three inches and a half, and in a garden nearer the house only two inches below the surface. Nine or ten successive frosty nights froze the bare

ground in the garden six inches and a half deep; and in the orchard, where a wall sheltered it from the south sun, to the depth of eight inches and a half. He also dug in an orchard, near a wall, about a week afterwards, and found the frost to have penetrated to the depth of 14 inches. In a garden at Moscow, the frost in a hard season only penetrates to two feet: and the utmost effect that Captain James mentions the cold to have had upon the ground of Charlton island, was to freeze it to two feet deep: whence may appear the different degrees of cold of that island and Russia. And as to the freezing of water at the abovementioned island, the Captain tells us, it does not naturally congeal above the depth of six feet, the rest being by accident. Water also, exposed to the cold air in large vessels, always freezes first at the upper surface; the ice gradually increasing and thickning downwards: for which reason, frogs retire in frosty weather to the bottom of ditches; and it is said, that shoals of fish retire in winter to these depths of the sea and rivers, where they are not to be found in summer. Water, like the earth, seems not disposed to receive any very intense degree of cold at a considerable depth or distance from the air. The vast masses of ice found in the northern seas being only many flakes and fragments, which, sliding under each other, are, by the congelation of the intercepted water, cemented together.

In cold countries, the frost often proves fatal to mankind; not only producing gangrenes, but even death itself. Those who die of it have their hands and feet first seized, till they grow past feeling it; after which the rest of their bodies is so invaded, that they are taken with a drowsiness, which if indulged, they awake no more, but die insensibly. But there is another way whereby it proves mortal, *viz.* by freezing the abdomen and viscera, which on dissection are found to be mortified and black.

The great power of frost on vegetables is a thing sufficiently known; but the differences between the frosts of a severe winter, and those which happen in the spring mornings, in their effects on plants and trees, were never perfectly explained, till by Mess. Du Hamel and Buffon in the Memoirs of the Paris Academy.

The frosts of severe winters are much more terrible than those of the spring, as they bring on a privation of all the products of the tenderer part of the vegetable world; but then they are not frequent, such winters happening perhaps but once in an age; and the frosts of the spring are in reality greater injuries to us than these, as they are every year repeated.

In regard to trees, the great difference is this, that the frosts of severe winters affect even their wood, their trunks and large branches; whereas those of the spring have only power to hurt the buds.

The winter frosts happening at a time when most of the trees in our woods and gardens have neither leaves, flowers, nor fruits upon them, and have their buds so hard as to be proof against slight injuries of weather, especially if the preceding summer has not been too wet; in this state, if there are no unlucky circumstances attending, the generality of trees bear moderate winters very well; but hard frosts, which happen late

Frost.

Frost. in the winter, cause very great injuries even to those trees which they do not utterly destroy. These are, 1. Long cracks following the direction of the fibres. 2. Parcels of dead wood inclosed round with wood yet in a living state. And, 3. That distemperature which the foresters call the *double blea*, which is a perfect circle of blea, or soft white wood, which, when the tree is afterwards felled, is found covered by a circle of hard and solid wood.

The opinions of authors about the exposition of trees to the different quarters, have been very different, and most of them grounded on no rational foundation. Many are of opinion that the effects of frost are most violently felt on those trees which are exposed to the north; and others think the south or the west the most strongly affected by them. There is no doubt but the north exposure is subject to the greatest cold. It does not, however, follow from this, that the injury must be always greatest on the trees exposed to the north in frosts; on the contrary, there are abundant proofs that it is on the south side that trees are generally more injured by frost: and it is plain from repeated experiments, that there are particular accidents, under which a more moderate frost may do more injury to vegetables, than the most severe one which happens to them under more favourable circumstances.

It is plain from the accounts of the injuries trees received by the frosts in 1709, that the greatest of all were owing to repeated false thaws, succeeded by repeated new frosts. But the frosts of the spring-season furnish abundantly more numerous examples of this truth; and some experiments made by the Count de Buffon, at large in his own woods, prove incontestably, that it is not the severest cold or most fixed frost that does the greatest injury to vegetables.

This is an observation directly opposite to the common opinion; yet is not the less true, nor is it any way discordant to reason. We find by a number of experiments, that humidity is the thing that makes frost fatal to vegetables; and therefore every thing that can occasion humidity in them, exposes them to these injuries, and every thing that can prevent or take off an over proportion of humidity in them, every thing that can dry them though with ever so increased a cold, must prevent or preserve them from those injuries. Numerous experiments and observations tend to prove this. It is well known that vegetables always feel the frost very desperately in low places where there are fogs. The plants which stand by a river side are frequently found destroyed by the spring and autumnal frosts, while those of the same species, which stand in a drier place, suffer little or perhaps not at all by them; and the low and wet parts of forests are well known to produce worse wood than the high and drier. The coppice wood in wet and low parts of common woods, though it push out more vigorously at first than that of other places, yet never comes to so good a growth; for the frost of the spring killing these early top-shoots, obliges the lower part of the trees to throw out lateral branches: and the same thing happens in a greater or lesser degree to the coppice wood that grows under cover of larger trees in great forests; for here the vapours not being carried off either by the sun or wind, stagnate and freeze, and in the same manner de-

stroy the young shoots, as the fogs of marshy places. It is a general observation also, that the frost is never hurtful to the late shoots of the vine, or to the flower-buds of trees, except when it follows heavy dews, or a long rainy season, and then it never fails to do great mischief, though it be ever so slight.

The frost is always observed to be more mischievous in its consequences on newly cultivated ground than in other places; and this is because the vapours which continually arise from the earth, find an easier passage from those places than from others. Trees also which have been newly cut, suffer more than others by the spring frosts, which is owing to their shooting out more vigorously.

Frosts also do more damage on light and sandy grounds, than on the tougher and firmer soils, supposing both equally dry; and this seems partly owing to their being more early in their productions, and partly to their lax texture suffering a greater quantity of vapours to transpire.

It also has been frequently observed, that the side-shoots of trees are more subject to perish by the spring frosts than those from the top; and M. Buffon, who examined into this with great accuracy, always found the effects of the spring frosts much greater near the ground than elsewhere. The shoots within a foot of the ground quickly perished by them; those which stood at two or three feet high, bore them much better: and those at four feet and upwards frequently remained wholly unhurt, while the lower ones were entirely destroyed.

There is a series of observations, which have proved beyond all doubt, that it is not the hard frosts which so much hurt plants, as those frosts, though less severe, which happen when they are full of moisture; and this clearly explains the account of all the great damages done by the severe frosts being on the south side of the trees which are affected by them, though that side has been plainly all the while less cold than the north. Great damage is also done to the western sides of trees and plantations, when after a rain with a west wind the wind turns about to the north at sunset, as is frequently the case in spring, or when an east wind blows upon a thick fog before sun-rising.

Hoar-Frost, a cold moist vapour, that is drawn up a little way into the air, and in the night falls again on the earth, where it is congealed into icy crystals of various figures. Hoar-frost, therefore, is nothing but dew turned into ice by the coldness of the air.

Melioration of Aromatic Spirits by Frost. Mr Baumè observes, that aromatic spirituous waters have less scent when newly distilled than after they have been kept about six months: and he found that the good effects of age was produced in a short time by means of cold; and that, by plunging quart-bottles of the liquor into a mixture of pounded ice and sea-salt, the spirit, after having suffered for six or eight hours the cold hence resulting, proves as grateful as that which hath been kept many years. Simple waters also, after having been frozen, prove far more agreeable than they were before. Geoffroy takes notice of this melioration by frost; *Hist. Acad.* 1713.

Melioration of Land by Frost. See AGRICULTURE, n^o 137.

Froth
|
Fructes-
centia.

FROTH, a white light substance, formed on the surface of fluids by vehement agitation, consisting of little spherules or globules.

FROTH-Spit, or *Cuckow-Spit*, a name given to a white froth or spume, very common in the spring and first months of summer, on the leaves of certain plants, particularly on those of the common white field-lychnis or catch-fly, thence called by some *spatling poppy*.

All writers on vegetables have taken notice of this froth though few have understood the cause or origin of it till of late. It is formed by a little leaping animal, called by some the *flea grass-hopper*, by applying its anus close to the leaf, and discharging thereon a small drop of a white viscous fluid, which, containing some air in it, is soon elevated into a small bubble; before this is well formed, it deposits such another drop, and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see. Within this spume it is seen to acquire four tubercles on its back, wherein the wings are inclosed; these bursting, from a reptile it becomes a winged animal: and thus, rendered perfect, it flies to meet its mate, and propagate its kind. It has an oblong, obtuse body, and a large head with small eyes. The external wings, for it has four, are of a dusky brown colour, marked with two white spots: the head is black. It is a species of **CICADA**.

FROWDE (Philip), an English poet, was the son of a gentleman who had been post-master in the reign of queen Anne. He was sent to the university of Oxford, where he had the honour of being distinguished by Addison, who took him under his protection. While he remained there, he became the author of several pieces of poetry, some of which in Latin were pure and elegant enough to intitle them to a place in the *Musæ Anglicanæ*. He likewise wrote two tragedies; *The Fall of Saguntum*, dedicated to Sir Robert Walpole; and *Philotas*, addressed to the earl of Chesterfield. He died at his lodgings at Cecil-street in the Strand, in 1738, and in the London Daily-Post had the following character given him: "Though the elegance of Mr Frowde's writings has recommended him to the general public esteem, the politeness of his genius is the least amiable part of his character; for he esteemed the talents of wit and learning only as they were conducive to the excitement and practice of honour and humanity. Therefore, with a soul cheerful, benevolent, and virtuous, he was in conversation genteelly delightful, in friendship punctually sincere, in death Christianly resigned. No man could live more beloved, no private man could die more lamented." A fine eloge! and we have no reason to doubt the truth of it.

FRUCTESCENTIA, (from *fructus*, "fruit,") comprehends the precise time in which, after the fall of the flowers, the fruits arrive at maturity, and disperse their seeds.

In general, plants which flower in spring, ripen their fruits in summer, as rye; those which flower in summer, have their fruits ripe in autumn, as the vine; the fruit of autumnal flowers ripens in winter, or the following spring, if kept in a stove or otherwise defended from excessive frosts. These frosts, says M. Adanson, are frequently so pernicious and violent as to destroy the greatest part of the perennial plants of Vir-

ginia and Mississippi, that are cultivated in France, even before they have exhibited their fruit. The plants which flower during our winter, such as those of the Cape of Good Hope, ripen their fruit in spring in stoves.

FRUCTIFEROUS, signifies properly any thing that produces fruit.

FRUCTIFICATION OF PLANTS, is defined by Linnæus to be the temporary part of a vegetable appropriated to generation, terminating the old vegetable, and beginning the new. It consists of the following seven parts; viz. the calyx, corolla, stamen, pistillum, pericarpium, semen or seed, and receptaculum. See **BOTANY**, p. 446.

FRUIT, in its general sense, includes whatever the earth produces for the nourishment and support of animals; as herbs, grain, pulse, hay, corn, flax, and every thing expressed by the Latins under the name *fruges*.

FRUIT, in natural history, denotes the last production of a tree or plant, for the propagation or multiplication of its kind; in which sense fruit includes all kinds of seeds, with their furniture, &c.

FRUIT, in botany, is properly that part of a plant wherein the seed is contained; called by the Latins *fructus*; and by the Greeks *καρπός*. The fruit in the Linnæan system is one of the parts of fructification, and is distinguished into three parts, viz. the pericarpium, seed, and receptacle or *receptaculum seminum*. See **BOTANY**.

Colours Extracted from FRUITS. See the article *COLOUR-Making*, n^o 36.

Bread-FRUIT. See **BREAD**.

FRUITS, with regard to commerce, are distinguished into *recent* or *fresh*, and *dry*.

Recent FRUITS, are those sold just as they are gathered from the tree, without any farther preparation; as are most of the productions of our gardens and orchards, sold by the fruiterers.

Dry FRUITS, are those dried in the sun, or by the fire, with other ingredients sometimes added to them to make them keep; imported chiefly from beyond sea, and sold by the grocers. Such are raisins, currants, figs, capers, olives, cloves, nutmegs, pepper, and other spices; which see under their respective articles.

Under the denomination of *dry fruits* are also frequently included apples, pears, almonds, filberds, &c.

FRUIT-Flies, a name given by gardeners and others to a sort of small black flies found in vast numbers among fruit trees, in the spring season, and supposed to do great injury to them, Mr Lenwenhoek preserved some of these flies for his microscopical observations. He found that they did not live longer than a day or two, but that the females during this time laid a great number of longish eggs. The gardeners who suppose that these flies wound the leaves of the trees, are mistaken: it is true that they feed on their juices; but they have no instruments wherewith they can extract these for themselves: they feed on such as are naturally extravasated; and when there is not a sufficient quantity of these for their purpose, they haunt the places to which the pucerons resort, and feed on the juices which these little creatures extravasate by means of the holes they bore in the leaves with their trunks.

FRUIT-Stones. The mischiefs arising from the custom which many people have of swallowing the stones.

Fructife-
rous
||
Fruit.

Fruit. of plums and other fruit are very great. The Philosophical Transactions give an account of a woman who suffered violent pains in her bowels for 30 years, returning once in a month or less. At length, a strong purge being given her, the occasion of all these complaints was driven down from the bowels to the anus; where it gave a sensation of distension and stoppage, producing a continual desire of going to stool, but without voiding any thing. On the assistance of a careful hand in this case, there was taken out with a forceps a ball of an oval figure, of about ten drachms in weight, and measuring five inches in circumference. This had caused all the violent fits of pain which she had suffered for so many years; and, after voiding it, she became perfectly well. The ball extracted looked like a stone, and felt very hard, but it swam in water. On cutting it through with a knife, there was found in the centre of it a plum-stone; round which, several coats of this hard and tough matter had gathered. Another instance given in the same papers is of a man, who, dying of an incurable colic which had tormented him many years, and baffled the effects of medicines, was opened after death; and in his bowels was found a ball similar to that abovementioned; but somewhat larger, being six inches in circumference, and weighing an ounce and an half. In the centre of this, as of the other, there was found the stone of a common plum, and the coats were of the same nature with those of the former.

These and several other instances mentioned in the same place, sufficiently show the folly of that common opinion that the stones of fruits are wholesome. For though by nature the guts are so defended by their proper mucus, that people very seldom suffer by things of this kind; yet if we consider the various circumvolutions of the guts, their valves and cells, and at the same time consider the hair of the skins of animals we feed on, the wool or down on herbs and fruit, and the fibres, vessels, and nerves of plants, which are not altered by the stomach; it will appear a wonder that instances of this sort of mischief are not much more common. Cherry-stones, swallowed in great quantities, have occasioned the death of many people; and there have been instances even of the seeds of strawberries collecting into a lump in the guts, and causing violent disorders, which could not be cured without great difficulty.

FRUIT-Trees. With regard to these it may be observed, 1. That the cutting and pruning them when young, scrimp their bearing, though it contributes to the richness and flavour of the fruit, as well as to the beauty of the tree. 2. That kernel-fruit trees come later to bear than stone-fruit trees: the time required by the first, before they come to any fit age for bearing, being one with another five years; but when they do begin, they bear in greater plenty than stone-fruit. 3. The stone-fruit, figs, and grapes, commonly bear considerably in three or four years, and bear full crops the fifth and sixth years; and hold it for many years, if well ordered. 4. The fruit-trees in the same neighbourhood will ripen a fortnight sooner in some grounds than in others of a different temperature. 5. That in the same country, hot or cold summers set considerably forwards, or put backwards, the same fruit. 6. That the fruit on wall-trees generally ripen before those on

standards, and those on standards before those on dwarfs. 7. That the fruit of all wall-trees planted in the south and west quarters, commonly ripen about the same time, only those on the south rather earlier than those in the east; those in the west are later by eight or ten days; and those on the north, by 15 or 20. For the planting, pruning, grafting, &c. of fruit-trees, see the articles PLANTING, TRANSPLANTING, PRUNING, GRAFTING, ORCHARD, NURSERY, &c.

FRUITERY, a place for the keeping of fruit, a fruit-house, or fruit-loft.

A fruitery should be inaccessible to any thing of moisture; and should be as much as possible so, even to frost.

FRUMENTACEOUS, a term applied by botanists to all such plants as have a conformity with wheat, in respect of their fruits, leaves, ears, or the like.

FRUMENTARII, a kind of soldiers or archers under the western empire.

The first time we read of these officers is in the reign of the emperor Adrian, who made use of them to inform himself of whatever passed. They did not make any particular corps distinct from the rest of the forces, but there was a certain number of them in each legion. It is supposed, that they were at first a number of young persons, disposed by Augustus throughout the provinces, particularly on all the grand roads, to acquaint the emperor, with all expedition, of every thing that happened.

Afterwards they were incorporated into the troops themselves, where they still retained their ancient name. As their principal office was their giving intelligence, they were often joined with the curiosi, with whom they agreed in this part of their office.

Their name of *frumentarii* is derived from their being also a sort of purveyors to the armies, cities, &c. collecting all the corn from the several provinces to furnish the commonwealth.

FRUMENTATION, in Roman antiquity, a largess of corn bestowed on the people. This practice of giving corn to the people was very ancient among the Romans, and frequently used to soothe the turbulent humour of the populace. At first the number of those to whom this largess was given was indeterminate, till Augustus fixed it at 200,000.

FRUSH, or **RUNNING-THRUSH**. See **FARRIERY**. Sect. xlii.

FRUSTUM, in mathematics, a part of some solid body separated from the rest.

The frustum of a cone is the part that remains, when the top is cut off by a plane parallel to the base; and is otherwise called a *truncated cone*. See **CONIC Sections**.

The frustum of a pyramid is also what remains after the top is cut off by a plane parallel to its base.

The frustum of a globe or sphere is any part thereof cut off by a plane, the solid contents of which may be found by this rule: To three times the square of the semidiameter of the base add the square of its height; then multiply that sum by the height, and this product multiplied by .5236 gives the solidity of the frustum.

FRUTEX, a **SHRUB**. Shrubs, according to Linnæus, make a branch of the seventh family in the vegetable

Fucinus.

getable kingdom; and are distinguished from trees, in that they come up without buds. But this distinction is not universal, though it be generally just with regard to those of Europe. Nature hath made no absolute distinction between trees and shrubs. *Frutex*, in its general acceptation, is a plant whose trunk is perennial, gemmiparous, woody, dividing and subdividing into a great number of branches. In short, it is the epitome of a tree, exemplified in the rose-bush.

FRY, in zoology, signifies the spawn, or rather young, of fish.

FRYTH (John), a martyr to the Protestant religion in the reign of Henry VIII. He was the son of an inn-keeper at Seven-oaks in Kent; and educated in the king's college, Cambridge, where he took the degree of Bachelor of arts. Thence he removed to Oxford, and was made a junior canon of Wolfey's college. He had not been long in this university before he became acquainted with William Tyndale, a zealous Lutheran, with whom he conversed frequently on the abuses in religion. Fryth became a convert to Lutheranism, and publicly avowed his opinions. He was apprehended, examined by the commissary, and confined to his college. At length having obtained his liberty, in 1528 he went over to Germany, where he continued about two years; and then returned to England, more than ever determined in his religious sentiments. Finding at that time but few associates, he wandered about from place to place, till at last he was taken up at Reading as a vagrant, and set in the stocks, where he remained till he was near expiring for want of sustenance. He was at length relieved by the humanity of Leonard Cox, a schoolmaster; who finding him a man of letters, procured his enlargement, and administered to his necessities. Fryth now set out for London, where, with more zeal than prudence, he began to make profelytes; but was soon apprehended by order of the chancellor Sir Thomas Moore, and sent prisoner to the Tower. Refusing to recant his opinions, he was condemned to the flames, and accordingly burnt in Smithfield, on the 4th of July 1533. He left several works behind him, which were printed in folio in 1573.

FUAGE, in old English writers, a tax of 12d. for every fire, levied in the time of Edward III.

FUCINUS LACUS (anc. geog.), a lake of Italy in the country of the Marsi. Now *Lago di Celano*, from a cognominal citadel, lying in the south of the Abruzzo Ultra, in the kingdom of Naples, near the Apennine. This lake was under the protection of a god of the same denomination, whose temple stood on its banks. According to the testimony of ancient authors, it was subject to extraordinary risings and decreasings. The actual circumference is 47 miles: the breadth in the widest part is 10, in the narrowest 4; its depth 12 feet upon an average. But all these have varied prodigiously. Two miles up the plain, behind Avezzano, the fragments of boats, shells, and other marks of its ancient extent, have been casually discovered: and, on the contrary, there are people who remember when it did not flow nearer than within two miles of Avezzano. An immense tract of excellent land is lost at every increase of its level. All round this noble piece of water rises a circle of grand mountains, some of them the highest in Italy, if we except

the Alps, and many of them covered with snow; and at the foot of them are numerous villages, with rich and well cultivated farms. The environs of the lake, Mr Swinburn describes as all well-inclosed, and the sides of the hills as covered with fine woods; its waters abound with fish of various kinds, and thither repair at stated seasons innumerable flights of wild-fowl. As the swelling of the lake was attended with incredible damage, the Marsi had often petitioned the senate to drain it; Julius Cæsar would have attempted it, had he lived longer. His successors were averse to the project; till Claudius, who delighted in expensive difficult enterprises, undertook it. During the space of eleven years he employed 30,000 men in digging a passage through the mountain; and when every thing was ready for letting off the water, exhibited a superb naval spectacle on the lake. A great number of condemned criminals were obliged to act the parts of Rhodians and Sicilians in separate fleets, to engage in earnest, and to destroy one another for the entertainment of the court and the multitude of spectators that covered the hills: A line of well-armed vessels and rafts loaded with soldiers surrounded the scene of action, in order to prevent any of the wretches from escaping; but it was with great difficulty and many threats that they could be brought to an engagement. When this savage diversion was ended, the operations for opening the emissary or outlet commenced, and the emperor was very near being swept away and drowned by the sudden rushing of the waters towards his vent. However, either through the ignorance or negligence of the engineers, the work did not answer as was expected, and Claudius did not live long enough to have the faults amended: Nero abandoned the scheme through envy. Hadrian is said to have let off the waters of the Fucinus; but none now escape except through hidden channels formed by nature, which are probably subject to be obstructed, and thus occasion a superabundance of water in the lake, till some unknown cause removes the obstructions and again gives free passage.

Sir William Hamilton, who visited the Fucinus in 1785, says, "it is the most beautiful lake he ever saw, and would be complete if the neighbouring mountains were better wooded." It furnishes abundance of fish, though not of the best quality. There are a few large trout, but mostly tench, barbel, and dace. In the shallow water on the borders of the lake, he saw thousands of water-snakes pursuing and preying upon a little kind of fish like thornbacks, but much better armed; though their defensive weapons seemed to avail them but little against such ravenous foes. Claudius's emissary he describes as still entire, though filled up with earth and rubbish in many parts. He went into it with torches as far as he could. It is a covered underground canal three miles long, and part of it cut through a hard rock; and other parts supported by mason work, with wells to give light. Hadrian is said to have let off the waters of the lake: and our author is of opinion, that if the canal were cleared and repaired, it would still answer that purpose, and thereby restore a great deal of rich land fit for cultivation.

FUCUS, a name given by the ancients to certain dyes and paints. By this name they called a purple sea-plant used by them to dye woollen and linen things

Fucinus;
Fucus.

Fucus. of that colour. The dye was very beautiful, but not lasting; for it soon began to change, and in time went wholly off. This is the account Theophrastus gives of it.

The women of those times also used something called *fucus*, to stain their cheeks red; and many have supposed, from the same word expressing both, that the same substance was used on both occasions. But this, on a strict inquiry, proves not to be the case. The Greeks called every thing *fucus*, that would stain or paint the flesh. But this peculiar substance used by the women to paint their cheeks was distinguished from the others by the name of *rixion* among the more correct writers, and was indeed a root brought from Syria into Greece. The Latins, in imitation of the Greek name, called this root *radicula*, and Pliny very erroneously confounds the plant with the *radix lunaria*, or *struthion* of the Greeks.

The word *fucus* was in those times become such an universal name for paint, that the Greeks and Romans had a *fucus metallicus*, which was the cerufs used for painting the neck and arms white: after which they used the *purpurissum*, or red fucus of the *rixium*, to give the colour to the cheeks. In after-times they also used a peculiar *fucus* or paint for the purpose, prepared of the *Creta argentaria*, or silver-chalk, and some of the rich purple dyes that were in use at that time: and this seems to have been very little different from our rose-pink; a colour commonly sold at the colour-shops, and used on like occasions.

Fucus, in the Linnæan system of botany, is a genus of the order of algæ, belonging to the cryptogamia class of plants. The most remarkable species are,

1. The *ferratus*, ferrated fucus, or sea-wrack. This is frequent at all seasons of the year upon the rocks at low-water mark, but produces its seeds in July and August. It consists of a flat, radical, and dichotomous leaf, about two feet long; the branches half an inch wide, serrated on the edges with dents of unequal size, and at unequal distances, having a flat stalk or rib divided like the leaf, and running in the middle of it through all its various ramifications. A small species of coralline called by Linnæus *Sertularia pumila*, frequently creeps along the leaf. All the species of fucus afford a quantity of impure alkaline salt; but this much less than some others; eight ounces of the ashes yielding only three of fixed salt. The Dutch cover their crabs and lobsters with this fucus to keep them alive and moist; and prefer it to any other, as being destitute of those mucous vesicles with which some of the rest abound, and which would sooner ferment and become putrid.

2. The *vesiculosus*, bladder fucus, common sea-wrack, or sea-ware. It grows in great abundance on the sea-rocks about low-water mark; producing its fructifications in July and August. It has the same habit, colour, and substance as the foregoing; but differs from it in the following respects: The edges of the leaf have no serratures, but are quite entire. In the disc or surface are immersed hollow, spherical, or oval air-bladders, hairy within, growing generally in pairs, but often single in the angle of the branches, which are most probably air-bladders destined to buoy up the plant in the water. Lastly, on the summits or

extreme segments of the leaves, appear tumid vesicles about three quarters of an inch long, sometimes oval and in pairs, sometimes single and bifid, with a clear viscid mucus interspersed with downy hairs.—This species is an excellent manure for land; for which purpose it is often applied in the maritime parts of Scotland and other countries. In the islands of Jura and Skye it frequently serves as a winter-food for cattle, which regularly come down to the shores at the recess of the tides to seek for it. And sometimes even the stags have been observed, after a storm, to descend from the mountains to the sea-sides to feed upon this plant.

Linnæus informs us, that the inhabitants of Gothland in Sweden boil this fucus in water, and mixing therewith a little coarse meal or flour, feed their hogs with it; for which reason they call the plant *fwintang*. And in Scania, he says, the poor people cover their cottages with it, and sometimes use it for fuel.

In Jura, and some other of the Hebrides, the inhabitants dry their cheefes without salt, by covering them with the ashes of this plant: which abounds with such quantity of salts, that from five ounces of the ashes may be procured two ounces and a half of fixed alkaline salts, that is, half of their whole weight.

But the most beneficial use to which the fucus vesiculosus is applied, in the way of economy, is in making pot-ash or kelp, a work much practised in the Western Isles. There is great difference in the goodness and price of this commodity, and much care and skill required in properly making it. That is esteemed the best which is hardest, finest grained, and free from sand or earth. The price of kelp in Jura is 3*l.* 10*s.* per ton, and about 40 or 50 tons are exported annually from that island. So great a value is set upon this fucus by the inhabitants of that place, that they have sometimes thought it worth their while to roll fragments of rocks and huge stones into the sea, in order to invite the growth of it.

Its virtues in the medical way have been much celebrated by Dr Russel, in his Dissertation concerning the use of Sea-water in the Diseases of the Glands. He found the saponaceous liquor or mucus in the vesicles of this plant to be an excellent resolvent, extremely serviceable in dispersing all scorbutic and scrophulous swellings of the glands. He recommends the patient to rub the tumor with these vesicles bruised in his hand, till the mucus has thoroughly penetrated the part, and afterwards to wash with sea-water. Or otherwise, to gather two pounds of the tumid vesicles, in the month of July, when they are full of mucus, and infuse them in a quart of sea-water, in a glass-vessel, for the space of 15 days, when the liquor will have acquired nearly the consistence of honey. Then strain it off through a linen cloth, and rub this liquor with the hand, as before, three or four times a-day, upon any hard or scrophulous swellings, washing the parts afterwards with sea-water, and nothing can be more efficacious to disperse them. Even scirrhoties, he says, in womens breasts, have been dispelled by this treatment. The same author, by calcining the plant in the open air, made a very black salt-powder, which he called *vegetable æthiops*; a medicine much in use as a resolvent and deobstruent, and recommended

Fucus.

Fucus.

also as an excellent dentrifice, to correct the scorbutic laxity of the gums, and take off the foulness of the teeth.

3. The plicatus, matted or Indian-grass fucus, grows on the sea-shores in many places both of Scotland and England. It is generally about three or four, but sometimes six, inches long. Its colour, after being exposed to the sun and air, is yellowish, or auburn: its substance pellucid, tough, and horny, so as to bear a strong resemblance to what the anglers call *Indian grass*, that is, the tendrils issuing from the ovary of the dog-fish.

4. The palmatus, palmated or sweet fucus, commonly called *dulse* or *dilse*. This grows plentifully on the sea-coasts of Scotland, and the adjoining islands. Its substance is membranaceous, thin, and pellucid; the colour red, sometimes green with a little mixture of red; its length generally about five or six inches, but varies from three inches to a foot; its manner of growth fan-shaped, or gradually dilated from the base upwards. Its divisions are extremely various. The inhabitants both of Scotland and England take pleasure in eating this plant, without expecting any medical virtues from it. The inhabitants of the Archipelago also are fond of it, as we learn from Steller. They sometimes eat it raw, but esteem it most when added to ragouts, oglios, &c. to which it gives a red colour; and, dissolving, renders them thick and gelatinous. In the Isle of Skye it is sometimes used in fevers to promote a sweat, being boiled in water with the addition of a little butter. In this manner it also frequently purges. The dried leaves, infused in water, exhale the scent of violets.

5. The esculentus, eatable fucus, or bladder-locks, commonly called *tangle* in Scotland, is likewise a native of the British shores. It is commonly about four feet long, and seven or eight inches wide; but is sometimes found three yards or more in length, and a foot in width. Small specimens are not above a cubit long, and two inches broad. The substance is thin, membranaceous, and pellucid; the colour green or olive. The root consists of tough cartilaginous fibres. The stalk is about six inches long and half an inch wide, nearly square, and pinnated in the middle between the root and origin of the leaf, with ten or a dozen pair of thick, cartilaginous, oval-obtuse, foliaceous ligaments, each about two inches long, and crowded together. The leaf is of an oval-lanceolate, or long elliptic form, simple and undivided, waved on the edges, and widely ribbed in the middle from bottom to top, the stalk running through its whole length, and standing out on both sides of the leaf. This fucus is eaten in the north both by men and cattle. Its proper season is in the month of September, when it is in greatest perfection. The membranous part is rejected, and the stalk only is eaten. It is recommended in the disorder called *pica*, to strengthen the stomach and restore the appetite.

6. The saccharinus, sweet fucus, or sea-belt, is very common on the sea-coast. The substance of this is cartilaginous and leathern; and the leaf is quite ribless. By these characters it is distinguished from the preceding, to which it is nearly allied. It consists only of one simple, linear, elliptic leaf, of a tawney green colour, about five feet long and three inches wide in its full-grown state; but varies so exceedingly as to be found from a foot to four yards in length. The

ordinary length of the stalk is two inches, but it varies even to a foot. The root is composed of branched fibres, which adhere to the stones like claws. This plant is often infested with the *fertularia ciliata*. The inhabitants of Iceland make a kind of pottage of this fucus; boiling it in milk, and eating it with a spoon. They also soak it in fresh water, dry it in the sun, and then lay it up in wooden vessels, where in a short time it is covered with a white efflorescence of sea-salt, which has a sweet taste like sugar. This they eat with butter; but if taken in too great a quantity, the salt is apt to irritate the bowels and bring on a purging. Their cattle feed and get fat upon this plant, both in its recent and dry state; but their flesh acquires a bad flavour. It is sometimes eaten by the common people on the coast of England, being boiled as a pot-herb.

7. The ciliatus, ciliated or ligulated fucus, is found on the shores of Iona and other places, but is not common. The colour of this is red, the substance membranous and pellucid, without rib or nerve; the ordinary height of the whole plant about four or five inches. It is variable in its appearance, according to the different stages of its growth. This fucus is eaten by the Scots and Irish promiscuously with the fucus palmatus or dilse.

8. The prolifer, or proliferous fucus, is found on the shores of the western coast, adhering to shells and stones. The colour is red; the substance membranaceous, but tough, and somewhat cartilaginous, without rib or nerve, though thicker in the middle than at the edges. The whole length of the plant is about four or five inches, the breadth of each leaf about a quarter of an inch. The growth of this fucus, when examined with attention, appears to be extremely singular and wonderful. It takes its origin either from a simple, entire, narrow, elliptic leaf, about an inch and a half long; or from a dilated forked one, of the same length. Near the extremity of the elliptic leaf, or the points of the forked one (but out of the surface, and not the edge), arises one or more elliptic or forked leaves, which produce other similar ones, in the same manner, near the summits; and so on continually one or more leaves from near the ends of each other, in a proliferous and dichotomous order, to the top of the plant; which in the manner of its growth resembles in a good measure the cactus opuntia, or flat-leaved Indian-fig. Sometimes two or three leaves, or more, grow out of the middle of the disc of another leaf; but this is not the common order of their growth. The fructifications are red, spherical, rough warts, less than the smallest pin's head, scattered without order on the surface of the leaves. These warts when highly magnified, appear to be the curled rudiments of young leaves; which in due time either drop off and form new plants, or continue on and germinate upon the parent. This plant is very much infested with the *flustra pilosa*, the *mandrepora verrucaria*, and other corallines, which make it appear as if covered with white scabs.

9. The pinnatifidus, jagged fucus, or pepper-dilse, is frequent on sea-rocks which are covered by the tides; both on the eastern and western coasts. It is of a yellow olive-colour, often tinged with red. The substance is cartilaginous, but yet tender and transparent; the height about two or three inches. This fu-

cus

Fucus.

Fucus. *cus* has a hot taste in the mouth, and is therefore called *pepper-dulse* by the people in Scotland, who frequently eat it as a salad in the same manner they do the *fucus palmatus*.

10. The *plocamium*, or *pectinated fucus*, is frequent on the sea-rocks, and in basins of water left by the recesses of the tides. Its natural colour is a most beautiful bright red or purple, but is often variegated with white or yellow. Its substance is cartilaginous, but extremely thin, delicate, and transparent; its height commonly about three or four inches. The stalk is compressed, about half a line in diameter, erect, but waved in its growth, and divided almost from the base into many widely expanded branches. These primary branches are very long, alternate, exactly like the stalk, and subdivided into alternate secondary branches, which are again frequently compounded in like manner, and these divisions decorated with subulated teeth growing in alternate rows, curiously pectinated or finely toothed on the upper side like a comb, the smallest of these teeth scarcely visible to the naked eye. The fructifications are minute spherical capsules, or smooth dark-red globules, scattered without order on the sides of the branches; generally sessile, but some few of them supported on short peduncles. This *fucus*, on account of its elegant colours and fine divisions, is the species most admired by the ladies who are fond of pictures and mimic landscapes composed of marine vegetables.

11. The *filum*, *thread-fucus*, or *sea-laces*, is found on the sea-rocks, and waving under the water like long strings, frequent on many parts of the coast. The substance of this is opaque and cartilaginous, but not difficult to be broken. The colour, when recent, a dull olive-green; when dry, fuscous, or nearly black; and when exposed for some time on the shores to the sun and air, it becomes yellow, straw-coloured, or white. It consists only of a simple, unbranched, naked cylindrical stalk, three or four yards long, more or less, from the size of a large fiddle-string to that of a thick whip-cord; smallest at the base and summit; smooth on the outside, full of mucus within; often twisted, and always intercepted by numerous transverse diaphragms, visible when the plant is held between the eye and the light. The fructifications have not yet been discovered; but from the transverse septa in its structure, it is reasonable to suppose this plant to belong rather of the genus of *conserva* than that of *fucus*. The stalks, skinned when half dry and twisted, acquire so considerably a degree of strength and toughness, that we are informed the Highlanders sometimes use them for the same intentions as Indian grass.

12. The *giganteus*, or *gigantic fucus*, is a native of the Straits Le Maire; and grows on rocky ground, which in some countries is distinguished from sand or ooze by the enormous length of the sea-weeds that grow upon it. The leaves are four feet long, and some of the stalks, though not thicker than a man's thumb, are 120. Sir Joseph Banks and Dr Solander founded over some of them which were 84 feet long; and as they made a very acute angle with the bottom, they were thought to be at least one half longer.

FUEGO, or **FOGA**, one of the Cape de Verd islands, in the Atlantic ocean. It is much higher than any of the rest; and seems, at sea, to be one single mountain,

though on the sides there are deep valleys. There is a volcano at the top, which burns continually, and may be seen a great way off at sea. It vomits a great deal of fire and smoke, and throws out huge pieces of rock to a vast height; and sometimes torrents of melted matter run down the sides. The Portuguese, who first inhabited it, brought negro slaves with them, and a stock of cows, horses, and hogs; but the chief inhabitants now are blacks, of the Romish religion. W. Long. 24. 47. N. Lat. 15. 20.

FUEL, whatever is proper to burn or make a fire; as wood, turf, peat, bituminous earths, coal, &c.

FUEN-HOA, a city of China, in the province of **PE-TCHELI**, celebrated for its extent and the number of its inhabitants, as well as for the beauty of its streets and triumphal arches. It is situated near the great wall, amidst mountains; and has under its jurisdiction, besides two cities of the second and eight of the third class, a great number of fortresses, which bar the entrance of China against the Tartars.

FUGALIA, in Roman antiquity, a feast supposed by some to be the same with the *refugium*, held on 24th of February, in memory of the expulsion of the kings and the abolishing of monarchical government. Others again distinguish the *fugalia* from the *refuge*. And others think, that the *fugalia* was the same with the *poplifugia*, or the feast of *Fugia*, the goddess of joy, occasioned by the rout of an enemy, which was the reason the people abandoned themselves to riot and debauchery.

FUGITIVE, a person obliged to fly his country, or remove from a place where he had some abode or establishment, on account of his crimes, debts, or other occasions.

Fugitive Pieces, among the learned, denote those little compositions which are printed on loose sheets or half sheets; thus called, because easily lost and soon forgot.

FUGUE, in music, (from the Latin *fuga*, "a chase:") A piece of music, sometimes longer and sometimes shorter, in which, agreeable to the rules of harmony and modulation, the composer treats a subject; or, in other words, what expresses the capital thought or sentiment of the piece, in causing it to pass successively and alternately from one part to another.

These are the principle rules of the fugue; of which some are peculiar to itself, and others common to it with what the French call *imitation*.

1. The subject proceeds from the tonic to the dominant, or from the dominant to the tonic, in rising or descending.

2. Every fugue finds its response in the part immediately following that which commenced.

3. That response ought to resume the subject in the interval of a fourth or fifth above or below the key, and to pursue it as exactly as the laws of harmony will admit; proceeding from the dominant to the tonic when the subject is introduced from the tonic to the dominant, and moving in a contrary direction when the subject is introduced from the dominant to the tonic. One part may likewise resume the same subject in the octave or unison of the preceding; but in that case, it is a repetition rather than a real response.

4. As the octave is divided into two unequal parts, of which the one contains four gradations ascending from the tonic to the dominant, and the other only

Fuel

Fugue.

Fugue.

three in continuing the ascent from the dominant to the tonic; this renders it necessary to have some regard to this change in the expression of the subject, and to make some alterations in the response, that we may not quit the chords that are essential to the mode. It is a different case when the composer intends to alter the modulation; for there the exactness of the response itself, when taken in a different tone, produces the alteration proper for this change.

5. It is necessary that the fugue should be planned in such a manner, that the response may commence before the close of the first air, so that both the one and the other may be in part heard at the same time; that, by this anticipation, the subject may be as it were connected with itself, and that the art of the composer may discover itself in this concurrence. It is absolute mockery, instead of a fugue, to impose upon the hearers the same air, merely transposed from one key to another, without any other restraint than an accompaniment afterwards formed at pleasure. This deserves at best no better name than what the French call *imitation*. See IMITATION.

Besides the rules, which are fundamental, there are others which, though prescribed by taste alone, are not less essential. Fugues, in general, render music more noisy than agreeable; it is for this reason that they are more agreeable in the chorus than any where else. Now, as their chief merit consists in fixing the ear on the principal air or subject, which for this reason is made to pass incessantly from part to part, and from mode to mode, the composer ought to exert his care in preserving that air always distinct; or to prevent it from being absorbed in, or confounded with, the other parts. To produce this effect, there are two different ways: one in the movement, which must be incessantly contrasted with itself; so that, if the procedure of the fugue be accelerated, the other parts more gravely and with protracted notes; or, on the contrary, if the motion of the fugue be slow and solemn, the accompaniments must have more and quicker business. The other method is to extend the harmony, by removing the parts at a greater distance one from the other; lest the others, too nearly approximated to that which contains the subject, should be confounded with it, and prevent it from being distinguished with sufficient clearness; so that what would be an imperfection any where else, becomes here a beauty.

The unity of melody should be preserved: that is the great and general rule, which must frequently be practised by different means. The chords must be chosen, and the intervals, so that one particular sound may produce the chief effect: this can only result from the unity of the melody. It will sometimes be necessary to employ voices and instruments of different kinds, that the part which ought to prevail may be most easily distinguished: this again shows the necessity of preserving the unity of the melody. Another object of attention, no less necessary, is, in the different connections of modulation which are introduced by the procedure and progress of the fugue, to cause all these modulations to correspond at the same time in all the parts, to connect the whole in its progress by an exact conformity of modes; lest, if one part be in one mode, and another in another, the general harmony should be in none at all, and for that reason should no longer be

able to produce simple effects upon the ear, nor simple ideas in the mind; which is another reason for preserving unity of melody. In a word in every fugue the confusion of melodies and modulations is at once what a composer has most to fear, and will find the greatest difficulty in avoiding; and as this kind of music never produces a pleasure above mediocrity one may say that a fine fugue is, though the master piece of an excellent harmonist, ungrateful to his toils.

There are still several other kinds of fugues; such as the perpetual fugue*, the double fugue, the inverted * Sec Canon. fugue.

The inverted fugue is a manner of composition, in which the flying part proceeds in a contrary direction to the other fugue, which had been formerly fixed in the same piece of music. Thus, when the first fugitive part is heard in ascending from the tonic to the dominant, or from the dominant to the tonic, the counter fugue ought to be heard in descending from the dominant to the tonic, or from the tonic to the dominant, and *vice versa*. Its other rules are exactly like those of the common fugue.

FULCRUM, in mechanics, the prop or support by which a lever is sustained.

FULDE, a considerable town of Germany, in the circle of the upper Rhine, and in Buchow, with a celebrated abbey; whose abbot is primate of the abbey of the empire, perpetual chancellor of the emperor, and sovereign of a small territory lying between Hesse, Franconia, and Thuringia. It is seated on the river Fulde, 55 miles south of Cassel, and 58 north-east of Francfort. E. Long. 9. 53. N. Lat. 50. 40.

FULGORA, in zoology, a genus of insects belonging to the order of hemiptera; the characters of which are these: The front, or fore-part of the head, is drawn extended and empty; the antennæ are seated below the eyes, having two articulations, whereof the exterior is larger, and of a globular form: the rostrum is inflected, or bent inwards under the body; and the feet are made for walking. There are nine species, the most remarkable of which is the candelaria, or lantern-fly. The head and thorax are generally of a ruddy brown; and the ground colour of the elytra is fresh green, but quaintly figured with spots of a yellowish clay colour, sometimes pale, at other seasons of a deeper hue. The wings are of a deep and beautiful yellow, with a broad band of glossy black bordering the extremities. The tarsi of the feet are composed of three articulations, and are of a paler colour than the legs and thighs, which are brown. When the insect is on the wing, the waving of the elytra (whose thinness renders the spots thereon transparent), assisted by the luminous quality peculiar to the tribe, and the golden yellow of the under wings, bordered with black, occasion, in Mr Barbut's opinion, the flashes they dart around in the night, and create images beyond probability in the minds of persons too ready to credit hyperboles. It is an inhabitant of China.

FULHAM, a village of Middlesex, four miles from London. The Danes in 869 wintered at this place till they retired to the continent. It was in the Conqueror's time held of the king by the canons of St Paul's; and there is an ancient house here, which is moated about, and belongs to the see of London, whose bishop has a palace here, and the demesne, has belong-

Fulcrum
||
Fulham.

Fulica. ed to that diocese from 1067. From this place to Putney there is a wooden bridge over the Thames, where not only horses, coaches, and all carriages, but even foot passengers, pay toll. The church here is both a rectory and a vicarage.

FULICA, the GALLINULE and COOT, in ornithology; a genus of birds of the order of grallæ. It has a convex bill, with the upper mandible fornicated over the lower at the edge; the lower mandible is gibbous behind the tip. The forehead is bald; and the feet have four toes subpinnated. There are 25 species; 18 of which belong to the gallinule division, distinguished by having the toes furnished with broad scalloped membranes; and 7 comprehend the coots which have the toes divided to their origin. The following species are among the most noted.

1. The *chloropus*, or COMMON GALLINULE, is in length about 14 inches, and has a bald forehead and broad flat toes. It gets its food on grassy banks, and borders near fresh waters, and in the very waters if they be weedy. It builds upon low trees and shrubs by the water-side; breeding twice or thrice in a summer, and, when the young are grown up, drives them away to shift for themselves. They lay seven eggs of a dirty white, thinly spotted with rust-colour. This bird strikes with its bill like a hen, and in the spring has a shrill call. In flying, it hangs down its legs; in running, it often flirts up its tail, and shows the white feathers. We may observe, that the bottoms of its toes are so very flat and broad (to enable it to swim), that it seems to be the bird which connects the cloven-footed aquatics with the next tribe, *viz.* the fin-toed. It is pretty common on the continent, though in some parts more scarce than in others. It is also an inhabitant of America, from New York to Carolina; and is recorded as a native of Jamaica and other islands in the West Indies. It is said to feed on plants and small fish; and the flesh is for the most part pretty good.

2. The *porphyrio*, or PURPLE GALLINULE, is about the size of a fowl, or 17 inches in length. The bill is an inch and an half long, and of a deep red colour. The forehead is bare and red; the head and hind part of the neck are glossy violet: the legs are very stout, and of the colour of the bill. This bird is more or less common in all the warmer parts of the globe. On the coasts of Barbary they abound, as well as in some of the islands of the Mediterranean. In Sicily they are bred in plenty, and kept for their beauty; but whether indigenous there, is uncertain. It is frequently met with in various parts of the South of Russia and western parts of Siberia, among reedy places; in the neighbourhood of the Caspian Sea it is not uncommon; but in the cultivated rice-grounds of Ghilar in Persia it is in great plenty and high plumage. The female makes the nest among the reeds in the middle of March; lays three or four eggs, and sits from three to four weeks. That it is common in China, the paper-hangings from thence will every where testify. It is also met with in the East Indies, the islands of Java, Madagascar, and many others. The late navigators saw them at Tongataboo in vast numbers, as well as in the island of Tanna and other parts. It is also common in the southern parts of America. In respect to its manners, is a very docile bird, being easily tamed, and feeding with the poul-

try, scratching the ground with the foot as the cock and hen. It will feed on many things, such as fruit, roots of plants, and grain; and will eat fish with avidity, dipping them into the water before it swallows them. It will frequently stand on one leg, and lift the food to its mouth with the other like a parrot. A pair of these kept in an aviary in France, made a nest of small sticks mixed with a quantity of straw, and laid six white eggs, perfectly round; but the hen was careless of them, and they came to nothing. The flesh is said to be exquisite in taste.

3. The *atra*, or COMMON COOT, hath a bald forehead, a black body, and lobated toes; and is about 15 inches in length. They frequent lakes and still rivers; making their nest among the rushes, with grass, reeds, &c. floating on the water, so as to rise and fall with it. They lay five or six large eggs, of a dirty whitish hue, sprinkled over with minute deep rust-coloured spots; and it is said that sometimes they will lay 14 or more eggs. The young when just hatched are very deformed and the head mixed with a red coarse down. In winter they often repair to the sea, and the channel near Southampton, England, is sometimes observed almost covered with them. They are often brought to that market, where they are exposed to sale without their feathers, and scalded like pigs. This species is not so numerous as might be expected; for we find that vast numbers fall a prey while young to the buzzards, which frequent the marshes. Their food is small fish and water-insects: but they will sometimes eat the roots of the bulrush, and with it feed the young; they are said likewise to eat grain. This species is supposed to extend throughout the old continent, and perhaps the new also. Authors record it as inhabiting Greenland, Sweden, Norway, Russia, Siberia, Persia, and China, and many of the intermediate parts. It is also met with in Jamaica, Carolina, and other parts of North America. The Indians about Niagara dress the skins of these birds, and use them for pouches. They are called in Carolina *flusterers*.

4. The *aterrima*, or GREATER COOT, is of a larger size than the last, and its plumage is blacker. This species is said to be found in Lancashire and Scotland: but is more plentiful on the continent, being found in Russia and the western part of Siberia very common; and is also in plenty at Sologne and the neighbouring parts, where they call it *judelle*. The people eat this bird on maigre days, and its flesh is much esteemed.

FULIGINOUS, whatever proceeds from a thick sooty smoke, such as litharge and lamp black.

FULIGNO, a city of Italy, in the pope's territories, 10 miles north of Spoleto.

FULIGO, in natural history, a species of pumice-stone. See PUMICE.

FULK (William), a learned and eminent divine of the church of England, in the 16th century. He was patronised by the earl of Leicester, who in 1571 presented him to the living of Warley in Essex, and soon after to that of Diddington in Suffolk. He attended Leicester, when he went ambassador to France; and on his return was made master of Pembroke-hall, and Margaret professor of divinity at Cambridge. His works are very numerous, levelled chiefly at the Papists, the most considerable of them is his Comment on the Rhemish Testament. He died in 1589.

Fuller.

FULLER (Nicholas), prebendary of Salisbury, and a learned English critic; who published in 1617 *Miscellanea Theologica* in four books, and afterward two more of *Miscellanea Sacra*. He died in 1623; and there are some MSS of his remaining in the Bodleian library, that show his great skill in Hebrew and philology.

FULLER (Dr Thomas), a learned English divine, was born at Alvinckle, near Oundle, in Northamptonshire, about the year 1608, and studied at Cambridge. He was chosen minister of St Bennet's there; and at about 23 years of age, his merit procured him fellowship in Sidney-college, and a prebend in Salisbury cathedral. He was soon after presented to the rectory of Broad Windsor in Dorsetshire; and afterwards was made lecturer of the Savoy in London: but upon the pressing of the covenant, he retired to Oxford; and soon after accompanied Sir Ralph Hopton as his chaplain in the army, which he attended in their marches from place to place. After the death of king Charles I. he obtained the living of Waltham-abbey, and was appointed lecturer of St Clement's; and shortly after removed to the lecture of St Bride's, Fleet-street. Upon the restoration, he recovered his prebend in the cathedral of Salisbury, was appointed chaplain extraordinary to his majesty, and created doctor of divinity. It is said, his memory was so amazingly tenacious and comprehensive, that he could make use of a sermon *verbatim* if he once heard it. He once undertook, in passing to and from Temple-bar to the Poultry, to tell at his return every sign as it stood in order on both sides of the way, repeating them either backwards or forwards; and this task he actually performed. He wrote, 1. A History of the Holy War. 2. The Church-history of Britain, in folio. 3. Andronicus, or the Unfortunate Politician, in 8vo. 4. A Pisgah-sight of Palestine. 5. A History of English Worthies; and other works. He died in August 1661; and was interred in the chancel of Cranford church, in Middlesex, whither his body was attended by at least 200 of his brethren of the ministry.

FULLER, a workman employed in the woollen manufactories to mill or scour cloths, serges, and other stuffs, in order to render them more thick, compact, and durable. See FULLING.

* See Clay, n° 4.

FULLER'S Earth, in natural history, a species of clay*, of a greyish ash-coloured brown, in all degrees from very pale to almost black, and it has generally something of a greenish cast. It is very hard and firm, of a compact texture, of a rough and somewhat dully surface that adheres slightly to the tongue. It is very soft to the touch, not staining the hands; nor breaking easily between the fingers. It has a little harshness between the teeth, and melts freely in the mouth. Thrown into water, it makes no ebullition or hissing; but swells gradually in bulk, and falls into a fine soft powder. It makes no effervescence with aquafortis.

The greatest quantity and the finest earth of this kind in the world, is dug in the pits at Wavedon, near Woburn in Bedfordshire. The strata in these pits lie thus: From the surface to the depth of six feet, there are several layers or beds of sand, all reddish, but some lighter coloured than others. Under these there is a thin stratum of sand-stone, which they break through, and then there is the fuller's earth. The upper stratum of this is about a foot thick: the workmen call

it *clodge*, and throw it aside as useless; being commonly fouled with the sand which originally covered it, and which insinuates itself a good way into it. After this, they come to the fine fuller's earth for sale, which lies to the depth of eight feet more. The matter of this is divided into several layers, their being commonly about a foot and an half between one horizontal fissure and another. Of these several layers, the upper half, where the earth breaks itself, is tinged red; which seems to be owing to the running of the water upon it from among the sands above; some of which are probably of a ferruginous nature, or have ferruginous matter among them. This reddish fuller's earth the workmen call *crop*; and between the clodge and this there is a thin stratum of matter, of less than an inch, which in taste, colour, and external appearance, resembles the terra Japonica of the shops. The lower half of the strata of fuller's earth they call *wall-earth*. This is untinged with the red colour of the other, and seems the most proper for fulling. Under the fuller's earth there is a stratum of white and coarse stone about two feet thick. They seldom dig through this; but if they do, they find more strata of sand.

This earth is of great use in scouring cloths, stuffs, &c. imbibing all the grease and oil used in preparing, dressing, &c. of the wool; for which reason it is made a contraband commodity, and is not to be exported under the penalty of 1 s. for every pound weight. See FULLING.

FULLER'S Weed, or Teazle. See DIPSACUS.

FULLERY, a place where cloths, &c. are fulled. See the next article.

FULLING, the art or act of cleansing, scouring, and pressing cloths, stuffs, and stockings, to render them stronger, closer, and firmer: called also *milling*. Pliny (*lib. vii. cap. 36.*) assures, that one Nicias, the son of Hermias, was the first inventor of the art of fulling: and it appears by an inscription, quoted by Sir G. Wheeler, in his Travels thro' Greece, that this same Nicias was a governor in Greece in the time of the Romans.

The fulling of cloths and other stuffs is performed by a kind of water-mill, thence called a *fulling* or *scouring-mill*.

These mills, excepting in what relates to the mill-stones and hopper, are much the same with corn-mills: and there are even some which serve indifferently for either use; corn being ground, and cloths fulled, by the motion of the same wheel. Whence, in some places, particularly in France, the fullers are called *millers*; as grinding corn and milling stuffs at the same time.

The principal parts of the fulling-mill are, The wheel, with its trundle; which gives motion to the tree or spindle, whose teeth communicate it to the pestles or stampers, which are thereby raised and made to fall alternately according as its teeth catch on or quit a kind of latch in the middle of each pestle. The pestles and troughs are of woods; each trough having at least two, sometimes three pestles, at the discretion of the master, or according to the force of the stream of water. In these troughs are laid the cloths, stuffs, &c. intended to be fulled: then, letting the current of water fall on the wheel, the pestles are successively let fall thereon, and by their weight and velocity stamp and press the stuffs very strongly, which by this means become thickened and condensed. In the course of the

Fuller

Fulling.

Fulling the operation, they sometimes make use of urine, sometimes of fuller's earth, and sometimes of soap. **Fulminating.** To prepare the stuffs to receive the first impressions of the pestle, they are usually laid in urine; then in fuller's earth and water; and, lastly, in soap dissolved in hot water. Soap alone would do very well; but this is expensive: though fuller's earth, in the way of our dressing, is scarce inferior thereto; but then it must be well cleared of all stones and grittiness, which are apt to make holes in the stuff. As to urine, it is certainly prejudicial, and ought to be entirely discarded; not so much on account of its ill smell, as of its sharpness and saltness, which qualities are apt to render the stuffs dry and harsh.

The true method of fulling with soap is delivered by Monsr. Colinet, in an authentic memoir on that subject, supported by experiments made by order of the marquis de Louvois, then superintendant of the arts and manufactories of France; the substance of which we shall here subjoin.

Method of FULLING Cloths and Woollen Stuffs with Soap:—A coloured cloth, of about 45 ells, is to be laid in the usual manner in the trough of a fulling-mill; without first soaking it in water, as is commonly practised in many places. To full this trough of cloth, 15 pounds of soap are required; one-half of which is to be melted in two pails of river or spring water, made as hot as the hand can well bear it. This solution is to be poured by little and little upon the cloth, in proportion as it is laid in the trough: and thus it is to be fullled for at least two hours; after which, it is to be taken out and stretched. This done, the cloth is immediately returned into the same trough, without any new soap, and there fullled two hours more. Then taking it out, they wring it well, to express all the grease and filth. After the second fulling, the remainder of the soap is dissolved as in the former, and cast four different times on the cloth; remembering to take out the cloth every two hours, to stretch it, and undo the plains and wrinkles it has acquired in the trough. When they perceive it sufficiently fullled, and brought to the quality and thickness required, they scour it for good in hot water, keeping it in the trough till it be quite clean. As to white cloths; in regard these full more easily and in less time than coloured ones, a third part of the soap may be spared.

FULLING of Stockings, Caps, &c. should be performed somewhat differently; viz. either with the feet or the hands; or a kind of rack, or wooden machine, either armed with teeth of the same matter, or else horses or bullocks teeth. The ingredients made use of herein are, urine, green soap, white soap, and fuller's earth. But the urine is also reckoned prejudicial here. Woven stockings, &c. should be fullled with soap alone: for those that are knit, earth may be used with the soap. Indeed it is frequent to full these kinds of works with the mill, after the usual manner of cloth, &c. But that is too coarse and violent a manner, and apt to damage the work unless it be very strong.

FULMAR, in ornithology. See **PROCELLARIA**.

FULMAR, or *Foumart*. See **MUSTELA**.

FULMINATING, something that thunders or resembles thunder.

FULMINATING Gold, Silver, Copper, Quicksilver, &c. See **CHEMISTRY-Index at Fulminating.**

FULMINATION, in chemistry, the same with detonation. See **DETONATION** and **NITRE**.

FULMINATION, in the Romish canon law, a sentence of a bishop, official, or other ecclesiastic appointed by the pope, by which it is decreed that some bull sent from the pope shall be executed.

FUMARIA, FUMITORY: A genus of the pentandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 24th order, *Corydalis*. The calyx is diphyllous; the corolla ringent; and there are two membranaceous filaments, each of which has three antheræ. There are a number of different species; all of them low, shrubby, and deciduous and evergreen plants, growing from two to six or seven feet high, adorned with small simple leaves, and papilionaceous flowers of different colours. The most remarkable is the officinalis, or common fumitory; which grows naturally in shady cultivated grounds, and produces spikes of purplish flowers in May and June. It is very juicy, of a bitter taste, without any remarkable smell.—The medical effects of this herb are, to strengthen the tone of the bowels, gently loosen the belly, and promote the urinary and other natural secretions. It is principally recommended in melancholic, scorbutic, and cutaneous disorders, for opening obstructions of the viscera, attenuating and promoting the evacuation of viscid juices. Frederic Heffinan had a very great opinion of it as a purifier of the blood; and assures us, that in this intention scarce any plant exceeds it. Cows and sheep eat the plant; goats are not fond of it; horses and swine refuse it.

FUMIGATION, in chemistry, a kind of calcination, when metals or other hard bodies are corroded or softened by receiving certain fumes for that purpose.

FUMIGATION, in medicine. By the subtle fumes that are inspired as well as inhaled into our bodies, much benefit or prejudice is produced, according to the nature of the matter, and the constitution into which it is received; as is evident from the palsies produced among workers in lead mines, &c. and the benefits received in many cases when the air is impregnated with salutary materials. Catarrhs and catarrhus coughs are relieved by fumes received with the breath; and by the same method, expectoration is assisted in humoural asthmas; and even ulcers in the lungs are said to have been healed by this method. The advantage of mercurial fumigations in the cure of venereal ulcers is known to every practitioner.

FUMITORY, in botany. See **FUMARIA**.

FUNAMBULUS, among the Romans, was what we call a *rope-dancer*, and the Greeks *schanobates*. See **ROPE-DANCER**.

There was a funambulus, it seems, who performed at the time when the Hecyra of Terence was acted; and the poet complains, that the spectacle prevented the people from attending to his comedy. *Ita populus studio stupidus in funambulo, animum occupat.*

At Rome, the funambuli first appeared under the consulate of Sulpicius Pæticus and Licinius Stolo, who were the first introducers of the scenic representations. It is added, that they were first exhibited in the island of the Tyber, and that the censors Messala and Cassius afterwards promoted them to the theatre.

In the *Floralia*, or *Iudi Florales*, held under Galba, there

Funambulus.

Funchal
||
Fund.

there were funambulatory elephants, as we are informed by Suetonius. Nero also showed the like, in honour of his mother Agrippina. Vopiscus relates the same of the time of Carinus and Numerianus.

FUNCHAL, an episcopal town of Madeira, in an island of the Atlantic ocean, over-against the coast of Morocco. It is large, strong, handsome, and populous, with fine churches. The principal trade consists in sweetmeats and wines. It belongs to the Portuguese; and is seated in a fertile valley, at the foot of a mountain from whence several streams proceed. W. Long. 14. 30. N. Lat. 31. 30.

FUNCTION, the act of fulfilling the duties of any employment.

FUNCTION, being also applied to the actions of the body, is by physicians divided into vital, animal, and natural. The *vital* functions are those necessary to life, and without which the individual cannot subsist; as the motion of the heart lungs, &c. The *natural* functions are such as it cannot subsist any considerable time without; as the digestion of the aliment, and its conversion into blood. Under *animal* functions are included the senses of touching, tasting, &c. memory, judgment, and voluntary motion; without any or all of which an animal may live, but not very comfortably.

The animal functions perform the motion of the body by the action of the muscles; and this action consists chiefly in the shortening of the fleshy fibres, which is called *contraction*, the principal agents of which are the arteries and nerves distributed in the fleshy fibres.

All parts of the body have their own functions, or actions, peculiar to themselves. Life consists in the *exercise* of these functions, and health in the *free* and *ready* exercise of them.

FUND, in general, signifies any sum of money appropriated for a particular purpose. Thus, that part of the national revenue which is set aside for the payment of the national debt, is called the *sinking fund*. But, when we speak of *the funds*, we generally mean the large sums which have been lent to government, and constitute the national debt; and for which the lenders, or their assignees, receive interest from revenues allotted for that purpose. The term *stock* is used in the same sense, and is also applied to the sums which form the capital of the bank of England, the East India and South Sea companies; the proprietors of which are intitled to a share of the profits of the respective companies.

The practice of funding was introduced by the Venetians and Genoeze in the 16th century, and has been adopted since by most of the nations in Europe. Princes had often borrowed money, in former times, to supply their exigencies, and sometimes mortgaged their territories in security: but these loans were generally extorted, and their payment was always precarious; for it depended on the good faith and success of the borrower, and never became a regular burden on posterity. The origin of funds is derived from the peculiar manners and circumstances of modern Europe. Since the invention of gun-powder, and the progress of commerce, the military occupation has become a distinct employment in the hands of mercenaries; the apparatus of war is attended with more expence; and

the decision of national quarrels has often been determined by command of money rather than by national bravery. Ambitious princes have therefore borrowed money, in order to carry on their projects with more vigour. Weaker states have been compelled, in self-defence, to apply to the same resource; the wealth introduced by commerce has afforded the means; the regularity of administration, established in consequence of the progress of civility, has increased the confidence of individuals in the public security; the complicated system of modern policy has extended the scenes of war, and prolonged their duration; and the colonies established by the mercantile nations have rendered them vulnerable in more points, and increased the expence of defending them.

When a greater sum has been required for the annual expence than could easily be supplied by annual taxes, the government have proposed terms, to their own subjects, or foreigners, for obtaining an advance of money, by mortgaging the revenue of future years for their indemnification. This mortgage may either be for a limited period, or perpetual. If the sum allotted annually for the benefit of those who advance the money, be considerably greater than the interests of the sums advanced, they may agree to accept of such allowance, for a limited time, as a full equivalent. Thus, they may either agree for the casual produce of the revenue assigned; or a fixed annuity for a greater or less number of years; or a lifeannuity to themselves or nominees; or an annuity for two or more lives; or an annuity, with the benefit of survivorship, called a *tontine*, in which scheme, the whole sum to which the original annuitants were intitled continues to be distributed among the survivors.

The establishment of the funds was introduced in Britain at the revolution; and has since been gradually enlarged, and carried to an amazing extent. The various methods abovementioned have been used in their turns, but perpetual annuities have been granted for the greatest part; and, even when the money was originally advanced on other conditions, the lenders have been sometimes induced, by subsequent offers, to accept of perpetual annuities, instead of the former terms. The debt for which perpetual annuities are granted, is called the *redeemable debt*, and the other is called the *irredeemable debt*. Although the debts thus contracted by government are seldom paid for a long term of years; yet any creditor of the public may obtain money for what is due him when he pleases, by transferring his property in the funds to another; and regular methods are appointed for transacting these transfers in an easy manner. By means of this, the stocks become a kind of circulating capital; and have the same effect, in some respects, as the circulating money in the nation. When a stockholder transfers his share, he may sometimes be able to obtain a greater price than the original value, and at other times be obliged to accept of a less one. The value of the funds depends on the proportion between the interest they bear, and the benefit which may be obtained by applying the money to other purposes. It is influenced by the plenty or scarcity of money, and by the quantity of the public debt; and it is impaired by any event which threatens the safety, or weakens the credit of the government.

Fund.

Funds.

The business of stock-jobbing is founded on the variation of the prices of stock. Persons possessed of real property may buy or sell stock, according to their notion that the value is likely to rise or fall, in expectation of making profit by the difference of price. And a practice has taken place among persons who often possess no property in the funds, to contract for the sale of stock against a future day, at a price now agreed on. For instance; A agrees to sell B 1000 l. of bank-stock, to be transferred, in 20 days, for 1200 l. A has, in fact, no such stock; but, if the price of bank-stock, on the day appointed for the transfer, should be only 118 *per cent.* A may purchase as much as will enable him to fulfil his bargain for 1180 l. and thus gains 20 l. by the transaction; on the contrary, if the price of bank stock be 125 *per cent.* he will lose 50 l. The business is generally settled without any actual purchase or transfer of stock, by A paying to B, or receiving from him, the difference between the current price of the stock on the day appointed and the price bargained for.

This practice, which is really nothing else than a wager concerning the price of stock, is contrary to law; yet it is carried on to a great extent. In the language of Exchange-alley, where matters of this kind are transacted, the buyer is called a *bull*, and the seller a *bear*. As neither party can be compelled by law to implement these bargains, their sense of honour, and the disgrace and loss of future credit, which attend a breach of contract, are the principles by which the business is supported. When a person declines to pay his loss, he is called a *lame duck*, and dare never afterwards appear in the Alley. This opprobrious appellation, however, is not bestowed on those whose failure is owing to want of ability, providing they make the same surrender of their property voluntarily, which the law would have exacted if the debt had been intitled to its sanction.

The interest or dividend on the stock is paid half-yearly; and the purchaser has the benefit of the interest due on the stock he buys, from the last term to the time of purchase. Therefore the prices of the stocks rise gradually, *ceteris paribus*, from term to term, and fall at the term when the interest is paid. In comparing the prices of the different stocks, it is necessary to advert to the term when the last interest was paid; and, allowance being made for this circumstance, the prices of all the government stock, which bear interest at the same rate, must be nearly the same, as they all depend upon the same security.

When a loan is proposed, such terms must be offered to the lenders, as may render the transaction beneficial: and this is now regulated by the prices of the old stocks. If the stocks, which bear interest at 4 *per cent.* sell at par, or rather above, the government may expect to borrow money at that rate; but, if these stocks are under par, the government must either grant a higher interest, or some other advantage to the lenders, in compensation for the difference. For this purpose, besides the perpetual annuity, another annuity has sometimes been granted for life, or for a term of years. Lotteries have frequently been employed to facilitate the loan, by intitling the subscribers to a certain number of tickets, for which no higher price is charged than the exact value distributed in prizes, tho'

their market-price is generally 2 l. or 3 l. higher. Sometimes an abatement of a certain proportion of the capital has been granted, and a lender intitled to hold 100 l. stock, though in reality he advanced no more perhaps than 95 l.

It belongs to the Chancellor of the Exchequer to propose the terms of the loan in parliament; and he generally makes a previous agreement with some wealthy merchants who are willing to advance the money on the terms proposed. The subscribers to the loan deposit a certain part of the sum subscribed; and are bound to pay the rest by instalments, or stated proportions, on appointed days, under pain of forfeiting what they have deposited. For this they are intitled, perhaps not only to hold their share in the capital, but to an annuity for 10 years, and to the right of receiving a certain number of lottery-tickets on advantageous terms. They may sell their capital to one person, their annuity to a second, and their right to the tickets to a third. The value of all these interests together is called *omnium*; and, in order to obtain a ready subscription, it ought to amount to 102 l. or upwards, on 100 l. of capital. This difference is called the *bonus* to the subscribers.

The capital advanced to the public, in the form of transferable stocks, and bearing interest from taxes appropriated for that purpose, is called the *funded debt*. Besides, there is generally a considerable sum due by government, which is not disposed of in that manner, and therefore is distinguished by the appellation of the *unfunded debt*. This may arise from any sort of national expence, for which no provision has been made, or for which the provision has proved insufficient. The chief branches are,

1st, *Exchequer Bills*. These are issued from the exchequer, generally by appointment of parliament, and sometimes without such appointment, when exigencies require. They bear interest from the time when issued, and are taken in by the bank of England, which promotes their circulation.

2d, *Navy-Bills*. The sums annually granted for the navy have always fallen short of what that service required. To supply that deficiency, the admiralty issues bills in payment of victuals, stores and the like, which bear interest six months after the time issued. The debt of the navy thus contracted is discharged, from time, to time by parliament.

In time of war the public expences, since the revolution, have always been much greater than the annual revenue: and large sums have consequently been borrowed. In the time of peace, the revenue exceeds the expence, and part of the public debts have frequently been paid off. But though there have been more years of peace than of war since the funds were established, the debts contracted during each war have much exceeded the payments during the subsequent, peace. This will appear by the following abstract of the progress of the national debt.

Debt at peace of Ryswich, 1697	L. 21,515,472
Debt at the beginning of war 1701	16,394,701
Discharged during peace 1697 to 1701	5,121,071

FUNDAMENT, in anatomy, the lowest part of the intestinum rectum, called by anatomists the *anus*. See ANATOMY, n° 93.

FUNDAMENTAL, in general, something that serves as a base or foundation for another.

FUNDAMENTAL, in music. A *fundamental sound* is that which forms the lowest note of the CHORD, and from whence are deduced the harmonical relations of the rest; or, which serves for a key to the tone*. The *fundamental bass* is that which serves for a foundation to the harmony. A *fundamental chord* is that whose bass is fundamental, and in which the sounds are ranged in the same order as when they are generated, according to the experiment so often repeated, by M. d'Alembert, in his Preliminary Discourse and Elements of Music †. But as this order removes the parts to an extreme distance from the other, they must be approximated by combinations or inversions; but if the bass remains the same the chord does not for this reason cease to bear the name of *fundamental*. Such an example is this chord, *ut mi sol*, included in the interval of a fifth: whereas, in the order of its generation *ut sol mi*, it includes a tenth, and even a seventeenth; since the fundamental *ut* is not the fifth of *sol*, but the octave of that fifth.

FUNDAMENTAL Bass. This part in music is, according to Rousseau, and indeed according to all authors who have proceeded upon M. Rameau's experiment, in its primary idea, that bass which is formed by the fundamental notes of every perfect chord that constitutes the harmony of the piece; so that under each chord it causes to be heard, or understood, the fundamental sound of that particular chord; that is to say, the sound from whence it is derived by the rules of harmony. From whence we may see, that the fundamental bass can have no other contexture than that of a regular and fundamental succession, without which the procedure of the upper parts would be illegitimate.

To understand this well, it is necessary to be known, that, according to the system of Rameau, which Rousseau has followed in his Dictionary, every chord, tho' composed of several sounds, can only have one which is its fundamental, *viz.* that which produces this chord, and which is its bass according to the direct and natural order. Now the bass which prevails under all the

other parts, does not always express the fundamental sound, of the chords: for amongst all the sounds which form a chord, the composer is at liberty to transfer to the bass that which he thinks preferable; regard being had to the procedure of that bass, to the beauty of the melody, and above all to the expression, as may afterwards be explained. In this case the real fundamental sound, instead of retaining its natural station, which is in the bass, will either be transferred to some of the other parts; or perhaps even entirely suppressed, and such a chord is called an *inverted chord*.

In reality, says Rameau, a chord inverted does not differ from the chord in its direct and natural order from which it was produced: but as these sounds form different combinations, these combinations have long been taken for fundamental chords; different names, have been given them, (which may be seen at the word ACCORD, in Rousseau's Dictionary). These names, by the persons who bestowed them, were thought to create and sanctify their distinctions; as if a difference in names could really produce a difference in the species.

M. Rameau in his Treatise of Harmony has shown, and M d'Alembert in his Elements of Music has still more clearly evinced, that many of these pretendedly different chords were no more than inversions of one single chord. Thus the chord of the sixth is no more than the perfect chord of the third transferred to the bass; by adding a fifth, we shall have the chord of the sixth and fourth. Here there are three combinations of a chord, which only consists of three sounds; those which contain four sounds are susceptible of four combinations, since each of these sounds may be transferred to the bass. But in adding beneath this another bass which, under all the combinations of one and the same chord, always presents the fundamental sound; it is evident, that consonant chords are reduced to the number three, and the number of dissonant chords to four. Add to this all the chords by supposition, which may likewise be reduced to the fundamentals, and you will find harmony brought to a degree of simplicity in which no person could ever hope to see it whilst its rules remained in that state of confusion where M. Rameau found them. It is certainly, as that author observes, an astonishing occurrence, that the practice of this art could be carried so far as it really was, without knowing its foundation; and that all the rules were so exactly found, without having discovered the principle on which they depended.

After having shown what is the fundamental bass beneath the chords, let us now speak of its procedure, and of the manner in which it connects these chords among themselves. Upon this point the precepts of the art may be reduced to the six following rules.

1. The fundamental bass ought never to found any other notes than those of the series or tone in which the composer finds himself, or at least those of the series or tone to which he chooses to make a transition. This of all the rules for the fundamental bass is the first and most indispensable.

2. By the second, its procedure ought to be so implicitly subjected to the laws of modulation, as never to suffer the idea of a former mode to be lost till that of a subsequent one can be legitimately assumed; that is to say, that the fundamental bass ought never to be de-
vions,

Fundamen-
tal. vious, or suffer us to be one moment at a loss in what mode we are,

3. By the third, it is subjected to the connection of chords and the preparation of dissonances: a manœuvre which, as we shall afterwards see, is nothing else but a method of producing this connection, and which of consequence is only necessary when the connection cannot subsist without it. See CONNECTION, PREPARATION.

4. By the fourth, it is necessitated, after every dissonance, to pursue that career, which the resolution of the dissonance indispensably prescribes. See RESOLUTION.

5. By the fifth, which is nothing else but a consequence of the former, the fundamental bass ought only to move by consonant intervals; except alone in the operation of a broken cadence, or after a chord of the seventh diminished, where it rises diatonically. Every other motion of the fundamental bass is illegitimate.

6. By the sixth, in short, the fundamental bass or harmony ought not to be syncopated; but to distinguish the bars and the times which they contain, by changes of chords properly marked with cadences; in such a manner, for instance, that the dissonances which ought to be prepared may find their preparation in the imperfect time, but chiefly that all the rests may happen in the perfect time. This sixth rule admits of an infinite number of exceptions; but the composer ought however to be attentive to it, if he would form a music in which the movements are properly marked, and in which the bars may end gracefully.

Wherever these rules are observed, the harmony shall be regular and without fault: this, however, will not hinder the music from being detestable. See COMPOSITION.

A word of illustration on the fifth rule may not be useless. Whatever turn may be given to a fundamental bass, if it is properly formed, one of these alternatives must always be found; either perfect chords moving by consonant intervals, without which these chords would have no connection; or, dissonant chords in operations of cadence: in every other case, the dissonance can neither be properly placed nor properly resolved.

From thence it follows, that the fundamental bass cannot move regularly but in one of these three manners. 1st, To rise or descend by a third or by a sixth. 2dly, By a fourth or a fifth. 3dly, To rise diatonically by means of the dissonance which forms the connection, or by a licence upon a perfect chord. With respect to a diatonic descent, it is a motion absolutely prohibited to the fundamental bass; or, at most, merely tolerated in cases where two perfect chords are in succession, divided by a close expressed or understood. This rule has no other exception: and it is from not discerning the foundation of certain transitions, that, M. Rameau has caused the fundamental bass to descend diatonically under chords of the seventh; an operation which is impracticable in legitimate harmony. See CADENCE, DISSONANCE.

The fundamental bass, which they add for no other reason than to serve as a proof of the harmony, must be retrenched in execution, and often in practice it would have a very bad effect; for it is, as M. Rameau

Fundamen-
tal. very properly observes, intended for the judgment, and not for the ear. It would at least produce a monotony extremely nauseous by frequent returns of the same chord, which they disguise and vary more agreeably by combining it in different manners upon the continued bass, without reckoning upon the different inversions of harmony, which furnish a thousand means of adding new beauties to the music and new energy to the expression. See CHORD, INVERSION.

But it will be objected, If the fundamental bass is not useful in composing good music, if it must even be retrenched in practice, what good purpose, then, can it serve? We answer, that, in the first place, it serves for a rule to scholars, upon which they may learn to form a regular harmony, and to give to all the parts such a diatonic and elementary procedure as is prescribed them by that fundamental bass. It does more, as we have already said: it proves whether a harmony already formed be just and regular; for all harmony which cannot be subjected to the test of a fundamental bass, must according to all rules be bad. Finally, it serves for the investigation of a continued bass under a given air: though, in reality, he who cannot directly form a continued bass, will scarcely be able to form a fundamental bass, which is better; and much less still will he be able to transform that fundamental bass into a legitimate continued bass. These which follow are, however, the principal rules which M. Rameau prescribes for finding the fundamental bass of a given air.

1. To ascertain with precision the mode in which the composer begins, and those through which he passes. There are also rules for investigating the modes; but so long, so vague, so incomplete, that with respect to this, the ear may be formed long before the rules are acquired; and the dunce who should try to use them, would gain no improvement but the habit of proceeding always note by note, without even knowing where he is.

2. To try in succession under each note the principal chords of the mode, beginning by those which are most analogous, and passing even to the most remote, when the composer sees himself under a necessity of doing so.

3. To consider whether the chord chosen can suit the upper part in what precedes and in what follows, by a just fundamental succession; and when this is impracticable to return the way he came.

4. Not to change the the note of the fundamental bass till after having exhausted all the notes which are allowed in succession in the upper part, and which can enter into its chord; or till some syncopated note in the air may be susceptible of two or a greater number of notes in the bass, to prepare the dissonance which may be afterwards resolved according to rule.

5. To study the intertexture of the phrases; the possible succession of cadences, whether full or avoided; and above all, the pauses which for ordinary return at the end of every four, or of every two bars, so that they may always fall upon perfect and regular cadences.

6. In short, to observe all the rules formerly given for the composition of the fundamental bass.—These are the principal observations to be made for finding one under any given air; for there are sometimes several

Fundi
||
Funeral.

ral different ones which may be investigated. But, whatever may be said to the contrary, if the air has accent and character, there is only one just fundamental bass which can be adapted to it.

After having given a summary explication of the manner in which a fundamental bass should be composed, it should remain to suggest the means of transforming it into a continued bass; and this would be easy, if it were only necessary to regard the diatonic procedure and the agreeable air of this bass. But let us not imagine that the bass, which is the guide and support of the harmony, the soul, and as it were the interpreter, of the air, should be limited to rules so simple: there are others which depend upon principles more certain and more radical; fruitful, but latent principles, which have been felt by every artist of genius without having been detected by any one. Rousseau hopes, that in his letter upon French music he insinuated this principle. For those who understand him, he imagines he has said enough concerning it, and can never say enough of it for those who do not. See *Rousseau's Miscellanies*, Vol. II. p. 1.

He does not here mention the ingenious system by M. Serre of Geneva, nor his double fundamental bass: because the principles which, with a sagacity meritorious of praise, he had half detected, have afterwards been unfolded by M. Tartini, in a work of which Rousseau has given an account in his article SYSTEM.

FUNDI (anc. geog.), a town of Latium, on the Via Appia, near Cajeta; enjoying all the privileges of Roman citizens, except the right of suffrage and of magistracy. Now *Fondi*; a city of Naples, on the confines of the pope's dominions. E. Long. 14. 20. N. Lat. 41. 35.

FUNDY-BAY, a bay seated between New-England and Acadia or New Scotland, in which there is an excellent fishery.

FUNEN, or FIONIA, a considerable island in Denmark, seated on the Baltic sea, and separated from Jutland by a strait called the *Lesser Belt*, and from the island of Zealand by another called the *Great Belt*. It is fertile in wheat and barley; and abounds in cattle, horses, game of all sorts, and fish. Odensee is the capital town.

FUNERAL RITES, ceremonies accompanying the interment or burial of any person. The word is formed of the Latin *funus*; and the of *funalia*, on account of the torches (which were *funes cera circumdati*) used in the funerals of the Romans; though others derive *funus* from the Greek *φονος*, death or slaughter.

These rites differed among the ancients according to the different genius and religion of each country.

The first people who seem to have paid any particular respect to their dead, were the Egyptians, the posterity of Ham. The first cultivators of idolatrous worship and superstition after the flood; they were also the first who asserted the immortality of the soul, its migration into all kinds of animals in earth, air, and sea, and its return to the human body; which they supposed to be within the term of 3000 years: Hence proceeded their very great care in embalming of their dead bodies, and their being at such vast expences, as they were, in building proper repositories for them; for they were more solicitous about their graves than their houses: This gave birth to those wonders of the

world the pyramids, which were built for the burial of their kings, with such vast charges, and almost incredible magnificence. See PYRAMID.

Funeral.

Whenever a person died among the *Egyptians*, his parents and friends put on mournful habits, and abstained from all banquets and entertainments. This mourning lasted from 40 to 70 days, during which time they embalmed the body. See EMBALMING.

When this ceremony was finished, the embalmed body was restored to the friends, who placed it in a kind of open chest, which was preserved either in their houses, or in the sepulchres of their ancestors. But before the dead were allowed to be deposited in the tomb, they underwent a solemn judgement, which extended even to their kings. Of this remarkable custom we have a particular account in the first book of Diodorus Siculus. "Those who prepare to bury a relation, give notice of the day intended for the ceremony to the judges, and to all the friends of the deceased; informing them, that the body will pass over the lake of that district to which the dead belonged: where, the judges assembled, to the number of more than 40, and ranging themselves in a semicircle on the farther side of the lake, the vessel is set afloat, which those who superintended the funeral have prepared for this purpose. This vessel is managed by a pilot, called the Egyptian language *Charon*; and hence they say, that Orpheus, travelling in old times into Egypt, and seeing this ceremony, formed his fable of the infernal regions, partly from what he saw and partly from invention. The vessel being launched on the lake before the coffin which contains the body is put on board, the law permits all, who are so inclined, to produce an accusation against it. If any one steps forth, and proves that the deceased has led an evil life, the judges pronounce sentence, and the body is precluded from burial; but if the accuser is convicted of injustice in his charge, he falls himself under a considerable penalty. When no accuser appears, or when the accuser is proved to be an unfair one, the relations, who are assembled, change their expressions of sorrow into encomiums on the dead; yet do not, like the Greeks, speak in honour of his family, because they consider all Egyptians as equally well-born; but they set forth the education and manners of his youth, his piety and justice in maturer life, his moderation, and every virtue by which he was distinguished; and they supplicate the infernal deities to receive him as an associate among the blest. The multitude join their acclamations of applause in this celebration of the dead, whom they consider as going to pass an eternity among the just below." Such is the description which Diodorus gives of this funeral judicature, to which even the kings of Egypt were subject. The same author asserts that many sovereigns had been thus judicially deprived of the honours of burial by the indignation of their people: and that the terrors of such a fate had the most salutary influence on the virtue of their kings.

The funeral rites among the *Hebrews* were solemn and magnificent. When any person was dead, his relations and friends rent their cloaths; which custom is but faintly imitated by the modern Jews, who only cut off a bit of their garment, in token of affliction. It was usual to bend the dead person's thumb into the hand, and fasten it in that posture with a string; be-
cause

Funeral.

cause the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying-place, they made a speech to the dead in the following terms: "Blessed be God, who has formed thee, fed thee, maintained thee, and taken away thy life. O dead! he knows your numbers, and shall one day restore your life, &c. Then they spoke the elogium, or funeral oration, of the deceased; after which they said a prayer, called the *righteousness of judgment*; then turning the face of the deceased towards heaven, they called out, "Go in peace."

Among the ancient *Greeks* it was usual sometimes before the interment, to put a piece of money into the mouth of the deceased, which was thought to be *Charon's fare* for wafting the departed soul over the infernal river. This ceremony was not used in those countries which were supposed to be situated in the neighbourhood of the infernal regions, and to lead thither by a ready and direct road. The corpse was likewise furnished with a cake, composed of flour, honey, &c. which was designed to appease the fury of *Cerberus* the door-keeper of hell, and to procure the ghost a safe and quiet entrance. During the time the corpse continued in the house, there stood before the door a vessel of water: the design of which was, that those concerned about the body might purify themselves by washing; it being the opinion of the *Greeks*, as well as of the *Jews*, that pollution was contracted by touching a dead body.

The ceremonies by which they expressed their sorrow for the death of their friends were various; but it seems to have been a constant rule to recede as much as possible in habit and behaviour from their ordinary customs. For this reason they abstained from banquets and entertainments; they divested themselves of all ornaments; they tore, cut off, or shaved their hair, which they cast into the funeral pile, to be consumed with the body of their deceased friend. Sometimes they threw themselves on the ground, and rolled in the dust, or covered their head with ashes; they beat their breasts, and even tore their flesh with their nails, upon the loss of a person they much lamented. When persons of rank, such as public magistrates or great generals, died, the whole city put on a face of mourning; all public meetings were intermitted; the schools, baths, shops, temples, and all places of concourse, were shut up.

After interment followed the *epulæ* or feasts, at which the company used to appear crowned; when they spoke in praise of the dead, so far as they could go with truth, it being esteemed a notorious wickedness to lie upon such an occasion. And not only at those feasts, but even before the company departed from the sepulchre, they were sometimes entertained with a panegyric upon the dead person.

The *Grecian* soldiers, who died in war, had not only their tombs adorned with inscriptions showing their names, parentage, and exploits, but were also honoured with an oration in their praise. Particularly the custom among the *Athenians* in the interment of their soldiers was as follows, namely, "They used to place the bodies of their dead in tents three days before the funeral, that all persons might have an opportunity to find out their relations, and pay their last respects

to them. Upon the fourth day, a coffin of cypress was sent from every tribe, to convey the bones of their own relations; after which, went a covered hearse, in memory of those whose bodies could not be found. All these, accompanied with the whole body of the people, were carried to the public burying-place, called *Ceramicus*, and there interred. One oration was spoken in commendation of them all, and their monuments adorned with pillars, inscriptions, and all other ornaments usual about the tombs of the most honourable persons. The oration was pronounced by the fathers of the deceased persons, who had behaved themselves most valiantly. Thus, after the famous battle at *Marathon*, the fathers of *Callimachus* and *Cynægyrus* were appointed to make the funeral oration. And upon the return of the day, upon which the solemnity was first held, the same oration was constantly repeated every year."

Interring or laying the dead in the ground, seems to have been the most ancient practice among the *Greeks*; though burning came afterwards to be generally used among them. It was customary to throw into the funeral pile those garments the deceased usually wore. The pile was lighted by one of the deceased's nearest relations or friends, who made prayers and vows to the winds to assist the flames, that the body might quickly be reduced to ashes; and during the time the pile was burning, the dead persons's friends stood by it, pouring libations of wine, and calling upon the deceased.

The funeral rites among the *ancient Romans* were very numerous. The deceased was kept seven days; and every day washed with hot water, and sometimes with oil, that, in case he were only in a slumber, he might be thus waked; and every now and then his friends meeting, made a horrible outcry or shout, with the same view; which last action they called *conclamatio*. The third conclamation was on the seventh day; when, if no signs of life appeared, the defunct was dressed and embalmed by the *pollinctores*; placed in a bed near the door, with his face and heels towards the street; and the outside of the gate, if the deceased were of condition, was garnished with cypress boughs. In the course of these seven days, an altar was raised near his bed side, called *acerra*; on which his friends every day offered incense; and the *libitinarii* provided things for the funeral.

On the seventh day a crier was sent about the city, to invite the people to the solemnization of the funeral in these words: *Exequias L. Tit. filii, quibus est commodum ire, jam tempus est. Ollus (i. e. ille) ex ædibus effertur*. The people being assembled, the last conclamation ended, and the bed was covered with purple: a trumpeter marched forth, followed by old women called *præficae*, singing songs in praise of the deceased; lastly, the bed followed, borne by the next relations; and, if the person were of quality and office, the waxen images of all his predecessors were carried before him on poles. The bed was followed by his children, kindred, &c. *atrati*, or in mourning: from which act of following the corpse, these funeral rites were called *exequiæ*. The body thus brought to the rostra, the next of kin, *laudabat defunctum pro rostris*, made a funeral oration in his praise and that of his ancestors. This done, the body was carried to the *pyra*, or funeral pile, and there burnt: his friends first cutting off a finger, to be buried

Funeral.

ried with a second solemnity. The body consumed, the ashes were gathered; and the priest sprinkling the company thrice with clean water, the eldest of the *præfice* crying aloud, *ilicet*, dismissed the people, who took their leave of the deceased in this form, *Vale, vale, vale: nos te ordine quo natura permisit, sequemur.*—The ashes, inclosed in an urn, were laid in the sepulchre or tomb.

The ancient Christians testified their abhorrence of the Pagan custom of burning the dead; and always deposited the body entire in the ground: and it was usual to bestow the honour of embalming upon the martyrs at least, if not upon others. They prepared the body for burial, by washing it with water, and dressing it in a funeral attire. The exportation or carrying forth of the body was performed by near relations, or persons of such dignity as the circumstances of the deceased required. Psalmody, or singing of psalms, was the great ceremony used in all funeral processions among the ancient Christians.

In the *Romish church*, when a person is dead, they wash the body, and put a crucifix in its hand. At its feet stands a vessel full of holy water, and a sprinkler, that they who come in may sprinkle both themselves and the deceased. In the mean time some priest stands by the corpse, and prays for the deceased till it is laid in the earth. In the funeral procession, the exorcist walks first, carrying the holy water; next the cross-bearer, afterwards the rest of the clergy, and last of all the officiating priest. They all sing the *miserere*, and some other psalms; and at the end of each psalm a *requiem*. We learn from Alet's ritual, that the faces of deceased laymen must be turned towards the altar, when they are placed in the church; and those of the clergy, towards the people. The corpse is placed in the church surrounded with lighted tapers: after the office for the dead, mass is said; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the friends and relations of the deceased sprinkle the grave with holy water.

The funeral ceremonies of the *Greek church* are much the same with those of the Latin. It needs only to be observed, that, after the funeral service, they kiss the crucifix, and salute the mouth and forehead of the deceased: after which each of the company eats a bit of bread and drinks a glass of wine in the church, wishing the soul a good repose, and the afflicted family all consolation.

FUNERAL-GAMES, a part of the ceremony of the ancient funerals.

It was customary for persons of quality, among the ancient Greeks and Romans, to institute games, with all sorts of exercises, to render the death of their friends more remarkable. This practice was generally received, and is frequently mentioned by ancient writers. Patroclus's funeral games take up the greatest part of one of Homer's *Iliads*; and Agamemnon's ghost is introduced by the same poet, telling the ghost of Achilles, that he had been a spectator at a great number of such solemnities.

The celebration of these games among the Greeks mostly consisted of horse-races; the prizes were of different sorts and value, according to the quality and magnificence of the person that celebrated them. The

garlands given to victors on this occasion were usually of parsley, which was thought to have some particular relation to the dead.

Those games, among the Romans, consisted chiefly of processions; and sometimes of mortal combats of gladiators around the funeral pile. They, as well as the Greeks, had also a custom, though very ancient, of cutting the throats of a number of captives before the pile, as victims to appease the manes of the deceased. Cæsar relates, that the Gauls had this custom.

The funeral games were abolished by the emperor Claudius.

FUNERAL Oration, a discourse pronounced in praise of a person deceased, at the ceremony of his funeral.

This custom is very ancient. In the latter part of the account above given of the Egyptian ceremonies of interment, may be perceived the first rudiments of funeral orations, and what was the subject of them, which were afterwards moulded into a more polite and regular form by other nations, who adopted this custom. Nor can we omit remarking, that those funeral solemnities were attended not only with orations in praise of the deceased, but with prayers for him; which prayers, it seems, were made by one who personated the deceased: an entire form of one of them is preserved by Porphyry, and perhaps it may in some measure gratify the reader's curiosity to recite it from him. When (says he) they (the Egyptians) embalm their deceased nobles, they privately take out the entrails, and lay them up in an ark or chest: moreover, among other things which they do in favour of the deceased, lifting up the ark or chest to the sun, they invoke him; one of the *Libitinarii* making a prayer for the deceased, which Euphrantus has translated out of the Egyptian language, and is as follows:—O Lord, the sun, and all the gods who give life to men, receive me, and admit me into the society of the immortal ones; for as long as I lived in this world, I religiously worshipped the gods whom my parents showed me, and have always honoured those who begat my body: nor have I killed any man, nor have I defrauded any of what has been committed to my trust, nor have I done any thing which is inexpiable. Indeed, whilst I was alive, if I have sinned either by eating or drinking any thing which was not lawful; not through myself have I sinned, but through these, showing the ark and chest where the entrails were. And having thus spoke, he casts it into the river, but the rest of the body he embalms as pure."

The Grecians received the seeds of superstition and idolatrous worship from the Egyptians, through the coming of Cecrops, Cadmus, Danaus, and Erechtheus, into Greece; and among other customs transplanted from Egypt, were the solemnities used at the burial of the dead. Of these, an encomium on the deceased always formed a part, as particularly noticed under the preceding article.

From the Egyptians and Grecians, especially from the latter, the Romans received many of their laws and customs, as well as much of their polytheism and idolatrous worship. It is well known, that the custom of making funeral orations in praise of the dead, obtained among them; and the manner in which their funeral services were performed has been already described.

Funeral. scribed. The corpse being brought into their great oratory, called the *Rostra*, the next of the kin *laudabat defunctum pro rostris*, that is, made a funeral oration, in the commendation principally of the party deceased, but touching the worthy acts also of those his predecessors whose images were there present. The account given by Dr Kennet is in these words: "In all the funerals of note, especially in the public or indictive, the corpse was first brought with a vast train of followers into the Forum; here one of the nearest relations ascended the rostra, and obliged the audience with an oration in praise of the deceased. If none of the kindred undertook the office, it was discharged by some of the most eminent persons in the city for learning and eloquence, as Appian reports of the funeral of Sylla. And Pliny the younger reckons it as the last addition to the happiness of a very great man, that he had the honour to be praised at his funeral by the most eloquent Tacitus, then consul; which is agreeable to Quintilian's account of this matter, *Nam et funebres*, &c. For the funeral orations (says he) depend very often on some public office, and by order of senate are many times given in charge to the magistrates to be performed by themselves in person. The invention of this custom is generally attributed to Valerius Poplicola, soon after the expulsion of the regal family. Plutarch tells us, that honouring his colleague's obsequies with a funeral oration, it so pleased the Romans, that it became customary for the best men to celebrate the funerals of great persons with speeches in their commendations." Thus Julius Cæsar, according to custom, made an oration in the rostra, in praise of his wife Cornelia, and his aunt Julia, when dead; wherein he shewed, that his aunt's descent, by her mother's side, was from kings, and by her father's from the gods. Plutarch says, that "he approved of the law of the Romans, which ordered suitable praises to be given to women as well as to men, after death." Though by what he says in another place, it seems that the old Roman law was, that funeral orations should be made only for the elder women; and therefore he says, that Cæsar was the first that made one upon his own wife, it not being then usual to take notice of younger women in that way: but by that action he gained much favour from the populace, who afterwards looked upon him, and loved him as a very mild and good man. The reason why such a law was made in favour of the women, Livy tell us, was this, That when there was such a scarcity of money in the public treasury, that the sum agreed upon to give the Gauls to break up the siege of the city and capital could not be raised, the women collected among themselves and made it up; who hereupon had not only thanks given them, but this additional honour, that after death, they should be solemnly praised as well as the men: which looks as if, before this time, only the men had those funeral orations made for them.

This custom of the Romans very early obtained among the Christians. Some of their funeral sermons or orations are now extant, as that of Eusebius on Constantine; and those of Nazianzen on Basil and Cæsarius; and of Ambrose on Valentinian, Theodosius, and others. Gregory, the brother of Basil, made *ἐπικνηθειον λόγον*, a funeral oration, for Melitius bishop of

Antioch: in which orations, they not only praised the dead, but addressed themselves to them, which seems to have introduced the custom of praying to departed saints. Now these orations were usually made before the bodies of the deceased were committed to the ground; which custom has been more or less continued ever since, to this day.

Thus it appears, that those rites and ceremonies among the heathens, which have been delivered from one people to another, are what have given birth to

FUNERAL Sermons and Orations among Christians. Though this practice is considerably improved, and cleared of many things which would smell too rank of paganism, and is thrown into a method which, perhaps, may be of some service to Christianity; yet, notwithstanding this new dress, its original may very easily be discerned. The method in which the characters of deceased persons are given in our funeral sermons, is very much the same with that observed in those pagan orations; where first an account is given of the parentage of the deceased, then of his education; after that, we hear of his conduct in riper years: then his many virtues are reckoned up, with his generous, noble, and excellent performances.—Nor let the practice be condemned because of its rise and original; for why may not the custom of heathens, if just and laudable in themselves, and no ways pernicious to Christianity in their consequences, be followed by Christians? Only, since we are come into this practice, there is one thing we should take care to follow them in; and that is, not to make those sermons or orations for every one; but for those only whose characters are distinguished, who have been eminently useful in the world, and in the church of Christ. The old heathens honoured those alone with this part of the funeral solemnity, who were men of probity and justice, renowned for their wisdom and knowledge, or famous for warlike exploits: This, as Cicero* informs us, being part of the law for burials, which directs, that the praises only of honourable persons shall be mentioned in the oration. It would be much more agreeable, therefore, if our funeral discourses were not so common, and if the characters given of the deceased were more just; devoid of that fulsome flattery with which they too often abound.

FUNGI (from *σφογγος fungus*), the name of the 4th order of the 24th class of vegetables, in the Linnæan system; comprehending all those which are of the mushroom kind, and which in Tournefort constitute the 2d, 3d, 4th, 5th, 6th, 7th, and 8th, genera of the first section in the class xvii. This order in Linnæus contains 10 genera. See **AGARICUS**, **BOLETUS**, **CLAVARIA**, **LYCOPERDON**, &c.

FUNGI, an order of plants in the *Fragmenta Methodi Naturalis* of Linnæus. See **BOTANY**, p. 470.

The ancients called fungi *children of the earth*, meaning, no doubt, to indicate the obscurity of their origin. The moderns have likewise been at a loss in what rank to place them; some referring them to the animal, some to the vegetable, and others to the mineral kingdom.

Messrs Wilck and Miinchaufen have not scrupled to rank these bodies in the number of animal productions; because, when fragments of them or their seeds were macerated in water, these gentlemen perceived a quantity of animalcules discharged, which they supposed capable

Funeral,
Fungi.

Fungi.

capable of being changed into the same substance. It was the ancient opinion, that beef could produce bees; but it was reserved for Messrs Wilck and Miinchaufen to suppose, that bees could produce beef. Wilck asserts, that fungi consist of innumerable cavities, each inhabited by a polype: and he does not hesitate to ascribe the formation of them to their inhabitants, in the same way as it has been said that the coral, the lichen, and the mucor, were formed. Hedwig has lately shown how ill founded this opinion is with respect to the lichen; and M. Durande has demonstrated its falsity with regard to the corallines. "Indeed (says M. Bonnet, talking of the animality, of fungi) nothing but the rage for paradox could induce any one to publish such a fable; and I regret that posterity will be able to reproach our times with it. Observation and experiment should enable us to overcome the prejudices of modern philosophy; now, that those of the ancient have disappeared and are forgotten."

It cannot be denied that the mushroom is one of the most perishable of all plants, and it is therefore the most favourable for the generation of insects. Considering the quickness of its growth, it must be furnished with the power of copious absorption; the extremity of its vessels must be more dilated than in other plants. Its root seems, in many cases, to be merely intended for its support; for some species grow upon stones or moveable sand, from which it is impossible that they can draw much nourishment. We must therefore suppose, that it is chiefly by the stalk that they absorb. These stalks grow in a moist and tainted air, in which float multitudes of eggs, so small, that the very insects they produce are with difficulty seen by the microscope. These eggs may be compared to the particles of the Byssus, 100,000 of which, as M. Gleditsch says, are not equal to the fourth of a grain. May we not suppose, that a quantity of such eggs are absorbed by the vessels of the fungus, that they remain there, without any change, till the plant begins to decay? Besides, the eggs may be only deposited on the surface of the plant, or they may exist in the water into which they are thrown for examination. Do not we see that such eggs, dispersed through the air, are hatched in vinegar, in paste, &c. and wherever they find a convenient nidus for their development? Can it be surprising then, that the corruption of the mushroom should make the water capable of disclosing certain beings that are really foreign to both?

It is not more easy to acquiesce in the opinions of those naturalists who place the fungi in the mineral kingdom, because they are found growing on porous stones, thence called *Lapides Fungarii*; which, however, must be covered with a little earth, and be watered with tepid water, in order to favour the growth. Such mushrooms are no more the produce of the stone, than the lichen is of the rock to which it adheres, or the moss of the tree on which it is found. We have only to observe the growth of mushrooms, to be convinced, that this happens by development, and not by addition or combination of parts as in minerals. The opinion of Boccone, who attributed them to an unctuous matter performing the function of seed, and acquiring extension by apposition of similar parts; and that of Morison, who conceived that they grew spontaneously out of the earth by a certain mixture of salt and sul-

phur, joined with oils from the dung of quadrupeds; have now no longer any adherents. Fungi are produced, they live, they grow, by development; they are exposed to those vicissitudes natural to the different periods of life which characterize living substances; they perish and die. They extract, by the extremity of their vessels, the juices with which they are nourished; they elaborate and assimilate them to their own substance. They are, therefore, organized and living beings, and consequently belong to the vegetable kingdom. But whether they are real plants, or only the production of plants, is still a matter in dispute with the ablest naturalists.

Some ancient authors have pretended to discover the seed of mushrooms; but the opinion was never generally received. Petronius, when he is laughing at the ridiculous magnificence of his hero Trimalcio, relates, that he had written to the Indies for the seed of the morelle.

These productions were generally attributed to the superfluous humidity of rotten wood, or other putrid substances. The opinion took its rise from observing that they grew most copiously in rainy weather. Such was the opinion of Tragus, of Bauhin, and even of Columna, who, talking of the peziza, says, that its substance was more solid and harder, because it did not originate from rotten wood, but from the *pituita* of the earth. It is not surprising that, in times when the want of experiment and observation made people believe that insects could be generated by putrefaction, we should find the opinion general, that fungi owed their origin to the putrescence of bodies, or to a viscid humour analogous to putridity.

Malpighi could not satisfy himself as to the existence of seeds which other botanists had pretended to discover. He only says, that these plants must have them, or that they perpetuate themselves and shoot by fragments. Micheli, among the moderns, appears to have employed himself most successfully on this subject. He imagined, that he not only saw the seeds, but even the stamina, as well as the little transparent bodies destined to favour the dissemination and the fecundation of these seeds. Before this author, Lister thought he perceived seeds in the *Fungus perosus crassus magnus* of John Bauhin: the little round bodies that are found in the pezizæ and helvellæ, at that time, passed for seeds; which did not appear at all probable to Marfigli, considering that the eye, when assisted with the very best microscopes, could perceive nothing similar in much larger fungi. Indeed these bodies may be the capsules or covers of the seeds, if they are not the seeds themselves. However this may be, Marfigli, observing that fungi were often without roots or branches, and that they wanted flowers and seeds, the means with nature employs for the productions of perfect plants, thought himself warranted in doubting whether these beings could be ranked in the number of vegetables.

The doubts of Marfigli prompted him to observe the formation of fungi. Their matrix he called *Situs*: he imagined they grew in places where they met with an unctuous matter, composed of an oil mixed with nitrous salt, which, by fermentation, produced heat and moisture, and insinuated itself between the fibres of wood; that is, he imagined them the production of a viscid and putrescent humour. Lancisi, in like manner, considered

Fungi.

Fungi.

sidered fungi as owing their existence to the putrefaction of vegetables, and supposed them a disease in the plant; but he imagined, "that the fibres of the tree were necessary to their production," as is the case in the formation of galls; he compared them to the warts and other excrescences of the human body. He added, that such fungous vegetable tumours must necessarily assume various forms and figures, from the fluids which distend the tubes and vessels relaxed by putrescence, from the ductility of the fibres and their direction, and from the action of the air.

This opinion has been refuted by the celebrated naturalist M. de Jussieu, in the Memoirs of the Academy of Sciences for the year 1728. He maintains, that the fungi have a great analogy with the lichen, which is allowed to be a vegetable; that, like the lichen, they are divested of stalk, branches, and leaves: that, like it, they grow and are nourished upon the trunks of trees, on pieces of rotten wood, and on all sorts of putrid vegetables; that they resemble the lichen too in the rapidity of their growth, and the facility with which many of them may be dried and restored to their former figure, upon being immersed in water; and, lastly, that there is a great similarity in the manner in which their seeds are produced. He affirms, that only the warts and excrescences which grow on animal bodies, and the knots and other tumors that are to be found on trees, can be compared with one another; for they are composed equally of the solid and liquid substance of the plant or animal on which they grow; whereas, the matter of the fungi is not only quite distinct from that of the plants on which they are found, but often entirely similar to the substance of those that spring immediately from the earth.

The organization, says M. de Jussieu, which distinguishes plants and other productions of nature, is visible in the fungi; and the particular organization of each species is constant at all times and in all places; a circumstance which could not happen if there were not an animal reproduction of species, and consequently a multiplication and propagation by seed. This is not, he says, an imaginary supposition; for the seeds may be felt like meal upon mushrooms with gills, especially when they begin to decay; they may be seen with a magnifying glass, in those that have gills with black margins: and, lastly, says he, botanists can have no doubt that fungi are a distinct class of plants, because, by comparing the observations made in different countries with the figures and descriptions of such as have been engraven, the same genera and the same species are every where found.

Notwithstanding this refutation by M. de Jussieu, another naturalist, M. de Necker, has lately maintained, in his work intitled *Mycitologia*, That the fungi ought to be excluded from the three kingdoms of nature, and be considered as intermediate beings. He has observed, like Marsigli, the matrix of the fungi: and has substituted the word *carchte* (initium faciens) instead of *situs*; imagining that the rudiment of the fungus cannot exist beyond that point in which the development of the filaments or fibrous roots is perceived. He allows, that fungi are nourished and grow like vegetables; but he thinks that they differ very much from them in respect of their origin, structure, nutrition, and rapidity of growth. He says, that the various ves-

sels which compose the organization of vegetables are not to be found in the fungi, and that they seem entirely composed of cellular substance and bark; so that this simple organization is nothing more than an aggregation of vessels endowed with a common nature, that suck up the moisture in the manner of a sponge; with this difference, that the moisture is assimilated into a part of the fungus. Lastly, That the fructification, the only essential part of a vegetable, and which distinguishes it from all other organized bodies, being wanting, fungi cannot be considered as plants. This he thinks confirmed by the constant observation of those people who gather the morelle and the mushroom, and who never find them in the same spots where they had formerly grown. As the generation of fungi, says M. Necker, is always performed when the parenchymatous or cellular substance has changed its nature, form, and function, we must conclude that it is the degeneration of that part which produces these bodies.

But if fungi were owing merely to the degeneration of plants, they would be still better intitled to constitute a new kingdom. They would then be a decomposition, not a new formation or new bodies. Besides, we cannot deny, that in those bodies which form the limit between the animal and vegetable kingdoms, the organization becomes simple, as the organs destined for nutrition are multiplied; but, as the last in the class of insects belongs to the animal kingdom, fungi ought, notwithstanding the simplicity of their organization, still to belong to the vegetable kingdom. The parenchymatous or cellular substance, which, as Mr Bonnet says, is universally extended, embraces the whole fibrous system, and becomes the principal instrument of growth, must naturally be more abundant in these productions; and this accounts for the rapidity of their enlargement. Besides, growth, whether slow or rapid, never was employed to determine the presence or absence of the vegetable or animal character. The *draba verna*, which in a few weeks shoots, puts forth its leaves, its flowers, and fruit, is not less a plant than the palm. The insect that exists but for a day, is as much an animal as the elephant that lives for centuries. As to the seeds of the fungi, it is probable that nature meant to withdraw from our eyes the dissemination of these plants, by making the seeds almost imperceptible; and it is likewise probable, that naturalists have seen nothing but their capsules. Since, however, from the imperfection of our senses, we are unable to perceive these seeds, ought we to infer that they do not exist? Are we authorized to conclude this, because we do not find mushrooms where we have found them a year before? Undoubtedly not; for the greater part of plants require a particular soil, and the same mould that this year will foster a rare plant, will next year allow it to perish. Neither are we at liberty to deny the existence of these seeds, because those bodies which have been called their seeds, and the fragments or cuttings of the plants themselves, have not produced others of the same species. Nature seems to have reserved for herself the care of disseminating certain plants: It is in vain, for instance, that the botanist sows the dust found in the capsules of the orchis, which every one allows to be the seed. But, after all, what are those parts in the fungi casually observed by

natralists,

Fungi.

Fungi
|
Furca.

naturalists, and which they have taken for the parts of fructification? These are quite distinct from the other parts; and whatever may be their use, they cannot have been formed by a prolongation of the cellular substance, or of the fibres of the tree on which the fungus grows: they are, therefore, owing, like flower and fruit, to the proper organization of the plant. These plants, therefore, have a particular existence, independent of their putrefying nidus. The gills of certain fungi, which differ essentially from the rest of the plant in their conformation, would be sufficient to authorize this latter opinion. But can putrefaction create an organic substance?

Nature undoubtedly disseminates through the air, and over the surface of the earth, innumerable seeds of fungi, as well as eggs of insects. The plant and the animal are excluded, when the nidus or the temperature is favourable for their development. No fortuitous concurrence, either of atoms or fluids, could produce bodies so exquisitely and so regularly organized. It is sufficient to throw one's eyes on the beautiful plates which Schæffer has published of them, and compare them, by the glass, with the warts and other excrescences of animals, to be convinced that they have not the same origin. The function of the cellular substance in vegetables must be greatly superior to that in animals, if it could produce any thing but deformities.

The greater part of fungi exhibit a configuration much too regular, constant, and uniform, to be the effect of chance or putrefaction. As this form is preserved the same in all places where fungi have been found, it follows, that they contain in themselves the principles of their reproduction. They resemble the mistletoe, and other parasitic plants, which are perfectly distinct from the trees on which they grow. The fungi, therefore, are organized and living substances, or true plants. If the manner of their production is unknown, that of some insects is so too.

FUNGIBLES, in Scots law, are such things as are estimated by number, weight, or measure; as, coin, butter, ale, &c.

FUNGITÆ, in natural history, a kind of fossile coral, of a conic figure, though sometimes flatted and striated longitudinally.

FUNGUS, in surgery, denotes any spongy excrecence. See SURGERY.

FUNNEL of a CHIMNEY, the shaft or smallest part of the waste, where it is gathered into its least dimensions.

Palladio directs, that the funnels of chimneys be carried through the roof four or five feet at least, that they may carry the smoke clear from the house into the air. See the article CHIMNEY.

He also advises, that chamber chimneys be not made narrower than 10 or 11 inches, nor broader than 15: for if too narrow, the smoke will not be able to make its way; and, if too wide, the wind will drive it back into the room.

FUR, or FURR, in commerce. See FURR.

FURBISHER, a person who furbishes, polishes, or cleans arms, as guns, swords, pistols, &c.; which is chiefly performed with emery. See the article EMERY.

FURCA, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment.

The punishment of the furca was of three kinds: the first only ignominious, when a master, for small offences, forced a servant to carry a furca on his shoulders about the city. The second was penal, when the party was led about the circus, or other place, with the furca about his neck, and whipped all the way. The third was capital, when the malefactor having his head fastened on the furca, was whipped to death.

FURCHE, in heraldry, a cross forked at the ends.

FURETIERE (Antony), an ingenious and learned Frenchman, was born at Paris in 1620; and after a liberal education became eminent in the civil and canon law. He was first an advocate in the parliament; and afterwards taking orders, was presented with the abbey of Chalivoy, and the priory of Chuines. Many works of literature recommended him to the public: but what he is chiefly known by and valued for, is his Universal Dictionary of the French Tongue, in which he explains the terms of art in all sciences. He had not, however, the pleasure of seeing this useful work published before his death; which happened in 1688. He was of the French academy; and the disputes and quarrels which he had with certain members of it made a great noise in the world.

FURIA, in zoology, a genus of insects belonging to the order of vermes zoophyta. There is but one species, viz. the infernalis. This has a linear smooth body ciliated on each side, with reflexed feelers pressed to its body. In Finland, Bothnia, and the northern provinces of Sweden, it was not unfrequently that people were seized with a pungent pain, confined to a point, in the hand or other exposed part of the body, which presently increased to a most excruciating degree, and hath sometimes been suddenly fatal. This disorder was more particularly observed in Finland, especially about boggy and marshy places, and always in autumn. At length it was discovered that this pain instantly succeeded somewhat that dropped out of the air, and in a moment penetrated and buried itself in the flesh. The Finlanders had tried a variety of applications to no purpose, until at length a poultice of curds or cheese was found the most effectual in easing the pain: and the event confirmed that the insect was allured by this application to leave the flesh; as, on its removal, this worm, no longer than the sixth of an inch, was found in it, and thus the cause of this painful disease explained. But by what means this creature is raised into the air, is as yet unknown.

FURIES, in Pagan antiquity, certain goddesses whose office it was to punish the guilty after death. They were three in number: Alecto, Megæra, and Tisiphone; who were described with snakes instead of hair, and eyes like lightning, carrying iron chains and whips in one hand, and in the other flaming torches; the latter to discover, and the former to punish, the guilty: and they were supposed to be constantly hovering over such persons as had been guilty of any enormous crime.

Mythologists suppose, that Tisiphone punished the crimes which sprang from hatred or anger; Megæra, those from envy: and Alecto, those from an insatiable pursuit after riches and pleasure. They were worshipped at Casina in Arcadia, and at Carmia in Peloponnesus. They had a temple at Athens near the Areopagus,

Furche
||
Furies.

Furius **Furnace.** **gus**, and their priests were chosen from amongst the judges of that court. At Telphusia, a city in Arcadia, a black ewe was sacrificed to them.

FURIUS (Bibaculus), a Latin poet who flourished about 103 B. C. He wrote annals in verse, of which Macrobius recites some fragments. Suetonius also relates some verses of his on Valerius Cato, in his *Illustrious Grammarians*.

FURLING, in the sea language, signifies the wrapping up and binding any sail close to the yard; which is done by hawling upon the clew-lines, buntlines, &c. which wraps the sail close together, and being bound fast to the yard the sail is furled.

FURLONG, a long measure, equal to one eighth of a mile, or 40 poles.

It is also used in some law-books for the eighth part of an acre.

FURLOUGH, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

FURNACE, an utensil or vessel proper to contain fire, or to raise and maintain a vehement fire in, whether of coal or wood. Of these there are a great variety, according to the different uses to which they are applied.

In all furnaces the principal things to be attended to are, 1. To confine the heat as much as possible to the matter to be operated upon; 2. To prevent its being dissipated; 3. To produce as much heat with as little fuel as possible; and, 4. To have it in our power to regulate the degree of heat according to our pleasure.

To answer the first intention, the fire is usually confined in a chamber or cavity built on purpose for it, and furnished with a door for putting in the fuel; a grate for supporting it, and allowing air to pass thro', as well as the ashes to drop down into a cavity provided on purpose, and called the *ash-pit*. Thus the heat produced by the inflamed fuel is confined by the sides of the furnace, and obliged to spend great part of its force upon the subject inclosed.

The second intention, *viz.* to prevent the dissipation of the heat, is obtained by shutting the door of the furnace; taking care that the chimney be not too wide, and that the matter to be acted upon be placed in such a manner that the fire may have its full effect upon it as it goes up the chimney.

The third intention, which is the most important, is at the same time the most difficult to answer, and depends entirely upon the proportion between the spaces betwixt the furnace bars and the wideness and height of the chimney. This will appear from a consideration of the principles on which the degrees of inflammation are produced. These depend entirely on the current of air which passes through the inflamed fuel. As soon as the fuel is set on fire, a certain degree of heat is produced; but unless a constant influx of air is admitted through the burning fuel, the fire is instantly extinguished; nor is it possible by any means to renew the inflammation until we admit a stream of fresh air among the fuel. When this is done, a rarefaction commences in the air of the fire-place of the furnace; so that it is no longer a counterpoise to the external air, and is therefore driven up the chimney

by that which enters at the ash-pit. This again passing through the fuel, is rarefied in its turn; and giving place to fresh quantities, there is a constant flow of air up the chimney. In proportion to the rarefaction of the air in the fire-place, the greater is the heat. But by a certain construction of the furnace, the under part of the chimney will become almost as strongly heated as the fire-place; by which means, though a very strong current of air is forced through the fuel; yet as great part of the heat is spent on the chimney, where it can be of no use, the fuel is wasted in a very considerable degree. To avoid this, we have no other method than to contract the throat of the chimney occasionally by a sliding plate; which when put quite in, shuts up the whole vent; and by being drawn out more or less, leaves a larger or smaller vent at pleasure. This plate ought to be quite drawn out till the fuel is thoroughly kindled, and the furnace well heated, so that a current of air may flow strongly through the fuel. After this the plate is to be put in a certain length, so as just to prevent the smoke from coming out at the door of the furnace. The rarefaction of the air in the fire-place will solicit a very considerable draught of air, which will keep the fuel inflamed to a great degree; at the same time that the heat, being reflected from every part of the furnace excepting that narrow passage where the smoke goes up, becomes very intense. A large quantity of fuel may be put in at once, which will consume slowly, and thus require but little attention in comparison with those furnaces where no such precaution is used. The sliding-plate may be made of cast-iron in those furnaces where no great heat is excited; but in others fire-clay will be more convenient. The contrivance, however, is scarce applicable to those furnaces where great quantities of metal are to be melted; and accordingly the waste of fuel there is immense. It is computed, that the iron works of Carron in Scotland consume annually as many coals as would be sufficient for a city containing 700,000 inhabitants.

The fourth intention, *viz.* that of regulating the heat, is accomplished by allowing only a certain quantity of air to pass through the fuel. For this purpose, according to Dr Black, it is necessary to have the command of the furnace below; the parts above being frequently filled with small quantities of soot. The best method of managing this is to shut up the door of the ash-hole perfectly close, and to have a set of round holes bearing a certain proportion to one another; and their areas being as 1, 2, 4, 8, 16, &c. Seven or eight of these ought to be made in the door of the ash-pit, which will give a sufficient command over the fire. When the fire is to be increased to the utmost, all the passages both above and below are to be thrown open, and the height of the vent augmented; which, by increasing the height of the column of rarefied air, increases also the motion of that through the fuel, and of consequence also the heat of the furnace. Macquer recommends another tube applied to the ash-pit, widest at the end farthest from the furnace, and tapering gradually towards it. The intention of this is to augment the current and velocity of the air by its being made to pass from a wider into a narrower vent; but though this is no doubt true, the air will not ultimately move with greater velocity than

Furnace.

Furnace. if the tube were not there. It can only be useful therefore in cases where the furnace is placed in a small room, and the tube itself has a communication with the external air.

Pl. CC. IV. *An Essay or Cupelling FURNACE* is made in the following manner. 1. Make with iron plates a hollow quadrangular prism, eleven inches broad and nine inches high (*aa, bb*), ending at top in a hollow quadrangular pyramid (*bb, cc*) seven inches high terminating in an aperture at top seven inches square. This prism must be closed at bottom with another iron plate, which serves as a basis or bottom to it (*aa*). 2. Near the bottom make a door (*e*), three inches high, and five inches broad, that leads to the ash hole. 3. Above this door and at the height of six inches from the basis, make another door (*f*), of the figure of a segment of a circle, four inches broad at its basis, and three inches and a half high in the middle. 4. Then fasten three iron plates on the forepart of this furnace. Let the first of them (*gg*), eleven inches long and half an inch high, be fastened, so that its lower edge shall rest against the bottom of the furnace, with three or four rivets; and in such a manner, that there may be between the upper edge of the said plate and the side of the furnace a groove so wide, as that the sliders of the lower door (*kk*) may be put into it, and freely move backwards and forwards therein: these must be made of a thicker iron-plate. The second iron-plate (*hh*), eleven inches long, three inches high, and perfectly parallel to the foregoing plate, must be fastened in the space between the two doors, in such manner that both the upper and lower edges of it may form a hollow groove with the side of the furnace. One of these grooves, which is turned downwards, serves to receive the upper edge of the sliders that shut the lower door (N^o 2). The other, that turns upwards, is to receive the inferior edges of the sliders of the small door above (N^o 3). The third plate (*ii*), which is like the first, must be riveted close above the upper door, in such manner, that it may form a groove turning downwards, and contiguous to the upper edge of the upper door (N^o 3). 5. In order to shut both doors (N^o 2, 3.), you must adapt to each of them two sliders made of iron-plates, that may move within the abovementioned grooves (*kk, ll*). But the two sliders belonging to the upper door (N^o 3.) must have each a hole near the top; that is, one a small hole one fifth part of an inch broad, and one inch and a half long (*m*); and the other a semicircular aperture, one inch high and two inches broad (*n*). Let, besides, each slider have a handle, that they may be laid hold of when they are to be moved. 6. Moreover, let five round holes, one inch broad, be bored in the furnace; two of which must be made in the fore-part of the furnace (*oo*), two others in the back part; all at the height of five inches from the bottom, but three inches and a half distant from each side of the furnace; and, finally, a fifth hole (*p*), at the height of one inch above the upper edge of the upper door (*f*). 7. In short, let the inside of the furnace be armed with iron-hooks, jetting out half an inch, and about three inches distant from each other, to fasten the lute with which the furnace is to be covered over within. 8. Let then an iron, moveable, hollow, quadrangular pyramid (*g*), three inches high, be adapted to the upper

aperture (*d*) of the furnace, at the basis seven inches broad, ending upwards in a hollow tube (*r*), three inches in diameter, two inches high, almost cylindrical, though somewhat convergent at top. This prominent tube serves to support a funnel or flue, which is almost cylindrical, hollow, made of iron plates, and two feet high; and which, when a very strong fire is required, is put perpendicularly upon the shorter tube, in such a manner, that it enters close into it, one inch and a half or two inches deep, and may again be taken off at pleasure, when there is no need of so strong a fire. But this pyramidal cover (*g*) must besides have two handles (*ss*) adapted to it, that it may be laid hold of, and thus be taken away or put on again: and that this, being put on the aperture (*d*) of the furnace, may not be easily thrown down, let an iron plate be riveted to the right and left upper edge of the furnace (*cc*), and be turned down towards the inside, so as to make a furrow open before and behind, into which the lateral edges of the cover may enter and be fastened, and at pleasure be moved backwards and forwards, whenever it must be put on, or moved. 9. Let a square ledge, made of a thick iron-plate, be fastened at top of the upper edge of the lower door (*e*): this is designed to support the grate and the lute; but it must be made of two pieces, that it may be easily introduced into the cavity of the furnace. Thus you will have an assay-oven, which must afterwards be covered over on the inside with lute. This you are to do as follows:

That the fire may be better confined, and that the iron may not be destroyed by growing red-hot, the whole inside of the furnace must be covered over with lute, one finger or one finger and a half thick. The lute fit for this is described under the article CHEMISTRY, n^o 604, 605. But before you cover the inside of your furnace with this lute, you must first put within the furnace small iron bars, equal in length to the diameter of the oven, quadrangular, prismatical, half an inch thick, having their extremities supported by a square iron ledge, and three fourths of an inch distant from each other; and you must fasten them so, that their flat sides may be oblique with regard to the transverse section of the furnace, and that the two opposite angles may look one upwards and the other downwards: the bars must not be laid flat, but edgewise; by which situation you hinder the ashes of the fuel of the fire from being detained too long between the interstices of the said iron bars, and from making an obstruction that would oppose the free draught of the air. The furnace being then covered over with lute, and dried up by a gentle heat, is at last fit for docimastical operations, and especially for such as must be performed in the assay-oven.

If then an operation is to be made in the furnace hitherto described, you must let through the four lower holes above described of the furnace (*oo*) placed before and behind, and directly opposite to each other, two iron-bars one inch thick, and long enough that their extremities on every side may jut out of the holes a small matter. These serve to support the muffle and its bottom. You then introduce the muffle through the upper aperture of the furnace (*d*), and place it upon the above described iron-bars, in such a manner, that the open fore-side of it be contiguous to the inward

Furnace. ward border of the upper door (*f*). The fuel of the fire is introduced through the top of the furnace (*d*); the cover of which (*g*), on this account, must be movable, and not very heavy. The best fuel for the fire is charcoal made of the hardest wood, especially of beech, broken into small pieces of the bigness of an inch, wherewith the muffle must be covered over some inches high. We then reject larger bits of coals, because they cannot fall through the narrow interstices, between the sides of the muffle and those of the furnace, and cannot of course sufficiently surround the circumference of the muffle. Whence it happens, that there are on every side places void of fuel, and the fire is either not strong enough or unequal. But if, on the contrary, you use coals too small, then a great part fall immediately through the interstices of the grate into the ash-hole; and the tenderest particles of them turn too soon into ashes, and, by increasing the heap of ashes, obstruct the free draught of the air, which is here greatly requisite.

A perfect management of the fire is most commonly necessary in the performing of operations in this furnace; therefore the chemical reader must give attention to what follows. If the door of the ash-hole (*e*) is quite open; and the sliders of the upper door (*f*) drawn towards each other, so as to touch one another in the middle of the door; and if, besides, the cover (*g*), and the funnel adapted to its tube (*r*), is upon the top (*q*) of the furnace; the fire will be then in the highest degree possible; though, in the mean time, it is hardly ever necessary to put the funnel on, except in a very cold season: but if, after having disposed the furnace in the manner just described, you put red burning coals into the open upper door (*f*) of it, the fire is still more increased thereby: however, this artifice is never, or very seldom, necessary. When you shut the upper door with only that slider that has a narrow oblong hole in it (*m*), then the heat becomes a little less; but it diminishes still more when you shut the door with the other slider that has in it the semicircular hole (*n*), which is larger than that of the first slider: nay, the heat again is less when you take away the funnel put at the top of the cover: finally, the door of the ash-hole being either in part or totally shut, the heat is still diminished; because the draught of air so necessary to excite the fire, is thereby hindered: but if, besides all these, you likewise open the upper door quite, then the cold air, rushing into the muffle, cools the bodies put under it, that are to be changed, to a degree never required in any operation, and such as will entirely hinder the boiling of lead. If, during the operation, the fire begins to decay, or to grow unequal, it is a sign that there are places void of coals between the sides of the furnace and those of the muffle: therefore, in this case, you must stir your coals on every side with an iron-rod, which is to be introduced through the upper hole (*p*) of the furnace, that they may fall together, and thus act in a proper manner and equality.

However, you are to observe concerning the regimen of the fire just described, that though the apparatus is made with all the exactness mentioned, nevertheless the effect does not always answer it. The cause of which difference has most commonly its origin in the various dispositions of the air: for as every fire is more excited by coals in proportion as the air, more

condensed, and more quickly agitated, strikes them more violently (which the effect of the bellows plainly shows); it thence appears, that in warm and wet weather, when the atmosphere is light, the fire must be less efficacious in furnaces; that likewise, when several furnaces, situated near each other, are burning at the same time, the fire is in part suffocated, because the ambient air is thereby rendered more rare and lighter. The same effect is produced by the sun, especially in summer-time, when it shines upon the place where the furnace is situated. The atmosphere, on the contrary being heavier in cold dry weather, excites a very great fire.

The heat of the fire acts the stronger upon the bodies to be changed, as the muffle put in the furnace is less; as the said muffle has more and larger segments cut out of it; as the sides of this muffle are thinner; in short, as there are more vessels placed in the hinder part of the muffle; and on the contrary. In this case, when many of the conditions requisite for the exciting of fire are wanting, then indeed the artificer, with all his skill, will hardly be able to excite the fire to a sufficient degree, in order to perform operations well, in common assay-ovens, even though he uses bellows, and puts coals into the upper door of the furnace. For this reason, the grate ought to be put almost three inches below the muffle, lest the air, rushing through the ash-hole, should cool the bottom of the muffle, which happens in common assay-ovens; and again, that the smaller coals, almost already consumed, and the ashes, may more easily fall through the interstices of the grate, and the larger coals still fit to keep up the fire be retained. Lastly, The above-mentioned funnel is added, that the blowing of the fire being, by means of it, increased as much as possible, this might at last be carried to the requisite degree; for the fire may always be diminished, but not always be increased at pleasure, without the assistance of a proper apparatus.

Machines for Blowing Air into FURNACES. The earliest method of animating large fires in the furnaces where ores were smelted, seems to have been by exposing them to the wind. Such was the practice of the Peruvians before the arrival of the Spaniards among them. Alonso Barba relates, that their furnaces, called *guairas*, were built on eminences, where the air was freest; that they were perforated on all sides with holes, through which the air was driven in when the wind blew, which was the only time when the work could be carried on; that under each hole was made a projection of the stone-work, on which were laid burning coals, to heat the air before it entered the furnace. Some authors speak of several thousands of these *guairas* burning at once on the sides and tops of the hills of Potosi; and several remains of this practice are to be found in different parts of Great Britain.

This method of supplying air being found excessively ineffectual and precarious, the instruments called *bellows* succeeded. These were at first worked by the strength of men; but as this was found to be very laborious and expensive, the force of running water was employed to give motion to these machines. Thus a much greater quantity of metal could be procured than formerly, and the separation was likewise more complete; inasmuch, that in many places the slags or cinders from which the iron had formerly been extracted were again used as fresh ore, and yielded plenty of metal.

But though this method was found to be greatly preferable to the others, yet great improvements were still wanted. In order to melt very large quantities of ore at a time, it was necessary to use bellows of an immense size; and in proportion to their size they stood in need of the more frequent and expensive repairs. The oil, also, which the bellows required in large quantity, becoming rancid, was found to generate a kind of inflammable vapour, which sometimes burst the bellows with explosion, and thus rendered them totally useless. A new method, therefore, of blowing up fires altogether free from the abovementioned inconveniences, was fallen upon by means of water. It depends on the following principle, viz. That a stream of water, running through a pipe, if by any means it is mixed with air at its entrance into the pipe, will carry that air along with it, and part with it again as soon as it comes out of the pipe; and if the air is then collected by a proper apparatus, it may with success be used for exciting the most violent degrees of heat.

Machines of this kind are represented on Plate CCIV. fig. 4. In the right hand machine, AB represents a stream of water falling into the funnel, whose throat is contracted at B; after which the stream runs through the perpendicular pipe EF, in the upper part of which there are some small holes represented by *cdef*. Through these holes the air has access to mix itself with the descending water, which being dashed against the sides of the pipe is reduced to froth, and thus fills the whole cavity of the pipe EF, which is considerably larger than the throat of the funnel B. When this frothy stream enters the vessel C, the air extricates itself from the water; and as it cannot return through the pipe EF because it is continually filled with a stream of li-

quid matter, it flies off with considerable force through the smaller pipe D, by which it is conveyed to the furnace.

From this description, it is evident that the principal thing to be kept in view in the construction of these machines is, to mix the descending stream of water with as great a quantity of air as possible. For this purpose the contrivance represented in the left hand machines answers much better than the former. By this the water descending from the reservoir A, falls into a kind of cullender B, perforated with a great number of holes in its sides. Thus the water being forced out in a number of small streams is very effectually dashed against the sides of the wide descending pipe, when it enters the condensing vessel C, and is sent off by the pipe D, as in the former.

In some machines of this kind the constructors seem to have been of opinion, that a great height was required in the water-fall; but Dr Lewis, who hath made a great number of experiments upon the subject, shows, that an excess in height can never make up for a deficiency in the quantity of the water. Four or five feet, he thinks, is a sufficient height for the water-fall; where there is a greater height, however, it may be rendered useful, by joining two or more machines together in the manner represented in the plate; where the water, after having once emitted its air in the condensing vessel C, flows out into a new reservoir E. From thence it descends through another cullender F, and descending from it into a condensing vessel G, the air is extricated, and carried off through the pipe H. The upper figure represents the cullender, with the shapes of the holes and their proportional distances, according to Dr Lewis.

Thus, with very little expence, where there is a sufficient quantity of water, as strong a blast of air as can be desired may be readily obtained; for several machines may be constructed, and joined together in a manner somewhat similar to that abovementioned, until all the quantity of water is employed. It is proper to observe, however, that as by this method the air is loaded with moisture, it is proper to make the condensing vessel as high as conveniently may be, that the air may arrive at the furnace in as dry a state as possible.—The long slender pipes in the left hand machines represent a gage filled with mercury or water, by which the strength of the blast may be determined.

In the large iron founderies another method is used for blowing up the fires by means of a kind of air-pumps. These consist of cast-iron cylinders of about three feet diameter, exactly fitted with a piston moved up and down by means of a water-wheel. In the bottom of the cylinder is a large valve like that of a bellows, which rises as the piston is lifted up, and thus admits the air into the cavity of the cylinder from below. Immediately above the bottom is a tube which goes to the furnace; and as it proceeds from the cylinder is furnished with a valve opening outward. Thus, when the piston is drawn up, the valve in the bottom rises and admits the air that way into the cylinder; while the lateral valve shuts, and prevents any air from getting into it through the pipe. When the piston is thrust down, the valve in the bottom shuts, while the air being compressed in the cavity of the cylinder is violently forced out through the lateral tube into

Furnace.

the furnace. In the great foundery at Carron, four of these large cylinders were a few years ago employed at their principal furnace, and so contrived that the strokes of the pistons, being made alternately, produced an almost uninterrupted blast. Some little intermission might indeed be perceived by the ear, but it was too trifling to produce any sensible effect on the heat of the furnace. Even this could have been prevented by means of a large reservoir into which all the four cylinders might discharge their blast. This should be furnished with an heavy piston; whose weight being supported by the air of the cylinder alone, would force it out through its lateral tube in a manner perfectly equable, without any of that puffing or interruption in the blast, perceptible though but in a small degree in the other.

FUROR UTERINUS, a disorder peculiar to women. See MEDICINE-Index.

FURR, in commerce, signifies the skin of several wild beasts, dressed in alum with the hair on; and used as a part of dress, by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hare, coney, &c. See MUSTELA.

It was not till the later ages that the furs of beasts became an article of luxury. The more refined nations of ancient times never made use of them: those alone whom the former stigmatized as barbarians were clothed in the skins of animals. Strabo describes the Indians covered with the skins of lions, panthers, and bears; and Seneca, the Scythians clothed with the skins of foxes and the lesser quadrupeds. Virgil exhibits a picture of the savage Hyperboreans, similar to that which the late circumnavigators can witness to in the clothing of the wild Americans, unseen before by any polished people.

*Gens effrena virum Riphao tunditur Euro;
Et pecudum fulvis velantur corpora setis.*

Most part of Europe was at this time in similar circumstances. Cæsar might be as much amazed with the skin-dressed heroes of Britain, as the celebrated Cook was at those of his new-discovered regions. What time hath done to us, time, under humane conquerors, may effect for them. Civilization may take place: and those spoils of animals, which are at present essential for clothing, become the mere objects of ornament and luxury.

It does not appear that the Greeks or old Romans ever made use of furs. It originated in those regions where they most abounded, and where the severity of the climate required that species of clothing. At first it consisted of the skins only, almost in the state in which they were torn from the body of the beast; but as soon as civilization took place, and manufactures were introduced, furs became the lining of the dress, and often the elegant facing of the robes. It is probable that the northern conquerors introduced the fashion into Europe. We find, that about the year 522, when Totila king of the Visigoths reigned in Italy, the Suethons (a people of modern Sweden) found means, by help of the commerce of numberless intervening people, to transmit for the use of the Romans, *saphilinas pelles*, the precious skins of the sables. As luxury advanced, furs, even of the most valuable species, were used by princes as linings for their tents: thus Marco Polo, in 1252, found those of the Cham

of Tartary lined with ermines and sables. He calls the last *Zibelines* and *Zambolines*. He says that those and other precious furs were brought from countries far north; from the *land of Darkness*, and regions almost inaccessible by reason of morasses and ice. The Welsh set a high value on furs as early as the time of Howel Dda, who began his reign about 940. In the next age, furs became the fashionable magnificence of Europe. When Godfrey of Boulogne and his followers appeared before the emperor Alexis Comnene, on their way to the Holy Land, he was struck with the richness of their dresses, *tan ex ostro quam aurifrigio et niveo opere harmelino et ex mardrino grifioque et vario*. How different was the advance of luxury in France from the time of their great monarch Charlemagne, who contented himself with the plain furr of the otter! Henry I. wore furs; yet in his distress was obliged to change them for warm Welsh flannel. But in the year 1337 the luxury had got to such a head, that Edward III. enacted, that all persons who could not spend a hundred a-year should absolutely be prohibited the use of this species of finery. These, from their great expence, must have been foreign furs, obtained from the Italian commercial states, whose traffic was at this period boundless. How strange is the revolution in the furr-trade! The north of Asia at that time supplied Europe with every valuable kind; at present is sent, by means of the possession of Hudson's Bay, furs, to immense amount, even to Turkey and the distant China.

New Voyages in Search of FURRS. During the late Captain Cook's last voyage to the Pacific Ocean, besides the various scientific advantages to be derived from it, a new source of wealth was laid open to future navigators, by trading for furs of the most valuable kind on the north-west coast of America. The first vessel which engaged in the new branch of trade pointed out by that great navigator, was equipped by some gentlemen in China. She was a brig of 60 tons and 20 men, commanded by James Hanna. She sailed from the Typa the end of April 1785; proceeded to the northward, along the coast of China; passed through Diemen's Straits, the south end of Japan; and arrived at Nootka in August following. Soon after her arrival, the natives, whom Captain Cook had left unacquainted with the effects of fire-arms, tempted probably by the diminutive size of the vessel (scarce longer than some of their own canoes) and the small number of her people, attempted to board her in open day; but were repulsed with considerable slaughter. This was the introduction to a firm and lasting friendship. Captain Hanna cured such of the Indians as were wounded; an unreserved confidence took place; they traded fairly and peaceably; a valuable cargo of furs was procured; and the bad weather setting in, he left the coast in the end of September, touched at the Sandwich Islands, and arrived at Macao the end of December of the same year.

Captain Hanna sailed again from Macao in May 1786, in the snow Sea-Otter of 120 tons and 30 men, and returned to Macao in February 1787. In this second voyage he followed his former track, and arrived at Nootka in August; traced the coast from thence as far as 53 degrees, and explored the extensive sound discovered a short time before by Mr Strange, and

Furr.

Furr.

and called by him Queen Charlotte's Sound, the latitude of which is 51 degrees north, longitude 128 west.

The Snow Lark, Captain Peters, of 220 tons and 40 men, sailed from Macao in July 1786. Her destination was Kamtschatka (for which she was provided with a suitable cargo of arrack, tea, &c.), Copper Islands, and the N. W. coast. Captain Peters was directed to make his passage between Japan and Corea, and examine the islands to the north of Japan, said to be inhabited by hairy people; which, if Captain Cook had lived, would not have been left to the French to determine. No account having been received of this vessel since her departure, there is every reason to fear she has perished.

In the beginning of 1786, two coppered vessels were fitted out at Bombay, under the direction of James Strange, Esq; who was himself a principal owner. These vessels were, the snow Captain Cook of 300 tons, and snow Experiment of 100 tons. They proceeded in company from the Malabar coast to Batavia; passed through the Straits of Macassar, where the Experiment was run upon a reef, and was obliged to haul ashore upon Borneo to repair; from thence they steered to the eastward of the Palaos Islands; made Sulphur Island; and arrived at Nootka the end of June following. From Nootka, where they left their surgeon's mate (Mackay) to learn the language and collect skins against their intended return (but who was brought away in the Imperial Eagle the following year), they proceeded along the coast to Queen Charlotte's Sound, of which they were the first discoveries; from thence in a direct course to Prince William's Sound. After some stay there, the Experiment proceeded to Macao (their vessels being provided with passes by the governor-general of Goa): the Captain Cook endeavoured to get to Copper Island, but without success, being prevented by constant west winds.

Two coppered vessels were also fitted out by a society of gentlemen in Bengal, viz. the snow Nootka of 200 tons, and the snow Sea Otter of 100 tons, commanded by John Mears and William Tipping, lieutenants in the royal navy. The Nootka sailed in March 1786 from Bengal; came through the China Seas; touched at the Bashees, where they were very civilly treated by the Spaniards, who have taken possession of these islands; arrived at Oonalaska the beginning of August; found there a Russian galliot and some furriers; discovered accidentally near Cape Greville a new strait into Cook's River, 15 leagues wide and 30 long; saw some Russian hunters in a small bay between Cape Elizabeth and Cape Bear; and arrived in Prince William's Sound the end of September. They determined wintering in Snug Corner Cove, lat. 60. 30. in preference to going to the Sandwich Islands, which seem placed by Providence for the comfort and refreshment of the adventurers in this trade, and were frozen up in this gloomy and frightful spot from the end of November to the end of May. By the severity of the winter they lost their third and fourth mates, surgeon, boatswain, carpenter, and cooper, and twelve of the fore-mast men; and the remainder were so enfeebled as to be under the necessity of applying to the commanders of the King George and Queen Charlotte, who just at this time arrived in the sound, for some hands to assist in carrying the ves-

sel to the Sandwich Islands, where, giving over all further thoughts of trade, they determined (after getting a sea-flock of fish off Cape Edgcombe) immediately to proceed. The Nootka arrived at Macao the end of October 1787.

The Imperial Eagle, Captain Barkley, fitted out by a society of gentlemen at Ostend, sailed from Ostend the latter end of November 1786; went into the bay of All Saints; from thence, without touching any where, to the Sandwich Islands, and arrived at Nootka the beginning of June; from thence to the south, as far as 47° 30', in which space he discovered some good and spacious harbours. In the lat. of 47° 45', lost his second mate, purser, and two seamen, who were upon a trading party with the long-boat, and imprudently trusting themselves ashore unarmed, were cut off by the natives. This place seems to be the same that Don Antonio Mourelle calls the *Ilha de los Dolores*, where the Spaniards going ashore to water, were also attacked and cut off.

The King George of 320, and the Queen Charlotte of 200 tons, commanded by Captains Portlock and Dixon, who served under Captain Cook in his last voyage, were fitted out by a society of gentlemen in England, who obtained a privilege to trade to the north-west coast of America, from the South-Sea and East India companies.

Those vessels sailed from England the beginning of September 1785; touched at the Falkland Islands, Sandwich Islands, and arrived in Cook's River in the month of August. From thence, after collecting a few furs, they steered in the end of September for Prince William's Sound, intending, it is said, to winter there; but were prevented entering, by heavy storms and extreme bad weather, which obliged them to bear away, and seek some other part of the coast to winter at. The storms and bad weather accompanied them till they arrived off Nootka Sound, when they were so near the shore, that a canoe came off to them: but though thus near accomplishing their purpose, a fresh storm came on, and obliged them finally to bear away for the Sandwich Islands, where they remained the winter months; and returning again to the coast, arrived in Prince William's Sound the middle of May. The King George remained in Prince William's Sound; and during her stay, her long-boat discovered a new passage from the Sound into Cook's River. The Queen Charlotte proceeded along the coast to the south; looked into Behring's Bay, where the Russians have now a settlement; examined that part of the coast from 56 to 50°, which was not seen by Captain Cook, and which consists of a cluster of islands, called by Captain Dixon *Queen Charlotte's Islands*, at a considerable distance from the Main, which is thus removed farther to the eastward than it was supposed to be: some part of the continent may, however, be seen from the east side of these islands; and it is probable, the distance does not any where exceed 50 leagues. On this estimation, Hudson's House, lat. 53° long. 106° 27' west, will not be more than 800 miles distant from that part of this coast in the same parallel. It is therefore not improbable, that the enterprising spirit of the Canadian furriers may penetrate to this coast (the communication with which is probably much facilitated by lakes or rivers), and add to the comforts and luxuries

Furr.

Furr. tries of Europe this invaluable furr, which in warmth, beauty, and magnificence, far exceeds the richest furs of Siberia. Queen Charlotte's islands are inhabited by a race of people differing in language, features, and manners, from all the other tribes of this coast. Among other peculiarities, they are distinguished by a large incision in the under lip, in which is inserted a piece of polished wood, sometimes ornamented with mother-of-pearl shell, in shape and size like a weaver's shuttle, which undoubtedly is the most effectual mode of deforming the human face divine that the ingenious depravity of taste of any savage nation has yet discovered. These ships, after disposing of their furs in China, were loaded with teas on account of the English company, sailed from Wampoa the end of February, and arrived in England a short time since, after an absence of three years.

The year after the departure of the King George and Queen Charlotte, the same society to which they belonged fitted out two other vessels, viz. the Princess Royal of 60 tons, and the Prince of Wales of 200 tons, commanded by Captains Colnet and Duncan, the former of whom had served under Captain Cook. These vessels left England in August 1786; touched at New Year's harbour on Staten Land, where they left an officer and 12 men to kill seals against the arrival of a vessel which was to follow them from England; from thence they proceeded directly to Nootka, where they arrived the 6th of July, sickly and in bad condition, and found here the Imperial Eagle, which had left Europe some months after them. Leaving Nootka, they steered along the shore to the northward, and soon after fell in with the Queen Charlotte.

In the beginning of 1788, Captain Mears sailed again with two other vessels, the Felice, which he commanded himself, and the Iphigenia, Captain Douglas, to Nootka Sound. Here he purchased of the chief of the district a spot, on which he built a house for his residence and more convenient intercourse with the natives, hoisting the British colours thereon, surrounding it with a breast-work, and mounting a three pounder on the front. Having so done, he sent Mr Douglas in the Iphigenia to trade along the northern coast, while he himself proceeded to the south; and by presents to the chiefs obtained the ports Cox and Effingham, and the promise of an exclusive trade with the natives of the district, and also some other places, which he took possession of in the name of the king. Captain Douglas likewise, by presents to the chiefs of the countries he visited, obtained similar privileges, no other European vessel having sailed there before him.

On their return to Nootka, they found a vessel finished which the commander had laid down before his departure. This, which he named the North-west America, he left at Nootka with the Iphigenia, while he sailed with a cargo of furs in the Felice to China.

A few days after his arrival at China, two vessels, the Prince of Wales and Princess Royal, came to Canton from their trading voyage abovementioned. Captain Mears, fearing a competition of interests might be injurious to both parties, proposed a copartnership,

which was mutually agreed to; and another ship was purchased by the firm, and called the *Argonaut*. In the month of April 1789, Captain Mears gave Mr Colnet the command of the Princess Royal and Argonaut, which were loaded with stores and articles estimated sufficient for three years trade, besides several artificers, and near 70 Chinese, who intended to become settlers on the north-west coast of America, under protection of the new company.

In the mean while, the Iphigenia, and North-west America (the vessel built at Nootka) having wintered in Sandwich Islands, returned to Nootka in the latter end of April. Soon after which, two Spanish ships of war, under the command of Don Martinez, anchored in the sound. For a few days mutual civilities passed between the Spanish captain and Mr Douglas; but at the end of about a week, Don Martinez summoned the latter on board his own ship the *Princesa*, telling him he was his prisoner, and that the king of Spain had commanded him, Don Martinez, to seize all vessels he should find on that coast. He therefore instructed his officers to take possession of the Iphigenia, which they accordingly did in the name of his Catholic majesty; and the officers and crew were conveyed as prisoners on board the Spanish ships, where they were put in irons, and otherwise ill treated. Immediately after this, Don Martinez took possession of the little settlement, hoisting the standard of Spain, and modestly declaring all the lands from Cape Horn to 60 degrees north latitude belonged to his master. To aggravate the insult, he forcibly employed the crew of the Iphigenia in building batteries, &c. and offered no kind of violence to two American vessels that were at the same time in the harbour. At this time the North-west America was sent to explore the Archipelago of St Lazarus. On her return to Nootka she met with a similar treatment, and the skins she had collected were seized, with the rest of her cargo.

A few days after the Princess Royal (which we have mentioned as leaving Canton in company with the Argonaut) arrived. The Spanish commander, for reasons that do not appear, suffered her to depart. The skins collected by the North-west America were shipped on board her for the benefit of her owner, and she proceeded to trade in the neighbouring isles. On the 3d of July, the Argonaut arrived at the Sound; and Don Martinez, after making every profession of civility to Mr Colnet the commander, took possession of the said ship in the name of his master, and made prisoners of the crew. Soon after, the Princess Royal returning to receive instructions from Colnet, director of the Enterprize, was seized by the Spanish captain.

The crews of the British vessels were differently disposed of; some sent to China by the American vessels, and others to Spanish America: but the Chinese were all detained, and employed in the mines which were opened on the lands purchased by Captain Mears. What these mines consisted of we are no where informed. Mr Colnet was so much affected at the failure of the enterprize as to be deprived of reason.

This, as soon as known, occasioned a spirited representation from the British court to that of Spain; at the same time that vigorous preparations were made for

Furten-
burgh
||
Fufec.

for war in case adequate satisfaction should be refused. Matters, however, were prevented from coming to extremities, by a compliance on the part of Spain, after many delays and much artifice of negotiation, with the requisitions of Britain: in consequence of which, among other advantages unnecessary to be here recited, the whole trade from California to China is completely laid open; and the British allowed the full exercise of navigation and commerce in those parts of the world which were the subject of discussion.

In some accounts of the voyages abovementioned, the furr-trade in those parts have been greatly magnified. In that published by Captain Portlock, however, this officer observes, that the gains hitherto have certainly not been 'enviously' great; tho' the merchants have no doubt found the trade lucrative.

FURSTENBURGH, a town and castle of Germany, the capital of the county of the same name, 30 miles north-west of Constance. E. Long. 8. 30. N. Lat. 47. 50.

FURTHCOMING, in law, the name of an action competent to any person who has used arrestment in the hands of his debtor's creditor, for having the subject arrested declared his property.

FURUNCULE, or BoIL, in surgery, a small resisting tumor, with inflammation, redness, and great pain, arising in the adipose membrane, under the skin. See SURGERY.

FURZE, in botany. See ULEX.

FUSANUS, in botany: A genus of the monœcia order, belonging to the polygamia class of plants. The hermaphrodite calyx is quinquefid; there is no corolla; there are four stamina; the germen beneath; there are four stigmata; the fruit a plum.

FUSAROLE, in architecture, a moulding or ornament placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

FUSE, or FUZE, in artillery. See FUSEE.

FUSEE, in clock-work, is that conical part drawn by the spring, and about which the chain or string is wound; for the use of which, see CLOCK and WATCH.

FUSEE, or Firelock. See MUSQUET.

FUSEE, Fuze, or Fuse, of a bomb or grenado, is that which makes the whole powder or composition in the shell take fire, to do the designed execution.

Fuzes are chiefly made of very dry beech-wood, and sometimes of hornbeam, taken near the root. They are turned rough, and bored at first, and then kept for several years in a dry place; the diameter of the hole is about 1-4th of an inch; the hole does not come quite through, leaving about 1-4th of an inch at the bottom; and the head is made hollow, in the form of a bowl.

The composition for fuzes is saltpetre 3, sulphur 1, and mealed powder 3, 4, and sometimes 5. This composition is drove in with an iron-driver (whose ends are capped with copper to prevent the composition from taking fire), and equally hard as possible; the last shovel-full being all mealed powder, and two stands of quickmatch laid across each other being drove in with it, the ends of which are folded up into the hollow top, and a cap of parchment tied over it till used.

When these fuzes are driven into the loaded shell, the lower end is cut off in a slope, so that the compo-

sition may inflame the powder in the shell: the fuze must have such a length as to continue burning all the time the shell is in its range, and to set fire to the powder as soon as it touches the ground, which instantly bursts into many pieces. When the distance of the battery from the object is known, the time of the shell's flight may be computed to a second or two; which being known, the fuze may be cut accordingly, by burning two or three, and making use of a watch or a string by way of a pendulum to vibrate seconds.

FUSIBILITY, in natural philosophy, that quality of bodies which renders them fusible. Gold is more fusible than iron or copper; but less so than silver, tin, and lead. Borax is frequently mixed with metals, to render them more fusible.

FUSIL, in heraldry, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute and sharp than the other two in the middle. It is called in Latin *fusus*, "a spindle," from its shape.

FUSILIERS, FUSILEERS, or *Fuzileers*, in the military art, are soldiers armed as the rest of the infantry, but wearing caps like the grenadiers, though somewhat shorter. There are three regiments in the British service: the royal regiment of Scots fuzileers raised in 1678; the royal regiment of English fuzileers raised in 1685; and the royal regiment of Welsh fuzileers raised in 1688-9.

FUSION, the state of a body rendered fluid by fire. See FLUIDITY; and CHEMISTRY-Index.

FUST, or FAUSTUS, a citizen of Mentz, and one of the earliest printers. He had the policy to conceal his art; and to this policy we are indebted for the tradition of "The Devil and Dr Faustus," handed down to the present times. Fust, in partnership with Peter Schoeffer, having in 1462 printed off a considerable number of copies of the Bible to imitate those which were commonly sold in MS. Fust undertook the sale of them at Paris, where the art of printing was then unknown. At first he sold his copies for so high a sum as 500 or 600 crowns, the prices usually demanded by the scribes. He afterwards lowered his price to 60 crowns, which created universal astonishment: but when he produced copies as fast as they were wanted, and lowered the price to 30 crowns, all Paris was agitated. The uniformity of the copies increased the wonder; informations were given into the police against him as a magician; his lodgings were searched; and a great number of copies being found, they were seized: the red ink with which they were embellished was said to be his blood; it was seriously adjudged that he was in league with the devil; and if he had not fled, most probably he would have shared the fate of those whom ignorant and superstitious judges condemned in those days for witchcraft. See (History of) PRINTING.

FUSTIAN, in commerce, a kind of cotton stuff, which seems as it were whaled on one side.

Right fustians should be altogether made of cotton-yarn, both woof and warp; but a great many are made, the warp of which is flax, or even hemp.

There are fustians made of several kinds, wide, narrow, fine, coarse; with shag or nap, and without it.

FUSTIAN, is also used for a bombast-style, or a high swelling

Fusibility
||
Fustain.

Military
Dist. voce
Laboratory.

Fustick || swelling kind of writing made up of heterogeneous parts.

Future. || **FUSTICK**, or **FUSTOCK**, a yellow wood, that grow in all the Caribbee islands, used in dying yellow. It pays no duty on importation into Britain. It is a species of **MORUS**.

FUSTIGATIO, in the Roman customs, a punishment inflicted by beating with a cudgel. This punishment was peculiar to freemen: for the slaves were scourged or lashed with whips.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth.

FUTURE, something to come hereafter. We say a *future* state, a *future* contingency; there is none but God to whom *future* things are present.

FUTURE, or *FUTURE Tense*, in grammar, denotes an inflexion of verbs, whereby they denote, that a thing will be in some time yet to come. See **GRAMMAR**.

FUZES, or **FUSEES**, in artillery. See **FUSEE**.

FUZILEERS. See **FUSILEERS**.

FYTT (John), a celebrated painter of animals and flowers, &c. was born at Antwerp about the year 1625, and proved one of the best artists of his time. He frequently painted in conjunction with Rubens, and Jordaens; and whatever subject he chose to represent in the style which he adopted, was always designed and finished in a masterly manner. His general subjects were live and dead game, wild boars, hares, dogs, fruits, flowers, and birds, particularly partridges; which he described with surprising truth, nature, and strength. He likewise imitated successfully the bas-relieves on vases of marble or porphyry: and gave uncommon freshness to his fruits and flowers; and in objects of the animal kind, he described even the hairs of the animals and the plumage of his fowl with wonderful spirit, exactness, and freedom of pencil.

Fuzes

Fytt.

G.

G THE seventh letter and fifth consonant of our alphabet; though in the alphabets of all the oriental languages, the Hebrew, Phenician, Chaldee, Syriac, Samaritan, Arabic, and even Greek, *G* is the third letter. The Hebrews call it *ghimel* or *gimel*, *q. d.* "camel;" by reason it resembles the neck of that animal; and the same appellation it bears in the Samaritan, Phenician, and Chaldee: in the Syriac it is called *gamel*, in Arabic *gim*, and in Greek *gamma*.

The gamma (Γ) of the Greeks is manifestly the *gimel* (γ) of the Hebrews or Samaritans. All the difference between the gamma and *gimel* consists in this, that the one is turned to the right and the other to the left, according to the different manners of writing and reading which obtained among those different nations; so that all the pains Salmatius has taken on Solinus, to prove that the *G* was derived from the Greek kappa, is lost.

From the Greeks the Latins borrowed their form of this letter; the Latin *G* being certainly a corruption of the Greek gamma Γ , as might easily be shown, had our printers all the characters and forms of this letter which we meet with in the Greek and Latin MSS. through which the letter passed from Γ to *G*.

Diomed, lib. ii. cap. *De Litera*, calls *G* a new letter. His reason is, that the Romans had not introduced it before the first Punic war; as appears from the rostral column erected by C. Duilius, on which we every where find a *C* in lieu of *G*. It was Sp. Carvillus who first distinguished between those two letters, and invented the figure of the *G*; as we are assured by Terentius Scaurus. The *C* served very well for *G*; it being the third letter of the Latin alphabet, as the Γ or γ was of the Greek.

VOL. VII.

The *G* is found instead of *C* on several medals: *Vaillant, Num. Imperat.* tom. i. p. 39.

M. Beger produces a medal of the *Familia Ogulnia*, where *GAR* is read instead of *CAR*, which is on those of M. Patin. But the *C* is more frequently seen on medals in lieu of *G*; as, *AUCUSTALIS CALLAECIA CARTACINENSIS*, &c. for *AUGUSTALIS*, &c. Not that the pronunciation of those words was altered, but only that the *G* was unartfully or negligently cut by the workmen: as is the case in divers inscriptions of the eastern empire; where *AUC*, *AUCC*, *AUCCC*, are frequently found for *AUG*, &c.

The northern people frequently change the *G* into *V* or *W*; as in *Gallus*, *Wallus*; *Gallia*, *Wallia*, *Vallia*, &c. For in this instance it must not be said that the French have changed the *W* into *G*; because they wrote *Gallus* long before *Wallus* or *Wallia* was known, as appears from all the ancient Roman and Greek writers. And yet it is equally true, that the French change the *W* of the northern nations, and *V* consonant, into *G*; as, *Willielmus*, "William," into *Guillaume*; *Wulphilas* into *Culphilas*; *Vasco* into *Gascon*, &c.

The letter *G* is of the mute kind, and cannot be any way sounded without the help of a vowel. It is formed by the reflexion of the air against the palate, made by the tongue as the air passes out of the throat; which Martianus Capella expresses thus, *G spiritus cum palato*; so that *G* is a palatal letter.

The modern *G* takes its form from that of the Latins. In English it has two sounds, one from the Greek Γ , and the Latin, which is called that of the hard *G*, because it is formed by a pressure somewhat hard on the fore-part of the tongue against the upper gum;

3 T

which

Gabale
|
Gabel.

which sound it retains before *a, o, u, l, r*; as *gate, go, gull*. At the end of a word it is always hard, as *ring, sing, &c.* The other sound, called that of the soft *G*, resembles that of *j*; and is commonly, though not always, found before *e* and *i*, as in *gesture, giant, &c.* To this rule, however, there are many exceptions; *G* is often hard before *i*, as *give, &c.* and sometimes before *e* as *get, &c.* It is also hard in derivatives from words ending in *g*, as *singing, stronger, &c.* and generally before *er*, at the end of words, as *finger*. *G* is mute before *n*, as *gnash, sign*. *Gh* has the sound of the hard *G* in the beginning of a word, as *ghosily*; in the middle, and sometimes at the end, it is quite silent, as *right, though*. At the end of a word *Gh* has often the sound of *f*, as *laugh, rough, tough*.

As a numeral, *G* was anciently used to denote 400; and with a dash over it thus *Ḡ*, 40,000.

As an abbreviature, *G*. stands for *Gaius, Cellius, gens, genius, &c.* *G. G.* for *gemina, gessit, gesserunt, &c.* *G. C.* for *genio civitatis* or *Cæsaris*. *G. L.* for *Gaius libertus*, or *genio loci*. *G. V. S.* for *genio urbis sacrum*. *G. B.* for *genio bono*. And *G. T.* for *genio tutelari*.

In music, *G* is the character or mark of the treble cleff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name of *gamut*.

GABALE, in mythology, a deity worshipped at Heliopolis under the figure of a lion, with a radiant head; and it is thus represented on many medals of Caracalla.

GABARDINE, from the Italian *gavardina*, has been sometimes used to denote a coarse frock, or mean dress. In this sense it is used by Shakespeare in his *Tempest* and *Merchant of Venice*, and by Butler in his *Hudibras*, book i.

GABARA, or GABBARA, in antiquity, the dead bodies which the Egyptians embalmed, and kept in their houses, especially those of such of their friends as died with the reputation of great piety and holiness, or as martyrs. See EMBALMING, and MUMMY.

GABEL (*Gabella, Gablum, Gablagium*), in French *Gabelle*, i. e. *Vestigal*, hath the same signification among the ancient English writers that *gabelle* hath in France. It is a tax; but hath been variously used, as for a rent, custom, service, &c. And where it was a payment of rent, those who paid it were termed *gablatores*. When the word *gabel* was formerly mentioned without any addition to it, it signified the tax on salt, though afterwards it was applied to all other taxes.

In the French customs, the *gabelle*, or tax on salt, computed to make one-fourth of the whole revenue of the kingdom, is said to have had its rise in France in 1286, under Philip the Fair. Philip the Long took a double per livre on salt, by an edict in 1318, which he promised to remit when he was delivered from his enemies; which was renewed by Philip de Valois in 1345; and the duty was raised to four deniers per livre; king John resumed it in 1355, and it was granted to the dauphin in 1358, to ransom king John. It was continued by Charles V. in 1366; after his decease it was suppressed, but revived again by Chas. VI. in 1381. Louis XI. raised it to 12 deniers per livre; and Francis I. in 1542 to 24 livres per muid; and it has been considerably augmented since that time; so

that a muid of salt latterly paid a duty of 52 livres, 8 sols, and 6 deniers. Philip de Valois first established granaries and officers of the *gabelles*, and prohibited any other persons from selling salt: from which time the whole commerce of salt for the inland consumption continued wholly in the king's hands, every grain thereof being sold and distributed by his farmers and officers created for the purpose.—This very odious and oppressive tax has lately been abolished by the National Assembly.

GABII, (anc. geog.), a town of Latium, midway almost between Rome and Preneste to the east, often mentioned in the history of Tarquin the Proud. *Cinctus Gabinus* denoted a particular way of tucking the gown, by drawing it forwards on the breast, and tying it into a knot; as the people of Gabii did at a solemn sacrifice, on the sudden attack of an enemy, in order to be fitter for action. In this manner the consul used to declare war, to sacrifice, and burn the spoils of the enemy; and then he was said to be *præcinctus*. The place now extinct.

GABINIAN LAWS, in Roman antiquities; laws instituted upon several occasions by persons of the name of *Gabinus*. The first was the *Gabinian lex de Comitiis*, by A. Gabinus the tribune, in the year of Rome 614. It required that in the public assemblies for electing magistrates, the votes should be given by tablets, and not *vivâ voce*.—Another *de Comitiis*, which made it a capital punishment to convene any clandestine assembly, agreeable to the old law of the 12 tables.—Another *de Militiâ*, by A. Gabinus the tribune, year of Rome 685. It granted Pompey the power of carrying on the war against the pirates during three years, and of obliging all kings, governors, and states, to supply him with all the necessaries he wanted, over all the Mediterranean sea, and in the maritime provinces as far as 400 *stadia* from the sea.—Another *de Usurâ* by Aul. Gabinus the tribune, year of Rome 685. It ordained that no action should be granted for the recovery of any money borrowed upon small interest to be lent upon larger. This was an usual practice at Rome, which obtained the name of *versuram facere*. Another against fornication.

GABIONS, in fortification, baskets made of ozier-twigs, of a cylindrical form, six feet high and four wide; which, being filled with earth, serve as a shelter from the enemy's fire.

GABLE, or GABLE-End, of a house (from *gaval*, Welsh), is the upright triangular end from the cornice or eaves to the top of the house.

GABRES, or GAVRES, a religious sect in Persia and India; called also *Gebres, Guebres, Gevres, Gours, &c.* See MAGI.

The Turks call the Christians *Gabres*, q. d. infidels, or people of a false religion; or rather, as Leunclavius observes, heathens or gentiles: the word *Gabre*, among the Turks, having the same signification as *pagan* or *infidel* among the Christians, and denoting any thing not Mahometan.

In Persia the word has a more peculiar signification; wherein it is applied to a sect dispersed through the country, and said to be the remains of the ancient Persians or followers of Zoroaster, being worshippers of fire. They have a suburb at Ispahan, which is called *Gaurabad*, or "the town of the *Gours*," where they are

Gabii
||
Gabres.

Gabriel
||
Gad.

are employed in the meanest and vilest drudgery: some of them are dispersed through other parts of Persia; but they principally abound in Kermau, the most barren province in the whole country, where the Mahometans allow them liberty and the exercise of their religion. Several of them fled many ages ago into India, and settled about Surat, where their posterity remain to this day. There is also a colony of them at Bombay. They are a poor, ignorant, inoffensive people, extremely superstitious, and zealous for their rites, rigorous in their morals, and honest in their dealings. They profess to believe a resurrection and a future judgment, and to worship only one God. And though they perform their worship before fire, and direct their devotion towards the rising sun, for which they have an extraordinary veneration, yet they strenuously maintain that they worship neither; but that these are the most expressive symbols of the Deity, and that for this reason they turn towards them in their devotional services.—However, some have supposed, that these are Persians converted to Christianity, who, being afterwards left to themselves, mingled their ancient superstitions with the truths and practices of Christianity, and so formed for themselves a religion apart: and they allege, that throughout the whole of their system of doctrine and practice, we may discern the marks and traces of Christianity, though grievously defaced; the annunciation, the magi, the massacre of the infants, our Saviour's miracles, his persecutions, ascension, &c.

GABRIEL, the name of one of the principal angels in heaven. It signifies *the strength of God*. There are a few events, in which this exalted being was concerned, recorded in scripture. He was sent to the prophet Daniel, to explain to him the vision of the ram and goat, and the mystery of the seventy weeks, which had been revealed to him. He was sent to Zacharias, to declare to him the future birth of John the Baptist. Six months after, he was sent to Nazareth to the Virgin Mary, to warn her of the birth of Jesus Christ.

The Orientalists add several particulars to what the scriptures inform us concerning the angel Gabriel. The Mahometans call him the *faithful spirit*; and the Persians, by way of metaphor, the *peacock of heaven*. We read, in the second chapter of the Koran, that *whosoever is an enemy to Gabriel shall be confounded*. It was Gabriel, they believe, who brought to Mahomet their false prophet the revelations which he published; and it was he who conducted him to heaven mounted upon the animal Borak.

GABRIELITES, in ecclesiastical history, a sect of anabaptists that appeared in Pomerania in 1530. They derive their name from Gabriel Scherling; who, after having been for some time tolerated in that country, was obliged to remove, and died in Poland.

GAD (anc. geog.), a district of the Transjordan Palestine, situated between Gilead and the kingdom of Bashan to the north, and the kingdom of the Amorrites to the south; having the Jordan to the west, and bounded by various people on the east; so called from a tribe of that name.

GAD, among miners, a small punch of iron, with a long wooden handle, used to break up the ore.

One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge-hammer.

GAD-Bee, or Gad-Fly. See OESTRUS.

GADARA (anc. geog.), a town of the Peræa, or Transjordan, in the Decapolis, a very strong place. Restored by Pompey after its demolition by the Jews (Josephus). After Herod's death it was joined to the province of Syria by Augustus.

GADARENORUM AGER (anc. geog.) the country of the Gadarenes, called by Matthew the country of the Gergesens, because it was a district that lay between Gadara and Gergesa, otherwise called *Gerasa*, both which lay within the Decapolis on the other side Jordan.

GADES, or GADIRA (anc. geog.), a small island in the Atlantic, on the Spanish coast, 25 miles from the Columns of Hercules. It was sometimes called *Tartessus* and *Erythia* according to Pliny. Geryon, whom Hercules killed, fixed his residence there. Hercules, surnamed Gaditanus, had there a celebrated temple in which all his labours were engraved with excellent workmanship. The inhabitants are called Gaditani.

GADUS, in ichthyology, a genus of fishes belonging to the order of jugulares. The head is smooth; there are seven cylindrical rays in the branchiostege membrane; the body is oblong, with deciduous scales; the whole fins are covered with the common skin of the fish; the rays of the back-fins are blunt, and those of the breast are sharp. There are 17 species, principally distinguished by their cirri and the number of back-fins. The most remarkable are,

1. The *morhua*, or COMMON COD, is cinereous on the back and sides, and commonly spotted with yellow: the belly is white; but they vary much, not only in colour, but in shape, particularly that of the head. The side-line is white, and broad, and straight, till it reaches opposite the vent, when it bends towards the tail. Codlings are often taken of a yellow, orange, and even red colour, while they remain among the rocks; but on changing their place assume the colour of other cod-fish. The jaws are of an equal length, and at the end of the lower is a small beard; the teeth are disposed in the palate as well as in the jaws.

The cod is found only in the northern parts of the world; it is, as Rondeletius calls it, an ocean fish, and never met with in the Mediterranean Sea. It affects cold climates, and seems confined between the latitudes 66° and 50°; what are caught north and south of those degrees being either few in quantity or bad in quality. The Greenland fish are small, and emaciated through want of food; being very voracious, and having in those seas a scarcity of provision. This locality of situation is common to many other species of this genus, most of them being inhabitants of the cold seas, or such as lie within regions that can just claim the title of *temperate*. There are nevertheless certain species found near the Canary Islands, called *cherny*, of which we know no more than the name; but which, according to Captain Glas, are better tasted than the Newfoundland kind.

The great rendezvous of the cod-fish is on the banks of Newfoundland, and the other sand banks that lie off the coasts of Cape Breton, Nova Scotia, and New England. They prefer those situations, by reason of the quantity of worms produced in those sandy bottoms, which tempt them to resort there for food; but

Gad-Ecc
||
Gadus.

Gadus.

another cause of the particular attachment the fish have to these spots, is their vicinity to the polar seas, where they return to spawn; there they deposite their roes in full security; but want of food forces them, as soon as the first more southern seas are open, to repair thither for subsistence. Few are taken north of Iceland, but on the south and west coasts they abound: they are again found to swarm on the coasts of Norway, in the Baltic, off the Orkney and the Western Isles; after which their numbers decrease, in proportion as they advance towards the south, when they seem quite to cease before they reach the mouth of the Straits of Gibraltar.

Before the discovery of Newfoundland, the greater fisheries of cod were on the seas of Iceland, and off the Western Isles, which were the grand resort of ships from all the commercial nations; but it seems that the greatest plenty was met with near Iceland. The English resorted thither before the year 1415: for we find that Henry V. was disposed to give the king of Denmark satisfaction for certain irregularities committed on those seas by his subjects. In the reign of Edward IV. the English were excluded from the fishery by treaty; and forbidden to resort there under pain of forfeiture of life and goods. Notwithstanding this, that monarch afterwards gave licence to a ship of Hull to sail to Iceland, and there relade fish and other goods, without regard to any restrictions to the contrary. The right of the English in latter times was far from being confirmed: for we find Queen Elizabeth condescending to ask permission to fish in those seas from Christian IV. of Denmark; yet afterwards she so far repented her request, as to instruct her ambassadors at that court to insist on the right of a free and universal fishery. In the reign of her successor, however, they had not fewer than 150 ships employed in the Iceland fishery; which indulgence might arise from the marriage of James with a princess of Denmark. But the Spanish, the French, and the Bretons, had much the advantage of the English in all fisheries at the beginning, as appears by the state of that in the seas of Newfoundland in the year 1578, when the number of ships belonging to each nation stood thus:

Spaniards, 100, besides 20 or 30 that came from Biscay to take whale for train, being about five or six thousand tons.

Portuguese 50, or three thousand tons.

French and Bretons 150, or seven thousand tons.

English, from 30 to 50.

The increase of shipping that resort to those fertile banks is now unspeakable. Britain now enjoys the greatest share: which ought to be esteemed their chiefest treasure, as it brings wealth to individuals, and strength to the state. See FISHERY.

All this immense fishery is carried on by the hook and line only. We have been informed that they fish from the depth of 16 to 60 fathoms, according to the inequality of the bank, which is represented as a vast mountain, under water, above 500 miles long, and near 300 broad; and that seamen know when they approach it by the great swell of the seas and the thick mists that impend over it. The bait is herring, a small fish called a *capelin*, a shell-fish called *clams*, and bits of sea-fowl; and with these are caught fish sufficient to find employ for near 15,000 British seamen, and to af-

ford subsistence to a much more numerous body of people at home, who are engaged in the various manufactures which so vast a fishery demands.

The food of the cod is either small fish, worms, testaceous or crustaceous animals, such as crabs, large whelks, &c.; and their digestion is so powerful as to dissolve the greatest part of the shells they swallow. They are very voracious, and catch at any small body they perceive moved by the water, even stones and pebbles, which are often found in their stomachs.

Fishermen are well acquainted with the use of the air-bladder or sound of the cod; and are very dextrous in perforating this part of a live fish with a needle, in order to disengage the inclosed air; for without this operation it could not be kept under water in the well-boats, and brought fresh to market. The sounds of the cod salted is a delicacy often brought from Newfoundland. Singlass is also made of this part by the Iceland fishermen: a process which deserves the attention of the natives of the north of Scotland, where these fish are plentiful. It is given under the article ICHTHYOCOLLA.

Providence hath kindly ordained, that this fish, so useful to mankind, should be so very prolific as to supply more than the deficiencies of the multitudes annually taken. Leuwenhoeck counted 9,384,000 eggs in a cod-fish of a middling size, a number, sure, that will baffle all the efforts of man, or the voracity of the inhabitants of the ocean, to exterminate, and which will secure to all ages an inexhaustible supply of grateful provision.

In the British seas they begin to spawn in January, and deposite their eggs in rough ground among rocks. Some continue in roe till the beginning of April. The codfish in general recover quicker after spawning than any other fish; therefore it is common to take some good ones all the summer. When they are out of season, they are thin-tailed and lousy; and the lice chiefly fix themselves on the inside of their mouths.

The fish of a middling size are most esteemed for the table; and are chosen by their plumpness and roundness, especially near the tail, by the depth of the fulcus or pit behind the head, and by the regular undulated appearance of the sides, as if they were ribbed. The glutinous parts about the head lose their delicate flavour after it has been 24 hours out of the water, even in winter, when these and other fish of this genus are in highest season.

One mentioned by Mr Pennant as the largest that he ever heard of taken on the British coasts, weighed 78 pounds: the length was five feet eight inches, and the girth round the shoulders five feet. It was taken at Scarborough in 1755, and was sold for one shilling. But the general weight of these fish in the Yorkshire seas, he says, is from 14 to 40 pounds. This species is short in proportion to its bulk, the belly being very large and prominent.

2. The *eglesinus*, or HADDOCK, has a long body; the upper part of a dusky brown colour, and the belly and lower part of the sides silvery: On the back are three fins resembling those of the common cod-fish; the lateral line is black; and the tail is forked: The head slopes down to the nose; on the chin is a short beard; and on each side beyond the gills is a large black spot. Superstition assigns this mark to the im-

pression

Gadus.

Gadus. pression St Peter left with his finger and thumb when he took the tribate out of the mouth of a fish of this species, which has been continued to the whole race of haddocks ever since that miracle. Large haddocks begin to be in roe in the middle of November, and continue so to the end of January; from that time till May they are very thin-tailed, and much out of season. In May they begin to recover; and some of the middling-sized fish are then very good, and continue improving till the time of their greatest perfection. The small ones are extremely good from May till February, and some even in February, March, and April, *viz.* those which are not old enough to breed.

The fishermen assert that in rough weather haddocks sink down into the sand and ooze in the bottom of the sea, and shelter themselves there till the storm is over; because in stormy weather they take none, and those that are taken immediately after a storm are covered with mud on their backs.

In summer they live on young herrings and other small fish; in winter on the stone coated worms*, which the fishermen call *haddock-meat*.

* A species of *Serpula*.

The grand shoal of haddocks comes periodically on the Yorkshire coasts. It is remarkable that they appeared in 1766 on the 10th of December, and exactly on the same day in 1767: these shoals extended from the shore near three miles in breadth, and in length from Flamborough head to Tinmouth-castle, and perhaps much farther northwards. An idea may be given of their numbers by the following fact: Three fishermen, within the distance of a mile from Scarborough harbour, frequently loaded their coble or boat with them twice a-day, taking each time about a ton of fish: when they put down their lines beyond the distance of three miles from the shore, they caught nothing but dog-fish, which shows how exactly these fish keep their limits. The best haddocks were sold from eightpence to a shilling *per score*; and the poor had the smaller sort at a penny and sometimes a halfpenny *per score*.

The large haddocks quit the coast as soon as they go out of season, and leave behind great plenty of small ones. It is said that the large ones visit the coasts of Hamburgh and Jutland in the summer. It is no less remarkable than providential, that all kinds of fish (except makrel) which frequent the Yorkshire coast, approach the shore, and as it were offer themselves to the inhabitants generally remaining there as long as they are in high season, and retire when they become unfit for use. It is the commonest species in the London markets. They do not grow to a great bulk, one of 14 pounds being of an uncommon size, but those are extremely coarse: the best for the table weighing from two to three pounds.

3. The *barbatus*, or *POUT*, never grows to a large size, seldom exceeding a foot in length. It is distinguished from all others by its great depth; and of the size abovementioned being near four inches deep in the broadest part. The back is very much arched, and carinated: the colour of the fins and tail are black: at the bottom of the pectoral fins is a black spot. The lateral line is white, broad, and crooked. The tail is even at the end, and of a dusky colour. The colour of the body is white; but more obscure on the back than the belly, and tinged with yellow.—It is called at Scarborough a *kleg*, and is a very delicate fish.

Gadus. 4. The *Minutus*, or *POOR*, is the smallest species yet discovered, being little more than six inches long. On the chin is a small beard; the eyes are covered with a loose membrane: on the gill-covers and the jaws there are on each side nine punctures. The colour on the back is a light brown; on the belly a dirty white. It is taken near Marseilles, and sometimes in such quantities as to become a nuisance, for no other kinds of fish are taken during their season. It is esteemed good, but incapable of being salted or dried. Belon says, that when it is dried in the sun it grows as hard as horn. We owe the discovery of this kind in our seas to the Reverend Mr Jago.

5. The *carbonarius*, or *COAL-FISH*, is of a more elegant form than the cod-fish: they generally grow to the length of two feet and an half, and weigh about 28 or 30 pounds at most. The head is small; the under jaw a little longer than the upper; The tail is broad and forked. They vary in colour: some have their back, nose, dorsal fins, and tail of a deep black; the gill-covers, silver and black; the ventral and anal fins, and the belly, white: Others are dusky, others brown; but, in all, the lateral line is straight and white, and the lower part of the ventral and anal fins, white. This fish takes its name from the black colour that it sometimes assumes. Belon calls it the *colfsch*, imagining that it was so named by the English, from its producing the Ichthyocolla; but Gesner gives the true etymology. These fish are common on most of the rocky and deep coasts, but particularly those of the north of Great Britain. They swarm about the Orkneys, where the fry are the great support of the poor. The young begin to appear on the Yorkshire coast the beginning of July in vast shoals, and are at that time about an inch and an half long. In August they are from three to five inches in length, and are taken in great numbers with the angling rod: they are then esteemed a very delicate fish; but grow so coarse when they are a year old, that few people will eat them. Fish of that age are from 8 to 15 inches long, and begin to have a little blackness near the gills and on the back, and the blackness increases as they grow older.

The fry is known by different names in different places: they are called at Scarborough *parrs*; and when a year old, *billets*. About 20 years ago such a glut of parrs visited that part, that for several weeks it was impossible to dip a pail into the sea without taking some.

Though this fish is so little esteemed when fresh, yet it is salted and dried for sale.

6. The *pollachius*, or *POULLACK*, has the under jaw longer than the upper; the head and body rises pretty high, as far as the first dorsal fin. The side line is incurvated, rising towards the middle of the back, then sinking and running straight to the tail; it is broad, and of a brown colour. The colour of the back is dusky, sometimes inclining to green: the sides beneath the lateral line are marked with lines of yellow; and the belly is white.—This fish is common on many of our rocky coasts: during summer they are seen in great shoals frolicking on the surface of the water, and flinging themselves into a thousand forms. They are at that time so wanton as to bite at any thing that appears on the top of the waves, and are often taken with

Gadus. with a goose-feather fixed to the hook. They are very strong, being observed to keep their stations at the feet of the rocks in the most turbulent and rapid sea. They are a good eating fish. They do not grow to a very large size; at least the biggest seldom exceed six or seven pounds; but some have been taken in the sea near Scarborough, which they frequent during winter, that weighed near 28 pounds. They are there called *leets*.

7. The *merlangus*, or WHITING is a fish of an elegant make: the upper jaw is the longest; the eyes are large, the nose is sharp; the teeth of the upper jaw are long, and appear above the lower when closed. The colour of the head and back is pale brown: the lateral line white, and crooked; the belly and sides are silvery, the last streaked lengthwise with yellow.

These fish appear in vast shoals in the British seas in the spring, keeping at the distance of about half a mile to that of three from the shore. They are caught in vast numbers by the line, and afford excellent diversion. They are the most delicate, as well as the most wholesome, of any of the genus; but they do not grow to a large size, the biggest not exceeding 20 inches; and even that is very uncommon, the usual length being 10 or 12; though, it is said, that whittings from 4 to 8 pounds in weight have been taken in the deep water at the edge of the Dogger-Bank.

8. The *merlucius*, or HAKE, is found in vast abundance on the British coasts, and of those of Ireland. There was formerly a vast stationary fishery of hake on the Nymph Bank off the coast of Waterford, immense quantities appearing there twice a-year; the first shoal coming in June, during the mackrel-season; the other in September, at the beginning of the herring season, probably in pursuit of those fish: it was no unusual thing for six men with hooks and lines to take a thousand hake in one night, besides a considerable quantity of other fish. These were salted and sent to Spain, particularly to Bilboa. We are at this time uniformed of the state of this fishery; but find that Mr Smith, who wrote the history of the county of Waterford, complains even in his time (1746) of its decline. Many of the gregarious fish are subject to change their situations, and desert their haunts for numbers of years, and then return again. Mr Smith instances the loss of the haddock on the Waterford shores, where they used to swarm; and we can bring the capriciousness of the herrings which so frequently quit their stations, as another example.—Sometimes the irregular migration of fish is owing to their being followed and harassed by an unusual number of fish of prey, such as the shark kind; sometimes to a deficiency of the smaller fish, which served them as food; and lastly, in many places to the custom of trawling, which not only demolishes a quantity of their spawn, which is deposited in the sand, but also destroys or drives into deeper waters numberless worms and insects, the repast of many fish.—The hake is in England esteemed a very coarse fish, and is seldom admitted to table either fresh or salted. When cured it is known by the name of *Poor John*. These fish are from a foot and an half to near twice that length; they are of a slender make, of a pale ash-colour on their backs, and of a dirty white on their bellies.

9. The *molva*, or LING, is usually from three to

four feet long, but have been heard of seven feet long. The body is very slender; the head flat: the upper jaw is the longest; the teeth in that jaw are small and very numerous; in the lower, few, slender, and sharp; on the chin is a small beard. They vary in colour, some being of an olive hue on the sides and back, others cinereous; the belly white. The ventral fins are white: the dorsal and anal edged with white. The tail is marked near the end with a transverse black bar, and tipped with white. The ling takes its English name from its length, being corrupted from the word *long*. It abounds about the Scilly Isles, on the coast of Scarborough, and those of Scotland and Ireland, and forms a considerable article of commerce. This branch of trade was considerable so long ago as the reign of Edward III. an act for regulating the price of lob, *ling*, and cod, being made in his 31st year. In the Yorkshire seas they are in perfection from the beginning of February to the beginning of May, and some till the end of that month. In June they spawn, depositing their eggs in the soft oozy ground of the mouth of the Tees: at that time the males separate from the females, and resort to some rocky ground near Flamborough-head, where the fishermen take great numbers without ever finding any of the female or roe'd fish among them. While a ling is in season its liver is very white, and abounds with a fine-flavoured oil; but as soon as the fish goes out of season, the liver becomes red as that of a bullock, and affords no oil. The same happens to the cod and other fish in a certain degree, but not so remarkably as in the ling. When the fish is in perfection, a very large quantity of oil may be melted out of the liver by a slow fire; but if a violent sudden heat be used for that purpose, they yield very little. The oil, which nature hoards up in the cellular membranes of the fishes, returns into their blood, and supports them in the engendering season, when they pursue the business of generation with so much eagerness as to neglect their food. Vast quantities of ling are salted for exportation as well as for home-consumption. When it is cut or split for curing, it must measure 26 inches or upwards from the shoulder to the tail: if less than that, it is not reckoned a sizeable fish, and consequently not intitled to the bounty on exportation; such are called *drizzles*, and are in season all summer.

11. The *lota*, or BURBOT, in its body has some resemblance to that of an eel, only shorter and thicker; and its motions also resemble those of that fish; they are besides very smooth, slippery, and slimy. The head is very ugly, being flat and shaped like that of a toad: the teeth are very small, but numerous. On the end of the nose are two small beards; on the chin another. The colour varies: some are dusky, others are of a dirty green, spotted with black, and oftentimes with yellow; and the belly in some is white; but the real colours are frequently concealed by the slime. This fish abounds in the lake of Geneva, where it is called *lota*; and it is also met with in the Lago Maggiore and Lugano. In Britain it is found in the Trent; but in greater plenty in the river Witham, and in the great east fen in Lincolnshire. It is a very delicate fish for the table, though of a disgusting appearance when alive. It is very voracious, and preys on the fry and lesser fish. It does not often take a bait, but is generally

Gaelic
||
Gage.

rally caught in weels. The largest taken in Britain weigh between two and three pounds, but in other parts are sometimes found of double that weight.

12. The *mustela*, or FIVE BEARDED COD, very much resembles the former. The beards on the upper jaw are four, viz. at the very end of the nose, and two a little above them: on the end of the lower jaw a single one. The fish are of a deep olive brown, their belly whitish. They grow to the same size as the former.---The Cornish fishermen are said to whistle, and make use of the words *bod, bod, vean*, when they are desirous of taking this fish, as if by that they facilitated the capture. In the same manner the Sicilian fishermen repeat their *mamassu di pajanu*, &c. when they are in pursuit of the sword-fish.

13. The TORSK, or, as it is called in the Shetlands, *tusk* and *brismack*, is a northern fish; and as yet undiscovered lower than about the Orkneys, and even there it is rather scarce. In the seas about Shetland, it swarms, and forms (barrelled or dried) a considerable article of commerce. The length is about 20 inches, the greatest depth four and a half. The head is small; the upper jaw a little longer than the lower; both jaws furnished with multitudes of small teeth: on the chin is a small single beard: from the head to the dorsal fin is a deep furrow. The colour of the head is dusky: the back and sides yellow; belly white; edges of the dorsal, anal, and caudal fins, white; the other parts dusky; the pectoral-fins, brown.

GAELIC LANGUAGE. See HIGHLANDS.

GÆTULIA, (anc. geog.), a country of Africa, lying to the south of Mauritania, called *Gætulia Propria*, and *Vetus Gætuli*, the people, were distinguished by different epithets; as *Nigri*, *Autololes*, *Daræ*, and *Baniuræ*, (Pliny). The *Gætuli* were among the first inhabitants of Africa; a rough, unpolished people, living on venison and the spontaneous productions of the earth; a roving wandering people, who took up with the first place in which night surprised them, (Sallost.)

GAFF, a sort of boom or pole, frequently used in small ships, to extend the upper edge of the mizen; and always employed for the same purpose on those sails whose foremost edges are joined to the mast by hoops or lacings, and which are usually extended by a boom below. Such are the main-sails of all sloops, brigs, and schooners.

GAFFAREL (James), a French divine, and very learned writer, born about 1601. He acquired great skill in the oriental and several other languages; and was particularly versant in the cabalistic and occult sciences, which he learned, exposed, and refuted. Cardinal Richelieu made choice of him for his library-keeper, and sent him into Italy to collect the best manuscripts and books. He published a book, intitled *Curiositez Innouies*, i. e. Unheard of Curiosities. It is said the cardinal designed to employ him in his grand project for the re-union of religions. He died in 1681, aged 80. He had been labouring for many years, and had almost finished a history of the subterranean world; containing on account of the caves, grottoes, vaults, catacombs, and mines, he had met with in 30 years travels.

GAGATES, or JET. See JET.

GAGE, in ancient customs, signifies a pledge

or pawn, given by way of security. The word is only properly used in speaking of moveables; for immoveables, *hypotheca* is used.

If the gage perith, the person who received it is not to answer for it, but only for extreme negligence, &c.

GAGE is also used for a challenge to combat: See CARTEL. In which sense, it was a pledge, which the accuser or challenger cast on the ground, and the other took up as accepting the challenge: it was usually a glove, gauntlet, chaperoon, or the like. See COMBAT, and DUEL.

GAGE is only now retained as a substantive. As a verb, the *G* is changed into *W*, and of *gage* is formed *wage*: as, to wage law, to wage deliverance, *q. d.* to give security a thing shall be delivered. See WAGE.

If a person who has distrained be sued for not having delivered what he had taken by distress, he should wage, or gage, or gager, deliverance; that is, put in surety that he will deliver them.

Mort-GAGE, is that which is left in the hands of the proprietor, so that he reaps the fruits thereof.

In opposition to *vif-gage*, where the fruits or revenues are reaped by the creditor, and reckoned on the foot of the debt, which diminishes in proportion thereto. The second acquits or discharges itself; the first does not.

GAGE, in the sea-language. When one ship is to windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's gage; this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under water is the ship's gage.

GAGE, among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. See FOUNDERY.

GAGE, in joinery, is an instrument made to strike a line truly parallel to the strait side of any board or piece of stuff. Its chief use is for gaging of tenons true, to fit into mortises; and for gaging stuff of an equal thickness. It is made of an oval piece of wood, fitted upon a square stick, to slide up and down stiffly thereon; and with a tooth at the end of a staff, to score, to strike a line upon the stuff at any distance, according to the distance of the oval from it.

Sliding GAGE, a tool used by mathematical instrument-makers for measuring and setting off distances.

Sea-GAGE, an instrument invented by Dr Hales and Dr Desaguliers for finding the depth of the sea; the description whereof is this, AB (Plate CCV. fig. 1. n° 1.) is the gage-bottle, in which is cemented the gage-tube *Ff* in the brass cape at G. The upper end of tube *F* is hermetically sealed, and the open lower end *f* is immersed in mercury, marked C, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass HG, pierced with several holes to admit the water into the bottle AB. The body K is a weight hanging by its shank L, in a socket N, with a notch on one side at *m*, in which is fixed the catch *l* of the spring S, and passing

Gage.

Gage. passing through the hole L, in the shank of the weight K, prevents its falling out when once hung on. On the top, in the upper part of the brass tube at H, is fixed a large empty ball, or full blown bladder I, which must not be so large, but that the weight K may be able to sink the whole under water.

The instrument thus constructed is used in the following manner. The weight K being hung on, the gage is let fall into deep water, and sinks to the bottom; the socket N is somewhat longer than the shank L; and therefore, after the weight K comes to the bottom, the gage will continue to descend till the lower part of the socket strikes against the weight: this gives liberty to the catch to fly out of the hole L, and let go the weight K: when this is done, the ball or bladder I instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube Ff, and the height to which it had been forced by the greatest pressure, viz. that at the bottom, will be shown by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shows into what space the whole air in the tube Ff is compressed; and consequently the height or depth of the water which by its weight produced that compression, which is the thing required.

If the gage-tube Ff be of glass, a scale might be drawn on it with the point of a diamond, showing, by inspection, what height the water stands above the bottom. But the length of 10 inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is no more than 634 feet, which is not half a quarter of a mile.

If to remedy this we make use of a tube 50 inches long, which for strength may be a musket-barrel, and suppose the air compressed into an hundredth part of half an inch; then by saying, as 1 : 99 :: 400 : 35600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface; therefore to explore such great depths, the doctor contrived a new form for his sea-gage, or rather for the gage-tube in it, as follows. BCDF (*ibid.* n^o 2.) is a hollow metalline globe communicating on the top with a long tube AB, whose capacity is a ninth part of that globe. On the lower part at D, it has also a short tube DE, to stand in the mercury and treacle. The air contained in the compound gage-tube is compressed by the water as before; but the degree of compression, or height to which the treacle has been forced, cannot there be seen through the tube; therefore, to answer that end, a slender rod of metal or wood, with a knob on the top of the tube AB, will receive the mark of the treacle, and show it when taken out.

If the tube AB be 50 inches long, and of such a bore that every inch in length should be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then, when the air is compressed within an hundredth part of the whole, it is

evident the treacle will not approach nearer than five inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, viz. 2 $\frac{1}{2}$ inches, which correspond to 6600, which is a mile and a quarter. Again, half that space, or 1 $\frac{1}{2}$ inch, will show double the former depth, viz. 1300 feet, or 2 $\frac{1}{2}$ miles; which is probably very nearly the greatest depth of the sea.

Bucket Sea-GAGE; an instrument contrived by Dr Hales, to find the different degrees of coolness and saltness of the sea, at different depths; it consists of a common household pail or bucket, with two heads. These heads have each a round hole in the middle, about four inches in diameter, covered with square valves opening upward; and that they may both open and shut together, there is a small iron rod fixed to the upper part of the lower valve, and the other end to the lower side of the upper valve. So that as the bucket descends with its sinking weight into the sea, both the valves may open by the force of the water, which by that means has a free passage through the bucket. But when the bucket is drawn up, then both the valves shut by the force of the water at the upper part of the bucket; so that the bucket is drawn up full of the lowest sea water to which it has descended. When the bucket is drawn up, the mercurial thermometer fixed in it is examined; but great care must be taken to observe the degree at which the mercury stands, before the lower part of the thermometer is taken out of the water in the bucket, lest it be affected by the different temperature of the air. In order to keep the bucket in a right position, there are four cords fixed to it, reaching about three feet below it; to which the sinking weight is fixed. The result of several trials with this gage was, that when it was let down to different depths, from 360 feet to 5346 feet, in lat. 25. 13. N. and long. 25. 12. W. it was discovered by the thermometer, that the cold increased gradually in proportion to the depths, till it descended to 3900 feet, viz. near $\frac{3}{4}$ ths of a mile, whence the mercury in the thermometer came up at 53 $^{\circ}$; and though it was afterwards sunk to 5346 feet, *i. e.* a mile and 66 feet, it came up no lower: the warmth of the water upon the surface, and that of the air, was all that time 84 $^{\circ}$. When the water in the bucket was become of the same temperature with that on the surface of the sea, equal quantities of both were weighed and tried by the hydrometer; that from below was found to be the heaviest, and consequently the saltest.

Dr Hales was probably led to the construction of this sea-gage from an instrument invented by Dr Hook, and designed for the same purpose. This consists of a square wooden bucket C, whose bottoms are so contrived; that as the weight A sinks the iron B, to which the bucket C is fastened by two handles D, D, on the end of which are the moveable bottoms or valves E E, and thereby draws down the bucket, the resistance of the water keeps up the bucket in the posture C, whereby the water, whilst the bucket is descending, hath a free passage through it; whereas, as soon as the bucket is pulled upwards by the line F, the resistance of the water to that motion beats the bucket downwards, and keeps it in the posture G, whereby the in-

Gage.

Gage. cluded water is kept from getting out, and the ambient water kept from getting in. Phil. Trans. N^o 9. p. 149. and N^o 24. p. 447. or abr. vol. ii. p. 260.

Aqueo-mercurial GAGE, is the name of an apparatus contrived by Dr Hales, and applied in various forms to the branches of trees, in order to determine the force with which they imbibe moisture. Let *e r*, be a cylindric glass, *e. gr.* of an inch diameter within, and eight inches long. Into this glass is introduced the branch of a young thriving apple-tree *b*, about three feet long, with lateral branches; the diameter of the transverse cut *i* being $\frac{3}{4}$ of an inch. Having fitted the joint *r* to the tube at *r*, by folding a piece of sheep's skin round the stem, it is cemented with a mixture of bees-wax and turpentine melted together, in such a proportion as to make a very stiff clammy paste when cold, and over the cement folds of wet bladders are bound firmly with pack-thread. To the lower end *e* of the large tube, a smaller tube *z e* is cemented, being about $\frac{1}{2}$ of an inch diameter, and 18 inches long, and in substance full $\frac{1}{2}$ of an inch thick. These tubes are cemented together at *e* with common hard brick-dust or powdered chalk cement, and the joint is farther secured with the cement of bees-wax and turpentine, over which a wet bladder is bound. The apparatus being thus prepared, the branch is turned downwards, and the glass tube upwards, and then both tubes are filled with water; with the finger applied to the open end of the small tube, it is inverted and immersed in the glass cistern *x*, full of mercury and water. In this situation the lower end of the branch was immersed six inches in water, viz. from *r* to *i*; the water was imbibed by the branch at its transverse cut *i*; and during its ascent into the sap-vessels of the branch, the mercury rose in the tube *e z* from the cistern *x*, so that in half an hour it was risen $5\frac{3}{4}$ inches high, as far as *z*. The height of the mercury indicated, in some measure, the force with which the sap was imbibed, though not the whole force; because, while the water was imbibed by the branch, its transverse cut was covered with innumerable little hemispheres of air, and many air-bubbles issued out of the sap-vessels, which partly filled the tube *e r*, as the water was drawn out of it: and therefore, the height of the mercury could only be proportionable to the excess of the quantity of water drawn off above the quantity of the air which issued out of the wood. If the quantity of air issuing from the wood had been equal to the quantity of water imbibed, it is plain that the mercury could not rise at all, because there would be no room for it in the tube: but if nine parts in twelve of the water be imbibed by the branch, and only three such parts of air issue into the tube in the same time, the mercury must rise near six inches, and so proportionably in other cases. Dr Hales observed, that the mercury rose highest, in most cases, when the sun was clear and warm, and that it subsided three or four inches towards evening, but rose again the next day as it grew warm, though seldom so high as at first. Dr Hales adapted the size and shape of the glass apparatus to a great variety of branches of several sizes and of different kinds of trees, and repeated the experiment above described, *mutatis mutandis*, in a variety of instances. See his Vegetable Statics, vol. i. chap. ii. p. 84, &c.

VOL. VII.

Tide-GAGE, is the name of an instrument used for determining the height of the tides by Mr Bayly, in the course of a voyage towards the south-pole, &c. in the Resolution and Adventure, in 1772, 1773, 1774, and 1775. This instrument consists of a glass tube, whose internal diameter was seven-tenths of an inch, lashed fast to a ten feet fir rod; divided into feet, inches, and quarters: this rod was fastened to a strong post fixed upright and firm in the water. At the lower end of the tube was an exceeding small aperture, through which the water was admitted. In consequence of this construction, the surface of the water in the tube was so little affected by the agitation of the sea, that its height was not altered one-tenth of an inch; when the swell of the sea was two feet; and Mr Bayly was certain, that with this instrument he could discern a difference of one-tenth of an inch in the height of the tide.

Wind-GAGE, an instrument for measuring the force of the wind upon any given surface. It was invented by Dr Linn, who gives the following description of it, Phil. Trans. Vol. LXV.

This instrument consists of two glass tubes AB, CD, of five or six inches in length. Their bores, which are so much the better for being equal, are about four-tenths of an inch in diameter. They are connected together like a siphon, by a small bent glass-tube *a b*, the bore of which is about one-tenth of an inch in diameter. On the upper end of the leg AB there is a tube of latten brass, which is kneed or bent perpendicularly outwards, and has its mouth open towards F. On the other leg CD, is a cover with a round hole G in the upper part of it, two-tenths of an inch in diameter. This cover and the kneed tube are connected together by a slip of brass *ed*, which not only gives strength to the whole instrument, but also serves to hold the scale HI. The kneed tube and cover, are fixed on with hard cement or sealing wax. To the same tube is soldered a piece of brass *e*, with a round hole in it to receive the steel spindle KL; and at *f* there is just such another piece of brass soldered to the brass-hoop *gh*, which surrounds both legs of the instrument. There is a small shoulder on the spindle at *f*, upon which the instrument rests, and a small nut at *i*, to prevent it from being blown off the spindle by the wind. The whole instrument is easily turned round upon the spindle by the wind, so as always to present the mouth of the kneed tube towards it. The end of the spindle has a screw on it; by which it may be screwed into the top of a post or a stand made on purpose. It has also a hole at L, to admit a small lever for screwing it into wood with more readiness and facility. A thin plate of brass *k* is soldered to the kneed tube, about half an inch above the round hole G, so as to prevent rain from falling into it. There is likewise a crooked tube AB (fig. 5.) to be put occasionally upon the mouth of the kneed tube F, in order to prevent rain from being blown into the mouth of the wind-gage when it is left out all night, or exposed in the time of rain.

The force or momentum of the wind may be ascertained by the assistance of this instrument, by filling the tubes half full of water, and pushing the scale a little up or down, till the o of the scale, when the instrument is held up perpendicularly, be on a line with

3 U

the

Gage.

Fig. 4.

Gage.

the surface of the water in both legs of the wind-gage. The instrument being thus adjusted, hold it up perpendicularly, and turning the mouth of the kneed tube towards the wind, observe how much the water is depressed by it in the one leg, and raised in the other. The sum of the two is the height of a column of water, which the wind is capable of sustaining at that time; and every body that is opposed to that wind will be pressed upon by a force equal to the weight of a column of water, having its base equal to the altitude of the column of water sustained by the wind in the wind-gage. Hence the force of the wind upon any body where the surface opposed to it is known, may be easily found; and a ready comparison may be made betwixt the strength of one gale of wind and that of another.

The force of the wind may be likewise measured with this instrument, by filling it until the water runs out at the hole G. For if we then hold it up to the wind as before, a quantity of water will be blown out; and if both legs of the instrument are of the same bore, the height of the column sustained will be equal to double the column of water in either leg, or the sum of what is wanting in both legs. But if the legs are of unequal bores, neither of these will give the true height of the column of water which the wind sustained. But the true height may be obtained by the following formulæ.

Suppose that after a gale of wind which had blown the water from A to B (fig. 6.), forcing it at the same time through the other tube out at E, the surface of the water should be found standing at some level D G, and it were required to know what was the height of the column E F or A B, which the wind sustained. In order to obtain this, it is only necessary to find the height of the columns D B or G F, which are constantly equal to one another; for either of these added to one of the equal columns A D, E G, will give the true height of the column of water which the wind sustained.

1. Let the diameters A C, E H, of the tubes, be respectively represented by cd ; and let $a=AD$, or EG , and $x=DB$, or GF : Then it is evident that the column D B is to the column E G, as c^2x to d^2a . But these columns are equal. Therefore $c^2x=d^2a$; and consequently $x=\frac{d^2a}{c^2}$.

2. But if at any instant of time whilst the wind was blowing, it was observed, that, when the water stood at E, the top of the tube out of which it is forced, it was depressed in the other to some given level B F, the altitude at which it would have stood in each had it immediately subsided, may be found in the following manner.—Let $b=AB$ or EF .—Then it is evident that the column D B is equal to the difference of columns E F, G F. But the difference of these columns is as d^2b-d^2x ; and consequently $x=\frac{d^2b}{c^2+d^2}$.

For the cases when the wind blows in at the narrow leg of the instrument; Let $AB=EF=b$, EG , or $AD=a$, $GF=DB=x$, and the diameters E H, G A, respectively $=d, c$, as before. Then it is evident, that the column A D is to the column G F as ac^2 to d^2x . But these columns are equal; therefore $d^2x=ac^2$;

and consequently $x=\frac{ac^2}{d^2}$. It is also evident, that the column A D is equal to the difference of the columns AB, D B; but the difference of these columns is as bc^2-c^2x . Therefore $d^2x=bc^2-c^2x$. Whence we get $x=\frac{bc^2}{d^2+c^2}$.

The use of the small tube of communication ab (fig. 4.), is to check the undulation of the water, so that the height of it may be read off from the scale with ease and certainty. But it is particularly designed to prevent the water from being thrown up to a much greater or less altitude, than the true height of the column which the wind is able at that time to sustain, from its receiving a sudden impulse whilst it is vibrating either in its ascent or descent. As in some cases the water in this instrument might be liable to freeze, and thus break the tubes, Dr Lind recommends a saturated solution of sea-salt to be used instead of it, which does not freeze till Fahrenheit's thermometer falls to 0.

GAHNIA, in botany: A genus of the monogynia order, belonging to the hexandria class of plants. The calyx is an involucre with two or five flowers; the corolla is two-valved; the stamina six capillary and very short filaments; the antheræ linear, sharp-pointed at the apex, and as long as the corolla; there is no pericarpium: the seed is single and oblong.

GAIETA, an ancient, handsome, and strong town of Italy, in the kingdom of Naples, and in the Terra di Lavoro, with a fort, citadel, harbour, and bishop's see. It was taken by the Austrians in 1707, and by the Spaniards in 1734. It is seated at the foot of a mountain near the sea, in E. Long. 13. 37. N. Lat. 41. 30.

GAIN, the profit or lucre a person reaps from his trade, employment, or industry. Some derive the word from the German *gewin*: whereof the Italians had made *guadagno*; the French and English *gain*.

There are legal and reputable gains, as well as fordid and infamous ones. What is gained beyond a certain sum, by gaming, is all liable to be restored again, if the loser will take the benefit of the law.

GAIN, in architecture, is the workmens term for the bevelling shoulder of a joist or other timber. It is used, also, for the lapping of the end of the joist, &c. upon a trimmer or girder; and then the thickness of the shoulder is cut into the trimmer, also bevelling upwards, that it may just receive the gain; and so the joist and trimmer lie even and level with the surface. This way of working is used in floors and hearths.

To GAIN the wind, in sea-language, is to arrive on the weather-side or to windward, of some other vessel in sight, when both are plying to windward, or sailing as near the wind as possible.

GAINAGE, GAINAGIUM, in ancient writers, signifies the draught-oxen, horses, wain, plough, and furniture, for carrying on the work of tillage by the baser sort of sokemen and villains.

Gainage is the same with what is otherwise called *wainage*. Bracton, lib. i. cap. 9. speaking of lords and servants, says, *Ut si eos destruunt, quod saluum non possit eis esse wainagium suum*. And again, lib. iii. tract. 2. cap.

Gage
||
Gainage.

Gainage || Galanthus. cap. I. *Villanus non amercabitur, nisi salvo wainagio suo.* For anciently, as it appears both by Magna Charta and other books, the villain, when amerced, had his gainage or wainage free; to the end his plough might not stand still: and the law, for the same reason, does still allow a like privilege to the husbandman; that is, his draught-horses are not in many cases distrainable.

GAINAGE is also used for the land itself, or the profit raised by cultivating it.

GAINSBOROUGH, a town of Lincolnshire in England 150 miles from London, seated on the river Trent near the sea. It is a large well built town, with a pretty good trade, and has the title of an earldom. W. Long. 0 40. N. Lat. 53. 26. The north marsh in its neighbourhood is noted for horse-races. The Danes who invaded the kingdom brought their ships up to this place. It was here that Sweno the Dane was murdered by one of the English, who was never discovered.

GALACTITES, in the history of fossils, a substance much resembling the morochthus or French chalk, in many respects; but different from it in colour. The ancients found it in the Nile and in some rivers in Greece, and used it in medicine as an astringent, and for defluxions and ulcers of the eyes. At present it is common in Germany, Italy, and some parts of France, and is wholly overlooked, being esteemed a worse kind of morochthus. See MOROCHTHUS.

GALACTOPHAGI, and ΓΑΛΑΚΤΟΠΟΤΕ in antiquity, persons who lived wholly on milk, without corn or the use of any other food. The words are compounded of γαλα, γαλακτο, milk; θασειν, to eat and ποτις of πιω, I drink.

Certain nations in Scythia Asiatica, as the Getæ, Nomades, &c. are famous, in ancient history, in quality of *galactophagi*, or milk-eaters. Homer makes their elege, Iliad, lib.iii.

Ptolemy, in his geography, places the Galactophagi between the Riphæan mountains on one side, and the Hircanian sea on the other.

GALANGALS, in the materia medica. See KÆMPFERIA.

GALANTHUS, the SNOW-DROP, in botany: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the ninth order, *Spathaceæ*. There are three concave petals, and the nectarium consists of three small emarginated petals; the stigma is simple. There is but one species, viz. the *nivalis*; which is a bulbous-rooted flowery perennial, rising but a few inches in height, and adorned at top with small tripetalous flowers of a white colour. There are three varieties, viz. the common singled-flowered snow-drop, the semi-double snow-drop, and the double snow-drop. They are beautiful little plants; and are much valued on account of their early appearance, often adorning the gardens in January or February, when scarce any other flower is to be seen. They frequently burst forth when the ground is covered with snow, and continue very often till the beginning of march, making a very ornamental appearance, especially when disposed in clusters towards the fronts of the borders, &c. The single kind comes first into bloom, then the semi-double, and after

that the double. They will succeed any where, and multiply exceedingly by off-sets from the roots.

GALATA, a great suburb belonging to Constantinople, opposite to the seraglio, on the other side of the harbour. It is here the Greeks, Armenians, Franks, Christians, and Jews inhabit, and are allowed the exercise of their respective worships.

GALATÆA and GALATHÆA, (fab. hist.), a sea-nymph, daughter of Nereus and Doris. She was passionately loved by the Cyclops Polyphemus, whom she treated with coldness and disdain; while Acis, a shepherd of Sicily enjoyed her unbounded affection. The happiness of these two lovers was disturbed by the jealousy of the Cyclops, who crushed his rival to pieces with a piece of a broken rock while he reposed on the bosom of Galatæa. The nymph was inconsolable for the loss of Acis; and as she could not restore him to life, she changed him into a fountain.

GALATIA, the ancient name of a province of Asia Minor, now called *Amasia*. It was bounded on the east by Cappadocia, on the west by Bithynia, on the south by Pamphylia, and on the north by the Euxine sea. It was the north part of Phrygia Magna; but upon being occupied by the Gauls was called *Galatia*; and because situated amidst Greek colonies, and itself mixed with Greeks, *Gallogræcia*. Strabo calls it *Galatia*, and *Gallogræcia*: hence a two-fold name of the people; *Galatæ* and *Gallogræci*. The Greeks called it *Gallia Parva*; to distinguish it from the *Transalpina*, both which they called *Galatia*. It was reduced under the subjection of the Romans in the time of Augustus, and is now in the hands of the Turks. Here St Paul founded a church, to which he directed that epistle which is still known by the name of the *Epistle to the Galatians*, and was written to reclaim them from the observation of Jewish ordinances, into which they had been seduced by some false teachers.

GALAX, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is salver-shaped; the calyx decaphyllous; the capsule unilocular, bivalved, and elastic.

GALAXY, in astronomy, that long, white, luminous track, which seems to encompass the heavens like a swath, scarf, or girdle: and which is easily perceivable in a clear night, especially when the moon does not appear. The Greeks call it Γαλαξίας, *Galaxy*, of γαλα, γαλακτο, *Milk*; on account of its colour and appearance: the Latins, for the same reasons, call it *via lactea*; and we, the *milky-way*. It passes between Sagittarius and Gemini, and divides the sphere into two parts; it is unequally broad; and in some parts is single; in others double.

The ancient poets, and even philosophers, speak of the Galaxy, as the road or way by which the heroes went to heaven.

Aristotle makes it a kind of meteor, formed of a crowd of vapours, drawn into that part by certain large stars disposed in the region of the heavens answering hereto.

Others, finding that the Galaxy was seen all over the globe, that it always corresponded to the same fixed stars, and that it transcended the height of the highest planets, set aside Aristotle's opinion, and placed

Galata

|| Galaxy.

Galba
||
Gale.

the Galaxy in the firmament, or region of the fixed stars, and concluded it to be nothing but an assemblage of an infinite number of minute stars.

Since the invention of the telescope, this opinion has been abundantly confirmed. By directing a good telescope to any part of the milky-way; where, before, we only saw a confused whiteness, we now descry an innumerable multitude of little stars, so remote, that a naked eye confounds them. See ASTRONOMY, n^o 119.

GALBA (Servius Sulpicius), a Roman emperor, born the 24th of December, five years before the Christian era. He was gradually raised to the greatest offices of the state, and exercised his power in the provinces with the greatest equity and unremitting diligence. He dedicated the greatest part of his time to solitary pursuits, chiefly to avoid the suspicions of Nero. His disapprobation of the emperor's oppressive command in the provinces was the cause of new disturbances. Nero ordered him to be put to death; but he escaped from the hands of the executioner, and was publicly saluted emperor. When he was seated on the throne, he suffered himself to be governed by favourites, who exposed the goods of the citizens to sale to gratify their avarice. Exemptions were sold at a high price; and the crime of murder was blotted out, and impunity purchased with a large sum of money. Such irregularities in the emperor's ministers greatly displeased the people; and when Galba refused to pay the soldiers the money which he had promised them when he was raised to the throne, they assassinated him in 73d year of his age, and the eighth month of his reign. The virtues which had shone so bright in Galba when a private man, totally disappeared when he ascended the throne; and he who showed himself the most impartial judge, forgot the duties of an emperor and of a father of his people.

GALBANUM, in pharmacy, a gum issuing from the stem of an umbelliferous plant growing in Persia and many parts of Africa. See BUBON.

The juice, as brought to us, is semipellucid, soft, tenacious; of a strong, and to some unpleasant, smell; and a bitterish warm taste: the better sort is in pale coloured masses, which, on being opened, appear composed of clear white tears. Geoffroy relates, that a dark greenish oil is to be obtained from this simple by distillation, which, upon repeated rectifications, becomes of an elegant sky blue colour. The purer sorts of galbanum are said by some to dissolve entirely in wine, vinegar, or water; but these liquors are only partial menstrua with regard to this drug; nor do spirit of wine or oils prove more effectual in this respect: the best dissolvent is a mixture of two parts spirit of wine and one of water. Galbanum agrees in virtue with gum ammoniacum; but is generally accounted less efficacious in asthmas, and more so in hysterical complaints. It is an ingredient in the gum pills, the gum plaster, and some other officinal compositions.

GALE, in the sea-language, a term of various import. When the wind blows not so hard but that a ship may carry her top-sails a-trip (that is, hoisted up to the highest), then they say it is a loom-gale. When it blows very strong, they say it is a stiff, strong, or fresh gale. When two ships are near one another at sea, and, there being but little wind blowing, one of

them finds more of it than the other, they say that the one ship gales away from the other:

GALE (Dr John), an eminent and learned minister among the Baptists, was born at London in 1680. He studied at Leyden, where he distinguished himself very early, and afterwards at Amsterdam, under Dr Limborch. He was chosen minister of the Baptist congregation at Barbican; where his preaching, being chiefly practical, was greatly resorted to by people of all persuasions. Four volumes of his sermons were published after his death, which happened in 1721. His *Reflections on Dr Wall's History of Infant-baptism*, is the best defence of the Baptists ever published, and the reading of that performance induced the learned Mr William Whiston and Dr Foster to become baptists.

GALE (Theophilus), an eminent nonconformist minister, born in 1628. He was invited to Winchester in 1657; and continued there a stated preacher until the re-establishment of the church by Charles II. when he rather chose to suffer the penalties of the act of conformity, than to submit to it contrary to his conscience. He was afterwards engaged by Philip lord Wharton as tutor to his sons, whom he attended to an academy at Caen in Normandy; and when this duty was fulfilled, he became pastor over a congregation of private conventiclers in Holborn. He died in 1678; and is principally known by an elaborate work, intitled, the *Court of the Gentiles*, calculated to show, that the Pagan philosophers derived their most sublime sentiments from the Scriptures.

GALE (Dr Thomas), a learned divine, born at Scruton in Yorkshire, in the year 1636, was educated at Cambridge, and at length became professor of the Greek language in that university. He was afterwards chosen head master of St Paul's school, London; and was employed by the city in writing those elegant inscriptions on the monument erected in memory of the conflagration in 1666. In 1676 he was collated to a prebend in the cathedral of St Paul's; and was likewise elected a fellow of the Royal Society, to which he presented a Roman urn with its ashes. About the year 1697, he gave to the new library of Trinity college, in Cambridge, a great number of Arabic manuscripts; and in 1697 was admitted dean of York. He died in that city in 1702; and was interred in the cathedral, where a monument, with a Latin inscription, was erected to his memory. He was a learned divine, a great historian, one of the best Greek scholars of his age, and maintained a correspondence with the most learned men abroad as well as at home. He published, 1. *Historia Poetica Antiqui Scriptores*, octavo. 2. *Opuscula Mythologica, Ethica, & Physica*, in Greek and Latin octavo. 3. *Herodoti Historia*, folio. 4. *Historia Anglicana Scriptores quinque*, in folio. 5. *Historia Britannica, Saxonica, Anglo-Danica. Scriptores quindecim*, in folio. 6. *Rhetores Selecti*, &c.

GALEA, in antiquity, a light casque, head-piece, or morrion, coming down to the shoulders, and commonly of brass; though Camillus, according to Plutarch, ordered those of his army to be of iron, as being the stronger metal. The lower part of it was called *buccula*, and on the top was a crest. The Velites wore a light galea, made of the skin of some wild beast to make it more terrible.

GALEASSE, a large low-built vessel, using both sails

Galega,
Galen.

sails and oars, and the biggest of all the vessels that make use of the latter. It may carry twenty guns, and has a stern capable of lodging a great number of marines. It has three masts, which are never to be lowered or taken down. It has also thirty-two benches of rowers; and to each bench six or seven slaves, who sit under cover. This vessel is at present used only by the Venetians.

GALEGA, in botany: A genus of the decandria order, belonging to the diadelphica class of plants; and in the natural method ranking under the 32d order, *Fapilionaceæ*. The calyx is composed of subulated nearly equal dents or segments; the legumen has oblique striæ, and seeds lying between them.

GALEN (Claudius), in Latin *Galenus*, prince of the Greek physicians after Hippocrates, was born at Pergamus in the Lesser Asia, about the year 131. His father was possessed of a considerable fortune; was well versed in polite literature, philosophy, astronomy, and geometry, and was also well skilled in architecture. He himself instructed his son in the first rudiments of learning, and afterwards procured him the greatest masters of the age in philosophy and eloquence. Galen having finished his studies under their care, chose physic for his profession, and chiefly studied the works of Hippocrates. Having at length exhausted all the sources of literature that were to be found at home, he resolved to travel, in order to converse with the most able physicians in all parts, intending at the same time to take every opportunity of inspecting on the spot the plants and drugs of the countries through which he passed. With this view he went to Alexandria, and staid some years in that metropolis of Egypt: from thence he travelled through Cilicia; passed through Palestine; visited the isles of Crete and Cyprus; and made two voyages to Lemnos, in order to examine the Lemnian earth, which was then esteemed an admirable medicine. With the same view he went into the Lower Tyria, in order to obtain a thorough insight into the nature of the opobalsamum, or balm of Gilead; and having completed his design, returned home by the way of Alexandria.

Galen had been four years at Pergamus, where his practice was attended with extraordinary applause, when some seditious commotions induced him to go to Rome, where he resolved to settle: but the proofs he gave of his superior skill, added to the respect shown him by several persons of very high rank, created him so many enemies among his brethren of the faculty, that he was obliged to quit the city, after having resided there four or five years. But he had not long returned to Pergamos, when he was recalled by the emperors Aurelius and Verus. After their death, he retired to his native country; where he died, about the year 200. He wrote in Greek; and is said to have composed two hundred volumes, which were unhappily burnt in the temple of Peace. The best editions of those that remain, are, that printed at Basil in 1538, in five volumes, and that of Venice in 1625, in seven volumes. Galen was of a weak and delicate constitution, as he himself asserts: but he nevertheless, by his temperance and skill in physic, arrived to a great age; for it was his maxim, always to rise from table with some degree of appetite. He is justly considered as the greatest physician of antiquity, next to Hippo-

crates; and he performed such surprising cures, that he was accused of magic.

GALEN, a name given by mineralists to a species of poor lead-ore. It was also the original name given by Andromachus to the theriaca, from its effect in bringing on a pleasing calm over the blood and spirits on taking it.

GALENIA, in botany: A genus of the digynia order, belonging to the octandria class of plants; and in the natural method ranking under the 13th order, *Succulentæ*. The calyx is trifid; there is no corolla; the capsule is roundish and dispermous.

GALENIC, or GALENICAL, in medicine, is that manner of considering and treating diseases, founded on the principles of Galen, or introduced by GALEN. This author, collecting and digesting what the physicians before him had done, and explaining every thing according to the strictest doctrine of the Peripatetics, set physic on a new footing: he introduced the doctrine of the four elements; the cardinal qualities and their degrees; and the four humours or temperaments.

GALENIC is more frequently used as contradistinguished from *chemical*.

The distinction of *galenical* and *chemical* was occasioned by a division of the practitioners of medicine into two sects, which happened on the introduction of chemistry into medicine. Then the chemists, arrogating to themselves every kind of merit and ability, stirred up an opposition to their pretensions, founded on the invariable adherence of the other party to the ancient practice. And though this division into the two sects of galenists and chemists has long ceased, yet the distinction of medicines which resulted from it is still retained.

Galenical medicines are those which are formed by the easier preparations of herbs, roots, &c. by infusion, decoction, &c. and by combining and multiplying ingredients; while those of chemistry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, digestion, fermentation, &c.

GALENISTS, a denomination given to such physicians as practise, prescribe, or write, on the galenical principles; and stand opposed to the *chemists*. See GALENICAL. At present the galenists and chemists are pretty well accommodated; and most of our physicians use the preparations and remedies of both.

GALENISTS, or *Galenites*, in church-history, a branch of Mennonites or Anabaptists, who take in several of the opinions of the Socinians, or rather Ariens, touching the divinity of our Saviour. In 1664 the Waterlandians were divided into two parties, of which the one were called *Galenists*, and the other *Apostolians*. They are thus called from their leader Abr. Galenus, a learned and eloquent physician of Amsterdam, who considered the Christian religion as a system that laid much less stress on faith than practice; and who was for taking into the communion of the Mennonites all those who acknowledged the divine origin of the books of the Old and New Testament, and led holy and virtuous lives.

GALEON. See GALLEON.

GALEOPSIS, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the

Galea
||
Galeopsis.

Galericulum 42d order, *verticillata*. The upper lip of the corolla is a little crenated or arched; the under lip more than bidentate.

Galileo.

GALERICULUM, was a cap worn both by men and women amongst the ancient Romans. It consisted of skin, which was so neatly dressed with human hair, that the artificial covering could scarcely be distinguished from the natural. It was used by those whose hair was thin; and by wrestlers, to keep their own hair from receiving any injury from the nasty oils with which they were rubbed all over before they exercised. It seems to have resembled our wigs.

GALIC, or *GAELIC*, Language. See **HIGHLANDS**.

GALICIA, a province of Spain, bounded on the north and west by the ocean, on the south by Portugal, and on the east by Asturias and the kingdom of Leon. The air is temperate along the coast; but, in other places, it is cold and moist. It is but thin of people; and the produce is wine, flax, and citrons: here also are good pastures, copper, and lead, and the forests yield wood for building of ships. St Jago di Compostella is the capital town.

GALILEE, once a province of Judea, now of Turkey in Asia, was bounded by mount Lebanon on the north, by the river Jordan and the sea of Galilee on the east, by the Chifon on the south, and by the Mediterranean on the west. It was the scene of many of our Saviour's miracles; but the bounds of the country are not now well known, nor yet the places where many of the towns stood.

GALILEANS, a sect of the Jews. Their founder was one Judas a native of Galilee, from which place they derived their name. Their chief, esteeming it an indignity for the Jews to pay tribute to strangers, raised up his countrymen against the edict of the emperor Augustus, which had ordered a taxation or enrolment of all the subjects of the Roman empire.

They pretended that God alone should be owned as Master and Lord, and in other respects were of the opinion of the Pharisees; but, as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

As our Saviour and his apostles were of Galilee, they were suspected to be of the sect of Galileans; and it was on this principle, as St Jerome observes, that the Pharisees laid a snare for him; asking, Whether it was lawful to give tribute to Cæsar; that in case he denied it, they might have an occasion of accusing him.

GALILEO (Galilei), the famous mathematician and astronomer, was the son of a Florentine nobleman, and born in the year 1564. He had from his infancy a strong inclination to philosophy and the mathematics; and made prodigious progress in these sciences. In 1592, he was chosen professor of mathematics at Padua; and during his abode there he *invented*, it is said, the telescope; or, according to others, improved that instrument, so as to make it fit for astronomical observations: (See **ASTRONOMY**, p. 423, col. I.) In 1611, Cosmo II. grand duke of Tuscany sent for him to Pisa, where he made him professor of mathematics, with a handsome salary; and soon after inviting him to Florence, gave him the office and title of *principal philosopher and mathematician to his highness*,

He had been but a few years at Florence, before he was convinced by sad experience, that Aristotle's doctrine, however ill-grounded, was held too sacred to be called in question. Having observed some solar spots in 1612, he printed that discovery the following year at Rome; in which, and in some other pieces, he ventured to assert the truth of the Copernican system, and brought several new arguments to confirm it. For these he was cited before the inquisition; and, after some months imprisonment, was released upon a simple promise, that he would renounce his heretical opinions, and not defend them by word or writing. But having afterwards, in 1632, published at Florence his "Dialogues of the two greatest systems of the world, the Ptolemaic and Copernican," he was again cited before the inquisition, and committed to the prison of that ecclesiastical court at Rome. In June, 32d N. S. that year, the congregation convened; and in his presence pronounced sentence against him and his books, obliging him to abjure his errors in the most solemn manner; committed him to the prison of their office during pleasure; and enjoined him, as a saving penance, for three years to come, to repeat once a-week the seven penitential psalms: reserving to themselves, however, the power of moderating, changing, or taking away altogether or in part, the abovementioned punishment and penance. On this sentence, he was detained a prisoner till 1634; and his "Dialogues of the system of the World" were burnt at Rome.

He lived ten years after this, seven of which were employed in making still further discoveries with his telescope. But by the continual application to that instrument, added to the damage he received in his sight from the nocturnal air, his eyes grew gradually weaker, till he became totally blind in 1639. He bore this calamity with patience and resignation, worthy of a great philosopher. The loss neither broke his spirit, nor hindered the course of his studies. He supplied the defect by constant meditation; whereby he prepared a large quantity of materials, and began to dictate his own conceptions; when, by a distemper of three months continuance, wasting away by degrees, he expired at Arcetti near Florence, in January 1642, N. S. in the 78th year of his age.

Among various useful inventions of which Galileo was the author, is that of the simple pendulum, which he had made use of in his astronomical experiments. He had thoughts of applying it to clocks; but did not execute it: the glory of that invention was reserved for Vincenzo his son, who made the experiment at Venice in 1649; and M. Huygens afterwards carried this invention to perfection. He wrote a great number of treatises, several of which were published in a collection by Signor Mendessi, under the title of *L'opera di Galileo Galilei Linceo*. Some of these, with others of his pieces, were translated into English and published by Thomas Salisbury, Esq; in his mathematical collections, &c. in two volumes folio. A volume also of his letters to several learned men, and solutions of several problems, were printed at Bologna in quarto. Besides these, he wrote many others, which were unfortunately lost through his wife's devotion; who, solicited by her confessor, gave him leave to peruse her husband's manuscripts; of which he tore and took away as many as he said were not fit to be published.

GALINACEUS

Galileo.

Galina-
ceus
||
Gall.

GALINACEUS LAVIS. See GALLINACEUS.

GALIUM, in botany: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 47th order, *Stellatae*. The corolla is monopetalous and plain; and there are two roundish seeds. There are a great many species; of which the most remarkable are, the *verum*, or yellow lady's bed-straw; and the *aperine*, clivers, or goose-grafs. The former has a firm, erect, brown, square, stem; the leaves generally eight in each whirl, linear, pointed, brittle, and often reflex; branches short generally two from each joint, terminating in spikes of small yellow flowers. It grows commonly in dry ground, and on road sides. The flowers will coagulate boiling milk; and the best Cheshire cheese is said to be prepared with them. The French prescribe them in hysteric and epileptic cases. Boiled in alum-water, they tinge wool yellow. The roots dye a red not inferior to madder; for which purpose they are used in the island of Jura. In the Edinburgh medical commentaries we have accounts of some violent scorbutic complaints being cured by the juice of this plant.—Sheep and goats eat the plant; horses and swine refuse it; cows are not fond of it. The *aperine*, or clivers, has a square, very rough, jointed, very weak stem, two, three, or four feet long, and adhesive: the branches are opposite; the joints hairy at the base: the leaves, consisting of eight or ten at each joint, are narrow, pointed, above rough, beneath smooth, and carinated: the seeds are rough; flowers white, small, few on slender foot-stalks on the tops of the branches. It is frequent in fields by the sides of hedges, &c. The expressed juice of this plant taken internally, and the bruised leaves applied by way of poultice, are said to have been used with success as a cure for the cancer. The effects being slow, though sure, the course, it is said, often requires to be continued for nine or ten months.

GALL, in the animal economy. See BILE.

Gall, was generally given among the Jews, to persons suffering death under the execution of the law, to make them less sensible of their pain; but gall and myrrh are supposed to have been the same thing; because at our Saviour's crucifixion, St Matthew says, they gave him vinegar to drink mingled with gall; whereas St Mark calls it wine mingled with myrrh: The truth of the matter perhaps is, that they distinguished every thing bitter by the name of gall. The Greeks and Romans also gave such a mixture to persons suffering a death of torture.

A great number of experiments have been made upon the gall of different animals, but few conclusions can be drawn from them with any certainty. Dr Percival, however, hath shown, that putrid bile may be perfectly corrected and sweetened by an admixture of the vegetable acids, vinegar, and juice of lemons. These, he observes, have this effect much more completely than the mineral ones: and hence, he thinks, arises the great usefulness of the vegetable acids in autumnal diseases; which are always attended with a putrescent disposition of the bile, owing to the heat of the preceding summer. On this occasion he takes notice of a common mistake among physicians, who frequently prescribe elixir of vitriol in those diseases, where vinegar or lemon juice would be much more effectual.

From this effect of acids on the gall, he also thinks, we may see why the immoderate use of acids is so pernicious to digestion. It is necessary to health that the gall should be in some degree acrid and alkalescent: but as acids have the property of rendering it perfectly mild and sweet, they must be proportionably pernicious to the due concoction and assimilation of the food; which without an acrid bile cannot be accomplished. Hence the body is deprived of its proper nourishment and support, the blood becomes vapid and watery, and a fatal cachexy unavoidably ensues. This hath been the case with many unfortunate persons, who, in order to reduce their excessive corpulency, have indulged themselves in the too free use of vinegar. From the mild state of the gall in young children, Dr Percival also thinks it is, that they are so much troubled with acidities.

GALL Bladder. See ANATOMY, n^o 97.

GALL, in natural history, denotes any protuberance or tumor produced by the puncture of insects on plants and trees of different kinds.

These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed *gall nuts*, and the latter *berry galls*, or *apple-galls*.

The general history of the gall is this. An insect of the fly kind* is instructed by nature to take care for the safety of her young, by lodging her eggs in a woody substance, where they will be defended from all injuries: she for this purpose wounds the leaves or tender branches of a tree; and the lacerated vessels, discharging their contents, soon form tumors about the holes thus made. The external coat of this excrescence is dried by the air; and grows into a figure which bears some resemblance to the bow of an arch, or the roundness of a kernel. This little ball receives its nutriment, growth, and vegetation, as the other parts of the tree, by slow degrees, and is what we call the *gall-nut*. The worm that is hatched under this spacious vault, finds in the substance of the ball, which is as yet very tender, a subsistence suitable to its nature; gnaws and digests it till the time comes for its transformation to a nymph, and from that state of existence changes into a fly. After this, the insect, perceiving itself duly provided with all things requisite, disengages itself soon from its confinement, and takes its flight into the open air. The case, however, is not similar with respect to the gall-nut that grows in autumn. The cold weather frequently comes on before the worm is transformed into a fly, or before the fly can pierce through its inclosure. The nut falls with the leaves: and although you may imagine that the fly which lies within is lost, yet in reality it is not so; on the contrary, its being covered up so close, is the means of its preservation. Thus it spends the winter in a warm house, where every crack and cranny of the nut is well stopp'd up; and lies buried as it were under a heap of leaves, which preserves it from the injuries of the weather. This apartment, however, though so commodious a retreat in the winter, is a perfect prison in the spring. The fly, roused out of its lethargy by the first heats,

Gall.

Gall,
Galla.

beats, breaks its way through, and ranges where it pleases. A very small aperture is sufficient, since at this time the fly is but a diminutive creature. Besides the ringlets whereof its body is composed, dilate and become pliant in the passage.

Oak galls put, in a very small quantity, into a solution of vitriol in water, though but a very weak one, give it a purple or violet colour: which, as it grows stronger, becomes black; and on this property depends the art of making our writing ink, as also the arts of dying and dressing leather, and other manufactures. See *INK*.

The best galls come from Aleppo: these are not quite round and smooth like the other sorts, but have several tubercles on the surface. Galls have a very austere styptic taste, without any smell: they are very strong astringents, and as such have been sometimes made use of both internally and externally, but are not much taken notice of by the present practice. Some recommend an ointment of powdered galls and hog's lard as very effectual in certain painful states of hæmorrhoids; and it is alleged, that the internal use of galls has cured intermittents after the Peruvian bark has failed. A mixture of galls with a bitter and aromatic has been proposed as a substitute for the bark.

GALL (St), a considerable town in Swisserland, and in the Upper Thurgow, with a rich and celebrated abbey, whose abbot is a prince of the empire. This place has for some time been a republic, in alliance with the Cantons. It is not very large; but is well built, neat, populous. It contains about 10,000 inhabitants, who are chiefly employed in the linen manufacture; and make annually, it is said, 40,000 pieces of linen, of 200 ells each; which renders it one of the richest towns in Swisserland. The inhabitants are Protestants; for which reason there are often great contests between them and the abbey about religious affairs. It is seated in a narrow barren valley, between two mountains, and upon two small streams. E. Long. 29. 5. N. Lat. 47. 38.

GALL-Fly. See *CYNIPS*.

GALLA, an Abyssinian nation, originally dwelling, as Mr Bruce supposes, under the line, and exercising the profession of shepherds, which they still continue to do. For a number of years, our author tells us, they have been constantly migrating northwards, though the cause of this migration is not known. At first they had no horses; the reason of which was, that the country they came from did not allow these animals to breed: but as they proceeded northward and conquered some of the Abyssinian provinces, they soon furnished themselves with such numbers, that they are now almost entirely cavalry, making little account of infantry in their armies. On advancing to the frontiers of Abyssinia, the multitude divided, and part directed their course towards the Indian Ocean; after which, having made a settlement in the eastern part of the continent, they turned southward into the countries of Bali and Dawaw, which they entirely conquered, and settled there in the year 1537. Another division having taken a westerly course, spread themselves in a semicircle along the banks of the Nile; surrounding the country of Gojam, and passing eastward behind the country of the Agows, extended their possessions as far as the territories of the Gongas and Gafats.

Galla.

Since that time the Nile has been the boundary of their possessions; though they have very frequently plundered, and sometimes conquered, the Abyssinian provinces on the other side of the river, but have never made any permanent settlement in these parts. A third division has settled to the southward of the low country of Shoa, which the governor of that province has permitted, in order to form a barrier betwixt him and the territories of the emperor, on whom he scarcely acknowledges any dependence.

The Galla are of a brown complexion, and have long black hair; but some of them who live in the valleys are entirely black. At first their common food was milk and butter; but since their intercourse with the Abyssinians, they have learned to plough and sow their land, and to make bread. They seem to have a predilection for the number seven, and each of the three divisions already mentioned are subdivided into seven tribes. In their behaviour they are extremely barbarous; and live in continual war with the Abyssinians, whom they murder without mercy as often as they fall into their hands. They cut off the privities of the men, and hang them up in their houses by way of trophies; and are so cruel as to rip up women with child, in hopes of thus destroying a male. Yet notwithstanding their excessive cruelty abroad, they live under the strictest discipline at home; and every broil or quarrel is instantly punished according to the nature of the offence. Each of the three divisions of the Galla abovementioned has a king of its own; and they have also a kind of nobility, from among whom the sovereign can only be chosen: however, the commonalty are not excluded from rising to the rank of nobles if they distinguish themselves very much in battle. None of the nobility can be elected till upwards of 40 years of age, unless he has with his own hand killed a number of enemies which added to his own age makes up 40. There is a council of each of the seven tribes, which meets separately in its own district, to settle how many are to be left behind for the governing and cultivating of the territory, and other matters of importance. These nations have all a great veneration for a tree which grows plentifully in their country, called *wanzey*, and which these superstitious people are even said to adore as a god. Their assemblies for the choice of a king are all held under one of these trees; and when the sovereign is chosen, they put a bludgeon of this wood in his hand by way of sceptre, and a garland of the flowers upon his head.

The Galla are reported to be very good soldiers, especially in cases of surprise; but, like most other barbarians, have no constancy nor perseverance after the first attack. They will, however, perform extraordinary marches, swimming rivers holding by the horse's tail, and thus being enabled to do very great mischief by reason of the rapidity of their movements. They are excellent light-horse for a regular army in an hostile country; but are very indifferently armed on account of the scarcity of iron among them. Their principal arms are lances made of wood sharpened at the end and hardened in the fire; and their shields are composed only of one single fold of bull's hide; so that they are extremely apt to warp by heat, or become too soft in wet weather. They are exceedingly cruel; and make a shrill horrid noise at the beginning of every

Galla
↓
Galle.

every engagement, which greatly terrifies the horses, and very often the barbarous riders which oppose them.

The Galla, according to Mr Bruce's account, are somewhat below the middle size, but extremely light and nimble. The women are fruitful; and suffer so little in child-bearing, that they do not even confine themselves for a single day after delivery. They plough, sow, and reap the corn, which is trodden out by the cattle; but the men have all the charge of the cattle in the fields. In their customs they are filthy to the last degree; plaiting their hair with the guts of oxen, which they likewise twist round their middle, and which by the quick putrefaction occasion an abominable stench. They anoint their heads and whole bodies with butter or grease; in which, as well as in other respects, they greatly resemble the Hottentots. It has been supposed that they have no religion whatever; but Mr Bruce is of opinion that this is a mistake. The wanzey, he says, is undoubtedly worshipped by all the nations as a god; and they have likewise certain stones which are worshipped as gods: besides these, they worship the moon, and some stars, when in certain positions, and at some particular seasons of the year. They all believe in a resurrection; and have some faint notions of a state of happiness, but no idea of future punishment. Some of them to the southward profess the Mahometan religion, but those to the east and west are generally pagans. All of them intermarry with each other; but will not allow strangers to live among them, though the Moors have at last found out a method of trading safely with them. The commodities they deal in are blue Surat cloths, myrrh, and salt; the last being the most valuable article.

The marriages among the Galla are celebrated with some of the disgusting customs of the Hottentots; and after these ceremonies the bridegroom promises to give the bride meat and drink while she lives, and to bury her when dead. Polygamy is allowed among them; but it is singular, that among these people the women solicit their husbands to take others to their embraces. The reason of this custom is, that the men may have numerous families of children, who may be capable of defending them against their enemies; as the Galla, according to our author, always fight in families, whether against foreign enemies or with one another.

GALLAND (Anthony), a learned antiquarian, member of the Academy of Inscriptions, and professor of Arabic in the Royal College of Paris, was born of poor parents at Rollo, a village in Picardy. Having studied at the Sorbonne and other universities, he travelled into the east; where he acquired great skill in the Arabic tongue, and in the manners of the Mahometans. He wrote several works; the principal of which are, 1. An Account of the Death of the Sultan Osman, and the Coronation of the Sultan Mustapha. 2. A Collection of Maxims, drawn from the works of the Orientals. 3. A Treatise on the Origin of Coffee. 4. The Arabian Nights Entertainments, &c.

GALLANT, or GALANT, a French term adopted into our language, and signifying polite, civil, and well-bred, with a disposition to please, particularly the ladies. It also signifies brave or courageous.

GALLE, the name of several engravers, of whom the principal was Cornelius, who flourished about the

Vol. VII.

year 1600. He learned the art of engraving from his father, and imitated his stiff style, till he went to Rome, where he resided a considerable time, and there acquired that freedom, taste, and correctness of drawing, which are found in his best works. He settled at Antwerp upon his return from Italy, where he carried on a considerable commerce in prints. His best prints are those done after Rubens.

GALLEON, in naval affairs, a sort of ships employed in the commerce of the West Indies. The Spaniards send annually two fleets; the one for Mexico, which they call the *flota*; and the other for Peru, which they call the *galleons*. See *FLOTA*.

By a general regulation made in Spain, it has been established, that there should be twelve men of war and five tenders annually fitted out for the armada or galleons; eight ships of 600 tons burden each, and three tenders, one of 100 tons, for the island Margarita, and two of 80 each, to follow the armada; for the New Spain fleet, two ships of 600 tons each, and two tenders of 80 each; and for the Honduras fleet, two ships of 500 tons each: and in case no fleet happened to sail any years, three galleons and a tender should be sent to New Spain for the plate.

They are appointed to sail from Cadiz in January, that they may arrive at Porto Bello about the middle of April; where, the fair being over, they may take aboard the plate, and be at Havannah with it about the middle of June, where they are joined by the *flota*, that they may return to Spain with the greater safety.

GALLEOT, a small galley designed only for chace, carrying but one mast and two patereroes: it can both sail and row, and has 16 or 20 oars. All the seamen on board are soldiers, and each has a musket by him on quitting his oar.

GALLERY, in architecture, a covered place in a house, much higher than broad, and usually in the wings of a building; its use being chiefly to walk in.

GALLERIES, in gardening, are certain ornaments made with trees of different kinds; which are very common in all the French gardens, but are seldom introduced into the British ones, especially since the taste for clipped trees has been exploded. For those however, who may still choose to have them, Mr Miller gives the following directions.

In order to make a gallery in a garden with porticoes and arches, a line must first be drawn of the length you design the gallery to be; which being done, it is to be planted with hornbeam, as the foundation of the gallery. The management of galleries is not difficult. They require only to be digged round about; and sheared a little when there is occasion. The chief curiosity required is in the ordering the forepart of the gallery, and in forming the arches. Each pillar of the porticoes or arches ought to be four feet distant from another, and the gallery 12 feet high and 10 feet wide, that there may be room for two or three persons to walk abreast. When the hornbeams are grown to the height of three feet, the distance of the pillars well regulated, and the ground-work of the gallery finished, the next thing to be done is to form the frontispiece; to perform which, you must stop the hornbeam between two pillars for that purpose, which forms the arch. As it grows, you must with your sheers cut off those

Galleon
||
Galleries.

Gallery, boughs which outshoot the others. In time they will grow strong, and may be kept in form by the sheers. **Galley.** Portico-galleries may be covered with lime-trees.

GALLERY, in fortification, a covered walk across the ditch of a town, made of strong beams covered over with planks, and loaded with earth: sometimes it is covered with raw hides, to defend it from artificial fires of the besieged.

GALLERY of a Mine, is a narrow passage or branch of a mine carried on under ground to a work designed to be blown up. See **MINE**.

GALLERY, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

GALLEY, a kind of low flat-built vessel, furnished with one deck, and navigated with sails and oars, particularly in the Mediterranean. By the Greek authors under the eastern empire, this kind of vessel was called *γαλαία* and *γαλεία*: and by the Latin authors of the same time, *galea*; whence, according to some, the modern denomination. Some say it was called *galea*, on account of a casque or helmet which it carried on its prow, as Ovid attests, *de Tristib.* The French call it *galere*; by reason, they say, that the top of the mast is usually cut in the form of a hat, which the Italians call *galero*. Others derive both *galea*, and *galere*, from a fish by the Greeks called *γαλεωπύς*, or *ξιφίας*, and by us the *sword-fish*, which this vessel resembles. Lastly, others derive the *galley*, *galea*, *galere*, *galeasse*, &c. from the Syriac and Chaldee *gaul*, and *gallin*, a man exposed on the water in a vessel of wood.

The largest sort of these vessels is employed only by the Venetians. They are commonly 162 feet long above, and 133 feet by the keel; 32 feet wide, with 23 feet length of stern-post. They are furnished with three masts, and 32 banks of oars; every bank containing two oars, and every oar being managed by six or seven slaves, who are usually chained thereto. In the fore-part they have three little batteries of cannon, of which the lowest is of two 36 pounders, the second of two 24 pounders, and the uppermost of two 2 pounders: three 18 pounders are also planted on each quarter. The complement of men for one of these galleys is 1000 or 1200. They are esteemed extremely convenient for bombarding or making a descent upon an enemy's coast, as drawing but little water; and having by their oars frequently the advantage of a ship of war, in light winds or calms, by cannonading the latter near the surface of the water; by scouring her whole length with their shot, and at the same time keeping on her quarter or bow, so as to be out of the direction of her cannon.

The galleys next in size to these, which are also called *half-galleys*, are from 120 to 130 feet long, 18 feet broad, and 9 or 10 feet deep. They have two masts, which may be struck at pleasure; and are furnished with two large lateen sails, and five pieces of cannon. They have commonly 25 banks of oars, as described above. A size still less than these are called *quarter-galleys*, carrying from 12 to 16 banks of oars. There are very few galleys now besides these in the Mediterranean, which are found by experience to be

of little utility except in fine weather; a circumstance which renders their service extremely precarious. They generally keep close under the shore, but sometimes venture out to sea to perform a summer cruise.

GALLERY-Worm, in zoology. See **IULUS**.

GALLI, in antiquity, a name given to the priests of Cybele, from the river Gallus in Phrygia; but of the etymology of the name we have no certain account. All that we learn with certainty about them is, that they were eunuchs and Phrygians, and that in their solemn processions they danced, bawled, drummed, cut and flashed themselves, playing upon timbrels, pipes, cymbals, &c. and driving about an ass loaded with the sacred rites and trumpery of their goddesses. When a young man was to be initiated, he was to throw off his cloaths, run crying aloud into the midst of their troop, and there draw a sword and castrate himself; after this he was to run into the street with the parts cut off, in his hand, throw them into some house, and in the same house put on a woman's dress.

These priests had the names also of *Curetes*, *Corybantes*, and *Dactyli*. The chief priest was called *Archigallus*. This order of priesthood is found both amongst Greeks and Romans. See an account of them in *Lucret. lib. ii.* and *Juv. sat. vi.*

GALLI, the *Gauls*. See **GALLIA** and **GAULS**.

GALLI, five small desolate islands on the coast of the Principato Citra of Naples. They are supposed to be the Sirenaeæ, or islands once inhabited by the Sirens, which Ulysses passed with so much caution and hazard. Great revolutions, however, have been occasioned in their shape, size, and number, by the effects of subterranean fire; and some learned persons go so far as to assert, that these rocks have risen from the bottom of the sea since Homer sang his rhapsodies; consequently, that those monsters dwelt on some other spot, probably Sicily or Capri. The tradition of Sirens residing hereabouts is very ancient and universally admitted; but what they really were, divested of their fabulous and poetical disguise, it is not easy to discover. See **SIREN**.

The Sirenaeæ were only three in number; and therefore if these and the Galli be the same, two more must have since risen, or the three have been split into five by a subterraneous convulsion. On the largest is a watch-tower, and the next has a deserted hermitage. The principal island is only a narrow semicircular ridge covered with a shallow coat of soil; two other little islands and some jagged rocks just peeping above the waves, correspond with this one so as to trace the outline of a volcanical crater. The composition of them all is at top a calcareous rock extremely shaken, tumbled, and confused, mixed with masses of breccia, disposed in a most irregular manner; below these is lava, and the deeper the eye follows it the stronger are the marks of fire: below the surface of the water, and in some places above it, the layers are complete blocks of basalt. Hence it is fair to presume, that central fires have heaved up to light the torrifed substances that originally lay near their focus, with all the intermediate strata that covered them from the sea. The layers incline downwards from east to west; the air seems to have forced its way into part of the mass while in fusion, and by checking its workings caused many large

CAVERNS

Galley,
Galli.

Gallia. caverns to be left in it. These islands are uncultivated and uninhabited since the old hermit of St Antonio died. Myrtle covers most of the surface.

GALLIA, a large country of Europe, called *Gallia* by the Greeks. The inhabitants were called *Galli*, *Celtae*, *Celtiberi*, and *Celtofrythæ*. Ancient Gaul was divided into four different parts by the Romans, called *Gallia Belgica*, *Narbonensis*, *Aquitania*, and *Celtica*. *Gallia Belgica* was the largest province, bounded by Germany, *Gallia Narbonensis*, and the German ocean; and contained the modern country of Alsace, Lorraine, Picardy, with part of the low countries, and of Champagne, and of the isle of France. *Gallia Narbonensis*, which contained the provinces now called *Languedoc*, *Provence*, *Dauphiné*, *Savoy*, was bounded by the Alps and Pyrenean mountains, by *Aquitania Belgicum*, and the Mediterranean. *Aquitania Gallia*, now called the provinces of *Pottou*, *Santonge*, *Guienne*, *Berry*, *Limosin*, *Gascogny*, *Auvergne*, &c. was situated between the *Garumna*, the Pyrenean mountains, and the ocean. *Gallia Celtica*, or *Lugdunensis*, was bounded by Belgium, *Gallia Narbonensis*, the Alps, and the ocean. It contained the country at present known by the name of *Lyonnois*, *Touraine*, *Franche Comté*, *Senenois*, *Switzerland*, and part of *Normandy*. Besides these grand divisions, there is often mention made of *Gallia Cisalpina* or *Citerior*, *Transalpina* or *Uterior*, which refers to that part of Italy which was conquered by some of the Gauls who crossed the Alps. By *Gallia Cisalpina*, the Romans understood that part of Gaul which lies in Italy, and by *Transalpina*, that which lies beyond the Alps, in regard only to the inhabitants of Rome. *Gallia Cispadana*, and *Transpadana*, is applied to a part of Italy conquered by some of the Gauls; and then it means the country on this side of the Po, or beyond the Po, with respect to Rome. By *Gallia Togata*, the Romans understood *Cisalpine Gaul*, where the Roman gowns *togæ* were usually worn. *Gallia Narbonensis* was called *Braccata*, on account of the peculiar covering of the inhabitants for their thighs. The epithet of *Comata* is applied to *Gallia Celtica*, because the people suffered their hair to grow to an uncommon length. The inhabitants were great warriors, and their valour overcame the Roman armies, took the city of Rome, and invaded Greece in different ages. They spread themselves over the greatest part of the world. They were very superstitious in their religious ceremonies, and revered the sacerdotal order as if they had been gods. They long maintained a bloody war against the Romans, and Cæsar resided 10 years in their country before he could totally subdue them. See **GAUL**.

GALLIARD, or **GAGLIARDA**, a sort of dance anciently in great request; consisting of very different motions and actions, sometimes proceeding *terra à terra* or smoothly along; sometimes capering; sometimes along the room, and sometimes across. The word is French, *gailliarde*, or rather Italian; and literally signifies "gay, merry, sprightly." This dance was also called *Romanesque*, because brought from Rome.

Thoinot Arbeau, in his *Orchesography*, describes it as consisting of five steps, and five positions of the feet, which the dancers performed before each other, and whereof he gives us the score or tablature, which is of six minims, and two triple times.

GALLIARDA, in the Italian music, the name of

a tune that belongs to a dance called a *galliard*. The air of it is lively in triple time.

GALLICAN, any thing belonging to France: thus the term *Gallican church* denotes the church of France, or the assembly of the clergy of that kingdom.

GALLICISM, a mode of speech peculiar to the French language, and contrary to the rules of grammar in other languages. With us it is used to denote such phrases or modes of speech in English as are formed after the French idiom.

GALLINACEUS LAPIS, a glossy substance produced by volcanic fires; the same with the *lapis obsidianus* of the ancients. A kind of it is brought from Paris, of a beautiful black, resembling the colour of a large crow in that country named *gallinago*.

GALLINÆ, in ornithology, an order of birds. See **ORNITHOLOGY**.

GALLINACIOUS, an appellation given to the birds of the order of the *gallinæ*.

GALLING, or **EXCORIATION**, in medicine. See **EXCORIATION**.

GALLING of a Horse's Back, a disorder occasioned by heat, and the chafing or pinching of the saddle.

In order to prevent it, some take a hind's skin well garnished with hair, and fit it neatly under the pannel of the saddle, so that the hairy side may be next the horse.

When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside of the pannel: anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it again with butter, or, for want of that, with grease: wash the swelling, or hurt, every evening with cold water and soap; and strew it with salt, which should be left on till the horse be saddled in the morning.

GALLINULE. See **FULICA**.

GALLIPOLI, a sea-port town of Italy, in the kingdom of Naples, and in the *Terra-di-Otranto*, with a bishop's see. It stands on a rocky island, joined to the continent by a bridge. From the remotest antiquity this was a station so favourable to commerce, that every maritime power wished to secure it; and it is a reproach to government, that nothing has been done to improve its natural advantages: at present, Mr Swinburn informs us, it has neither harbour nor shelter for shipping. Charles II. demolished Gallipoli for its adherence to Frederick of Aragon. The Venetians treated it with great cruelty in the 15th century; and in 1481 it was pillaged by the Turks. To preserve it from future calamities, Charles V. repaired and strengthened its fortifications; and, since that period, it has enjoyed the benefits of peace and trade, which have rendered it the most opulent and gayest town upon the coast, though its inhabitants do not exceed 6000 in number. Consumptions and spitting of blood are rather frequent here, occasioned by the great subtilty of the air, which is ventilated from every quarter. The buildings are tolerable, and some of the churches have good paintings. The cotton trade brings in about 30,000 ducats a-year. Good muslins, cotton stockings, and other parts of apparel, are manufactured here, and purchased by the Proven-

Gallois.

gals; for Gallipoli has no direct trade with the metropolis. Silk and Saffron were formerly objects of traffic; but heavy duties and oppression have caused them to be abandoned. The wine of this territory is good; but from dryness of climate, and shallowness of soil, the vintage frequently fails in quantity; and then the Gallipolitans have recourse to Sicily for a supply. Oil is the great support of the place: two-thirds of the produce of its olive plantations are exported to France, and the north of Italy; the remainder is sent to Naples, and other ports of the kingdom. Neapolitan merchants, by means of agents settled at Gallipoli, buy up the oils, from year to year, long before an olive appears upon the tree; and the price is afterwards settled by public authority. The Neapolitans sell their oil to the merchants of Leghorn; and, if faithfully served by their factors in Terra di Otranto, ought to double their capital in two years. But, to balance this advantage, they run great risks, pay exorbitant interest, and have frequent bankruptcies to guard against. E. Long. 18. 10. N. Lat. 40. 20.

GALLIPOLI, a sea-port town of Turkey in Europe, in the province of Romania, seated at the mouth of the sea of Marmora, with a good harbour, and a bishop's see. It contains about 10,000 Turks, 3500 Greeks, besides a great number of Jews. The bazar or bezestein, the place where merchandizes are sold, is a handsome structure, with domes covered with lead. It is an open place, and has no other defence than a paltry square castle. The houses of the Greeks and Jews have doors not above three feet and an half high, to prevent the Turks riding into their houses. E. Long. 26. 59. N. Lat. 40. 30.

GALLIUM, in botany. See GALIUM.

GALLO, an island of the South Sea, near the sea-coast of Peru, in South America, which was the first place possessed by the Spaniards when they attempted the conquest of Peru; it is also the place where the bucaniers used to come for wood and water, and to refit their vessels when they were in these parts. W. Long. 88. 0. N. Lat. 2. 30.

GALLO-græcia, a county of Asia minor, near Bithynia and Cappadocia. It was inhabited by a colony of Gauls, who assumed the name of *Gallogræci*, because a number of Greeks had accompanied them in their emigration. See GALLATIA.

GALLOIS (John), born at Paris in 1632, was an universal scholar; but chiefly noted for having been, in conjunction with M. de Sallo who formed the plan, the first publisher of the *Journal des Sçavans*. The first journal was published January 5th 1665; but these gentlemen criticised new works so rigorously, that the whole tribe of authors united and cried it down. De-Sallo declined entirely after the publication of the third number: but Gallois ventured to send out a fourth, on January 4th 1666; though not without a most humble advertisement at the beginning, wherein it was declared, that the author "would not presume to criticise, but simply give an account of the books." This, with the protection of M. Colbert, who was greatly taken with the work, gradually reconciled the public to it: and thus began literary journals, which have been continued from that time to this, under va-

rious titles, and by various writers. Gallois continued his journal to the year 1674, when more important occupations obliged him to turn it over to other hands. M. Colbert had taken him into his house to teach him Latin; and when he lost his patron in 1683, he was first made librarian to the king, and then Greek professor in the royal college. He died in 1707.

GALLON, a measure of capacity both for dry and liquid things, containing four quarts. But these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured: For instance, the wine-gallon contains 231 cubic inches, and holds eight pounds averdupois of pure water; the beer and ale-gallon contains 281 solid inches, and holds ten pounds three ounces and a quarter averdupois of water; and the gallon for corn, meal, &c. 272½ cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOP, in the manege, is the swiftest natural pace of a horse, performed by reaches or leaps; the two fore-feet being raised almost at the same time; and when these are in the air, and just ready to touch the ground again, the two hind-feet are lifted almost at once. The word is borrowed from the barbarous Latin *calupare*, or *calpare*, "to run." Some derive it from *caballicare*; others from the Greek *καλπάζειν*, or *καλπαν*, to spur a horse.

GALLOPER, in Artillery, is the name of a carriage which serves for a pound and a half gun. This carriage has shafts so as to be drawn without a limbon, and is thought by some to be more convenient and preferable to other field carriages; it may likewise serve for light three and six pounders.

GALLOWAY, a county of Scotland, which gives the title of earl to a branch of the noble family of Stuart. It is divided into two districts; the western, called *Upper Galloway*, being the same with Wigtonshire; and the eastern, or stewartry of Kircudbright, called *Lower Galloway*. See KIRCUDBRIGHT and WIGTONSHIRE.

Mull of Galloway, the South Cape or promontory of all Scotland in the county of Galloway on the Irish Sea.

GALLOWAYS is the name of a peculiar sort of horses, so called from the county of Galloway in Scotland, where they are bred. Tradition reports that this kind of horses sprung from some Spanish stallions, which swam on shore from some of the ships of the famous Spanish armada, wrecked on the coast; and coupling with the mares of the country, furnished the kingdom with their posterity. They were much esteemed, and of a middling size, strong, active, nervous, and hardy.

GALLOWES; an instrument of punishment, whereon persons convicted capitally of felony, &c. are executed by hanging.

Among our ancestors it was called *furca*, "fork;" a name by which it is still denominated abroad, particularly in France and Italy, in this latter country, the reason of the name still subsists; the gallows being a real fork drove into the ground, across the legs whereof is laid a beam, to which the rope is tied. See FURCA.

Gallus
||
Galway.

GALLUS (Cornelius), an ancient Roman poet, born at Forum Julium, now called *Frejus*, in France. He was a particular favourite with Augustus Cæsar, who made him governor of Egypt: but his maladministration there occasioned his banishment, and the loss of his estate; for grief of which he put an end to his own life. He wrote four books of love-elegies; and Virgil has complimented him in many places.

GALLUS, or **COCK**, in ornithology. See **PHASIANUS**.

GALLY, in printing, a frame into which the compositor empties the lines out of his composing-stick, and in which he ties up the page when it is completed.

The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom, called a *gally-slice*.

GALWAY, or **GALLOWAY**, a county of Ireland, which is 82 miles in length; and 42 in breadth, bounded by the counties of Clare, Tipperary, King's County, Roscommon, and the sea. The river Shannon washes the frontiers of the east and south-east, and forms a lake several miles in length. There is another great lake called *Corbis*, or *Carib*, which is near 20 miles long, and five broad. The county contains 15,420 houses, 136 parishes, 17 baronies, and 13 boroughs; and sends 8 members to parliament. The capital town is of the same name.

GALWAY, a town of Ireland, in the county of the same name, and province of Connaught, of which it is the capital. It is seated on the bay of Galway on the western ocean, 108 miles west of Dublin, and gives title of Viscount to the family of Monkton. It is surrounded with strong walls, has large straight streets, and the houses are generally well built with stone. It has a good trade into foreign parts, on account of its harbour, which is defended by a fort. It is governed by a mayor, sheriffs, and recorder, and returns two members to parliament. It has but one parish church, which is a large and beautiful Gothic structure; an exchange; barracks for 10 companies of foot, a charter-school, and an hospital. This was one of the strongest towns in the kingdom: it held out some time against General Ginkle, who invested and took it after the battle of Aughrim. Its fortifications were then repaired; the walls are flanked by bastions, but are mostly gone to decay. The salmon and herring fisheries are carried on here with great spirit, and employ 700 boats, the quantity of kelp manufactured and exported is considerable; and the growth of the linen manufacture, though of late introduction, is become very important. In 1296, Sir William de Burgh founded a monastery here for Franciscan friars, on St Stephen's island, situated without the north gate of the town. In 1381, there being two popes at Rome, and the people of Ireland being doubtful to which they should pay obedience, pope Urban, to fix them entirely to his interest, empowered the guardian of this monastery to excommunicate every person in the province of Connaught who should adhere to Clement VII. who he assured them was antipope. The tomb of the founder of this monastery was discovered in June 1779, upwards of four feet under ground, with

his family-arms, and a very long broad sword, elegantly carved thereon; some of the remains are still to be seen.—Near the west gate of the town, without the walls, was the monastery of St Mary of the hill: on the nuns forsaking it, the secular clergy entered into and kept possession of it for a considerable time; but on the petition of the inhabitants of the town, to pope Innocent VIII. it was granted to the Dominican friars, by a bull dated the 4th December 1488; there are no remains of this foundation except the cemetery; the whole building having been demolished by the townsmen in the year 1652, in order to prevent Cromwell from turning it into a fortification against themselves: there was also an Augustinian friary, on a hill near this town, founded by Stephen Lynch, and Margaret his wife, in the year 1508, at the earnest solicitation of Richard Nangle, a friar of the same order, who afterwards became archbishop of Tuam.

GAMA (Vasco de), a Portuguese admiral, celebrated for his discovery of the East Indies by the Cape of Good Hope, was born at Synes; and, in 1497, was sent to the Indies by king Emanuel: he returned in 1502, and sailed thither again with 13 vessels richly laden. He was made viceroy of the Indies by king John III; and died at Cochin, on the 24th of December 1525. Don Stephen and Don Christopher de Gama, his sons, were also viceroys of the Indies, and celebrated in history.

GAMBIA, a large river of Negroland in Africa, generally supposed to be a branch of the Niger. See **NILE**, **NIGER**, and **SENEGAL**.

GAMBOGE, is a concreted vegetable juice *, * See *Gambogia*. partly of a gummy and partly of a resinous nature. It is chiefly brought to us in large cakes or rolls from Cambaja in the East Indies. The best sort is of a deep yellow or orange colour, breaks shining and free from dross: it has no smell, and very little taste, unless kept in the mouth for some time, when it imparts a slight sense of acrimony. It immediately communicates to spirit of wine a bright golden colour, and almost entirely dissolves in it; Geoffroy says, except the sixth part. Alkaline salts enable water to act upon this substance powerfully as a menstruum: the solution made by their means is somewhat transparent, of a deep blood red colour, and passes the filtre: the dulcified spirit of sal ammoniac readily and entirely dissolves it, and takes up a considerable quantity; and what is pretty remarkable, this solution mixes either with water or spirit without growing turbid.

As a pigment it makes a beautiful yellow, which is much used by the painters. Dr Lewis says, that it makes a beautiful and durable citron yellow stain upon marble, whether rubbed in substance on the hot stone, or applied as dragon's blood sometimes is, in form of a spirituous tincture. When it is applied on cold marble, the stone is afterwards to be heated, to make the colour penetrate.

As a medicine, gamboge evacuates powerfully both upwards and downwards; some condemn it as acting with too great violence, and occasioning dangerous hypercatharses; whilst others are of a contrary opinion. Geoffroy seems particularly fond of this medicine, and informs us, that he has frequently given from two to four grains, without its proving at all emetic;

Gama
||
Gamboge.

Game. emetic; that from four to eight grains, it both vomits and purges, without violence; that its operation is soon over; and that if given in a liquid form, and sufficiently diluted, it stands not in need of any corrector; that in the form of a bolus or pill, it is most apt to prove emetic, but very rarely has this effect if joined along with *mercurius dulcis*. He nevertheless cautions against its use where the patient cannot easily bear vomiting.—It has been used in dropsy with cream of tartar of jalap, or both, to quicken their operation. It is also recommended by some to the extent of 15 grains with an equal quantity of vegetable alkali in cases of the tape-worm. This dose is ordered in the morning; and if the worm is not expelled in two or three hours, it is repeated even to the third time with safety and efficacy. It is asserted that it has been given to this extent even in delicate habits. This is said to be the remedy alluded to by Baron Van Swieten, which was employed by Dr Herenschward, and with him proved so successful in the removal of the *tænia lata*.

GAME, in general, signifies any diversion or sport, that is performed with regularity, and restrained to certain rules. See **GAMING**.

Games are usually distinguished into those of exercise and address, and those of hazard. To the first belong chess, tennis, billiards, &c. and to the latter those performed with cards or dice, as back-gammon, ombre, picquet, whist, &c. See **BACK-GAMMON**, &c.

GAMES, in antiquity, were public diversions, exhibited on solemn occasions. Such among the Greeks, were the Olympic, Pythian, Isthmian, Nemean, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games. See **OLYMPIC**, **PYTHIAN**, **FUNERAL**, &c.

GAME, in law, signifies birds, or prey, taken or killed by fowling or hunting.

The property of such animals *feræ naturæ* as are known under the denomination of *game*, with the right of pursuing, taking, and destroying them, in Britain, is vested in the king alone, and from him derived to such of his subjects as have received the grants of a chase, a park, or a free warren.

By the law of nature, indeed, every man, from the prince to the peasant, has an equal right of pursuing, and taking to his own use, all such creatures as are *feræ naturæ*, and therefore the property of nobody, but liable to be seized by the first occupant. But it follows from the very end and constitution of society, that this natural right, as well as many others belonging to man as an individual, may be restrained by positive laws enacted for reasons of state, or for the supposed benefit of the community. This restriction may be either with respect to the *place* in which this right may, or may not, be exercised; with respect to the *animals* that are the subjects of this right; or with respect to the *persons* allowed or forbidden to exercise it. And, in consequence of this authority, we find that the municipal laws of many nations have exerted such power of restraint; have in general forbidden the entering on another man's grounds, for any cause, without the owner's leave; have extended their protection to such particular animals as are usually the objects of pursuit; and have invested the prerogative of

hunting and taking such animals, in the sovereign of the state only, and such as he shall authorize. Many reasons have concurred for making these constitutions; as, 1. For the encouragement of agriculture and improvement of lands, by giving every man an exclusive dominion over his own soil. 2. For the preservation of the several species of these animals, which would soon be extirpated by a general liberty. 3. For prevention of idleness and dissipation in husbandmen, artificers, and others of lower rank; which would be the unavoidable consequence of universal licence. 4. For prevention of popular insurrections and resistance to the government, by disarming the bulk of the people: which last is a reason oftener meant than avowed, by the makers of forest or game laws. Nor, certainly, in these prohibitions is there any *natural* injustice, as some have weakly enough supposed: since, as Puffendorf observes, the law does not hereby take from any man his present property, or what was already his own; but barely abridges him of one means of acquiring a future property, that of occupancy, which indeed the law of nature would allow him, but of which the laws of society have in most instances very justly and reasonably deprived him.

Yet, however defensible these provisions in general may be, on the footing of reason, or justice, or civil policy, we must, notwithstanding acknowledge, that, in their present shape they owe their immediate original to slavery. It is not till after the irruption of the northern nations into the Roman empire, that we read of any other prohibitions, than that natural one of not sporting on any private grounds without the owner's leave.

With regard to the rise and original of the present civil prohibitions, in England, it will be found, that all forest and game laws were introduced into Europe at the same time, and by the same policy, as gave birth to the feudal system; when those swarms of barbarians issued from their northern hive, and laid the foundation of most of the present kingdoms of Europe, on the ruins of the western empire. For when a conquering general came to settle the economy of a vanquished country, and to part it out among his soldiers or feudatories, who were to render him military service for such donations; it behoved him, in order to secure his new acquisitions, to keep the *rustici* or natives of the country, and all who were not his military tenants, in as low a condition as possible, and especially to prohibit them the use of arms. Nothing could do this more effectually than a prohibition of hunting and sporting: and therefore it was the policy of the conqueror to reserve this right to himself, and such on whom he should bestow it; which were only his capital feudatories, or greater barons. And, accordingly, we find, in the feudal constitutions, one and the same law prohibiting the *rustici* in general from carrying arms, and also proscribing the use of nets, snares, or other engines for destroying the game. This exclusive privilege well suited the martial genius of the conquering troops, who delighted in a sport which in its pursuit and slaughter bore some resemblance to war. *Vita omnis* (says Cæsar, speaking of the ancient Germans) *in venationibus atque in studiis rei militaris consistit*. And Tacitus in like manner observes, that *quoties bella non ineunt,*

Blackst.
Comment.

Game. incunt, multum venatibus, plus per otium transigunt.

And indeed, like some of their modern successors, they had no other amusement to entertain their vacant hours; they despising all arts as effeminate, and having no other learning, than was couched in such rude ditties as were sung at the solemn carousals which succeeded these ancient huntings. And it is remarkable, that, in those nations where the feudal policy remains the most uncorrupted, the forest or game laws continue in their highest rigour. In France, all game is properly the king's; and in some parts of Germany it is death for a peasant to be found hunting in the woods of the nobility.

In Britain, also, hunting has ever been esteemed a most princely diversion and exercise. The whole island was replenished with all sorts of game in the times of the Britons; who lived in a wild and pastoral manner, without inclosing or improving their grounds; and derived much of their subsistence from the chase, which they all enjoyed in common. But when husbandry took place under the Saxon government, and lands began to be cultivated, improved, and inclosed, the beasts naturally fled into the woody and desert tracts, which were called the *forests*; and, having never been disposed of in the first distribution of lands, were therefore held to belong to the crown. These were filled with great plenty of game, which the royal sportsmen reserved for their own diversion, on pain of a pecuniary forfeiture for such as interfered with their sovereign. But every freeholder had the full liberty of sporting upon his territories, provided he abstained from the king's forests.

However, upon the Norman conquest, a new doctrine took place; and the right of pursuing and taking all beasts of chase or *venary*, and such other animals as were accounted *game*, was then held to belong to the king, or to such only as were authorized under him. And this, as well upon the principles of the feudal law, that the king is the ultimate proprietor of all the lands in the kingdom, they being all held of him as the chief lord, or lord paramount of the fee; and that therefore he has the right of the universal soil, to enter thereon, and to chase and take such creatures at his pleasure: as also upon another maxim of the common law, that these animals are *bona vacantia*, and, having no other owner, belong to the king by his prerogative. As therefore the former reason was held to vest in the king a *right* to pursue and take them any where; the latter was supposed to give the king, and such as he should authorize, a *sole* and *exclusive* right.

This right, thus newly vested in the crown, was exerted with the utmost rigour, at and after the time of the Norman establishment; not only in the ancient forests, but in the new ones which the conqueror made, by laying together vast tracts of country, depopulated for that purpose, and reserved solely for the king's royal diversion; in which were exercised the most horrid tyrannies and oppressions, under colour of forest-law, for the sake of preserving the beasts of chase; to kill any of which, within the limits of the forest, was as penal as the death of a man. And, in pursuance of the same principle, king John laid a total interdict upon the *winged* as well as the *fourfooted* crea-

tion: *capturam avium per totam Angliam interdixit*.*

The cruel and unsupportable hardships which these forest-laws created to the subject, occasioned our ancestors to be as zealous for their reformation, as for the relaxation of the feudal rigours and the other exactions introduced by the Norman family; and accordingly we find the immunities of *carta de foresta* as warmly contended for, and extorted from the king with as much difficulty, as those of *magna carta* itself. By this charter, confirmed in parliament†, many forests were disafforested, or stripped off their oppressive privileges, and regulations were made in the regimen of such as remained; particularly killing the king's deer was made no longer a capital offence, but only punished by a fine, imprisonment, or abjuration of the realm. And by a variety of subsequent statutes, together with the long acquiescence of the crown without exerting the forest-laws, this prerogative is now become no longer a grievance to the subject.

But as the king reserved to himself the *forests* for his own exclusive diversion, so he granted out from time to time other tracts of lands to his subjects under the names of *chases* or *parks*; or gave them licence to make such in their own grounds; which indeed are smaller forests in the hands of a subject, but not governed by the forest-laws; and by the common law no person is at liberty to take or kill any beasts of chase, but such as hath an ancient chase or park; unless they be also beasts of prey.

As to all inferior species of game, called *beasts and fowls of warren*; the liberty of taking or killing them is another franchise or royalty, derived likewise from the crown, and called *free-warren*; a word which signifies preservation or custody: as the exclusive liberty of taking and killing fish in a public stream or river is called a *free-fishery*; of which, however, no new franchise can at present be granted, by the express provision of *magna carta*, c. 16. The principal intention of granting a man these franchises or liberties was in order to protect the game, by giving him a sole and exclusive power of killing it himself, provided he prevented other persons. And no man but he who has a chase or free-warren, by grant from the crown, or prescription, which supposes one, can justify hunting or sporting upon another man's soil; nor indeed, in thorough strictness of common law, either hunting or sporting at all.

However novel this doctrine may seem, it is a regular consequence from what has been before delivered, that the sole right of taking and destroying game belongs exclusively to the king. This appears, as well from the historical deduction here made, as because he may grant to his subjects an exclusive right of taking them; which he could not do, unless such a right was first inherent in himself. And hence it will follow, that no person whatever, but he who has such derivative right from the crown, is by common law intitled to take or kill any beasts of chase, or other game whatsoever. It is true, that, by the acquiescence of the crown, the frequent grants of free-warren in ancient times, and the introduction of new penalties of late by certain statutes for preserving the game, this exclusive prerogative of the king is little known or considered; every man that is exempted from those modern penalties, looking upon himself as at liberty to do what he pleases

Game.

* *M. Paris,*
303.

† 9 Hen. III.

Game.

pleases with the game : whereas the contrary is strictly true, that no man, however well *qualified* he may vulgarly be esteemed, has a right to encroach on the royal prerogative by the killing of game, unless he can show a particular grant of free-warren : or a prescription, which presumes a grant ; or some authority under an act of parliament. As for the latter, there are but two instances wherein an express permission to kill game was ever given by statute ; the one by 1 Jac. I. c. 27. altered by 7 Jac. I. c. 11. and virtually repealed by 22 and 23 Car. II. c. 25. which gave authority, so long as they remained in force, to the owners of free-warren, to lords of manors, and to all freeholders having 40l. *per annum* in lands of inheritance, or 80l. for life or lives, or 400l. personal estate (and their servants), to take partridges and pheasants upon their own, or their master's free-warren, inheritance, or freehold : the other by 5 Ann. c. 14. which empowers lords and ladies of manors to appoint gamekeepers, to kill game for the use of such lord or lady ; which with some alteration still subsists, and plainly supposes such power not to have been in them before. The truth of the matter is, that these game-laws do indeed *qualify* nobody, except in the instance of a gamekeeper, to kill game : but only to save the trouble and formal process of an action by the person injured, who perhaps too might remit the offence, these statutes inflict *additional* penalties, to be recovered either in a regular or summary way, by any of the king's subjects, from certain persons of inferior rank who may be found offending in this particular. But it does not follow that persons excused from these additional penalties are therefore *authorised* to kill game. The circumstance of having 100l. *per annum*, and the rest, are not properly qualifications, but exemptions. And these persons, so exempted from the penalties of the game-statutes, are not only liable to actions of trespass by the owners of the land ; but also, if they kill game within the limits of any royal franchise, they are liable to the actions of such who may have the right of chase or free-warren therein.

* See those articles.

Upon the whole, it appears, that the king, by his prerogative, and such persons as have, under his authority, the ROYAL FRANCHISE OF CHACE, PARK, OR *Free-WARREN**, are the *only* persons who may acquire any property, however fugitive and transitory, in these animals *feræ naturæ*, while living ; which is said to be vested in them *propter privilegium*. And it must also be observed, that such persons as may thus lawfully hunt, fish, or fowl, *ratione privilegii*, have only a qualified property in these animals : it not being absolute or permanent, but lasting only so long as the creatures remain within the limits of such respective franchise or liberty, and ceasing the instant they voluntarily pass out of it. It is held indeed, that if a man starts any game within his own grounds, and follows it into another's, and kills it there, the property remains in himself. And this is grounded on reason and natural justice : for the property consists in the possession ; which possession commences by the finding it in his own liberty, and is continued by the immediate pursuit. And so, if a stranger starts game in one man's chase or free-warren, and hunts it into another liberty, the property continues in the owner of the chase or warren ; this property arising from privilege, and not being changed

by the act of a mere stranger. Or if a man starts game on another's private grounds, and kills it there, the property belongs to him on whose ground it was killed, because it was also started there ; this property arising *ratione soli*. Whereas if, after being started there, it is killed in the grounds of a third person, the property belongs not to the owner of the first ground, because the property is local ; nor yet to the owner of the second, because it was not started in his soil ; but it vests in the person who started and killed it, though guilty of a trespass against both the owners. See the article *Game-LAWS*.

GAME-Cock, a fighting cock, or one kept for sport ; a barbarous practice, which is a disgrace to any civilized nation. See *Cock Fighting*.

GAMELIA, in Grecian antiquity, a nuptial feast, or rather sacrifice, held in the ancient Greek families on the day before a marriage ; thus called from a custom they had of shaving themselves on this occasion, and presenting their hair to some deity to whom they had particular obligations.

GAMELION, in the ancient chronology, was the eighth month of the Athenian year, containing 29 days, and answering to the latter part of our January and beginning of February. It was thus called, as being, in the opinion of the Athenians, the most proper season of the year for marriage.

GAMING, the art of playing or practising any game, particularly those of hazard ; as cards, dice, tables, &c.

Gaming has at all times been looked upon as a thing of pernicious consequence to the commonwealth ; and is therefore severely prohibited by law. It is considered as a practice generally intended to supply, or retrieve, the expences occasioned by LUXURY : it being a kind of tacit confession, that the company engaged therein do, in general, exceed the bounds of their respective fortunes ; and therefore they cast lots to determine upon whom the ruin shall at present fall, that the rest may be saved a little longer. But, taken in any light, it is an offence of the most alarming nature ; tending, by necessary consequence, to promote public idleness, theft, and debauchery, among those of a lower class ; and, among persons of a superior rank, it hath frequently been attended with the sudden ruin and desolation of ancient and opulent families, an abandoned prostitution of every principle of honour and virtue, and too often hath ended in self-murder. To restrain this pernicious vice among the inferior sort of people, the stat. 33 Hen. VIII. c. 9. was made ; which prohibits, to all but gentlemen, the games of tennis, tables, cards, dice, bowls, and other unlawful diversions there specified, unless in the time of Christmas, under pecuniary pains and imprisonment. And the same law, and also the statute 23 Geo. II. c. 24. inflict pecuniary penalties, as well upon the master of any public house wherein servants are permitted to game, as upon the servants themselves who are found to be gaming there. But this is not the principal ground of modern complaint : it is the gaming in high life that demands the attention of the magistrate ; a passion to which every valuable consideration is made a sacrifice, and which we seem to have inherited from our ancestors the ancient Germans ; whom Tacitus describes to have been bewitched with the spirit of play to a most exorbitant

Game
||
Gaming.

Gaming. bitant degree. "They addict themselves (says he) to dice (which is wonderful) when sober, and as a serious employment; with such a mad desire of winning or losing, that when stript of every thing else, they will stake at last their liberty, and their very selves. The loser goes into a voluntary slavery; and, though younger and stronger than his antagonist, suffers himself to be bound and sold. And this perseverance in so bad a cause they call the point of honour: *ea est in re prava pervicacia, ipsi fidem vocant.*" One would be almost tempted to think Tacitus was describing a modern Englishman. When men are thus intoxicated with so frantic a spirit, laws will be of little avail: because the same false sense of honour that prompts a man to sacrifice himself, will deter him from appealing to the magistrate. Yet it is proper that laws should be, and be known publicly, that gentlemen may consider what penalties they wilfully incur, and what a confidence they repose in sharpers; who, if successful in play, are certain to be paid with honour, or, if unsuccessful, have it in their power to be still greater gainers by informing. For, by stat. 16 Car. II. c. 7. if any person by playing or betting shall lose more than 100l. at one time, he shall not be compellable to pay the same; and the winner shall forfeit treble the value, one moiety to the king, the other to the informer. The statute 9 Ann. c. 14. enacts, that all bonds and other securities, given for money won at play, or money lent at the time to play withal, shall be utterly void: that all mortgages and incumbrances of lands, made upon the same consideration, shall be and enure to the heir of the mortgager: that, if any person at one time loses 100l. at play, he may sue the winner, and recover it back by action of debt at law; and, in case the loser does not, any other person may sue the winner for treble the sum so lost; and the plaintiff in either case may examine the defendant himself upon oath: and that in any of these suits no privilege of parliament shall be allowed. The statute farther enacts, that if any person cheats at play, and at one time wins more than 100l. or any valuable thing, he may be indicted thereupon, and shall forfeit five times the value, shall be deemed infamous, and suffer such corporal punishment as in case of wilful perjury. By several statutes of the reign of king George II. all private lotteries by tickets, cards, or dice (and particularly the games of faro, basset, ace of hearts, hazard, passage, roly polly, and all other games with dice, except backgammon), are prohibited under a penalty of 200l. for him that shall erect such lotteries, and 50l. a-time for the players. Public lotteries, unless by authority of parliament, and all manner of ingenious devices, under the denomination of *sales* or otherwise, which in the end are equivalent to lotteries, were before prohibited by a great variety of statutes under heavy pecuniary penalties. But particular descriptions will ever be lame and deficient, unless all games of mere chance are at once prohibited; the invention of sharpers being swifter than the punishment of the law, which only hunts them from one device to another. The stat. 13. Geo. II. c. 19. to prevent the multiplicity of horse races, another fund of gaming, directs, that no plates or matches under 50l. value shall be run, upon penalty of 200l. to be paid by the owner of each horse running, and 100l. by such as advertise the

VOL. VII.

plate. By statute 18 Geo. II. c. 34. the statute 9 Ann. is farther enforced, and some deficiencies supplied: the forfeitures of that act may now be recovered in a court of equity; and, moreover, if any man be convicted, upon information or indictment, of winning or losing at any sitting 100l. or 200l. within 24 hours, he shall forfeit five times the sum. Thus careful has the legislature been to prevent this destructive vice: which may show that our laws against gaming are not so deficient, as ourselves and our magistrates in putting those laws in execution.

Chance, or Hazard, in GAMING. Hazard, or chance, is a matter of mathematical consideration, because it admits of more and less. Gamesters either set out upon an equality of chance, or are supposed to do so. This equality may be altered in the course of the game, by the greater good-fortune or address of one of the gamesters, whereby he comes to have a better chance, so that his share in the stakes is proportionably better than at first. This more and less runs through all the ratios between equality and infinite difference, or from an infinitely little difference till it come to an infinitely great one, whereby the game is determined. The whole game, therefore, with regard to the issue of it, is a chance of the proportion the two shares bear to each other.

The probability of an event is greater or less, according to the number of chances by which it may happen, compared with the number of all the chances by which it may either happen or fail.

M. de Moivre, in a treatise *de Mensura Sortis*, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows.

Suppose p the number of cases in which an event may happen, and q the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as p to q .

If two gamesters, A and B, engage on this footing, that, if the cases p happen, A shall win; but if q happen, B shall win, and the stake be a ; the chance of A will be $\frac{p a}{q+p}$, and that of B $\frac{q a}{p+q}$; consequently, if they sell the expectancies, they should have that for them respectively.

If A and B play with a single die, on this condition, that, if A throw two or more aces at eight throws, he shall win; otherwise B shall win; What is the ratio of their chances? Since there is but one case wherein an ace may turn up, and five wherein it may not, let $a=1$, and $b=5$. And again, since there are eight throws of the die, let $n=8$; and you will have $\overline{a+b}^n - b^n - nab^n - 1$, to $b^n + nab^n - 1$: that is, the chance of A will be to that of B as 663991 to 10156525, or nearly as 2 to 3.

A and B are engaged at single quoits; and, after playing some time, A wants 4 of being up, and B 6; but B is so much the better gamester, that his chance against A upon a single throw would be as 3 to 2; What is the ratio of their chances? Since A wants 4, and B 6, the game will be ended at nine throws; therefore, raise $a+b$ to the ninth power, and it will be $a^9 + 9 a^8 b + 36 a^7 b^2 + 84 a^6 b^3 + 126 a^5 b^4 + 126 a^4 b^5$, to $84 a^2 b^6 + 36 a a b^7 + 6 a b^8 + b^9$: call a 3, and b 2, and

3 Y

you

Gaming.

Gaming. you will have the ratio of chances in numbers, viz. 1759077 to 194048.

A and B play at single quoits, and A is the best gameller, so that he can give B 2 in 3: What is the ratio of their chances at a single throw? Suppose the chances as z to 1, and raise $z+1$ to its cube, which will be z^3+3z^2+3z+1 . Now since A could give B 2 out of 3, A might undertake to win three throws running; and consequently the chances in this case will be as z^3 to $3z^2+3z+1$. Hence $z^3=3z^2+3z+1$; or $2z^3=z^3+3z^2-3z+1$. And therefore $z\sqrt[3]{2}=z+1$; and, consequently, $z=\sqrt[3]{2}-1$. The chances, therefore, are $\sqrt[3]{2}-1$, and 1, respectively.

Again, suppose I have two wagers depending, in the first of which I have 3 to 2 the best of the lay, and in the second 7 to 4; What is the probability I win both wagers?

1. The probability of winning the first is $\frac{3}{5}$, that is the number of chances I have to win, divided by the number of all the chances: the probability of winning the second is $\frac{7}{11}$: therefore, multiplying these two fractions together, the product will be $\frac{21}{55}$, which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is $\frac{34}{55}$, which is the probability I do not win both wagers: therefore the odds against me are 34 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus: the probability of winning the first is $\frac{3}{5}$, the probability of losing the second is $\frac{4}{11}$: therefore multiplying $\frac{3}{5}$ by $\frac{4}{11}$, the product $\frac{12}{55}$ will be the probability of my winning the first, and losing the second; which being subtracted from 1, there will remain $\frac{43}{55}$, which is the probability I do not win the first, and at the same time lose the second.

3. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: The probability of winning the second is $\frac{7}{11}$; the probability of losing the first is $\frac{2}{5}$: therefore, multiplying these two fractions together, the product $\frac{14}{55}$ is the probability I win the second, and also lose the first.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is $\frac{2}{5}$, and the probability of losing the second $\frac{4}{11}$: therefore the probability of losing them both is $\frac{8}{55}$: which, being subtracted from 1, there remains $\frac{47}{55}$: therefore, the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration. Thus if I would know what the probability is of missing an ace four times together with a die, this I consider as the failing of four different events. Now the probability of missing the first is $\frac{5}{6}$, the second is also $\frac{5}{6}$, the third $\frac{5}{6}$, and the fourth $\frac{5}{6}$; therefore the probability of missing it four times together is $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296}$; which being subtracted from 1, there will remain $\frac{671}{1296}$ for the probability of throwing it once or oftener in four times: therefore the odds of throwing an ace in four times, is 671 to 625.

But if the flinging of an ace was undertaken in three times, the probability of missing it three times would

be $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{216}$; which being subtracted from 1, there will remain $\frac{91}{216}$ for the probability of throwing it once or oftener in three times: therefore the odds against throwing it in three times are 125 to 91. Again, suppose we would know the probability of throwing an ace once in four times, and no more: since the probability of throwing it the first time is $\frac{1}{6}$, and of missing it the other three times, is $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6}$, it follows, that the probability of throwing it the first time, and missing it the other three successive times, is $\frac{1}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{1296}$; but because it is possible to hit every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing it the other three, is $\frac{4 \times 125}{1296} = \frac{500}{1296}$; which being subtracted from 1, there will remain $\frac{796}{1296}$ for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or 5 to 8 very near.

Suppose two events are such, that one of them has twice as many chances to come up as the other; what is the probability, that the event, which has the greater number of chances to come up, does not happen twice before the other happens once, which is the case of flinging 7 with two dice before 4 once? Since the number of chances is as 2 to 1, the probability of the first happening before the second is $\frac{2}{3}$, but the probability of its happening twice before it is but $\frac{2}{3} \times \frac{2}{3}$ or $\frac{4}{9}$: therefore it is 5 to 4 seven does not come up twice before four once.

But, if it were demanded, what must be the proportion of the facilities of the coming up of two events, to make that which has the most chances come up twice, before the other comes up once? The answer is, 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is $\frac{12}{17}$, and the probability of throwing it twice is $\frac{12}{17} \times \frac{12}{17}$, or $\frac{144}{289}$: therefore the probability of not doing it is $\frac{145}{289}$: therefore the odds against it are as 145 to 144, which comes very near an equality.

Suppose there is a heap of thirteen cards of one colour, and another heap of thirteen cards of another colour; What is the probability, that, taking one card at a venture out of each heap, I shall take out the two aces?

The probability of taking the ace out of the first heap is $\frac{1}{13}$, the probability of taking the ace out of the second heap is $\frac{1}{13}$; therefore the probability of taking out both aces is $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$, which being subtracted from 1, there will remain $\frac{168}{169}$: therefore the odds against me are 168 to 1.

In cases where the events depend on one another, the manner of arguing is somewhat altered. Thus, suppose that out of one single heap of thirteen cards of one colour I should undertake to take out first the ace; and, secondly, the two: though the probability of taking out the ace be $\frac{1}{13}$, and the probability of taking out the two be likewise $\frac{1}{13}$: yet, the ace being supposed as taken out already, there will remain only twelve cards in the heap, which will make the probability of taking out the two to be $\frac{1}{12}$; therefore the probability of taking out the ace, and then the two, will be $\frac{1}{13} \times \frac{1}{12}$.

In this last question the two events have a dependence on each other; which consists in this, that one of the events

Gaming events being supposed as having happened, the probability of the other's happening is thereby altered. But the case is not so in the two heaps of cards.

Ganges.

If the events in question be n in number, and be such as have the same number a of chances by which they may happen, and likewise the same number b of chances by which they may fail, raise $a+b$ to the power n . And if A and B play together, on condition that if either one or more of the events in question happen, A shall win, and B lose, the probability of A's winning will be $\frac{a \times b |^n - b^n}{a+b |^n}$; and that of B's win-

ning will be $\frac{b^n}{a+b |}$; for when $a+b$ is actually raised to the power n , the only term in which a does not occur is the last b^n : therefore all the terms but the last are favourable to A.

Thus if $n=3$, raising $a+b$ to the cube $a^3+3a^2b+3ab^2+b^3$, all the terms but b^3 will be favourable to A; and therefore the probability of A's winning will be $\frac{a^3+3a^2b+3ab^2}{a+b |}$, or $\frac{a+b |^3 - b^3}{a+b |^3}$; and the probability of B's winning will be $\frac{b^3}{a+b |^3}$. But if A and B

play on condition, that if either two or more of the events in question happen, A shall win; but in case one only happen, or none, B shall win; the probability of A's winning will be $\frac{a+b |^n - nabn - 1 - bn}{n+b |^n}$; for

the only two terms in which aa does not occur, are the two last, viz. $nabn - 1$ and bn .

GAMMONING, among seamen, denotes several turns of a rope taken round the bowsprit, and reeved through holes in knees of the head, for the greater security of the bowsprit.

GAMMUT, **GAMUT**, **GAM-ut**, in music, a scale whereon we may learn to sound the musical notes, *ut, re, mi, fa, sol, la*, in their several orders and dispositions. See **MUSIC**.

The invention of this scale is owing to Guido Aretin, monk of Arezzo, in Tuscany, about the year 1009; though it is not so properly an invention, as an improvement on the diagram or scale of the ancients. See **ARETIN**.

Several alterations have been made in the gammut. M. le Maire, particularly, has added a seventh note; viz. *si*; and the English usually throw out both *ut* and *si*, and make the other five serve for all.

GANDER, in ornithology, the male of the goose-kind; one of which, it is said, will serve five geese. See **ANAS**.

GANG-WAY, is the several passages or ways from one part of the ship to the other; and whatsoever is laid in any of those passages, is said to lie in the gang-way.

GANGANELLI. See **CLEMENT XIV**.

GANGES, a large and celebrated river of India. It has its source in the mountains which border on Little Thibet, in 96 degrees of longitude, and 35. 45. of latitude. It crosses several kingdoms, running from north to south; and falls into the bay of Bengal, by several mouths. The waters are lowest in April and May, and highest before the end of September. It

overflows yearly like the Nile; and renders the kingdom of Bengal as fruitful as that of the Delta in Egypt. The people in these parts hold the water of this river in high veneration; and it is visited annually by a prodigious number of pilgrims from all parts of India. The English have several settlements on this river, which will be taken notice of in their proper places. The greatest happiness that many of the Indians wish for, is to die in this river.

GANGLION, in anatomy, denotes a knot frequently found in the course of the nerves, and which is not morbid; for whenever any nerve sends out a branch, or receives one from another, or where two nerves join together, there is generally a ganglion or plexus, as may be seen at the beginning of all the nerves of the medulla spinalis, and in many other places of the body.

GANGLION, in surgery, a hard tubercle, generally moveable, in the external or internal part of the carpus, upon the tendons or ligaments in that part; usually without any pain to the patient.

GANGRENE, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a state of putrefaction. See **MEDICINE**, and **SURGERY**.

GANNET, or *SOLAND Goose*, in ornithology. See **PELICANUS**.

GANTLET, or **GAUNTLET**, a large kind of glove made of iron, and the fingers covered with small plates. It was formerly worn by the cavaliers, when armed at all points. The word is derived of the French *gantlet*; and that from *gant* or *gant*, "glove."

The casque and gauntlets were always borne in the ancient marches in ceremony. Gauntlets were not introduced till about the 13th century.

The gauntlet was frequently thrown like the glove, by way of challenge.

GANTLOPE. See **GAUNTLOPE**.

GANYMEDE, in mythology, a beautiful youth of Phrygia, son of Tros and brother to Ilus; according to Lucian, he was the son of Dardanus. Jupiter was charmed with him; and carrying him away, made him his cup-bearer in the room of Hebe. Some say that he caused him to be carried away by an eagle, and others affirm he was himself the ravisher under the form of that bird. He deified this youth; and to comfort his father, made a present to him of some of those very swift horses that the gods rode upon.

GAOL (*Gaola*, Fr. *Geole*. i. e. *Caveola*, "a cage for birds"), is used metaphorically for a prison. It is a strong place or house for keeping of debtors; &c. and wherein a man is restrained of his liberty to answer an offence done against the laws: and every county hath two goals, one for debtors, which may be any house where the sheriff pleases; the other for the peace and matters of the crown, which is the county gaol.

If a gaol be out of repair, or insufficient, &c. justices of peace, in their quarter sessions, may contract with workmen for the rebuilding or repairing it; and by their warrant order the sum agreed on for that purpose to be levied on the several hundreds, and other divisions in the county by a just rate, 11 & 12 Wil. III. c. 19. See **PRISON**.

GAOL-Delivery. The administration of justice being originally in the crown, in former times our kings

Ganglion
Gaol.

Gaoler
||
Garamond.

in person rode through the realm once in seven years, to judge of and determine crimes and offences; afterwards justices in eyre were appointed; and since, justices of assize and gaol-delivery, &c. A commission of gaol-delivery, is a patent in nature of a letter from the king to certain persons, appointing them his justices, or two or three of them, and authorising them to deliver his gaol, at such a place, of the prisoners in it: for which purpose it commands them to meet at such a place, at the time they themselves shall appoint; and informs them, that, for the same purpose, the king hath commanded his sheriff of the same county to bring all the prisoners of the gaol, and their attachments, before them at the day appointed.

The justices of gaol-delivery are empowered by the common law to proceed upon indictments of felony, trespass, &c. and to order to execution or reprieve: they may likewise discharge such prisoners, as on their trials are acquitted, and those against whom, on proclamation being made, no evidence has appeared: they have authority to try offenders for treason, and to punish many particular offences, by statute 2 *Hawk.* 24. 2 *Hale's hist. Placit. Cor.* 35.

GAOLER, the keeper of a gaol or prison. Sheriffs are to make such gaolers for whom they will be answerable: but if there be any default in the gaoler, an action lies against him for an escape, &c. yet the sheriff is most usually charged; 2 *Inst.* 592. Where a gaoler kills a prisoner by hard usage, it is felony; 3 *Inst.* 52. No fee shall be taken by gaolers, but what is allowed by law, and settled by the judges, who may determine petitions against their extortions, &c. 2 *Geo.* II. c. 22.

GAONS, a certain order of Jewish doctors, who appeared in the East, after the closing of the talmud. The word *Gaons* signifies "excellent, sublime;" as in the divinity-schools we formerly had Irrefragable, Sublime, Resolute, Angelic, and Subtile doctors. The Gaons succeeded the Seburæans or Opinians, about the beginning of the sixth century. Chanan Meischia was the head, and first of the excellents. He restored the academy of Pandebita, which had been shut up for 30 years.

GAR-FISH, *Horn-fish*, or *Sea-needle*. See *Esox*.

GARAMA (anc. geog.), the capital of the Garamantes in Libya Interior; near the springs of the Cinyphus, now in ruins. Garamantes the people. It lay to the south of the Gætulia, extending from the springs of the Cinyphus, and the adjacency of the river Gir, to the mountains which form at the *Vallis Garamantica* (Pliny); or from the springs of the Bagrades to the lake Nuba (Ptolemy).

GARAMOND (Claude), a very ingenious letter-founder, was born at Paris; where he began, in the year 1510, to found his printing types free from all the remains of the Gothic, or (as it is generally called) the *black letter*, and brought them to such perfection, that he had the glory of surpassing all who went before him, and of being scarcely ever excelled by his successors in that useful art. His types were prodigiously multiplied; both by the great number of matrices he struck, and the types formed in resemblance of his in all parts of Europe. Thus in Italy, Germany, England, and Holland, the booksellers, by way of recommending their books, distinguished the type by

his name; and in particular the small Roman was by way of excellence known among the printers of these nations by the name of *Garamond's small Roman*. By the special command of king Francis I. he founded three sizes of Greek types for the use of Robert Stephens, who with them printed all his beautiful editions of the New Testament, and other Greek authors. He died at Paris in 1561.

GARASSE (Francis), a remarkable jesuitical writer, the first author of that irreconcilable enmity that still subsists between the Jesuits and Jansenists in the church of Rome, was born at Angoulesme in 1585; and entered the Jesuits college in 1600. As he had a quick imagination, a strong voice, and a peculiar turn to wit, he became a popular preacher in the chief cities of France; but not content with this honour, he distinguished himself still more by his writings, which were bold, licentious, and produced much controversy. The most considerable in its consequences was intitled *La somme theologique des veritez capitales de la religion Chretienne*; which was first attacked by the abbot of St Cyran, who observing in it a prodigious number of falsifications of the scriptures and of the fathers, besides many heretical and impious opinions, conceived the honour of the church required him to undertake a refutation. Accordingly he published a full answer to it; while Garasse's book was also under examination of the doctors of the Sorbonne, by whom it was afterwards condemned. Garasse replied to St Cyran; but the two parties of Jesuits and Jansenists, of whom these were respectively the champions, grew to an implacable animosity against each other, that is not even now likely to subside. The Jesuits were forced to remove their brother to a distance from Paris; where, probably weary of his inactive obscurity, when the plague raged at Poitiers in 1631, he begged leave of his superior to attend the sick, in which charitable office he caught the disorder, and died.

GARBÉ, in heraldry, a sheaf of any kind of grain, borne in several coats of arms, and said to represent summer, as a bunch of grapes does autumn.

GARBLE, a word used to signify the action of separating the dross and dust from spice, drugs, &c. *Garbling* is the cleansing and purifying the good from the bad; and may come from the Italian *garbo*, i. e. finery or neatness: and hence, probably, we say, when we see a man in a neat habit, that he is in handsome *garb*.

GARCILASSO (de la Vega), a celebrated Spanish poet, born of a noble family at Toledo in 1500. He was educated near the emperor Charles V. who had a particular regard for him, and whom he attended in all his military expeditions; acquiring as much renown by his courage as by his poetry. In Provence he commanded a battalion; and was killed in the 36th year of his age, by a stone thrown at his head by a country man from a turret. He had strong natural talents for poetry; and not only extended the bounds, but introduced new beauties, into that of the Spanish language. — We must not confound this poet with another person of the same name, a native of Cusco, who wrote in Spanish a History of Florida, and of Peru and the Incas.

GARCINIA, in botany: A genus of the monogynia order, belonging to the dodecandria class of plants;

Garasse
||
Garcinia.

Garcinia plants; and in the natural method ranking under the 18th order, *Bicornes*. The calyx is tetraphilous inferior; there are four petals; the berry is octospermous; and crowned with a shield-like stigma. There is but one species, the mangostana, a tree of great elegance, and producing the most pleasant fruit of any yet known. See Plate CCVI.

This tree has been very accurately described by Dr Garcin *, in the 35th volume of the Philosophical Transactions. It grows, he informs us, to about 17 or 18 feet high, "with a straight taper stem like a fir," having a regular tuft in form of an oblong cone, composed of many branches and twigs, spreading out equally on all sides, without leaving any hollow. Its leaves, he observes, are oblong, pointed at both ends, entire, smooth, of a shining green on the upper side, and of an olive on the back. Its flower is composed of four petals, almost round, or a little pointed: their colour resembles that of a rose, only deeper and less lively. The calyx of this flower is of one piece, expanded, and cut into four lobes. The two upper lobes are something larger than the lower ones; they are greenish on the outside, and of a fine deep red within; the red of the upper is more lively than that of the lower ones. This calyx incloses all parts of the flower; it is supported by a pedicle, which is green and constantly comes out of the end of a twig above the last pair of leaves. The fruit is round, of the size of a small orange, from an inch and an half to two inches diameter. The body of this fruit is a capsula of one cavity, composed of a thick rind a little like that of a pomegranate, but softer, thicker, and fuller of juice. Its thickness is commonly of a quarter of an inch. Its outer colour is of a dark brown purple, mixed with a little grey and dark green. The inside of the peel is of a rose colour, and its juice is purple. Last of all, the skin is of a styptic or astringent taste, like that of a pomegranate, nor does it stick to the fruit it contains. The inside of this fruit is a furrowed globe, divided into segments, much like those of an orange, but unequal in size, which do not adhere to each other. The number of these segments is always equal to that of the rays of the top which covers the fruit. The fewer there are of these segments, the bigger they are. There are often in the same fruit segments as big again as any of those that are on the side of them. These segments are white, a little transparent, fleshy, membranous, full of juice like cherries or raspberries; of a taste of strawberries and grapes together. Each of the segments incloses a seed of the figure and size of an almond stripped of its shell, having a protuberance on one of its sides. These seeds are covered with two small skins, the outermost of which serves for a basis to the filaments and membranes of which the pulp is composed. The substance of those seeds comes very near that of chestnuts, as to their consistency, colour and astringent quality.

"This tree (according to our author) originally grows in the Molucca islands, where it is called *mangostan*; but has been transplanted from thence to the island of Java and Malaca, at which last place it thrives very well. Its tuft is so fine, so regular, so equal, and the appearance of its leaves so beautiful, that it is at present looked upon at Batavia as the most proper for adorning a garden, and affording an agreeable shade.

There are few seeds, however (he observes), to be met with in this fruit that are good for planting, most part of them being abortive."— He concludes his description by mentioning, that one may eat a great deal of this fruit without any inconvenience; and that it is the only one which sick people may be allowed to eat without any scruple.

Other writers concur in their praises of this fruit. Rumphius observes, that the mangostan is universally acknowledged to be the best and wholesomest fruit that grows in India; that its flesh is juicy, white, almost transparent, and of as delicate and agreeable a flavour as the richest grapes: the taste and smell being so grateful, that it is scarce possible to be cloyed with eating it.—He adds, that when sick people have no relish for any other food, they generally eat this with great delight; but should they refuse it, their recovery is no longer expected. "It is remarkable (says he) that the mangostan is given with safety in almost every disorder. The dried bark is used with success in the dysentery and tenesmus; and an infusion of it is esteemed a good gargle for a sore mouth or ulcers in the throat. The Chinese dyers use this bark for the ground or basis of a black colour, in order to fix it the firmer."

According to Captain Cook, in his Voyage round the World, vol. iii. p. 737, the *garcinia mangostana* of Linnæus is peculiar to the East Indies. It is about the size of the crab-apple, and of a deep red wine colour. On the top of it is the figure of five or six small triangles joined in a circle; and at the bottom several hollow green leaves, which are remains of the blossom. When they are to be eaten, the skin, or rather flesh, must be taken off; under which are found six or seven white kernels, placed in a circular order; and the pulp with which these are enveloped in the fruit, than which nothing can be more delicious. It is a happy mixture of the tart and the sweet, which is no less wholesome than pleasant; and, as well as the sweet orange, is allowed in any quantity to those who are afflicted with fevers either of the putrid or inflammatory kind.

GARCON, or GARSOON, a French term, literally signifying a boy or male child any time before his marriage.—It is also applied to divers inferior officers, among us called *grooms*, *garçions*. Thus all the servants in the French king's chambers, wardrobe, &c. who do the lesser offices thereof under the proper officers, are called *garçons de la chambre*, *de la garderobe*, &c.

GARDANT, or GUARDANT, in heraldry, denotes any beast full-faced, and looking right forward.

GARDEN, a piece of ground properly laid out, cultivated, and ornamented with a variety of plants, flowers, fruits, &c. See GARDENING.

Gardens are usually distinguished into flower-garden, fruit-garden, and kitchen-garden: the first of which, being designed for pleasure and ornament, is to be placed in the most conspicuous part, that is, next to the back-front of the house; and the two latter, being designed for use, should be placed less in sight. But though the fruit and kitchen gardens, are here mentioned as two distinct gardens, yet they are now usually in one; and that with good reason, since they both require a good soil and exposure, and equally require to be placed out of the view of the house. See KITCHEN-Garden.

In the choice of a place proper for the garden, the most

Garcinia,
||
Garden

* In honour of whom as its most accurate describer Linnæus gave it the name *Garcinia*.

Garden. most essential points to be considered are the situation, the soil, the exposure, water, and prospect.

1st, As to the situation, it ought to be such a one as is wholesome, and in a place neither too high nor too low; for if a garden to be too high, it will be exposed to the winds which are very prejudicial to trees; and if it be too low, the dampness, the vermin, and the venomous creatures that breed in ponds and marshy places, add much to their insalubrity. The most happy situation is on the side of a hill, especially if the slope be easy, and in a manner imperceptible; if a good deal of level ground be near the house; and if it abounds with springs of water: for, being sheltered from the fury of the winds, and the violent heat of the sun, a temperate air will be there enjoyed; and the water that descends from the top of the hill, either from springs or rain, will not only supply fountains, canals, and cascades for ornaments, but, when it has performed its office, will water the adjacent valleys, and, if it be not suffered to stagnate, will render them fertile and wholesome.

2dly, A good earth or soil is next to be considered; for it is scarce possible to make a fine garden in a bad soil. There are indeed ways to meliorate ground, but they are very expensive; and sometimes, when the expence has been bestowed of laying good earth three feet deep over the whole surface, a whole garden has been ruined, when the roots of the trees have come to reach the natural bottom. To judge of the quality of the soil, observe whether there be any heath, thistles, or such like weeds, growing spontaneously in it; for they are certain signs that the ground is poor. Or if there be large trees growing thereabouts, observe whether they grow crooked, ill-shaped, and grubby; and whether they are of a faded green, and full of moss, or infested with vermin: if this be the case, the place is to be rejected. But, on the contrary, if it be covered with good grass fit for pasture, you may then be encouraged to try the depth of the soil. To know this, dig holes in several places, six feet wide and four deep; and if you find three feet of good earth it will do very well, but less than two will not be sufficient. The quality of ground is, neither to be too stony nor too hard to work; neither too dry, too moist, nor too sandy and light; nor too strong and clayey, which is the worst of all for gardens.

3dly, The next requisite is water; the want of which is one of the greatest inconveniences that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts that often happen in a hot and dry situation in summer; besides its usefulness in fine gardens for making fountains, canals, cascades, &c. which are the greatest ornaments of a garden.

4thly, The last thing to be considered is the prospect of a fine country; and though this is not so absolutely necessary as water, yet it is one of the most agreeable beauties of a fine garden: besides, if a garden be planted in a low place that has no kind of prospect, it will not only be disagreeable, but unwholesome.

In the laying out and planting of gardens, the beauties of nature should always be studied; for the nearer a garden approaches to nature, the longer it will please. According to Mr Miller, the area of a handsome garden may take up 30 or 40 acres, but not more; and

the following rules should be observed in the disposition of it. There ought always to be a descent of at least three steps from the house to the garden; this will render the house more dry and wholesome, and the prospect on entering the garden more extensive. The first thing that ought to present itself to view should be an open lawn of grass, which ought to be considerably broader than the front of the building; and if the depth be one-half more than the width, it will have a better effect: if on the sides of the lawn, there are trees planted irregularly, by way of open groves, the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn should be surrounded with a gravel-walk, on the outside of which should be borders three or four feet wide for flowers: and from the back of these the prospect will be agreeably terminated by a slope of ever-green shrubs; which, however, should never be suffered to exclude agreeable prospects, or the view of handsome buildings. These walks may lead through the different plantations, gently winding about in an easy natural manner; which will be more agreeable than either those long straight walks, too frequently seen in gardens, or those serpentine windings that are twisted about into so many short turns as to render it difficult to walk in them; and as no garden can be pleasing where there is a want of shade and shelter, these walks should lead as soon as possible into plantations, where persons may walk in private, and be sheltered from the wind.

Narrow rivulets, if they have a constant stream, and are judiciously led about a garden, have a better effect than many of the large stagnating ponds or canals so frequently made in large gardens. When wildernesses are intended, they should not be cut into stars and other ridiculous figures, nor formed into mazes or labyrinths, which in a great design appear trifling.

In short, the several parts of a garden should be diversified; but in places where the eye takes in the whole at once, the two sides should be always the same. In the business of designs, the aim should be always at what is natural, great, and noble. The general disposition of a garden and of its parts ought to be accommodated to the different situations of the ground, to humour its inequalities, to proportion the number and sorts of trees and shrubs to each part, and to shut out from the view of the garden no objects that may become ornamental. But for a more extended view of this subject, see the article GARDENING.

A practical attention to a garden, is by some esteemed a degrading employment. It is true, indeed, that pastoral and agricultural manners, if we may form a judgment from the dignified descriptions of Virgil, are greatly degenerated. The employments of shepherds and husbandmen are now become mean and sordid. The work of the garden is usually left to a peasant. Nor is it unreasonable to assign the labour, which wears without amusement, to those who are sufficiently amused by the prospect of their wages. But the operations of grafting, of inoculating, of pruning, of transplanting, are curious experiments in natural philosophy; and that they are pleasing as well as curious, those can testify who remember what they felt on seeing their attempts in the amusement of practical gardening attended with success. Among the

Garden.

Garden. employments suitable to old age, Cicero has enumerated the superintendence of a garden. It requires no great exertion of mind or body; and its satisfactions are of that kind which please without violent agitation. Its beneficial influence on health is an additional reason for an attention to it at an age when infirmities abound.

In almost every description of the seats of the blessed, ideas of a garden seems to have predominated. The word Paradise itself is synonymous with garden. The fields of Elysium, that sweet region of poetry, are adorned with all that imagination can conceive to be delightful. Some of the most pleasing passages of Milton, are those in which he represents the happy pair engaged in cultivating their blissful abode. Poets have always been delighted with the beauties of a garden. Lucan is represented by Juvenal as reposing in his garden. Virgil's Georgics prove him to have been captivated with rural scenes; though, to the surprise of his readers, he has not assigned a book to the subject of a garden. Shenstone made it his study; but, with all his taste and fondness for it, he was not happy in it. The captivating scenes which he created at the Leasowes, afforded him, it is said, little pleasure in the absence of spectators. The truth is, he made the embellishment of his grounds, which should have been the amusement of his life, the business of it; and involved himself in such troubles, by the expences it occasioned, as necessarily excluded tranquil enjoyment.

It is the lot of few, in comparison, to possess territories like his, extensive, and sufficiently well-adapted to constitute an ornamented farm. Still fewer are capable of supporting the expence of preserving it in good condition. But let not the rich suppose they have appropriated the pleasures of a garden. The possessor of an acre, or a smaller portion, may receive a real pleasure, from observing the progress of vegetation, even in a plantation of culinary plants. A very limited tract, properly attended to will furnish ample employment for an individual. Nor let it be thought a mean care; for the same hand that raised the cedar, formed the hyssop on the wall. Even the orchard, cultivated solely for advantage, exhibits beauties unequalled in the shrubbery; nor can the green-house produce an appearance to exceed the blossom of the apple and the almond.

Hanging GARDENS, in antiquity, gardens raised on arches by Nebuchadnezzar king of Babylon, in order to gratify his new wife Amyctis, daughter of Astyages king of Media. Q. Curtius makes them equal in height to the walls of the city, viz. 50 feet. They contained a square of 400 feet on every side, and were carried up into the air in several terraces laid above one another, and the ascent from terrace to terrace was by stairs 10 feet wide. The arches sustaining the whole pile were raised above one another, and it was strengthened by a wall, surrounding it on every side, of 22 feet in thickness. The floors of each of the terraces were laid in the following manner: on the top of the arches were first laid large flat stones 16 feet

long and 4 broad, and over them was a layer of reed mixed with a great quantity of bitumen, over which were two rows of bricks closely cemented together by plaster, and over all were laid thick sheets of lead; and lastly, upon the lead was laid the mould of the garden. The mould or earth was of such a depth as to admit the largest trees to take root and grow; and it was covered with various kinds of trees, plants, and flowers. In the upper terrace there was an aqueduct or engine, whereby water was drawn up out of the river for watering the whole garden.

Floating GARDENS. We are informed by the abbé Clavigero in his History of Mexico, that when the Mexicans were brought under subjection to the Colhuan and Tepanecan nations, and confined to the miserable little islands on the lake of Mexico, they ceased for some years to cultivate the land, because they had none, until necessity and industry together taught them to form moveable fields and gardens, which floated on the waters of the lake. The method which they pursued to make those, and which they still practise, is extremely simple. They plait and twist willows and roots of marsh plants or other plait materials together, which are light, but capable of supporting the earth of the garden firmly united. Upon this foundation they lay the light bushes which float on the lake; and over all, the mud and dirt which they draw up from the bottom of the same lake. Their regular figure is quadrangular; their length and breadth various; but generally they are about eight perches long, and not more than three in breadth, and have less than a foot of elevation above the surface of the water. These were the first fields which the Mexicans owned after the foundation of Mexico; there they first cultivated the maize, great pepper, and other plants necessary for their support. In progress of time, as those fields grew numerous from the industry of the people, there were among them gardens of flowers and odoriferous plants, which were employed in the worship of their gods, and served for the recreation of the nobles. At present they cultivate flowers and every sort of garden herbs upon them. Every day of the year, at sun-rise, innumerable vessels loaded with various kinds of flowers and herbs, which are cultivated in those gardens, are seen arriving by the canal, at the great market-place of that capital. All plants thrive there surprisingly; the mud of the lake is an extremely fertile soil, and requires no water from the clouds. In the largest gardens there is commonly a little tree, and even a little hut to shelter the cultivator and defend him from rain or the sun. When the owner of the garden, or the *Chinampa* as he is usually called, wishes to change his situation, to remove from a disagreeable neighbour, or to come nearer to his own family, he gets into his little vessel, and by his own strength alone if the garden is small, or with the assistance of others if it is large, he tows it after him, and conducts it wherever he pleases with the little tree and hut upon it. That part of the lake where those floating gardens are, is a place of infinite recreation, where the senses receive the highest possible gratification.

Garden.

G A R D E N I N G ;

THE art of planning and cultivating gardens. In its utmost extent, whatever contributes to render the scenes of nature delightful, is amongst the subjects of gardening; and animate as well as inanimate objects are circumstances of beauty or character. The whole range of nature is open to the gardener, from the parterre to the forest; and whatever is agreeable to the senses or the imagination, he may appropriate to the spot he is to improve: it is a part of his business to collect into one place the delights which are generally dispersed through different species of country.

History of Gardening.

* *Hist. of Mod. Gardening*, subjoined to the 4th vol. of his *Anecdotes of Painting*.

GARDENING, Mr Walpole * observes, was probably one of the first arts that succeeded to that of building houses, and naturally attended property and individual possession. Culinary, and afterwards medicinal herbs, were the objects of every head of a family: it became convenient to have them within reach, without seeking them at random in woods, in meadows, and on mountains, as often as they were wanted. When the earth ceased to furnish spontaneously all those primitive luxuries, and culture became requisite, separate inclosures for rearing herbs grew expedient. Fruits were in the same predicament; and those most in use or that demand attention must have entered into and extended the domestic inclosure. The good man Noah, we are told, planted a vineyard, drank of the wine, and was drunken; and every body knows the consequences. Thus we acquired kitchen-gardens, orchards, and vineyards. No doubt the prototype of all these sorts was the garden of Eden; but as that Paradise was a good deal larger than any we read of afterwards, being inclosed by the rivers Pison, Gihon, Hiddekel, and Euphrates; as every tree that was pleasant to the sight and good for food grew in it; and as two other trees were likewise found there, of which not a slip or sucker remains; it does not belong to the present discussion. After the Fall, no man living was suffered to enter into the garden; and the poverty and necessities of our first ancestors hardly allowed them time to make improvements in their estates in imitation of it, supposing any plan had been preserved. A cottage and a slip of ground for a cabbage and a gooseberry-bush, such as we see by the side of a common, were in all probability the earliest seats and gardens: a well and bucket succeeded to the Pison and Euphrates. As settlements increased, the orchard and the vineyard followed; and the earliest princes of tribes possessed just the necessaries of a modern farmer.

Matters, we may well believe, remained long in this situation; and we have reason to think that for many centuries the term *garden* implied no more than a kitchen-garden or orchard.

The garden of Alcinous, in the *Odyssey*, is the most renowned in the heroic times. Is there an admirer of Homer who can read his description without rapture? or who does not form to his imagination a scene of delights more picturesque than the landscapes of Tinian

or Juan Fernandez? "Yet (continues our author) what was that boasted Paradise with which

the gods ordain'd
To grace Alcinous and his happy land?

Why, divested of harmonious Greek and bewitching poetry, it was a small orchard and vineyard, with some beds of herbs and two fountains that watered them, inclosed within a quick-set hedge. The whole compass of this pompous garden inclosed—four acres:

Four acres was th' allotted space of ground,
Fenc'd with a green inclosure all around.

The trees were apples, figs, pomegranates, pears, olives, and vines.

Tall thriving trees confess'd the fruitful mould;
The red'ning apple ripens into gold.
Here the blue fig with luscious juice o'erflows,
With deeper red the full pomegranate glows.
The branch here bends beneath the weighty pear,
And verdant olives flourish round the year.

* * * * *

Beds of all various herbs, for ever green,
In beauteous order terminate the scene.

Alcinous's garden was planted by the poet, enriched by him with the fairy gift of eternal summer, and no doubt an effort of imagination surpassing any thing he had ever seen. As he has bestowed on the same happy prince a palace with brazen walls and columns of silver, he certainly intended that the gardens should be proportionably magnificent. We are sure, therefore that, as late as Homer's age, an inclosure of four acres, comprehending orchard, vineyard, and kitchen-garden, was a stretch of luxury the world at that time had never beheld."

Previous to this, however, we have in the sacred writings hints of a garden still more luxuriously furnished. We allude to the Song of Solomon, part of the scene of which is undoubtedly laid in a garden †. Flowers and fruits are particularly spoken of as the ornaments and the produce of it; and besides these, aromatic vegetables formed a considerable part of the gratifications it afforded. The camphor and the cinnamon tree, with all trees of frankincense, and all the chief species, flourished there ‡. Solomon tells us in another place ||, That he made him great works;—gardens and orchards, and planted in them trees of every kind. Indeed we must suppose his gardens to have been both amply and curiously furnished, seeing the kinds, nature, and properties of the vegetable tribes, seem to have been a favourite study with the royal philosopher, and to have been deemed a subject worthy of his pen: for we are told, that he wrote of plants, from the great cedar of Lebanon down to the hyssop of the wall §. Fountains and streams of water appear also to have had a share in the composition, and probably for ornament as well as use.

The hanging gardens of Babylon, mentioned in a preceding article, were a still greater prodigy. But as they are supposed to have been formed on terraces and the walls of the palace, whither soil was conveyed on purpose, Mr Walpole concludes, "they were what sumptuous

tuous

tuous gardens have been in all ages till the present, unnatural, enriched by art, possibly with fountains, statues, ballustrades, and summer-houses, and were any thing but verdant and rural."

Others, however, have allowed them greater praise. They seem, in many respects, to have been laid out with good taste. Their elevation not only produced a variety and extent of view, but was also useful in moderating the heat. Such a situation would likewise suit a greater variety of trees and plants than a plain surface, and would contain a larger as well as a more diversified extent.

The suiting of the situation to the nature of the trees seems, from the account given by Josephus, to have been one view* in the erecting the building in such a manner. And the success seems to have been answerable, as the trees are said to have flourished extremely well†, and to have grown as tall as in their native situations. On the whole, then, however different these may appear from modern gardens, they seem to have been formed with judgment and taste, and well adapted to the situation and circumstances.

It seems probable, from several circumstances, that the eastern gardens were adjoining to the house or palace to which they belonged. Thus, king Ahasuerus goes immediately from the banquet of wine to walk in the garden of the palace‡. The garden of Cyrus, at Sardis, mentioned by Xenophon||, was probably contiguous to the palace; as was that of Attalus, mentioned by Justin§. The hanging gardens at Babylon, were not so much adjacent to the palace, as a part of the palace itself, since several of the royal apartments were beneath them¶.

It is not clear what the taste for gardening was among the Greeks. The Academus, we know, was a wooded shady place; and the trees appear to have been of the olive species. It was situated beyond the limits of the walls, and adjacent to the tombs of the heroes; and though we are no where informed of the particular manner in which this grove was disposed or laid out, it may be gathered from Pausanias, in his Attica, that it was an elegant ornamented place. At the entrance was an altar dedicated to Love, which was said to be the first erected to that Deity. Within the Academus were the altars of Prometheus, of the Muses, of Mercury, of Minerva, and Hercules; and at a small distance was the tomb of Plato. So that, in all probability, it was highly adapted by art, as well as nature, to philosophic reflection and contemplation.

We are told by Plutarch, that before the time of Cimon, the Academus was a rude and uncultivated spot: but that it was planted by that general, and had water conveyed to it; whether this water was brought merely for use to refresh the trees, or for ornament, does not appear. It was divided into gymnasia, or places of exercise, and philosophic walks, shaded with trees. These are said to have flourished very well, until destroyed by Sylla (when he besieged Athens), as well as those in the Lyceum.

Near the academy were the gardens of the philosophers, of Plato, and of Epicurus; which, however, were probably but small. The scene of Plato's Dialogue concerning Beauty is elegantly described as being on the banks of the river Ilissus, and under the shade of the plantane; but no artificial arrangement

of objects is mentioned, nor any thing which will lead us to imagine the prospect to be any other than merely natural.

Among the Romans, a taste for gardening, any otherwise than as a matter of utility, seems not to have prevailed till a very late period; at least the writers on husbandry, Cato, Varro, Columella, and Palladius, make not the least mention of a garden as an object of pleasure, but solely with respect to its productions of herbs and fruits. The Lucullan gardens are the first we find mentioned of remarkable magnificence; though probably from the extravagance to which these were arrived, they were not the first. Plutarch speaks of them as incredibly expensive, and equal to the magnificence of kings. They contained artificial elevations of ground to a surprising height, of buildings projected into the sea, and vast pieces of water made upon land. In short, his extravagance and expence were so great, that he acquired thence the appellation of the Roman Xerxes. It is not improbable, from the above account, and from the consideration of Lucullus having spent much time in Asia, in a situation wherein he had an opportunity of observing the most splendid constructions of this kind, that these gardens might be laid out in the Asiatic style. The vast masses of building said to have been erected, might have borne some resemblance, in the arrangement and style, to the Babylonian gardens; and the epithet of the Roman Xerxes might be applicable to the taste, as well as to the size and expence of his works.

The Tusculan Villa of Cicero, though often mentioned, is not any where described in his works, so as to give an adequate idea of the style in which his gardens or grounds were disposed.

There is but little to be traced in Virgil relative to this subject. Pines*, it seems probable, were a favourite ornament in gardens; and flowers†, roses especially, were much esteemed, perfumes indeed having been always highly valued in warm climates. Virgil places Anchises in Elysium, in a grove of bays; and is careful to remark, that they were of the sweet-scented kind. The Pæstan roses were chiefly valued for their excellent odour; and the same quality appears to be the cause why they were placed by Tibullus as ornaments to the Elysian fields. There appears also to have prevailed among the Romans a piece of luxury relative to gardens, which is equally prevalent at present among us, namely the forcing of flowers at seasons of the year not suited to their natural blowing: and roses were then, as at present, the principal flowers upon which these experiments were tried, as appears from Martial ‡ and others.

When Roman authors (Mr Walpole remarks), whose climate instilled a wish for cool retreats, speak of their enjoyments in that kind, they sigh for grottos, caves, and the refreshing hollows of mountains, near irriguous and shady founts; or boast of their porticos, walks of planes, canals, baths, and breezes from the sea. Their gardens are never mentioned as affording shade and shelter from the rage of the dog-star. Pliny has left us descriptions of two of his villas. As he used his Laurentine villa for his winter retreat, it is not surprising that the garden makes no considerable part of the account. All he says of it is, that the gestatio or place of exercise, which surrounded the garden (the latter

latter consequently not being very large), was bounded by a hedge of box, and, where that was perished, with rosemary; that there was a walk of vines; and that most of the trees were fig and mulberry, the soil not being proper for any other sorts. On his Tuscan villa he is more diffuse; the garden makes a considerable part of the description:—and what was the principal beauty of that pleasure-ground? Exactly what was the admiration of this country about threescore years ago; box-trees cut into monsters, animals, letters, and the names of the master and the artificer. In an age when architecture displayed all its grandeur, all its purity, and all its taste; when arose Vespasian's amphitheatre, the temple of Peace, Trajan's forum, Domitian's baths, and Adrian's villa, the ruins and vestiges of which still excite our astonishment and curiosity; a Roman consul, a polished emperor's friend, and a man of elegant literature and taste, delighted in what the mob now scarce admire in a college-garden. All the ingredients of Pliny's corresponded exactly with those laid out by London and Wife on Dutch principles. He talks of slopes, terraces, a wilderness, shrubs methodically trimmed, a marble basin, pipes spouting water, a cascade falling into the basin, bay-trees alternately planted with planes, and a straight walk from whence issued others parted off by hedges of box and apple-trees, with obelisks placed between every two. There wants nothing but the embroidery of a parterre, to make a garden in the reign of Trajan serve for a description of one in that of king William. In one passage above, Pliny seems to have conceived that natural irregularity might be a beauty; *in opere urbanissimo, says he, subita velut illati ruris imitatio*. Something like a rural view was contrived amidst so much polished composition. But the idea soon vanished, lineal walks immediately enveloped the slight scene, and names and inscriptions in box again succeeded to compensate for the daring introduction of nature.

In the paintings found at Herculaneum are a few traces of gardens, as may be seen in the second volume of the prints. They are small square inclosures, formed by trellis-work and espaliers, and regularly ornamented with vases, fountains, and caryatides, elegantly symmetrical, and proper for the narrow spaces allotted to the garden of a house in a capital city.

From what has been said, it appears how naturally and insensibly the idea of a kitchen-garden slid into that which has for so many ages been peculiarly termed a *garden*, and by our ancestors distinguished by the name of a *pleasure-garden*. A square piece of ground was originally parted off in early ages for the use of the family:—to exclude cattle, and ascertain the property, it was separated from the fields by a hedge. As pride and desire of privacy increased, the inclosure was dignified by walls; and in climes where fruits were not lavished by the ripening glow of nature and soil, fruit-trees were assisted and sheltered from surrounding winds by the like expedient; for the inundation of luxuries, which have swelled into general necessities, have almost all taken their source from the simple foundation of reason.

When the custom of making square gardens inclosed with walls was thus established to the exclusion of nature and prospect, pomp and solitude combined to call for something that might enrich and enliven the insipid and unanimated partition. Fountains, first in-

vented for use, which grandeur loves to disguise and throw out of the question, received embellishments from costly marbles, and at last, to contradict utility, tossed their waste of waters into air in spouting columns. Art, in the hands of rude man, had at first been made a succedaneum to nature; in the hands of ostentatious wealth, it became the means of opposing nature; and the more it traversed the march of the latter, the more nobility thought its power was demonstrated. Canals measured by the line were introduced in lieu of meandering streams, and terraces were hoisted aloft in opposition to the facile slopes that imperceptibly unite the valley to the hill. Balustrades defended these precipitate and dangerous elevations, and flights of steps rejoined them to the subjacent flat from which the terrace had been dug. Vases and sculpture were added to these unnecessary balconies, and statues furnished the lifeless spot with mimic representations of the excluded sons of men. Thus difficulty and expence were the constituent parts of those sumptuous and selfish solitudes; and every improvement that was made, was but a step farther from nature. The tricks of water-works to wet the unwary, not to refresh the panting spectator, and parterres embroidered in patterns like a petticoat, were but the childish endeavours of fashion and novelty to reconcile greatness to what it had forfeited on. To crown these impotent displays of false taste, the sheers were applied to the lovely wildness of form with which nature has distinguished each various species of tree and shrub. The venerable oak, the romantic beech, the useful elm, even the aspiring circuit of the lime, the regular round of the chestnut, and the almost moulded orange-tree, were corrected by such fantastic admirers of symmetry. The compass and square were of more use in plantations than the nursery-man. The measured walk, the quincunx, and the étoile, imposed their unsatisfying sameness on every royal and noble garden. Trees were headed, and their sides pared away; many French groves seem green chests set upon poles. Seats of marble, arbours, and summer-houses, terminated every vista; and symmetry, even where the space was too large to permit its being remarked at one view, was so essential, that, as Pope observed,

—each alley has a brother,
And half the garden just reflects the other.

Knots of flowers were more defensibly subjected to the same regularity. Leisure, as Milton expressed it,

—in trim gardens took his pleasure.

In the garden of Marshal de Biron at Paris, consisting of 14 acres, every walk is buttoned on each side by lines of flower-pots, which succeed in their seasons.

It does not precisely appear what our ancestors meant by a bower: It was probably an arbour; sometimes it meant the whole frittered inclosure, and in one instance it certainly included a labyrinth. Rosamond's bower was indisputably of that kind; though whether composed of walls or hedges, we cannot determine. A square and a round labyrinth were so capital ingredients of a garden formerly, that in Du Cerceau's architecture, who lived in the time of Charles IX. and Henry III. there is scarce a ground-plot without one of each.

In Kip's Views of the Seats of our Nobility and Gentry, we see the same tiresome and returning uniformity. Every house is approached by two or three gardens, consisting perhaps of a gravel-walk and two
grass-

grafs-plats or borders of flowers. Each rises above the other by two or three steps, and as many walls and terraces, and so many iron gates, that we recollect those ancient romances in which every entrance was guarded by nymphs or dragons. Yet though these and such preposterous inconveniences prevailed from age to age, good sense in this country had perceived the want of something at once more grand and more natural. These reflections, and the bounds set to the waste made by royal spoilers, gave origin to Parks. They were contracted forests, and extended gardens. Hentzner says, that, according to Rous of Warwick, the first park was that at Woodstock. If so, it might be the foundation of a legend that Henry II. secured his mistress in a labyrinth: it was no doubt more difficult to find her in a park than in a palace, where the intricacy of the woods and various lodges buried in covert might conceal her actual habitation.

It is more extraordinary that, having so long ago stumbled on the principle of modern gardening, we should have persisted in retaining its reverse, symmetrical and unnatural gardens. That parks were rare in other countries, Hentzner, who travelled over great part of Europe, leads us to suppose, by observing that they were common in England. In France they retain the name, but nothing is more different both in compass and disposition. Their parks are usually square or oblong inclosures, regularly planted with walks of chestnuts or limes, and generally every large town has one for its public recreation.

“One man, one great man we had (continues Mr Walpole), on whom nor education nor custom could impose their prejudices; who, ‘on evil day though fallen, and with darkness and solitude compassed round,’ judged that the mistaken and fantastic ornaments he had seen in gardens, were unworthy of the Almighty hand that planted the delights of Paradise. He seems with the prophetic eye of taste to have conceived, to have foreseen modern gardening; as Lord Bacon announced the discoveries since made by experimental philosophy. The description of Eden is a warmer and more just picture of the present style than Claud Lorrain could have painted from Hagley or Stourhead. The first lines we shall quote exhibit Stourhead on a more magnificent scale;

Thro’ Eden went a river large,
Nor chang’d his course, but thro’ the shaggy hill
Pass’d underneath ingulph’d; for God had thrown
That mountain as his garden mound, high rais’d
Upon the rapid current——

Hagley seems pictured in what follows:

Which thro’ veins
Of porous earth with kindly thirst updrawn,
Rose a fresh fountain, and with many a rill
Water’d the garden——

What colouring, what freedom of pencil, what landscape in these lines!

——from that saphire fount the crisped brooks,
Rolling on orient pearl and sands of gold,
With mazy error under pendent shades,
Ran nectar, visiting each plant, and fed
Flower’s worthy of Paradise, which not nice art
In beds and curious knots, but *nature* boon
Pour’d forth profuse on hill and dale and plain,
Both where the morning sun first warmly smote
The *open field*, and where the impiere’d shade
Imbrown’d the noon-tide bow’rs—*Thus was this place*
A happy rural seat of various view.

Read this transporting description, paint to your mind the scenes that follow, contrast them with the savage but respectable terror with which the poet guards the bounds of his paradise, fenced

——with the champaign head
Of a steep wilderness, whose hairy sides
With thicket overgrown, grotesque and wild,
Access denied; and over head up grew
Insuperable height of loftiest shade,
Cedar and pine, and fir, and branching palm,
A sylvan scene, and, as the ranks ascend,
Shade above shade, a woody theatre,
Of stateliest view——

and then recollect, that the author of this sublime vision had never seen a glimpse of any thing like what he has imagined; that his favourite ancients had dropped not a hint of such divine scenery; and that the conceits in Italian gardens, and Theobalds and Nonsuch, were the brightest originals that his memory could furnish. His intellectual eye saw a nobler plan, so little did he suffer by the loss of sight. It sufficed him to have seen the materials with which he could work. The vigour of a boundless imagination told him how a plan might be disposed, that would embellish nature, and restore art to its proper office, the just improvement or imitation of it.

“Now let us turn to an admired writer, posterior to Milton, and see how cold, how insipid, how tasteless is his account of what he pronounced a perfect garden. We speak not of his style, which it was not necessary for him to animate with the colouring and glow of poetry. It is his want of ideas, of imagination, of taste, that deserve censure, when he dictated on a subject that is capable of all the graces that a knowledge of beautiful nature can bestow. Sir William Temple was an excellent man; Milton, a genius of the first order.

“We cannot wonder that Sir William declares in favour of parterres, fountains, and statues, as necessary to break the sameness of large grass-plats, which he thinks have an ill effect upon the eye, when he acknowledges that he discovers fancy in the gardens of Alcinous. Milton studied the ancients with equal enthusiasm, but no bigotry; and had judgment to distinguish between the want of invention and the beauties of poetry. Compare his paradise with Homer’s garden, both ascribed to a celestial design. For Sir William, it is just to observe, that his ideas centered in a fruit-garden. He had the honour of giving to his country many delicate fruits, and he thought of little else than disposing them to the best advantage.

“The best figure of a garden (says he) is either a square or an oblong, and either upon a flat or a descent: they have all their beauties, but the best I esteem an oblong upon a descent. The beauty, the air, the view, make amends for the expence, which is very great in finishing and supporting the terrace-walk, in levelling the parterres, and in the stone-stairs that are necessary from one to the other. The perfectest figure of a garden I ever saw, either at home or abroad, was that of Moor-park in Hertfordshire, when I knew it about 30 years ago. It was made by the Countess of Bedford, esteemed among the greatest wits of her time, and celebrated by Dr Donne; and with very great care, excellent contrivance, and much cost; but greater sums may be thrown away without effect or honour, if there want sense in proportion to money, or

‘if nature be not followed,’ which I take to be the great rule in this, and perhaps in every thing else, as far as the conduct not only of our lives but our governments.’ [We shall see how natural that admired garden was.] ‘Because I take the garden I have named to have been in all kinds the most beautiful and perfect, at least in the figure and disposition, that I ever have seen, I will describe it for a model to those that meet with such a situation, and are above the regards of common expence. It lies on the side of a hill, upon which the house stands, but not very steep. The length of the house, where the best rooms and of most use or pleasure are, lies upon the breadth of the garden; the great parlour opens into the middle of a terrace gravel-walk that lies even with it, and which may lie, as I remember, about 300 paces long, and broad in proportion; the border set with standard laurels and at large distances, which have the beauty of orange-trees out of flower and fruit. From this walk are three descents by many stone-steps, in the middle and at each end, into a very large parterre. This is divided into quarters by gravel-walks, and adorned with two fountains and eight statues in the several quarters. At the end of the terrace-walk are two summer-houses, and the sides of the parterre are ranged with two large cloisters, open to the garden, upon arches of stone, and ending with two other summer-houses even with the cloisters, which are paved with stone, and designed for walks of shade, there being none other in the whole parterre. Over these two cloisters are two terraces covered with lead and fenced with balusters; and the passage into these airy walks is out of the two summer-houses at the end of the first terrace-walk. The cloister facing the south is covered with vines, and would have been proper for an orange-house, and the other for myrtles or other more common greens, and had, I doubt not, been cast for that purpose, if this piece of gardening had been then in as much vogue as it is now. From the middle of this parterre is a descent by many steps flying on each side of the grotto that lies between them, covered with lead and flat, into the lower garden, which is all fruit-trees ranged about the several quarters of a wilderness, which is very shady; the walks here are all green, the grotto embellished with figures of shell rock-work, fountains, and water-works. If the hill had not ended with the lower garden, and the wall were not bounded by a common way that goes through the park, they might have added a third quarter of all greens; but this want is supplied by a garden on the other side the house, which is all of that sort, very wild, shady, and adorned with rough rock-work and fountains. This was Moor-park when I was acquainted with it, and the sweetest place, I think, that I have seen in my life, either before or since, at home or abroad.’

‘It is unnecessary to add any remarks on this description. Any man might design and build as sweet a garden, who had been born in and never stirred out of Holborn. It was not, however, peculiar to Sir William Temple to think in that manner. How many Frenchmen are there who have seen our gardens, and still prefer natural flights of steps and shady cloisters covered with lead! Le Nautre, the architect of the groves and grottos at Versailles, came hither on a mission to improve our taste. He planted St James’s and

Greenwich Parks—no great monuments of his invention.

‘To do farther justice to Sir William Temple, we must not omit what he adds. ‘What I have said of the best forms of gardens is meant only of such as are in some sort regular; for there may be other forms wholly irregular, that may, for aught I know, have more beauty than any of the others; but they must owe it to some extraordinary dispositions of nature in the seat, or some great race of fancy or judgment in the contrivance, which may reduce many disagreeing parts into some figure, which shall yet, upon the whole, be very agreeable. Something of this I have seen in some places, but heard more of it from others, who have lived much among the Chinese, a people whose way of thinking seems to lie as wide of ours in Europe as their country does. Their greatest reach of imagination is employed in contriving figures, where the beauty shall be great and strike the eye, but without any order or disposition of parts, that shall be commonly or easily observed. And though we have hardly any notion of this sort of beauty, yet they have a particular word to express it; and when they find it hit their eye at first sight, they say the Sharawadgi is fine or is admirable, or any such expression of esteem: but I should hardly advise any of these attempts on the figure of gardens among us; they are adventures of too hard achievement for any common hands; and though there may be more honour if they succeed well, yet there is more dishonour if they fail, and it is twenty to one they will; whereas in regular figures it is hard to make any great and remarkable faults.’

‘Fortunately Kent and a few others were not quite so timid, or we might still be going up and down stairs in the open air. It is true, we have heard much lately, as Sir William Temple did, of irregularity and imitations of nature in the gardens or grounds of the Chinese. The former is certainly true: they are as whimsically irregular, as European gardens are formally uniform and unvaried:—but with regard to nature, it seems as much avoided, as in the squares and oblongs and straight lines of our ancestors. An artificial perpendicular rock starting out of a flat plain, and connected with nothing, often pierced through in various places with oval hollows, has no more pretension to be deemed natural than a lineal terrace or a parterre. The late Mr Joseph Spence, who had both taste and zeal for the present style, was so persuaded of the Chinese Emperor’s pleasure-ground being lain out on principles resembling ours, that he translated and published, under the name of Sir Harry Beaumont, a particular account of that inclosure from the collection of the Letters of the Jesuits. But except a determined irregularity, one can find nothing in it that gives any idea of attention being paid to nature. It is of vast circumference, and contain 200 palaces, besides as many contiguous for the eunuchs, all gilt, painted, and varnished. There are raised hills from 20 to 60 feet high, streams and lakes, and one of the latter five miles round. These waters are passed by bridges:—but even their bridges must not be straight—they serpentine as much as the rivulets, and are sometimes so long as to be furnished with resting-places, and begin and end with triumphal arches. The colonades undulate in the same manner. In short, this pretty gaudy

dy scene is the work of caprice and whim, and, when we reflect on their buildings, presents no image but that of unsubstantial tawdriness. Nor is this all. Within this fantastic Paradise is a square town, each side a mile long. Here the eunuchs of the court, to entertain his imperial majesty with the bustle and business of the capital in which he resides, but which it is not of his dignity ever to see, act merchants and all sorts of trades, and even designedly exercise for his royal amusement every art of knavery that is practised under his auspicious government. Methinks this is the childish solace and repose of grandeur, not a retirement from affairs to the delights of rural life. Here too his majesty plays at agriculture: there is a quarter set apart for that purpose; the eunuchs sow, reap, and carry in their harvest, in the imperial presence; and his majesty returns to Peking, persuaded that he has been in the country.

“ Having thus cleared our way by ascertaining what have been the ideas on gardening in all ages, as far as we have materials to judge by, it remains to show to what degree Mr Kent invented the new style, and what hints he had received to suggest and conduct his undertaking.

“ We have seen what Moor-park was, when pronounced a standard. But as no succeeding generation in an opulent and luxurious country contents itself with the perfection established by its ancestors, more perfect perfection was still sought; and improvements had gone on, till London and Wise had stocked all our gardens with giants, animals, monsters, coats of arms, and mottos, in yew, box, and holly. Absurdity could go no farther, and the tide turned. Bridgman, the next fashionable designer of gardens, was far more chaste; and whether from good sense, or that the nation had been struck and reformed by the admirable paper in the Guardian, N^o 173, he banished verdant sculpture, and did not even revert to the square precision of the foregoing age. He enlarged his plans, disdained to make every division tally to its opposite; and though he still adhered much to straight walks with high clipped hedges, they were only his great lines; the rest he diversified by wilderness, and with loose groves of oak, though still within surrounding hedges. As his reformation gained footing, he ventured, in the royal garden at Richmond, to introduce cultivated fields, and even morsels of a forest appearance, by the sides of those endless and tiresome walks that stretched out of one into another without intermission. But this was not till other innovators had broke loose too from rigid symmetry.

“ But the capital stroke, the leading step to all that has followed, was the destruction of walls for boundaries, and the invention of fosses—an attempt then deemed so astonishing, that the common people called them Ha! Ha's! to express their surprise at finding a sudden and unperceived check to their walk.

“ A sunk fence may be called the *leading step*, for these reasons. No sooner was this simple enchantment made, than levelling, mowing, and rolling, followed. The contiguous ground of the park without the sunk fence was to be harmonized with the lawn within; and the garden in its turn was to be set free from its prim regularity, that it might assort with the wilder country

without. The sunk fence ascertained the specific garden; but that it might not draw too obvious a line of distinction between the neat and the rude, the contiguous out-lying parts came to be included in a kind of general design; and when nature was taken into the plan, under improvements, every step that was made pointed out new beauties, and inspired new ideas. At that moment appeared Kent, painter enough to taste the charms of landscape, bold, and opinionative enough to dare and to dictate, and born with a genius to strike out a great system from the twilight of imperfect essays. He leaped the fence, and saw that all nature was a garden. He felt the delicious contrast of hill and valley changing imperceptibly into each other, tasted the beauty of the gentle swell or concave scoop, and remarked how loose groves crowned an easy eminence with happy ornament; and while they called in the distant view between their graceful stems, removed and extended the perspective by delusive comparison.

“ Thus the pencil of his imagination bestowed all the arts of landscape on the scenes he handled. The great principles on which he worked were perspective, and light and shade. Groupes of trees broke too uniform or too extensive a lawn; evergreens and woods were opposed to the glare of the champaign; and where the view was less fortunate, or so much exposed as to be beheld at once, he blotted out some parts by thick shades to divide it into variety, or to make the richest scene more enchanting by reserving it to a farther advance of the spectator's step. Thus, selecting favourite objects, and veiling deformities by screens of plantation; sometimes allowing the rudest waste to add its soil to the richest theatre: he realised the compositions of the greatest masters in painting. Where objects were wanting to animate his horizon, his taste as an architect could bestow immediate termination. His buildings, his seats, his temples, were more the works of his pencil than of his compasses. We owe the restoration of Greece and the diffusion of architecture to his skill in landscape.

“ But of all the beauties he added to the face of this beautiful country, none surpassed his management of water. Adieu to canals, circular basins, and cascades tumbling down marble steps, that last absurd magnificence of Italian and French villas. The forced elevation of cataracts was no more. The gentle stream was taught to serpentine seemingly at its pleasure; and where discontinued by different levels, its course appeared to be concealed by thickets properly interspersed, and glittered again at a distance where it might be supposed naturally to arrive. Its borders were smoothed, but preserved their waving irregularity. A few trees scattered here and there on its edges sprinkled the tame bank that accompanied its meanders; and when it disappeared among the hills, shades descending from the heights leaned towards its progress, and framed the distant point of light under which it was lost, as it turned aside to either hand of the blue horizon.

“ Thus, dealing in none but the colours of nature, and catching its most favourable features, men saw a new creation opening before their eyes. The living landscape was chastened or polished, not transformed.

Freedom.

Freedom was given to the forms of trees: they extended their branches unrestricted; and where any eminent oak, or master beech, had escaped maiming and survived the forest, bush and bramble was removed, and all its honours were restored to distinguish and shade the plain. Where the united plumage of an ancient wood extended wide its undulating canopy, and stood venerable in its darkness, Kent thinned the foremost ranks, and left but so many detached and scattered trees, as softened the approach of gloom, and blended a chequered light with the thus lengthened shadows of the remaining columns.

“Succeeding artists have added new master-strokes to these touches; perhaps improved or brought to perfection some that have been named. The introduction of foreign trees and plants, which we owe principally to Archibald Duke of Argyle, contributed essentially to the richness of colouring so peculiar to our modern landscape. The mixture of various greens, the contrast of forms between our forest-trees and the northern and West Indian firs and pines, are improvements more recent than Kent, or but little known to him. The weeping willow, and every florid shrub, each tree of delicate or bold-leaf, are new tints in the composition of our gardens.

“But just as the encomiums are that have been bestowed on Kent’s discoveries, he was neither without assistance or faults. Mr Pope undoubtedly contributed to form his taste. The design of the Prince of Wales’s garden at Carlton-house was evidently borrowed from the Poet’s at Twickenham. There was a little of affected modesty in the latter, when he said, of all his works he was most proud of his garden. And yet it was a singular effort of art and taste to impress so much variety and scenery on a spot of five acres. The passing through the gloom from the grötto to the opening day, the retiring and again assembling shades, the dusky groves, the larger lawn, and the solemnity of the termination at the cypresses that lead up to his mother’s tomb, are managed with

exquisite judgment; and though Lord Peterborough assisted him

To form his quincunx and to rank his vines, those were not the most pleasing ingredients of his little perspective.

“Having routed professed art (for the modern gardener exerts his talents to conceal his art), Kent, like other reformers, knew not how to stop at the just limits. He had followed Nature, and imitated her so happily, that he began to think all her works were equally proper for imitation. In Kensington garden he planted dead trees, to give a greater air of truth to the scene—but he was soon laughed out of this excess. His ruling principle was, that nature abhors a straight line. His mimics, for every genius has his apes, seemed to think that she could love nothing but what was crooked. Yet so many men of taste of all ranks devoted themselves to the new improvements, that it is surprising how much beauty has been struck out, with how few absurdities. Still in some lights the reformation seems to have been pushed too far. Though an avenue crossing a park or separating a lawn, and intercepting views from the seat to which it leads, are capital faults; yet a great avenue cut through woods, perhaps before entering a park, has a noble air, and

Like footmen running before coaches
To tell the inn what lords approaches,

announces the habitation of some man of distinction. In other places the total banishment of all particular neatness immediately about a house, which is frequently left gazing by itself in the middle of a park, is a defect. Sheltered and even close walks, in so very uncertain a climate as ours, are comforts ill exchanged for the few picturesque days that we enjoy; and when ever a family can purloin a warm and even something of an old-fashioned garden from the landscape designed for them by the undertaker in fashion, without interfering with the picture, they will find satisfactions on those days that do not invite strangers to come and see their improvements.”

PART I. PRINCIPLES OF GARDENING.

GARDENING, in the perfection to which it has been lately brought in Britain, is intitled to a place of considerable rank among the liberal arts. It is (says Mr Wheatley) as superior to landscape-painting as a reality to a representation: it is an exertion of fancy; a subject for taste; and being released now from the restraints of regularity, and enlarged beyond the purposes of domestic convenience, the most beautiful, the most simple, the most noble scenes of nature, are all within its province. For it is no longer confined to the spots from which it takes its name; but, as already observed, regulates also the disposition and embellishments of a park, a farm, a forest, &c. and the business of a gardener is to select and apply whatever is great, elegant, or characteristic, in any of them to discover, and to show all the advantages of the place upon which he is employed; to supply its defects, to correct its faults, and to improve its beauties.

SECT. I. I *Materials of Gardening.*

THESE may be divided into two general classes; *Natural* and *Facitious*

§ I. *Of the NATURAL MATERIALS.*

THESE, according to Mr Wheatley’s enumeration, are: Ground, Wood, Water, and Rocks.

I. GROUND. By this is meant that portion of naked surface which is included within the place to be improved; whether that surface be swamp, lawn, roughet, or broken ground; and whether it be a height, a valley, a plain, or a composition of swells, dips, and levels.

The following passage has been quoted from Mr Gilpin’s observations on the Wye*, as affording a * P 62. sublime idea of what ground ought to be.—“Nothing (says he) gives so just an idea of the beautiful swellings of ground as those of water, where it has

Wood. has sufficient room to undulate and expand. In ground which is composed of very refractory materials, you are presented often with harsh lines, angular inflections, and disagreeable abruptnesses. In water, whether in gentle or in agitated motion, all is easy, all is softened into itself; and the hills and the valleys play into each other in a variety of the most beautiful forms. In agitated water, abruptnesses indeed there are, but yet they are such abruptnesses as in some part or other unite properly with the surface around them; and are on the whole peculiarly harmonious. Now, if the ocean in any of these swellings and agitations could be arrested and fixed, it would produce that pleasing variety which we admire in ground. Hence it is common to fetch our images from water, and apply them to land: we talk of an undulating line, a playing lawn, and a billowy surface; and give a much stronger and more adequate idea of such imagery, than plain language could possibly present."

The exertions of art, however, are here inadequate; and the artist ought not attempt to create a mountain, a valley, or a plain: he should but rarely meddle even with the smaller inequalities of grounds. Roughets and broken ground may generally be reduced to lawn, or hid with wood; and a swamp may be drained or covered with water; whilst lawn may be variegated at pleasure by wood, and sometimes by water.

II. WOOD, as a general term, comprehends all trees and shrubs in whatever disposition; but it is specifically applied in a more limited sense, and in that sense we shall now use it.

Every plantation must be either a *wood*, a *grove*, or a *clump*. A wood is composed both of trees and underwood, covering a considerable space. A grove consists of trees without underwood. A clump differs from either only in extent: it may be either close or open: when close, it is sometimes called a *thicket*; when open, a *groupe of trees*; but both are equally clumps, whatever may be the shape or situation.

I
Of the sur-
face of a
wood.

I. One of the noblest objects in nature (Mr Wheatley observes) is the *surface of a large thick wood*, commanded from an eminence, or seen from below hanging on the side of a hill. The latter is generally the more interesting object. Its aspiring situation gives it an air of greatness; its termination is commonly the horizon: and, indeed, if it is deprived of that splendid boundary, if the brow appears above it (unless some very peculiar effect characterises that brow), it loses much of its magnificence: it is inferior to a wood which covers a less hill from the top to the bottom; for a whole space filled is seldom little. But a wood commanded from an eminence is generally no more than a part of the scene below; and its boundary is often inadequate to its greatness. To continue it, therefore, till it winds out of sight, or loses itself in the horizon, is generally desirable: but then the varieties of its surface grow confused as it retires; while those of a hanging wood are all distinct, the furthest parts are held up to the eye, and none are at a distance though the whole be extensive.

The varieties of a surface are essential to the beauty of it: a continued smooth shaven level of foilage is neither agreeable nor natural; the different growths of trees commonly break it in reality, and their sha-

dows still more in appearance. These shades are so many tints, which, undulating about the surface, are its greatest embellishment; and such tints may be produced with more effect, and more certainty, by a judicious mixture of greens; at the same time an additional variety may be introduced, by grouping and contrasting trees very different in shape from each other; and whether variety in the greens or in the forms be the design, the execution is often easy, and seldom to a certain degree impossible. In raising a young wood, it may be perfect. In old woods, there are many spots which may be either thinned or thickened: and their the characteristic distinctions should determine what to plant, or which to leave; at the least will often point out those which, as blemishes, ought to be taken away; and the removal of two or three trees will sometimes accomplish the design. The number of beautiful forms, and agreeable masses, which may decorate the surface, is so great, that where the place will not admit of one, another is always ready: and as no delicacy of finishing is required, no minute exactness is worth regarding; great effects will not be disconcerted by small obstructions and little disappointments.

The contrasts, however, of masses and of groupes must not be too strong, where *greatness* is the character of the wood; for unity is essential to greatness: and if direct opposites be placed close together, the wood is no longer one object; it is only a confused collection of several separate plantations. But if the progress be gradual from the one to the other, shapes and tints widely different may assemble on the same surface; and each should occupy a considerable space: a single tree, or a small cluster of trees, in the midst of an extensive wood, is in size but a speck, and in colour but a spot; the groupes and the masses must be large to produce any sensible variety.

When, in a romantic situation, very broken ground is overspread with wood, it may be proper on the surface of the wood to mark the inequalities of the ground. *Rudeness*, not greatness, is the prevailing idea; and a choice directly the reverse of that which is productive of unity, will produce it. Strong contrasts, even oppositions, may be eligible; the aim is rather to disjoint than to connect: a deep hollow may sink into dark greens; an abrupt bank may be shown by a rising stage of aspiring trees, a sharp ridge by a narrow line of conical shapes: firs are of great use upon such occasions; their tint, their form, their singularity, recommend them.

A hanging *wood of thin forest-trees*, and seen from below, is seldom pleasing: those few trees are by the perspective brought nearer together; it loses the beauty of a thin wood, and is defective as a thick one: the most obvious improvement, therefore, is to thicken it. But, when seen from an eminence, a thin wood is often a lively and elegant circumstance in a view; it is full of objects; and every separate tree shows its beauty. To increase that vivacity, which is the peculiar excellence of a thin wood, the trees should be characteristically distinguished both in their tints and their shapes; and such as for their airiness have been proscribed in a thick wood, are frequently the most eligible here. Differences also in their growths are a further source of variety; each should be considered as a distinct object,

Wood.

ject, unless where a small number are grouped together; and then all that compose the little cluster must agree: but the groupes themselves, for the same reason as the separate trees, should be strongly contrasted; the continued underwood is their only connection, and that is not affected by their variety.

2
Of the outline of a wood.

Though the surface of a wood, when commanded, deserves all these attentions, yet the *outline* more frequently calls for our regard: it is also more in our power; it may sometimes be great, and may always be beautiful. The first requisite is irregularity. That a mixture of trees and underwood should form a long straight line, can never be natural; and a succession of easy sweeps and gentle rounds, each a portion of a greater or less circle, composing all together a line literally serpentine, is, if possible, worse. It is but a number of regularities put together in a disorderly manner, and equally distant from the beautiful both of art and of nature. The true beauty of an outline consists more in breaks than in sweeps; rather in angles than in rounds; in variety, not in succession.

Every variety in the outline of a wood must be a *prominence* or a *recess*. Breadth in either is not so important as length to the one and depth to the other. If the former ends in an angle, the latter diminishes to a point; they have more force than a shallow dent, or a dwarf excrescence, how wide soever. They are greater deviations from the continued line which they are intended to break; and their effect is to enlarge the wood itself, which seems to stretch from the most advanced point, back beyond the most distant to which it retires. The extent of a large wood on a flat, not commanded, can by no circumstance be so manifestly shown as by a deep recess; especially if that recess wind so as to conceal the extremity, and leave the imagination to pursue it. On the other hand, the poverty of a shallow wood might sometimes be relieved by here and there a prominence, or clumps which by their apparent junction should seem to be prominences from it. A deeper wood with a continued outline, except when commanded, would not appear so considerable.

Whitely's
Observat.
on Modern
Gardening.

An inlet into a wood seems to have been cut, if the opposite points of the entrance tally; and that show of art depreciates its merit: but a difference only in the situation of those points, by bringing one more forward than the other, prevents the appearance, though their forms be similar. Other points, which distinguish the great parts, should in general be strongly marked: a short turn has more spirit in it than a tedious circuit; and a line broken by angles has a precision and firmness, which in an undulated line are wanting; the angles should indeed commonly be a little softened; the rotundity of the plant which forms them is sometimes sufficient for the purpose; but if they are mellowed down too much, they lose all meaning. Three or four large parts thus boldly distinguished, will break a very long outline. When two woods are opposed on the sides of a narrow glade, neither has so much occasion for variety in itself as if it were single; if they are very different from each other, the contrast supplies the deficiency to each, and the interval between them is full of variety. The form of that interval is indeed of as much consequence as their own: though the outlines of both the woods be separately beautiful, yet if together they do not cast the open space into an

agreeable figure, the whole scene is not pleasing; and a figure is never agreeable, when the sides too closely correspond; whether they are exactly the same, or exactly the reverse of each other, they equally appear artificial.

Every variety of outline hitherto mentioned may be traced by the underwood alone; but frequently the same effects may be produced with more ease, and with much more beauty, by a few trees standing out from the thicket, and belonging, or seeming to belong to the wood, so as to make a part of its figure. Even where they are not wanted for the purpose, detached trees are such agreeable objects, so distinct, so light, when compared to the covert about them, that skirting along it in some parts, and breaking it in others, they give an unaffected grace, which can no otherwise be given to the outline. They have a still further effect, when they stretch across the whole breadth of an inlet, or before part of a recess into the wood: they are themselves shown to advantage by the space behind them; and that space, seen between their stems, they in return throw into an agreeable perspective.

2. The prevailing character of a wood is generally grandeur: the principal attention therefore which it requires, is to prevent the excesses of that character, to diversify the uniformity of its extent, to lighten the unwieldiness of its bulk, and to blend graces with greatness. The character of a *grove* is beauty. Fine trees are lovely objects: a grove is an assemblage of them; in which every individual retains much of its own peculiar elegance, and whatever it loses is transferred to the superior beauty of the whole. To a grove therefore, which admits of endless variety in the disposition of the trees, differences in their shapes and their greens are seldom very important, and sometimes they are detrimental. Strong contrasts scatter trees which are thinly planted, and which have not the connection of underwood; they no longer form one plantation; they are a number of single trees. A thick grove is not indeed exposed to this mischief, and certain situations may recommend different shapes and different greens for their effects upon the surface; but in the outline they are seldom much regarded. The eye attracted into the depth of the grove, passes by little circumstances at the entrance; even varieties in the form of the line do not always engage the attention: they are not so apparent as in a continued thicket, and are scarcely seen if they are not considerable.

But the surface and the outline are not the only circumstances to be attended to. Though a grove be beautiful as an object, it is besides delightful as a spot to walk or to sit in; and the choice and the disposition of the trees for effects within, are therefore a principal consideration. Mere irregularity alone will not please: strict order is there more agreeable than absolute confusion; and some meaning better than none. A regular plantation has a degree of beauty; but it gives no satisfaction, because we know that the same number of trees might be more beautifully arranged. A disposition, however, in which the lines only are broken, without varying the distances, is equally improper. The trees should gather into groupes, or stand in various irregular lines, and describe several figures: the intervals between them should be contrasted both in shape and in dimensions:

Wood.

3
Of a Grove.

Wood.
Ibid.

sions: a large space should in some places be quite open; in others the trees should be so close together, as hardly to leave a passage between them; and in others as far apart as the connection will allow. In the forms and the varieties of these groupes, these lines, and these openings, principally consists the interior beauty of a grove.

* New
Esher in
Surry, En-
gland.

The force of them is most strongly illustrated at Claremont*: where the walk to the cottage, though destitute of many natural advantages, and eminent for none; though it commands no prospect; though the water below it is a trifling pond; though it has nothing, in short, but inequality of ground to recommend it; is yet the finest part of the garden: for a grove is there planted in a gently curved direction, all along the side of a hill, and on the edge of a wood, which rises above it. Large recesses break it into several clumps, which hang down the declivity; some of them approaching, but none reaching quite to the bottom. These recesses are so deep as to form great openings in the midst of the grove; they penetrate almost to the covert: but the clumps being all equally suspended from the wood; and a line of open plantation, though sometimes narrow, running constantly along the top; a continuation of grove is preserved, and the connection between the parts is never broken. Even a groupe, which near one of the extremities stands out quite detached, is still in style so similar to the rest as not to lose all relation. Each of these clumps is composed of several others still more intimately united: each is full of groupes, sometimes of no more than two trees, sometimes of four or five, and now and then in larger clusters: an irregular waving line issuing from some little crowd, loses itself in the next; or a few scattered trees drop in a more distant succession from the one to the other. The intervals, winding here like a glade, and widening there into broader openings, differ in extent, in figure, and direction; but all the groupes, the lines, and the intervals, are collected together into large general clumps, each of which is at the same time both compact and free, identical and various. The whole is a place wherein to tarry with secure delight, or saunter with perpetual amusement.

The grove at Esher-place was planted by the same masterly hand; but the necessity of accommodating the young plantation to some large trees which grew there before, has confined its variety. The groupes are few and small; there was not room for larger or for more: there were no opportunities to form continued narrow glades between opposite lines; the vacant spaces are therefore chiefly irregular openings spreading every way, and great differences of distance between the trees are the principal variety; but the grove winds along the bank of a large river, on the side and at the foot of a very sudden ascent, the upper part of which is covered with wood. In one place, it presses close to the covert; retires from it in another; and stretches in a third across a bold recess, which runs up high into the thicket. The trees sometimes overspread the flat below; sometimes leave an open space to the river; at other times crown the brow of a large knole, climb up a steep, or hang on a gentle declivity. These varieties in the situation more than compensate for the want of variety in the disposition of the trees; and the many happy circumstances which concur

VOL. VII.

In Esher's peaceful grove,
Where Kent and nature vie for Pelham's love,

Wood.

render this little spot more agreeable than any at Claremont. But though it was right to preserve the trees already standing, and not to sacrifice great present beauties to still greater in futurity; yet this attention has been a restraint; and the grove at Claremont, considered merely as a plantation, is in delicacy of taste, and fertility of invention, superior to that at Esher.

It is, however, possible to secure both a present and a future effect, by fixing first on a disposition which will be beautiful when the trees are large, and then intermingling another which is agreeable while they are small. These occasional trees are hereafter to be taken away; and must be removed in time, before they become prejudicial to the others.

The consequence of variety in the disposition, is variety in the light and shade of the grove; which may be improved by the choice of the trees. Some are impenetrable to the fiercest sun-beam; others let in here and there a ray between the large masses of their foliage; and others, thin both of boughs and of leaves, only chequer the ground. Every degree of light and shade, from a glare to obscurity, may be managed, partly by the number, and partly by the texture, of the trees. Differences only in the manner of their growths have also corresponding effects: there is a closeness under those whose branches descend low, and spread wide; a space and liberty where the arch above is high; and frequent transitions from the one to the other are very pleasing. These still are not all the varieties of which the interior of a grove is capable: trees, indeed, whose branches nearly reach the ground, being each a sort of thicket, are inconsistent with an open plantation: but though some of the characteristic distinctions are thereby excluded, other varieties more minute succeed in their place; for the freedom of passage throughout brings every tree in its turn near to the eye, and subjects even differences in foliage to observation. These, slight as they may seem, are agreeable when they occur: it is true, they are not regretted when wanting; but a defect of ornament is not necessarily a blemish.

3. It has been already observed, that *Clumps* differ ⁴ Of Clumps. only in extent from woods, if they are close; or from groves, if they are open: they are small woods, and small groves, governed by the same principles as the larger, after allowances made for their dimensions. But besides the properties they may have in common with woods or with groves, they have others peculiar to themselves which require examination.

They are either *independent* or *relative*: when independent, their beauty, as single objects, is solely to be attended to; when relative, the beauty of the individuals must be sacrificed to the effect of the whole, which is the greater consideration.

The *occasions* on which independent clumps may be applied, are many. They are often desirable as beautiful objects in themselves; they are sometimes necessary to break an extent of lawn, or a continued line whether of ground or of plantation; but on all occasions a jealousy of art constantly attends them, which irregularity in their figure will not always alone remove. Though elevations show them to advantage, yet a hillock evidently thrown up on purpose to be crowned with a clump, is artificial to a degree of disgust:

4 A

Water.

Ibid.

gust: some of the trees should therefore be planted on the sides, to take off that appearance. The same expedient may be applied to clumps placed on the brow of a hill, to interrupt its sameness: they will have less ostentation of design, if they are in part carried down either declivity. The objection already made to planting many along such a brow, is on the same principle: a single clump is less suspected of art; if it be an open one, there can be no finer situation for it, than just at the point of an abrupt hill, or on a promontory into a lake or a river. It is in either a beautiful termination, distinct by its position, and enlivened by an expanse of sky or of water about and beyond it. Such advantages may balance little defects in its form: but they are lost if other clumps are planted near it: art then intrudes, and the whole is displeasing.

But though a multiplicity of clumps, when each is an independent object, seldom seems natural; yet a number of them may, without any appearance of art, be admitted into the same scene, if they bear a *relation* to each other: if by their succession they diversify a continued outline of wood, if between them they form beautiful glades, if all together they cast an extensive lawn into an agreeable shape, the *effect* prevents any scrutiny into the means of producing it. But when the reliance on that effect is so great, every other consideration must give way to the beauty of the whole. The figure of the glade, of the lawn, or of the wood, are principally to be attended to: the finest clumps, if they do not fall easily into the great lines, are blenishes; their connections, their contrasts, are more important than their forms.

5
Of a Lake.

III. WATER. All inland water is either *running* or *stagnated*. When stagnated, it forms a *lake* or a *pool*, which differ only in extent; and a *pool* and a *pond* are the same. Running waters are either a *rivulet*, a *river*, or a *rill*; and these differ only in breadth: a *rivulet* and a *brook* are synonymous terms; a *stream* and a *current* are general names for all.

1. Space or expansion is essential to a *Lake*. It cannot be too large as a subject of description or of contemplation; but the eye receives little satisfaction when it has not a form on which to rest: the ocean itself hardly atones by all its grandeur for its infinity; and a prospect of it is, therefore, always most agreeable, when in some part, at no great distance, a reach of shore, a promontory, or an island, reduces the immensity into shape. An artificial lake, again, may be comparatively extravagant in its dimensions. It may be so out of proportion to its appendages, as to seem a waste of water; for all size is in some respects relative: if this exceeds its due dimensions, and if a flatness of shore beyond it adds still to the dreariness of the scene; wood to raise the banks, and objects to distinguish them, are the remedies to be employed. If the length of a piece of water be too great for its breadth so as to destroy all idea of circuit, extremities should be considered as too far off, and made important to give them proximity; while at the same time the breadth may be favoured, by keeping down the banks on the sides. On the same principle, if the lake be too small, a low shore will, in appearance, increase the extent.

But it is not necessary that the whole scene be

bounded: if form be impressed on a considerable part, the eye can, without disgust, permit a large reach to stretch beyond its ken; it can even be pleased to observe a tremulous motion in the horizon, which shows that the water has not there yet attained its termination. Still short of this, the extent may be kept in uncertainty; a hill or a wood may conceal one of the extremities, and the country beyond it, in such a manner as to leave room for the supposed continuation of so large a body of water. Opportunities to choose this shape are frequent, and it is the most perfect of any: the scene is closed, but the extent of the lake is undetermined; a complete form is exhibited to the eye, while a boundless range is left open to the imagination.

But mere form will only give content, not delight: that depends upon the outline, which is capable of exquisite beauty; and the *bays*, the *creeks*, and the *promontories*, which are ordinary parts of that outline, together with the accidents of *islands*, of *inlets* and of *outlets* to rivers, are in their shapes and their combinations an inexhaustible fund of variety.

Bays, creeks, and promontories, however, though extremely beautiful, should not be very numerous: for a shore broken into little points and hollows has no certainty of outline; it is only ragged, not diversified; and the distinctness and simplicity of the great parts are hurt by the multiplicity of subdivisions. But islands, though the channels between them be narrow, do not so often derogate from greatness: they intimate a space beyond them whose boundaries do not appear; and remove to a distance the shore which is seen in perspective between them. Such partial interruptions of the sight suggest ideas of extent to the imagination.

2. Though the windings of a *River* are proverbially descriptive of its course; yet without being perpetually wreathed, it may be natural. Nor is the character expressed only by the turnings. On the contrary, if they are too frequent and sudden, the current is reduced into a number of separate pools, and the idea of progress is obscured by the difficulty of tracing it. Length is the strongest symptom of continuation: long reaches are therefore characteristic of a river, and they conduce much to its beauty; each is a considerable piece of water, and variety of beautiful forms may be given to their outlines.

A river requires a number of *accompaniments*. The changes in its course furnish a variety of situations; while the fertility, convenience, and amenity, which attend it, account for all appearances of inhabitants and improvement. Profusion of ornament on a fictitious river, is a just imitation of cultivated nature. Every species of building, every style of plantation, may abound on the banks; and whatever be their characters, their proximity to the water is commonly the happiest circumstance in their situation. A lustre is from thence diffused on all around; each derives an importance from its relation to this capital feature: those which are near enough to be reflected, immediately belong to it; those at a greater distance still share in the animation of the scene; and objects totally detached from each other, being all attracted towards the same interesting connection, are united into one composition.

In the front of Blenheim was a deep broad valley, which

Water.

6

Of a river.

Water.
Ibid.

which abruptly separated the castle from the lawn and the plantations before it; even a direct approach could not be made without building a monstrous bridge over the vast hollow: but this forced communication was only a subject of raillery: and the scene continued broken into two parts, absolutely distinct from each other. This valley has been lately flooded: it is not filled; the bottom only is covered with water: the sides are still very high; but they are no longer the steeps of a chasm, they are the bold shores of a noble river. The same bridge is standing without alteration: but no extravagance remains; the water gives it propriety. Above it the river first appears, winding from behind a small thick wood, in the valley; and soon taking a determined course, it is then broad enough to admit an island filled with the finest trees: others, corresponding to them in growth and disposition, stand in groupes on the banks, intermixed with younger plantations. Immediately below the bridge, the river spreads into a large expanse: the sides are open lawn. On that furthest from the house formerly stood the palace of Henry II. celebrated in many an ancient ditty by the name of Fair Rosamond's Bower. A little clear spring, which rises there, is by the country people still called Fair Rosamond's Well. The spot is now marked by a single willow. Near it is a fine collateral stream, of a beautiful form, retaining its breadth as far as it is seen, and retiring at last behind a hill from the view. The main river, having received this accession, makes a gentle bend; then continues for a considerable length in one wide direct reach; and, just as it disappears, throws itself down a high cascade, which is the present termination. On one of the banks of this reach is the garden: the steeps are there diversified with thickets and with glades; but the covert prevails, and the top is crowned with lofty trees. On the other side is a noble hanging wood in the park: it was depreciated when it sunk into a hollow, and was poorly lost in the bottom; but it is now a rich appendage to the river, falling down an easy slope quite to the water's edge, where, without overshadowing, it is reflected on the surface. Another face of the same wood borders the collateral stream, with an outline more indented and various; while a very large irregular clump adorns the opposite declivity. This clump is at a considerable distance from the principal river: but the stream it belongs to brings it down to connect with the rest; and the other objects, which were before dispersed, are now, by the interest of each in a relation which is common to all, collected into one illustrious scene. The castle is itself a prodigious pile of building: which, with all the faults in its architecture, will never seem less than a truly princely habitation; and the confined spot where it was placed, on the edge of an abyss, is converted into a proud situation, commanding a beautiful prospect of water, and open to an extensive lawn, adequate to the mansion, and an emblem of its domain. In the midst of this lawn stands a column, a stately trophy, recording the exploits of the Duke of Marlborough, and the gratitude of Britain. Between this pillar and the castle is the bridge, which now, applied to a subject worthy of it, is established in all the importance due to its greatness. The middle arch is wider than the Rialto, but

not too wide for the occasion; and yet this is the narrowest part of the river: but the length of the reaches is every where proportioned to their breadth. Each of them is alone a noble piece of water; and the last, the finest of all, loses itself gradually in a wood, which on that side is also the boundary of the lawn, and rises into the horizon. All is great in the front of Blenheim: but in that vast space no void appears; so important are the parts, so magnificent the objects. The plain is extensive, the valley is broad, the wood is deep. Though the intervals between the buildings are large, they are filled with the grandeur which buildings of such dimensions and so much pomp diffuse all around them; and the river, in its long varied course, approaching to every object, and touching upon every part, spreads its influence over the whole.

In the composition of this scene, the river, both as a part itself, and as uniting the other parts, has a principal share. But water is not lost though it be in so confined or so concealed a spot as to enter into no view; it may render that spot delightful. It is capable of the most exquisite beauty in its form; and though not in space, may yet in disposition have pretensions to greatness; for it may be divided into several branches, which will form a cluster of islands all connected together, make the whole place irriguous, and, in the stead of extent, supply a quantity of water. Such a sequestered scene usually owes its retirement to the trees and the thickets with which it abounds: but, in the disposition of them, one distinction should be constantly attended to. A river flowing through a wood which overspreads one continued surface of ground, and a river between two woods, are in very different circumstances. In the latter case, the woods are separate; they may be contrasted in their forms and their characters, and the outline of each should be forcibly marked. In the former, no outline ought to be discernible; for the river passes between trees, not between boundaries; and though, in the progress of its course, the style of the plantations may be often changed, yet on the opposite banks a similarity should constantly prevail, that the identity of the wood may never be doubtful.

A river between two woods may enter into a view; and then it must be governed by the principles which regulate the conduct and the accompaniments of a river in an open exposure. But when it runs through a wood, it is never to be seen in prospect: the place is naturally full of obstructions; and a continued opening, large enough to receive a long reach, would seem an artificial cut. The river must therefore necessarily wind more than in crossing a lawn, where the passage is entirely free. But its influence will never extend so far on the sides: the buildings must be near the banks; and, if numerous, will seem crowded, being all in one track, and in situations nearly alike. The scene, however, does not want variety: on the contrary, none is capable of more. The objects are not indeed so different from each other as in an open view; but they are very different, and in much greater abundance: for this is the interior of a wood, where every tree is an object, every combination of trees a variety, and no large intervals are requisite to distinguish the several dispositions; the grove, the thicket, or the groupes,

Water.

Water.
Ibid.

may prevail, and their forms and their relations may be constantly changed, without restraint of fancy, or limitation of number.

* Vale of
Aylesbury,
Bucking-
hamshire.

Water is so universally and so deservedly admired in a prospect, that the most obvious thought in the management of it, is to lay it as open as possible, and purposely to conceal it would generally seem a severe self-denial: yet so many beauties may attend its passage through a wood, that larger portions of it might be allowed to such retired scenes than are commonly spared from the view, and the different parts in different styles would be fine contrasts to each other. If the water at Wotton* were all exposed, a walk of near two miles along the banks would be of a tedious length, from the want of those changes of the scene which now supply through the whole extent a succession of perpetual variety. That extent is so large as to admit of a division into four principal parts, all of them great in style and in dimensions, and differing from each other both in character and situation. The two first are the least. The one is a reach of a river, about the third of a mile in length, and of a competent breadth, flowing through a lovely mead, open in some places to views of beautiful hills in the country, and adorned in others with clumps of trees, so large, that their branches stretch quite across, and form a high arch over the water. The next seems to have been once a formal basin encompassed with plantations, and the appendages on either side still retain some traces of regularity; but the shape of the water is free from them: the size is about 14 acres; and out of it issue two broad collateral streams, winding towards a large river, which they are seen to approach, and supposed to join. A real junction is however impossible, from the difference of the levels; but the terminations are so artfully concealed, that the deception is never suspected, and when known is not easily explained. The river is the third great division of the water; a lake into which it falls, is the fourth. These two do actually join; but their characters are directly opposite; the scenes they belong to are totally distinct; and the transition from the one to the other is very gradual: for an island near the conflux dividing the breadth, and concealing the end of the lake, moderates for some way the space; and permitting it to expand but by degrees, raises an idea of greatness, from uncertainty accompanied with increase. The reality does not disappoint the expectation; and the island, which is the point of view, is itself equal to the scene: it is large, and high above the lake; the ground is irregularly broken; thickets hang on the sides; and towards the top is placed an Ionic portico, which commands a noble extent of water, not less than a mile in circumference, bounded on one side with wood, and open on the other to two sloping lawns, the least of an hundred acres, diversified with clumps, and bordered by plantations. Yet this lake, when full in view, and with all the importance which space, form, and situation can give, is not more interesting than the sequestered river, which has been mentioned as the third great division of the water. It is just within the verge of a wood, three quarters of a mile long, every where broad, and its course is such as to admit of infinite variety without any confusion. The banks are cleared of underwood; but a few thickets still remain,

and on one side an impenetrable covert soon begins: the interval is a beautiful grove of oaks, scattered over a green sward of extraordinary verdure. Between these trees and these thickets the river seems to glide gently along, constantly winding, without one short turn or one extended reach in the whole length of the way. This even temper in the stream suits the scenes through which it passes; they are in general of a very sober cast, not melancholy, but grave; never exposed to a glare; never darkened with gloom; nor by strong contrasts of light and shade, exhibiting the excess of either. Undisturbed by an extent of prospect without, or a multiplicity of objects within, they retain at all times a mildness of character; which is still more forcibly felt when the shadows grow faint as they lengthen, when a little rustling of birds in the spray, the leaping of the fish, and the fragrant of the woodbine, denote the approach of evening; while the setting sun shoots its last gleams on a Tuscan portico, which is close to the great basin, but which from a seat near this river is seen at a distance, through all the obscurity of the wood glowing on the banks, and reflected on the surface of the water. In another still more distinguished spot is built an elegant bridge, with a colonnade upon it, which not only adorns the place where it stands, but is also a picturesque object to an octagon building near the lake, where it is shown in a singular situation, over-arched, encompassed, and backed with wood, without any appearance of the water beneath. This building in return is also an object from the bridge; and a Chinese room, in a little island just by, is another: neither of them are considerable, and the others which are visible are at a distance, but more or greater adventitious ornaments are not required in a spot so rich as this in beauties peculiar to its character. A profusion of water pours in from all sides round upon the view; the opening of the lake appears; a glimpse is caught of the large basin; one of the collateral streams is full in sight, and the bridge itself is in the midst of the finest part of the river: all seem to communicate the one with the other. Though thickets often intercept, and groupes perplex, the view, yet they never break the connection between the several pieces of water; each may still be traced along large branches, or little catches; which in some places are overshadowed and dim; in others glisten through a glade, or glimmer between the boles of trees in a distant perspective; and in one, where they are quite lost to the view; some arches of a stone-bridge, but partially seen among the wood, preserve their connection.

3. If a large river may sometimes, a smaller current undoubtedly may often, be conducted through a wood: it seldom adorns, it frequently disfigures, a prospect, where its course is marked, not by any appearance of water, but by a confused line of clotted grass, which disagrees with the general verdure. A rivulet may, indeed, have consideration enough for a home scene, though it be open; but a *Rill* is always most agreeable when most retired from public view. Its characteristic excellencies are vivacity and variety, which require attention, leisure, and silence, that the eye may pore upon the little beauties, and the ear listen to the low murmurs of the stream without interruption. To such indulgence a confined spot only is favourable; a close

Water.

7
Of a Rill
and a Rivulet.

copse

Water.
Ibid.

copse is therefore often more acceptable than a high wood, and a sequestered valley at all times preferable to any open exposure: a single rill at a very little distance is a mere water-course; it loses all its charms; it has no importance in itself, and bears no proportion to the scene. A number of little streams have indeed an effect in any situation, but not as objects; they are interesting only on account of the character they express, the irriguous appearance which they give to the whole.

The full tide of a large river has more force than activity, and seems too unwieldy to allow of very quick transitions. But in a rill, the agility of its motion accounts for every caprice: frequent windings disguise its insignificance; short turnings show its vivacity; sudden changes in the breadth are a species of its variety; and however fantastically the channel may be wreathed, contracted, and widened, it still appears to be natural. We find an amusement in tracing the little stream through all the intricacies of its course, and in seeing it force a passage through a narrow strait, expatiate on every opportunity, struggle with obstructions, and puzzle out its way. A rivulet, which is the mean betwixt a river and a rill, partakes of the character of both: it is not licensed to the extravagance of the one, nor under the same restraints as the other: it may have more frequent bends than the river, longer reaches than a rill: the breadth of a stream determines whether the principal beauty results from extent or from variety.

The murmurs of a rill are amongst the most pleasing circumstances which attend it. If the bed of the stream be rough, mere declivity will occasion a constant rippling noise: when the current drops down a descent, though but of a few inches, or forcibly bubbles up from a little hollow, it has a deep gurgling tone, not uniformly continued, but incessantly repeated, and therefore more engaging than any. The flattest of all, is that sound rather of the splashing than the fall of water, which an even gentle slope, or a tame obstruction, will produce: this is less pleasing than the others; but none should be entirely excluded: all in their turns are agreeable; and the choice of them is much in our power. By observing their causes, we may often find the means to strengthen, to weaken, or to change them; and the addition or removal of a single stone, or a few pebbles, will sometimes be sufficient for the purpose.

8
Of Cascades

A rill cannot pretend to any sound beyond that of a little water-fall: the roar of a cascade belongs only to larger streams; but it may be produced by a rivulet to a considerable degree, and attempts to do more have generally been unsuccessful. A vain ambition to imitate nature in her great extravagancies betrays the weakness of art. Though a noble river, throwing itself headlong down a precipice, be an object truly magnificent, it must however be confessed, that in a single sheet of water there is a formality which its vastness alone can cure. But the height, not the breadth, is the wonder: when it falls no more than a few feet, the regularity prevails; and its extent only serves to expose the vanity of affecting the style of a cataract in an artificial cascade. It is less exceptionable if divided into several parts: for then each separate part may be wide enough for its depth; and in the whole, variety, not greatness, will be the predominant character. But

a structure of rough, large, detached stones, cannot easily be contrived of strength sufficient to support a great weight of water: it is sometimes from necessity almost smooth and uniform, and then it loses much of its effect. Several little falls in succession are preferable to one great cascade which in figure or in motion approaches to regularity.

Rocks.

When greatness is thus reduced to number, and length becomes of more importance than breadth, a rivulet vies with a river; and it more frequently runs in a continued declivity, which is very favourable to such a succession of falls. Half the expence and labour which are sometimes bestowed on a river, to give it at the best a forced precipitancy in one spot only, would animate a rivulet through the whole of its course. And, after all, the most interesting circumstance in falling waters is their animation. A great cascade fills us with surprise: but all surprise must cease; and the motion, the agitation, the rage, the froth, and the variety of the water, are finally the objects which engage the attention: for these a rivulet is sufficient; and they may there be produced without that appearance of effort which rises a suspicion of art.

To obviate such a suspicion, it may be sometimes expedient to begin the descent out of sight; for the beginning is the difficulty: if that be concealed, the subsequent falls seem but a consequence of the agitation which characterises the water at its first appearance; and the imagination is, at the same time, let loose to give ideal extent to the cascades. When a stream issues from a wood, such management will have a great effect: the bends of its course in an open exposure may afford frequent opportunities for it; and sometimes a low broad bridge may furnish the occasion: a little fall hid under the arch will create a disorder; in consequence of which, a greater cascade below will appear very natural.

IV. ROCKS. Rocks are themselves too vast and too stubborn to submit to our controul; but by the addition or removal of appendages which we can command, parts may be shown or concealed, and the characters with their impressions may be weakened or enforced: to adapt the accompaniments accordingly, is the utmost ambition of art when rocks are the subject.

9
Of Rocks.

Their most distinguished characters are, *dignity*, *terror*, and *fancy*: the expressions of all are constantly wild: and sometimes a rocky scene is only wild, without pretensions to any particular character.

Rills, rivulets, and cascades, abound among rocks: they are natural to the scene; and such scenes commonly require every accompaniment which can be procured for them. Mere rocks, unless they are peculiarly adapted to certain impressions, though they may surprise, cannot be long engaging, if the rigour of their character be not softened by circumstances which may belong either to these or to more cultivated spots: and when the dreariness is extreme, little streams and water-falls are of themselves insufficient for the purpose; an intermixture of vegetation is also necessary, and on some occasions even marks of inhabitants are proper.

Large clefts, sloping or precipitous, with a dale at bottom, furnish scenes of the wildest nature. In such spots, verdure alone will give some relief to the dreariness of the scene; and shrubs or bushes, without trees, are

Rocks.
Ibid.

are a sufficiency of wood: the thickets may also be extended by the creeping plants, such as pyracantha, vines, and ivy, to wind up the sides or cluster on the tops of the rocks. And to this vegetation may be added some symptoms of inhabitants, but they must be slight and few; the use of them is only to cheer, not to destroy, the solitude of the place; and such therefore should be chosen as are sometimes found in situations retired from public resort; a cottage may be lonely, but it must not here seem ruinous and neglected; it should be tight and warm, with every mark of comfort about it, to which its position in some sheltered recess may greatly contribute. A cavity also in the rocks, rendered easy of access, improved to a degree of convenience, and maintained in a certain state of preservation, will suggest similar ideas of protection from the bitterest inclemencies of the sky, and even of occasional refreshment and repose. But we may venture still further; a mill is of necessity often built at some distance from the town which it supplies; and here it would at the same time apply the water to a use, and increase its agitation. The dale may besides be made the haunt of those animals, such as goats, which are sometimes wild, and sometimes domestic; and which accidentally appearing, will divert the mind from the sensations natural to the scene, but not agreeable if continued long without interruption. These and such other expedients will approximate the severest retreat to the habitations of men, and convert the appearance of a perpetual banishment into that of a temporary retirement from society.

But too strong a force on the nature of the place always fails. A winding path, which appears to be worn not cut, has more effect than a high road, all artificial and level, which is too weak to overbear, and yet contradicts, the general idea. The objects therefore to be introduced must be those which hold a mean between solitude and population; and the inclination of that choice towards either extreme, should be directed by the degree of wildness which prevails; for tho' that runs sometimes to an excess which requires correction, at other times it wants encouragement, and at all times it ought to be preserved: it is the predominant character of rocks, which mixes with every other, and to which all the appendages must be accommodated; and they may be applied so as greatly to increase it: a licentious irregularity of wood and of ground, and a fantastic conduct of the streams, neither of which would be tolerated in the midst of cultivation, become and improve romantic rocky spots; even buildings, partly by their style, but still more by their position, in strange, difficult, or dangerous situations, distinguish and aggravate the native extravagancies of the scene.

Greatness is a chief ingredient in the character of *dignity*, with less of wildness than in any other. The effect here depends more upon amplitude of surface, than variety of forms. The parts therefore, must be large: if the rocks are only high, they are but stupendous, not majestic: breadth is equally essential to their greatness; and every slender, every grotesque shape, is excluded. Art may interpose to show these large parts to the eye, and magnify them to the imagination, by taking away thickets which stretch quite across the rocks, so as to disguise their dimensions; or by filling with wood the small intervals between them,

and thus, by concealing the want, preserving the appearance of continuation. When rocks retire from the eye down a gradual declivity, we can, by raising the upper ground, deepen the fall, lengthen the perspective, and give both height and extent to those at a distance: this effect may be still increased by covering that upper ground with a thicket, which shall cease, or be lowered, as it descends. A thicket, on other occasions, makes the rocks which rise out of it seem larger than they are. If they stand upon a bank over-spread with shrubs, their beginning is at the least uncertain; and the presumption is, that they start from the bottom. Another use of this brushy underwood is to conceal the fragments and rubbish which have fallen from the sides and the brow, and which are often unsightly. Rocks are seldom remarkable for the elegance of their forms; they are too vast, and too rude, to pretend to delicacy: but their shapes are often agreeable; and we can affect those shapes to a certain degree, at least we can cover many blemishes in them, by conducting the growth of shrubby and creeping plants about them.

For all these purposes mere underwood suffices: but for greater effects larger trees are requisite: they are worthy of the scene; and not only improvements, but accessions to its grandeur: we are used to rank them among the noblest objects of nature; and when we see that they cannot aspire to the midway of the heights around them, the rocks are raised by the comparison. A single tree is therefore, often preferable to a clump: the size, though really less, is more remarkable: and clumps are besides generally exceptionable in a very wild spot, from the suspicion of art which attends them; but a wood is free from that suspicion, and its own character of greatness recommends it to every scene of magnificence.

On the same principle, all possible consideration should be given to the streams. No number of little rills are equal to one broad river; and in the principal current, some varieties may be sacrificed to importance: but a degree of strength should always be preserved: the water, though it needs not be furious, should not be dull; for dignity, when most serene, is not languid; and space will hardly atone for want of animation.

This character does not exclude marks of inhabitants, though it never requires them to tame its wildness: and without inviting, it occasionally admits an intermixture of vegetation. It even allows of buildings intended only to decorate the scene: but they must be adequate to it, both in size and in character. And if cultivation is introduced, that too should be conformable to the rest; not a single narrow patch cribbed out of the waste; but the confines of a country shelving into the vale, and suggesting the idea of extent: nothing trivial ought to find admittance. But, on the other hand, no extravagance required to support it: strange shapes in extraordinary positions, enormous weights unaccountably sustained, trees rooted in the sides, and torrents raging at the foot of the rocks, are at the best needless excesses. There is a temperance in dignity, which is rather hurt by a wanton violence on the common order of nature.

The terrors of a scene in nature are like those of a dramatic representation: they give an alarm; but the sensations are agreeable, so long as they are kept to
such

Rocks.

Rocks.

Ibid.

such as are allied only to terror, unmixed with any that are horrible and disgusting. Art may therefore be used to heighten them, to display the objects which are distinguished by greatness, to improve the circumstances which denote force, to mark those which intimate danger, and to blend with all here and there a cast of melancholy.

Greatness is as essential to the character of *terror* as to that of *dignity*: vast efforts in little objects are but ridiculous; nor can force be supposed upon trifles incapable of resistance. On the other hand, it must be allowed, that exertion and violence supply some want of space. A rock wonderfully supported, or threatening to fall, acquires a greatness from its situation, which it has not in dimensions; so circumstanced, the size appears to be monstrous: a torrent has a consequence which a placid river of equal breadth cannot pretend to: and a tree, which would be inconsiderable in the natural soil, becomes important when it bursts from a rock.

Such circumstances should be always industriously sought for. It may be worth while to cut down several trees, in order to exhibit one apparently rooted in the stone. By the removal perhaps of only a little brushwood, the alarming disposition of a rock, strangely undermined, rivetted, or suspended, may be shown; and if there be any soil above its brow, some trees planted there, and impending over it, will make the object still more extraordinary. As to the streams, great alteration may generally be made in them: and therefore it is of use to ascertain the species proper to each scene, because it is in our power to enlarge or contract their dimensions; to accelerate or retard their rapidity; to form, increase, or take away obstructions; and always to improve, often to change, their characters.

Inhabitants furnish frequent opportunities to strengthen the appearances of force, by giving intimations of danger. A house placed at the edge of a precipice, any building on the pinnacle of a craig, makes that situation seem formidable, which might otherwise have been unnoticed: a steep, in itself not very remarkable, becomes alarming, when a path is carried aslant up the side: a rail on the brow of a perpendicular fall, shows that the height is frequented and dangerous: and a common foot-bridge thrown over a cleft between rocks has a still stronger effect. In all these instances, the imagination immediately transports the spectator to the spot, and suggests the idea of looking down such a depth: in the last, that depth is a chasm, and the situation is directly over it.

In other instances, exertion and danger seem to attend the occupations of the inhabitants:

—————Half way down

Hangs one that gathers samphire; dreadful trade!
is a circumstance chosen by the great poet of nature, to aggravate the terrors of the scene he describes.

The different species of rocks often meet in the same place, and compose a noble scene, which is not distinguished by any particular character: it is only when one eminently prevails, that it deserves such a preference as to exclude every other. Sometimes a spot remarkable for nothing but its wildness, is highly romantic: and when this wildness rises to *fancy*; when the most singular, the most opposite forms and combi-

nations are thrown together; then a mixture also of several characters adds to the number of instances which there concur to display the inexhaustible variety of nature.

So much variety, so much fancy, are seldom found within the same extent as in Dovedale †. It is about two miles in length, a deep, narrow, hollow valley: both the sides are of a rock; and the Dove in its passage between them is perpetually changing its course, its motion, and appearance. It is never less than ten, nor so much as twenty yards wide, and generally about four feet deep; but transparent to the bottom, except when it is covered with a foam of the purest white, under water-falls, which are perfectly lucid. These are very numerous, but very different. In some places they stretch straight across, or aslant the stream: in others, they are only partial: and the water either dashes against the stones, and leaps over them, or, pouring along a steep, rebounds upon those below; sometimes it rushes through the several openings between them; sometimes it drops gently down; and at other times it is driven back by the obstruction, and turns into an eddy. In one particular spot, the valley almost closing, leaves hardly a passage for the river, which pent up, and struggling for a vent, rages; and roars, and foams, till it has extricated itself from the confinement. In other parts, the stream, though never languid, is often gentle; flows round a little desert island, glides between bits of bulrushes, disperses itself among tufts of grass or of moss, bubbles about a water-dock, or plays with the slender threads of aquatic plants which float upon the surface. The rocks all along the dale vary as often in their structure as the stream in its motion. In one place, an extended surface gradually diminishes from a broad base almost to an edge; in another, a heavy top hanging forwards, overshadows all beneath: sometimes many different shapes are confusedly tumbled together; and sometimes they are broken into slender sharp pinnacles, which rise upright, often two or three together, and often in more numerous clusters. On this side of the dale, they are universally bare; on the other they are intermixed with wood; and the vast height of both the sides, with the narrowness of the interval between them, produces a further variety: for whenever the sun shines from behind the one, the form of it is distinctly and completely cast upon the other; the rugged surface on which it falls diversifies the tints; and a strong reflected light often glares on the edge of the deepest shadow. The rocks never continue long in the same figure or situation, and are very much separated from each other: sometimes they form the sides of the valley, in precipices, in steeps, or in stages; sometimes they seem to rise in the bottom, and lean back against the hill; and sometimes they stand out quite detached, heaving up in cumbrous piles, or starting into conical shapes, like vast spars, 100 feet high; some are firm and solid throughout; some are cracked; and some, split and undermined, are wonderfully upheld by fragments apparently unequal to the weight they sustain. One is placed before, one over another, and one fills at some distance behind an interval between two. The changes in their disposition are infinite; every step produces some new combination; they are continually crossing, advancing, and re-

tiring:

Rocks.
Ibid.

tiring : the breadth of the valley is never the same 40 yards together : at the narrow pass which has been mentioned, the rocks almost meet at the top, and the sky is seen as through a chink between them : just by this gloomy abyss, is a wider opening, more light, more verdure, more cheerfulness, than any where else in the dale. Nor are the forms and the situations of the rocks their only variety : many of them perforated by large natural cavities; some of which open to the sky, some terminate in dark recesses, and through some are to be seen several more uncouth arches, and rude pillars, all detached, and retiring beyond each other, with the light shining in between them, till a rock far behind them closes the perspective : the noise of the cascades in the river echoes amongst them ; the water may often be heard at the same time gurgling near, and roaring at a distance ; but no other sounds disturb the silence of the spot : the only trace of men is a blind path, but lightly and but seldom trodden, by those whom curiosity leads to see the wonders they have been told of Dovedale. It seems indeed a fitter haunt for more ideal beings : the whole has the air of enchantment. The perpetual shifting of the scenes ; the quick transitions, the total changes ; then the forms all around, grotesque as chance can cast, wild as nature can produce, and various as imagination can invent ; the force which seems to have been exerted to place some of the rocks where they are now fixed immovable, the magic by which others appear still to be suspended ; the dark caverns, the illuminated recesses, the fleeting shadows, and the gleams of light glancing on the sides, or trembling on the stream ; and the loneliness and the stillness of the place, all crowding together on the mind, almost realize the ideas which naturally present themselves in this region of romance and of fancy.

The solitude of such a scene is agreeable, on account of the endless entertainment which its variety affords, and in the contemplation of which both the eye and the mind are delighted to indulge : marks of inhabitants and cultivation would disturb that solitude ; and ornamental buildings are too artificial in a place so absolutely free from restraint. The only accompaniments proper for it are wood and water ; and by these sometimes improvements may be made. When two rocks similar in shape and position are near together, by skirting one of them with wood, while the other is left bare, a material distinction is established between them : if the streams be throughout of one character, it is in our power, and should be our aim, to introduce another. Variety is the peculiar property of the spot, and every accession to it is a valuable acquisition. On the same principle, endeavours should be used not only to multiply, but to aggravate differences, and to increase distinctions into contrasts : but the subject will impose a caution against attempting too much. Art must almost despair of improving a scene, where nature seems to have exerted her invention.

§ 2. Of FACTITIOUS ACCOMPANIMENTS.

THESE consist of Fences, Walks, Roads, Bridges, Seats, and Buildings.

“I. The FENCE, where the place is large, becomes

necessary ; yet the eye dislikes constraint. Our ideas of liberty carry us beyond our own species : the imagination feels a dislike in seeing even the brute creation in a state of confinement. The birds waiving themselves from wood to grove are objects of delight ; and the hare appears to enjoy a degree of happiness unknown to the barriered flock. Besides, a tall fence frequently hides from the sight objects the most pleasing ; not only the flocks and herds themselves, but the surface they graze upon. These considerations have brought the unseen fence into general use.

This species of barrier it must be allowed incurs a degree of deception, which can scarcely be warranted upon any other occasion. In this instance, however, it is a species of fraud which we observe in nature's practice : how often have we seen two distinct herds feeding to appearance in the same extended meadow ; until coming abruptly upon a deep sunk rivulet, or an unfordable river, we discover the deception.

Besides the sunk fence, another sort of unseen barrier may be made, though by no means equal to that, especially if near the eye. This is constructed of paling, painted of the invisible green. If the colour of the back-ground were permanent, and that of the paint made exactly to correspond with it, the deception would at a distance be complete ; but back-grounds in general changing with the season, this kind of fence is the less eligible.

Clumps and patches of woodiness scattered promiscuously on either side of an unseen winding fence, assist very much in doing away the idea of constraint. For by this means

The wand'ring flocks that brouse between the shades,
Seen oft to pass their bounds, the dubious eye
Decides not if they crop the mead or lawn. MASON.

“II. The WALK, in extensive grounds is as necessary as the fence. The beauties of the place are disclosed that they may be seen ; and it is the office of the walk to lead the eye from view to view ; in order that whilst the tone of health is preserved by the favourite exercise of nature, the mind may be thrown into unison by the harmony of the surrounding objects.

The direction of the walk must be guided by the points of view to which it leads, and the nature of the ground it passes over : it ought to be made subservient to the natural impediments (the ground, wood, and water) which fall in its way, without appearing to have any direction of its own. It can seldom run with propriety any distance in a straight line ; a thing which rarely occurs in a natural walk. The paths of the negroes and the Indians are always crooked ; and those of the brute creation are very similar. Mr Mason's description of this path of nature is happily conceived.

The peasant driving through each shadowy lane
His team, that bends beneath th' incumbent weight
Of laughing Ceres, marks it with his wheel ;
At night and morn, the milk-maid's careless step
Has, through yon pasture green, from stile to stile
Imprest a kindred curve : the scudding hare
Draws to her dew-spent seat, o'er thymy heaths,
A path as gently waving. — Eng. Gard. v. 60.

“III. The ROAD may be a thing of necessity, as an approach to the mansion ; or a matter of amusement only, as a drive or a ride, from which the grounds and the surrounding country may be seen to advantage.

It

Bridge, &c. It should be the study of the artist to make the same road answer, as far as may be, the two-fold purpose.

Ibid.

The road and the walk are subject to the same rule of nature and use. The direction ought to be natural and easy, and adapted to the purpose intended. A road of necessity ought to be straighter than one of mere conveniency: in this, recreation is the predominant idea; in that, utility. But even in this the direct line may be dispensed with. The natural roads upon heaths and open downs, and the grassy glades and green roads across forests and extensive wastes, are proper subjects to be studied.

“IV. The BRIDGE should never be seen where it is not wanted: a useless bridge is a deception; deceptions are frauds; and fraud is always hateful, unless when practised to avert some greater evil. A bridge without water is an absurdity; and half an one stuck up as an eye-trap is a paltry trick, which, though it may strike the stranger, cannot fail of disgusting when the fraud is found out.

In low situations, and wherever water abounds, bridges become useful, and are therefore pleasing objects: they are looked for; and ought to appear not as objects of ornament only, but likewise as matters of utility. The walk or the road therefore ought to be directed in such a manner as to cross the water at the point in which the bridge will appear to the greatest advantage.

In the construction of bridges also, regard must be had to ornament and utility. A bridge is an artificial production, and as such it ought to appear. It ranks among the noblest of human inventions; the ship and the fortress alone excel it. Simplicity and firmness are the leading principles in its construction. Mr Wheatley's observation is just when he says, “The single wooden arch, now much in fashion, seems to me generally misapplied. Elevated without occasion so much above, it is totally detached from the river; it is often seen straddling in the air, without a glimpse of water to account for it; and the ostentation of it as an ornamental object, diverts all that train of ideas which its use as a communication might suggest.” But we beg leave to differ from this ingenious writer when he tells us, “that it is spoiled if adorned; it is disfigured if only painted of any other than a dusky colour.” In a rustic scene, where Nature wears her own coarse garb, “the vulgar foot-bridge of planks only guarded on one hand by a common rail, and supported by a few ordinary piles,” may be in character; but amidst a display of ornamented nature, a contrivance of that kind would appear mean and paltry; and would be an affectation of simplicity rather than the lovely attribute itself. In cultivated scenes, the bridge ought to receive the ornaments which the laws of architectural taste allow; and the more polished the situation, the higher should be the style and finishings.

“V. SEATS have a two-fold use; they are useful as places of rest and conversation, and as guides to the points of view in which the beauties of the surrounding scene are disclosed. Every point of view should be marked with a seat; and speaking generally, no seat ought to appear but in some favourable point of

VOL. VII.

view. This rule may not be invariable, but it ought seldom to be deviated from.

In the ruder scenes of neglected nature, the simple trunk, rough from the woodman's hands, and the butts or stools of rooted trees, without any other marks of tools upon them than those of the saw which severed them from their stems, are seats in character; and in romantic or reclusive situations, the cave or the grotto are admissible. But wherever human design has been executed upon the natural objects of the place, the seat and every other artificial accompaniment ought to be in unison; and whether the bench or the alcove be chosen, it ought to be formed and finished in such a manner as to unite with the wood, the lawn, and the walk, which lie around it.

The colour of seats should likewise be suited to situations: where uncultivated nature prevails, the natural brown of the wood itself ought not to be altered; but where the rural art presides, white or stone colour has a much better effect.”

“VI. BUILDINGS probably were first introduced into gardens merely for convenience, to afford refuge from a sudden shower, and shelter against the wind; or, at the most, to be seats for a party; or for retirement. They have since been converted into objects, and now the original use is too often forgotten in the greater purposes to which they are applied: they are considered as objects only; the inside is totally neglected, and a pompous edifice frequently wants a room barely comfortable. Sometimes the pride of making a lavish display to a visitor without any regard to the owner's enjoyments, and sometimes too scrupulous attention to the style of the structure, occasions a poverty and dullness within, which deprive the buildings of part of their utility. But in a garden they ought to be considered both as beautiful objects and as agreeable retreats: if a character becomes them, it is that of the scene they belong to; not that of their primitive application. A Grecian temple, or Gothic church may adorn spots where it would be affectation to preserve that solemnity within which is proper for places of devotion: they are not to be exact models, subjects only of curiosity or study: they are also seats: and such seats will be little frequented by the proprietor; his mind must generally be indisposed to so much simplicity, and so much gloom, in the midst of gaiety, richness, and variety.

But though the interior of buildings should not be disregarded, it is by their exterior that they become objects; and sometimes by the one, sometimes by the other, and sometimes by both, they are entitled to be considered as characters.

1. As objects, they are designed either to distinguish, or to break, or to adorn, the scenes to which they are applied.

The differences between one wood, one lawn, one piece of water, and another, are not always very apparent; the several parts of a garden would, therefore, often seem similar, if they were not distinguished by buildings: but these are so observable, so obvious at a glance, so easily retained in the memory, they mark the spots where they are placed with so much strength, they attract the relation of all around with so much

Mr Wheatley's Observations resumed.

^{to}
Of buildings intended for objects.

Buildings.

power, that parts thus distinguished can never be confounded together. Yet it by no means follows, that therefore every scene must have its edifice; the want of one is sometimes a variety; and other circumstances are often sufficiently characteristic: it is only when these too nearly agree, that we must have recourse to buildings for differences: we can introduce, exhibit, or contrast them as we please: the most striking object is thereby made a mark of distinction; and the force of this first impression prevents our observing the points of resemblance.

Observ. on
Mod. Gard-
ening.

The uniformity of a view may be broken by similar means, and on the same principle: when a wide heath, a dreary moor, or a continued plain, is in prospect, objects which catch the eye supply the want of variety: none are so effectual for this purpose as buildings. Plantations or water can have no very sensible effect, unless they are large or numerous, and almost change the character of the scene: but a small single building diverts the attention at once from the sameness of the extent; which it breaks, but does not divide; and diversifies, without altering, its nature. The design, however, must not be apparent. The merit of a cottage applied to this purpose, consists in its being free from the suspicion: and a few trees near it will both enlarge the object, and account for its position. Ruins are a hackneyed device immediately detected, unless their style be singular, or their dimensions extraordinary. The semblance of an ancient British monument might be adapted to the same end, with little trouble and great success. The materials might be brick, or even timber plastered over, if stone could not easily be produced: whatever they were, the fallacy would not be discernible; it is an object to be seen at a distance, rude, and large, and in character agreeable to a wild open view. But no building ought to be introduced, which may not in reality belong to such a situation: no Grecian temples, no Turkish mosques, no Egyptian obelisks, or pyramids; none imported from foreign countries, and unusual here. The apparent artifice would destroy an effect, which is so nice as to be weakened, if objects proper to produce it are displayed with too much ostentation; if they seem to be contrivances, not accidents; and the advantage of their position appear to be more laboured than natural.

But in a garden, where objects are intended only to adorn, every species of architecture may be admitted, from the Grecian down to the Chinese; and the choice is so free, that the mischief most to be apprehended is an abuse of this latitude in the multiplicity of buildings. Few scenes can bear more than two or three: in some, a single one has a greater effect than any number: and a carelefs glimpse, here and there, of such as belong immediately to different parts, frequently enliven the landscape with more spirit than those which are industriously shown. If the effect of a partial sight, or a distant view, were more attended to, many scenes might be filled, without being crowded; a greater number of buildings would be tolerated, when they seemed to be casual, not forced; and the animation, and the richness of the objects, might be had without pretence or display.

Too fond an ostentation of buildings, even of these

which are principal, is a common error; and when all is done, they are not always shown to the greatest advantage. Though their symmetry and their beauties ought in general to be distinctly and fully seen, yet an oblique is sometimes better than a direct view: and they are often less agreeable objects when entire, than when a part is covered, or their extent is interrupted; when they are bosomed in wood, as well as backed by it; or appear between the stems of trees which rise before or above them; thus thrown into perspective, thus grouped and accompanied, they may be as important as if they were quite exposed, and are frequently more picturesque and beautiful.

But a still greater advantage arises from this management, in connecting them with the scene: they are considerable, and different from all around them: inclined therefore to separate from the rest: and yet they are sometimes still more detached by the pains taken to exhibit them: that very importance which is the cause of the distinction ought to be a reason for guarding against the independence to which it is naturally prone, and by which an object, which ought to be a part of the whole, is reduced to a mere individual. An elevated is generally a noble situation. When it is a point or a pinnacle, the structure may be a continuation of the ascent; and on many occasions, some parts of the building may descend lower than others, and multiply the appearances of connection: but an edifice in the midst of an extended ridge, commonly seems naked alone, and imposed upon the brow, not joined to it. If wood, to accompany it, will not grow there, it had better be brought a little way down the declivity; and then all behind, above, and about it, are so many points of contact, by which it is incorporated into the landscape.

Accompaniments are important to a building; but they lose much of their effect when they do not appear to be casual. A little mount just large enough for it; a small piece of water below, of no other use than to reflect it; and a plantation close behind, evidently placed there only to give it relief; are as artificial as the structure itself, and alienate it from the scene of nature into which it is introduced, and to which it ought to be reconciled. These appendages therefore should be so disposed, and so connected with the adjacent parts, as to answer other purposes, though applicable to this: that they may be bonds of union, not marks of difference; and that the situation may appear to have been chosen at the most, not made, for the building.

In the choice of a situation, that which shows the building best ought generally to be preferred: eminence, relief, and every other advantage which can be, ought to be given to an object of so much consideration: they are for the most part desirable; sometimes necessary; and exceptionable only when, instead of rising out of the scene, they are forced into it, and a contrivance to procure them at any rate is avowed without any disguise. There are, however, occasions, in which the most tempting advantages of situation must be waved; the general composition may forbid a building in one spot, or require in in another; at other times, the interest of the particular groupe it belongs to, may exact a sacrifice of the opportunities to exhibit

Buildings.

Buildings. exhibit its beauties and importance : and at all times, the pretensions of every individual object must give way to the greater effect of the whole.

Ibid.
11
Of those expressive of character.

2. The same structure which adorns as an object, may also be expressive as a *character*. Where the former is not wanted, the latter may be desirable : or it may be weak for one purpose, and strong for the other ; it may be grave, or gay ; magnificent, or simple ; and, according to its style, may or may not be agreeable to the place it is applied to. But mere consistency is not all the merit which buildings can claim : their characters are sometimes strong enough to *determine, improve, or correct*, that of the scene : and they are so conspicuous, and so distinguished, that whatever force they have is immediately and sensibly felt. They are fit therefore to make a first impression ; and when a scene is but faintly characterised, they give at once a cast which spreads over the whole, and which the weaker parts concur to support, though perhaps they were not able to produce it.

Nor do they stop at fixing an uncertainty, or removing a doubt ; they raise and enforce a character already marked : a temple adds dignity to the noblest, a cottage simplicity to the most rural, scenes ; the lightness of a spire, the airiness on an open rotunda, the splendor of a continued colonnade, are less ornamental than expressive ; others improve cheerfulness into gaiety, gloom into solemnity, and richness into profusion : a retired spot, which might have been passed unobserved, is noticed for its tranquillity, as soon as it is appropriated by some structure to retreat ; and the most unfrequented place seems less solitary than one which appears to have been the haunt of a single individual, or even of a sequestered family, and is marked by a lonely dwelling, or the remains of a deserted habitation.

The means are the same, the application of them only is different, when buildings are used to correct the character of the scene ; to enliven its dulness, mitigate its gloom, or to check its extravagance ; and, on a variety of occasions, to soften, to aggravate, or to counteract, particular circumstances attending it. But care must be taken that they do not contradict too strongly the prevailing idea : they may lessen the dreariness of a waste, but they cannot give it amenity ; they may abate horrors, but they will never convert them into graces ; they may make a tame scene agreeable, and even interesting, not romantic ; or turn solemnity into cheerfulness, but not into gaiety. In these, and in many other instances, they correct the character, by giving it an inclination towards a better, which is not very different ; but they can hardly alter it entirely : when they are totally inconsistent with it, they are at the best nugatory.

The great effects which have been ascribed to buildings do not depend upon those trivial ornaments and appendages which are often too much relied on ; such as the furniture of a hermitage, painted glass in a Gothic church, and sculpture about a Grecian temple ; grotesque or bacchanalian figures to denote gaiety, and death's-heads to signify melancholy. Such devices are only descriptive, not expressive, of character ; and must not be substituted in the stead of those superior properties, the want of which they acknowledge, but do not supply. They besides often

require time to trace their meaning, and to see their application ; but the peculiar excellence of buildings is, that their effects are instantaneous, and therefore the impressions they make are forcible. In order to produce such effects, the general style of the structure, and its position, are the principal considerations : either of them will sometimes be strongly characteristic alone ; united, their powers are very great ; and both are so important, that if they do not concur, at least they must not contradict one another.

Every branch of architecture furnishes, on different occasions, objects proper for a garden ; and there is no restraint on our selection, provided it be conformable to the style of the scene, proportioned to its extent, and agreeable to its character.

The choice of situations is also very free. A hermitage, indeed, must not be close to a road ; but whether it be exposed to view on the side of a mountain, or concealed in the depth of a wood, is almost a matter of indifference ; that it is at a distance from public resort is sufficient. A castle must not be sunk in a bottom ; but that it should stand on the utmost pinnacle of a hill, is not necessary : on a lower knole, and backed by the rise, it may appear to greater advantage as an object, and be much more important to the general composition. Many buildings, which from their splendor best become an open exposure, will yet be sometimes not ill bestowed on a more sequestered spot, either to characterise or adorn it ; and others, for which a solitary would in general be preferred to an eminent situation, may occasionally be objects in very conspicuous positions. A Grecian temple, from its peculiar grace and dignity, deserves every distinction ; it may, however, in the depth of a wood, be so circumstanced, that the want of those advantages to which it seems intitled will not be regretted. A happier situation cannot be devised, than that of the temple of Pan on the south lodge on Enfield chace. It is of the usual oblong form, encompassed by a colonnade ; in dimensions, and in style, it is equal to a most extensive landscape : and yet the antique and rustic air of its Doric columns without bases : by the chastity of its little ornaments, a crook, a pipe, and a scrip, and those only over the doors ; and by the simplicity of the whole both within and without ; it is adapted with so much propriety to the thickets which conceal it from the view, that no one can wish it to be brought forward, who is sensible to the charms of the Arcadian scene which this building alone has created. On the other hand, a very spacious field, or sheep-walk, will not be disgraced by a farm-house, a cottage, or a Dutch barn ; nor will they, though small and familiar, appear to be inconsiderable or insignificant objects. Numberless other instances might be adduced to prove the impossibility of restraining particular buildings to particular situations, upon any general principles : the variety in their forms is hardly greater than in their application. Only let not their uses be disguised, as is often absurdly attempted with the humbler kinds. " A barn * dressed up in the habit of a * *Planting* country-church, or a farm-house figuring away in the *and Gard-* fierceness of a castle, are ridiculous deceptions. A *dining,* landscape daubed upon a board, and a wooden steeple *P. 59.* stuck up in a wood, are beneath contempt."

Temples, those favourite and most costly objects in gardens, too generally merit censure for their inutility, their

Buildings. their profusion, or the impropriety of their purpose. "Whether they be dedicated to Bacchus, Venus, Priapus, or any other demon of debauchery, they are in this age, enlightened with regard to theological and scientific knowledge, equally absurd. Architecture, in this part of its sphere, may more nobly, and with greater beauty and effect, be exercised upon a chapel, a mausoleum, a monument, judiciously disposed among the natural ornaments. The late Sir William Har-

Ibid. p. 599

bord, has given us a model of the first kind, at Gunton, in Norfolk; the parish-church standing in his park, and being, an old unsightly building, he had it taken down, and a beautiful temple, under the direction of the Adams's erected upon its site for the same sacred purpose:—The mausoleum at Castle-Howard, in Yorkshire, the seat of the earl of Carlisle, is a noble structure:—And as an instance of the last sort, may be mentioned the Temple of Concord and Victory at Stowe, erected to the memory of the great Lord Chatham and his glorious war; a beautiful monumental building, suited to the greatness of the occasion."

*Observations
on Mod.
Gardening.*

To the great variety abovementioned must be added, Mr Wheatley observes, the many changes which may be made by the means of ruins. They are a class by themselves, beautiful as objects, expressive as characters, and peculiarly calculated to connect with appendages into elegant groupes. They may be accommodated with ease to irregularity of ground, and their disorder is improved by it. They may be intimately blended with trees and thickets; and the interruption is an advantage: for imperfection and obscurity are their properties; and to carry the imagination to something greater than is seen, is their effect. They may for any of these purposes be separated into detached pieces; contiguity is not necessary, nor even the appearance of it, if the relation be preserved; but straggling ruins have a bad effect, when the several parts are equally considerable. There should be one large mass to raise an idea of greatness, to attract the others about it, and to be a common centre of union to all: the smaller pieces then mark the original dimensions of one extensive structure; and no longer appear to be the remains of several little buildings.

All remains excite an inquiry into the former state of the edifice, and fix the mind in a contemplation of the use it was applied to; besides the characters expressed by their style and position, they suggest ideas which would not arise from the buildings if entire. The purposes of many have ceased: an abbey, or a castle, if complete, can now be no more than a dwelling; the memory of the times, and of the manners to which they are adapted, is preserved only in history, and in ruins; and certain sensations of regret, of veneration, or compassion, attend the recollection. Nor are these confined to the remains of buildings which are now in disuse: those of an old mansion raise reflections on the domestic comforts once enjoyed, and the ancient hospitality which reigned there. Whatever building we see in decay, we naturally contrast its present to its former state, and delight to ruminat on the comparison. It is true that such effects properly belong to real ruins; they are however produced in a certain degree by those which are fictitious: the impressions are not so strong, but they are exactly similar; and the representation, though it does not

present facts to the memory, yet suggests subjects to the imagination. But, in order to affect the fancy, the supposed original design should be clear, the use obvious, and the form easy to be traced: no fragments should be hazarded without a precise meaning, and an evident connection; none should be perplexed in their construction, or uncertain as to their application. Conjectures about the form, raise doubts about the existence of the ancient structure: the mind must not be allowed to hesitate; it must be hurried away from examining into the reality, by the exactness and the force of the resemblance.

In the ruins of Tintern abbey †, the original construction, of the church is perfectly marked; and it is principally from this circumstance that they are celebrated as a subject of curiosity and contemplation. The walls are almost entire; the roof only is fallen in, but most of the columns which divided the ayles are still standing: of those which have dropped down, the bases remain, every one exactly in its place: and in the middle of the nave four lofty arches, which once supported the steeple, rise high in the air above all the rest, each reduced now to a narrow rim of stone, but completely preserving its form. The shapes even of the windows are little altered: but some of them are quite obscured, others partially shaded, by tufts of ivy; and those which are most clear, are edged with its slender tendrils, and lighter foliage, wreathing about the sides and the divisions: it winds round the pillars; it clings to the walls; and in one of the ayles clusters at the top in bunches, so thick and so large as to darken the space below. The other ayles, and the great nave, are exposed to the sky: the floor is entirely overspread with turf; and to keep it clear from weeds and bushes, is now its highest preservation. Monkish tomb-stones, and the monuments of benefactors long since forgotten, appear above the green sward; the bases of the pillars which have fallen, rise out of it; and maimed effigies, and sculpture worn with age and weather, Gothic capitals, carved cornices, and various fragments, are scattered about, or lie in heaps piled up together. Other shattered pieces, though disjointed and mouldering, still occupy their original places; and a stair-case much impaired, which led to a tower now no more, is suspended at a great height, uncovered and inaccessible. Nothing is perfect; but memorials of every part still subsist: all certain, but all in decay; and suggesting at once every idea which can occur in a seat of devotion, solitude, and desolation. Upon such models, fictitious ruins should be formed: and if any parts are entirely lost, they should be such as the imagination can easily supply from those which are still remaining. Distinct traces of the building which is supposed to have existed, are less liable to the suspicion of artifice, than an unmeaning heap of confusion. Precision is always satisfactory, but in the reality it is only agreeable; in the copy it is essential to the imitation.

A material circumstance to the truth of the imitation is, that the ruins appear to be very old. The idea is besides interesting in itself: a monument of antiquity is never seen with indifference; and a semblance of age may be given to the representation by the hue of the materials, the growth of ivy and other plants, and

crack.s

Arts, &c. cracks and fragments seemingly occasioned rather by decay than by destruction. An appendage evidently more modern than the principal structure will sometimes corroborate the effect: the shed of a Cottager amidst the remains of a temple, is a contrast both to the former and to the present state of the building; and a tree flourishing among ruins, shows the length of time they have lain neglected. No circumstance so forcibly marks the desolation of a spot once inhabited, as the prevalence of nature over it:

Campos ubi Troja fuit.

is a sentence which conveys a stronger idea of a city totally overthrown, than a description of its remains; but in a representation to the eye, some remains must appear; and then the perversion of them to an ordinary use, or an intermixture of a vigorous vegetation, intimates a settled despair of their restoration.

SECT. II. Principles of Selection and Arrangement in the Subjects of Gardening.

I. Of ART. In the lower classes of rural improvements, art should be seen as little as may be; and in the more negligent scenes of nature, every thing ought to appear as if it had been done by the general laws of nature, or had grown out of a series of fortuitous circumstances. But in the higher departments, art cannot be hid; and the appearance of design ought not to be excluded. A human production cannot be made perfectly natural; and held out as such it becomes an imposition. Our art lies in endeavouring to adapt the productions of nature to human taste and perceptions; and if much art be used, do not attempt to hide it. Art seldom fails to please when executed in a masterly manner: nay, it is frequently the design and execution, more than the production itself, that strikes us. It is the artifice, not the design, which ought to be avoided. It is the labour and not the art which ought to be concealed. The rural artist ought, therefore, upon every occasion, to endeavour to avoid labour; or, if indispensably necessary, to conceal it. No trace should be left to lead back the mind to the expensive toil. A mound raised, a mountain levelled, or a useless temple built, convey to the mind feelings equally disgusting.

Planting and Gardening, p. 602.

13
Of Scenery
Ibid. II. PICTURESQUE BEAUTY. Though the aids of art are as essential to gardening, as education is to manners; yet art may do too much: she ought to be considered as the hand-maid, not as the mistress, of nature; and whether she be employed in carving a tree into the figure of an animal, or in shaping a view into the form of a picture, she is equally culpable. The nature of the place is sacred. Should this tend to landscape, from some principal point of view, assist nature and perfect it; provided this can be done without injuring the views from other points. But do not disfigure the natural features of the place:—do not sacrifice its native beauties, to the arbitrary laws of landscape painting.

Great Nature scorns controul; she will not bear
One beauty foreign to the spot or soil
She gives thee to adorn: 'Tis thine alone
To mend, not change her features.

MASON.

Nature scarcely knows the thing mankind call a landscape.

Character. *scape.* The landscape-painter seldom, if ever, finds it perfected to his hands;—some addition or alteration is almost always wanted. Every man who has made his observations upon natural scenery, knows that the mistletoe of the oak occurs almost as often as a perfect natural landscape; and to attempt to make up artificial landscape upon every occasion is unnatural and absurd.

If, indeed, the eye were fixed in one point, the trees could be raised to their full height at command, and the sun be made to stand still,—the rural artist might work by the rules of light and shade, and compose his landscape by the painter's law. But whilst the sun continues to pour forth its light impartially, and the trees to rise with slow progression, it would be ridiculous to attempt it. Let him rather seek out, imitate and associate, such striking passages in nature as are immediately applicable to the place to be improved, with regard to rules of landscape, merely human;—and let him,

Be various, wild, and free, as Nature's self. MASON.

Instead of sacrificing the natural beauties of the place to one formal landscape, let every step disclose fresh charms unfought for.

III. Of CHARACTER. Character is very reconcilable with beauty; and, even when independent of it, has attracted so much regard, as to occasion several frivolous attempts to produce it: statues, inscriptions, and even paintings, history and mythology, and a variety of devices, have been introduced for this purpose. The heathen deities and heroes have therefore had their several places assigned to them in the woods and the lawns of a garden: natural cascades have been disfigured with river-gods, and columns erected on ly to receive quotations; the compartments of a summer-house have been filled with pictures of gambols and revels, as significant of gaiety; the cypress, because it was once used in funerals, has been thought peculiarly adapted to melancholy; and the decorations, the furniture, and the environs of a building, have been crowded with puerilities under pretence of propriety. All these devices are rather emblematical than expressive they may be ingenious contrivances, and recal absent ideas to the recollection; but they make no immediate impression: for they must be examined, compared, perhaps explained, before the whole design of them is well understood. And though an allusion to a favourite or well known subject of history, of poetry, or of tradition, may now and then animate or dignify a scene; yet as the subject does not naturally belong to a garden, the allusion should not be principal: it should seem to have been suggested by the scene; a transitory image, which irresistibly occurred; not sought for, not laboured; and have the force of metaphor, free from the detail of an allegory.

Wheatley's Observations

14
Of emblematical characters.

Another species of character arises from direct imitation; when a scene or an object, which has been celebrated in description, or is familiar in idea, is represented in a garden. Artificial ruins, lakes, and rivers, fall under this denomination. The air of a seat extended to a distance, and scenes calculated to raise ideas of Arcadian elegance of a rural simplicity, with many more which have been occasionally mentioned or will obviously

15
Of imitative characters.

Character. obviously occur, may be ranked in this class. They are all representations. But the materials, the dimensions, and other circumstances, being the same in the copy and the original, their effects are similar in both: and if not equally strong, the defect is not in the resemblance; but the consciousness of an imitation checks that train of thought which the appearance naturally suggests, yet an over-anxious solicitude to disguise the fallacy is often the means of exposing it: too many points of likeness sometimes hurt the deception; they seem studied and forced; and the affectation of resemblance destroys the supposition of a reality. A hermitage is the habitation of a recluse; it should be distinguished by its solitude, and its simplicity: but if it is filled with crucifixes, hour-glasses, beads, and every other trinket which can be thought of, the attention is diverted from enjoying the retreat to examining the particulars: all the collateral circumstances which agree with a character, seldom meet in one subject; and when they were industriously brought together, though each be natural, the collection is artificial.

¹⁶
Of original characters. But the art of gardening aspires to more than imitation: it can create *original* characters, and give expressions to the several scenes superior to any they can receive from allusions. Certain properties, and certain dispositions, of the objects of nature, are adapted to excite particular ideas and sensations: many of them have been occasionally mentioned, and all are very well known. They require no discernment, examination, or discussion; but are obvious at a glance, and instantaneously distinguished by our feelings. Beauty alone is not so engaging as this species of character: the impressions it makes are more transient and less interesting; for it aims only at delighting the eye, but the other affects our sensibility. An assemblage of the most elegant forms in the happiest situations is to a degree indiscriminate, if they have not been selected and arranged with a design to produce certain expressions; an air of magnificence, or of simplicity, of cheerfulness, tranquillity, or some other general character, ought to pervade the whole; and objects pleasing in themselves, if they contradict that character, should therefore be excluded: those which are only indifferent, must sometimes make room for such as are more significant; many will often be introduced for no other merit than their expression; and some, which are in general rather disagreeable, may occasionally be recommended by it. Barrenness itself may be an acceptable circumstance in a spot dedicated to solitude and melancholy.

The power of such characters is not confined to the ideas which the objects immediately suggest; for these are connected with others, which insensibly lead to subjects far distant perhaps from the original thought, and related to it only by a similitude in the sensations they excite. In a prospect enriched and enlivened with inhabitants and cultivation, the attention is caught at first by the circumstances which are gayest in their season, the bloom of an orchard, the festivity of a hay-field, and the carols of harvest-home; but the cheerfulness which these infuse into the mind, expands afterwards to other objects than those immediately presented to the eye; and we are thereby disposed to receive, and delighted to pursue, a variety of pleasing

ideas, and every benevolent feeling. At the sight of a ruin, reflections on the change, the decay, and the desolation before us, naturally occur; and they introduce a long succession of others, all tinged with that melancholy which these have inspired; or if the monument revive the memory of former times, we do not stop at the simple fact which it records, but recollect many more coeval circumstances, which we see, not perhaps as they were, but as they are come down to us, venerable with age, and magnified by fame. Even without the assistance of buildings or other adventitious circumstances, nature alone furnishes materials for scenes which may be adapted to almost every kind of expression: their operation is general, and their consequences are infinite: the mind is elevated, depressed, or composed, as gaiety, gloom, or tranquillity, prevails in the scene; and we soon lose sight of the means by which the character is formed; we forget the particular objects it presents; and giving way to their effects, without recurring to the cause, we follow the track they have begun, to any extent which the disposition they accord with will allow. It suffices that the scenes of nature have a power to affect our imagination and our sensibility; for such is the constitution of the human mind, that if once it is agitated, the emotion spreads far beyond the occasion; when the passions are roused, their course is unrestrained; when the fancy is on the wing, its flight is unbounded; and, quitting the inanimate objects which first gave them their spring, we may be led by thought above thought, widely differing in degree, but still corresponding in character, till we rise from familiar subjects up to the sublimest conceptions, and are rapt in the contemplation of whatever is great or beautiful, which we see in nature, feel in man, or attribute to divinity.

IV. GENERAL ARRANGEMENT. Notwithstanding the nature of the place, as already observed, ought not be sacrificed to the mansion;—the house must ever be allowed to be a principal in the composition. It ought to be considered as the centre of the system; and the rays of art, like those of the sun, should grow fainter as they recede from the centre. The house itself being entirely a work of art, its immediate environs should be highly finished; but as the distance increases, the appearance of design should gradually diminish, until nature and fortuitousness have full possession of the scene.

In general, the approach should be to the back-front, which, in suitable situations, ought to lie open to the pasture-grounds. On the sides more highly ornamented, a well-kept gravel-walk may embrace the walls; to this the shaven lawn and shrubbery succeed; next, the grounds closely pastured; and, lastly, the surrounding country, which ought not to be considered as out of the artist's reach: for his art consists not more in decorating particular spots, than in endeavouring to render the whole face of nature delightful.

Another reason for this mode of arrangement is, objects immediately under the eye are seen more distinctly than those at a distance, and ought to be such as are pleasing in the detail. The beauties of a flower can be discerned on a near view only; whilst at a distance a roughet of coppice wood, and the most elegant arrangement

General arrangement.

arrangement.

Hunting-
Box, &c.*Ibid.*
p. 606.

agement of flowering-shrubs have the same effect. The most rational entertainment the human mind is capable of receiving, is that of observing the operations of nature. The foliation of a leaf, the blowing of flowers, and the maturation of fruit, are among the most delightful subjects that a contemplative mind can be employed in. These processes of nature are slow; and except the object fall spontaneously under the eye of the observer, the inconveniences of visiting it in a remote part, so far interfere with the more important employments of life, as to blunt, if not destroy, the enjoyment. This is a strong argument in favour of shrubs and flowers being planted under or near our windows, especially those from whence they may be viewed during the hours of leisure and tranquillity.

Further, the vegetable creation being subject to the

animal, the shrub may be cropt, or the flower trodden down in its day of beauty. If therefore we wish to converse with nature in private, intruders must be kept off,—the shrubbery be severed from the ground;—yet not in such a manner as to drive away the pasturing stock from our sight. For this reason, the shaven lawn ought not to be too extensive, and the fence which incloses it should be such as will not interrupt the view: but whether it be seen or unseen, suspected or unsuspected, is a matter of no great import: its utility in protecting the shrubs and flowers,—in keeping the horns of the cattle from the window, and the feet of the sheep from the gravel and broken ground,—in preserving that neatness on the outside, which ought to correspond with the finishings and furniture within,—render it of sufficient importance to become even a part of the ornament.

Villa.

PART II. EXECUTION OF THE GENERAL SUBJECTS.

IMPROVEMENTS in general may be classed under the following heads: The *Hunting-Box*, The *Ornamented Cottage*, the *Villa*, and the *Principal Residence*.

But before any step can be taken towards the execution of the design, be it large or small, a map or plan of the place, exactly as it lies in its unimproved state, should be made; with a corresponding sketch, to mark the intended improvements upon. Not a hovel nor a twig should be touched, until the artist has studied maturely the natural abilities of the place, and has decidedly fixed in his mind, and finally settled on his plan, the proposed alterations: and even then, let him “dare with caution.”

1. *Of Improvements adapted to a HUNTING-BOX.*

HERE art has little to do. Hunting may be called the amusement of nature; and the place appropriated to it ought to be no farther altered from its natural state than decency and conveniency require:—With men who live in the present age of refinement, “a want of decency is a want of sense.”

The style throughout should be *masculine*. If shrubs be required, they should be of the hardier sorts; the box, the holly, the laurustinus. The trees should be the oak and the beech, which give in autumn an agreeable variety of foilage, and anticipate as it were the season of diversion. A suite of paddocks should be seen from the house; and if a view of distant covers can be caught, the back-ground will be complete. The stable, the kennel, and the leaping-bar, are the factitious accompaniments; in the construction of which simplicity, substantialness, and conveniency, should prevail.

2. *Of the Styles of an ORNAMENTED COTTAGE.*

NEATNESS and simplicity ought to mark the style of this rational retreat. Ostentation and show should be cautiously avoided; even elegance should not be attempted; though it may not be hid, if it offer itself spontaneously.

Nothing, however, should appear vulgar, nor should simplicity be pared down to baldness; every thing whimsical or expensive ought to be studiously avoided;—chasteness and frugality should appear in every part.

3.

Near the house a studied neatness may take place; but at a distance, negligence should rather be the characteristic.

If a taste for botany lead to a collection of native shrubs and flowers, a shrubbery will be requisite; but in this every thing should be native. A gaudy exotic ought not to be admitted; nor should the lawn be kept close shaven; its flowers should be permitted to blow; and the herbage, when mown, ought to be carried off, and applied to some useful purpose.

In the artificial accompaniments, ornament must be subordinate; utility must preside. The buildings, if any appear, should be those in actual use in rural economics. If the hovel be wanted, let it appear; and, as a side-screen, the barn and rick-yard are admissible; whilst the dove-house and poultry-yard may enter more freely into the composition.

In fine, the ornamented cottage ought to exhibit cultivated nature in the first stage of refinement. It ranks next above the farm-house. The plain garb of rusticity may be set off to advantage; but the studied dress of the artist ought not to appear. That becoming neatness, and those domestic conveniences, which render the rural life agreeable to a cultivated mind, are all that should be aimed at.

3. *Of the Embellishments of a VILLA.*

THIS demands a style very different from the preceding. It ought to be elegant, rich or grand, according to the style of the house itself, and the state of the surrounding country; the principal business of the artist being to connect these two in such a manner, that the one shall not appear naked or glaring, nor the other desolate and inhospitable.

If the house be stately, and the adjacent country rich and highly cultivated, a shrubbery may intervene, in which art may show her utmost skill. Here, the artist may even be permitted to play at landscape: for a place of this kind being supposed to be small, the purpose principally ornamental; and the point of view probably confined simply to the house, side screens may be formed, and a fore-ground laid out suitable to the best distance that can be caught.

If buildings or other artificial ornaments abound in the offscap, so as to mark it strongly, they ought also

10

Principal Residence.

to appear more or less in the fore-ground: if the distance abound with wood, the fore-ground should be thickened, lest baldness should offend; if open and naked, elegance rather than richness ought to be studied, lest heaviness should appear.

Ibid.

It is far from being any part of our plan to cavil unnecessarily at artists, whether living or dead; we cannot, however, refrain from expressing a concern for the almost total neglect of the principles here in ornamenting the vicinages of villas. It is to be regretted, that in the present practice these principles seem to be generally lost sight of. Without any regard to uniting the house with the adjacent country, and, indeed, seemingly without any regard whatever to the offscap, one invariable plan of embellishment prevails; namely, that of stripping the fore-ground entirely naked, or nearly so, and surrounding it with a wavy border of shrubs and a gravel walk; leaving the area, whether large or small, one naked sheet of green sward.

In small confined spots, this plan may be eligible. But a simple border round a large unbroken lawn only serves to show what more is wanted. Simplicity in general is pleasing; but even simplicity may be carried to an extreme, so as to convey no other idea than that of poverty and baldness. Besides, how often do we see in natural scenery, the holly and the fox-glove flourishing at the foot of an oak, and the primrose and the campion adding charms to the hawthorn scattered over the pastured lawn? And we conceive that single trees footed with evergreens and native flowers, and clumps as well as borders of shrubs, are admissible in ornamental as well as in natural scenery.

The species of shrub will vary with the purpose. If the principal intention be a winter retreat, evergreens and the early-blowing shrubs should predominate; but in a place to be frequented in summer and autumn, the deciduous tribes ought chiefly to be planted.

4. *Of the PRINCIPAL RESIDENCE.*

Here the whole art centers. The artist has here full scope for a display of taste and genius. He has an extent of country under his eye, and will endeavour to make the most of what nature and accident have spread before him.

Round a principal residence, a gentleman may be supposed to have some considerable estate, and it is not a shrubbery and a ground only which fall under the consideration of the artist: he ought to endeavour to disclose to the view, either from the house or some other point, as much as he conveniently can of the adjacent estate. The love of possession is deeply planted in every man's breast; and places should bow to the gratification of their owners. To curtail the view by an artificial side screen, or any other unnatural machinery, so as to deprive a man of the satisfaction of over-looking his own estate, is an absurdity which no artist ought to be permitted to be guilty of. It is very different, however, where the property of another intrudes upon the eye: Here the view may, with some colour of propriety, be bounded by a woody screen.

The grounds, however, by a proper management, may be made independent of whatever is external; and though prospects are no where more delightful than from a point of view which is also a beautiful spot, yet

if in the environs of such a garden they should be wanting, the elegant, picturesque, and various scenes within itself, almost supply the deficiency. Principal Residence.

“ This (says Mr Wheatley) is the character of the gardens at Stowe: for there the views in the country are only circumstances subordinate to the scenes; and the principal advantage of the situation is the variety of the ground within the inclosure. The house stands on the brow of a gentle ascent; part of the gardens lie on the declivity, and spread over the bottom beyond it: this eminence is separated by a broad winding valley from another which is higher and steeper; and the descents of both are broken by large dips and hollows, sloping down the sides of the hills. The whole space is divided into a number of scenes, each distinguished with taste and fancy; and the changes are so frequent, so sudden, and complete, the transitions so artfully conducted, that the same ideas are never continued or repeated to satiety. *Mr Wheatley's description of Stowe gardens.*

These gardens were begun when regularity was in fashion; and the original boundary is still preserved, on account of its magnificence: for round the whole circuit, of between three or four miles, is carried a very broad gravel-walk, planted with rows of trees, and open either to the park or the country; a deep sunk fence attends it all the way, and comprehends a space of near 400 acres. But in the interior scenes of the garden, few traces of regularity appear; where it yet remains in the plantations, it is generally disguised: every symptom, almost, of formality is obliterated from the ground; and an octagon basin in the bottom is now converted into an irregular piece of water, which receives on one hand two beautiful streams, and falls on the other down a cascade into a lake.

In the front of the house is a considerable lawn, open to the water: beyond which are two elegant Doric pavilions, placed in the boundary of the garden, but not marking it, though they correspond to each other; for still further back, on the brow of some rising grounds without the inclosure, stands a noble Corinthian arch, by which the principal approach is conducted, and from which all the gardens are seen, reclining back against their hills: they are rich with plantations; full of objects; and lying on both sides of the house almost equally, every part is within a moderate distance, notwithstanding the extent of the whole.

On the right of the lawn, but concealed from the house, is a perfect garden-scene, called the *queen's amphitheatre*, where art is avowed, though formality is avoided. The fore-ground is scooped into a gentle hollow. The plantations on the sides, though but just rescued from regularity, yet in style are contrasted to each other: they are, on one hand, chiefly thickets, standing out from a wood; on the other, they are open groves, through which a glimpse of the water is visible. At the end of the hollow on a little knole, quite detached from all appendages, is placed an open Ionic rotunda: beyond it, a large lawn slopes across the view; a pyramid stands on the brow; the queen's pillar, in a recess on the descent; and all the three buildings, being evidently intended for ornament alone, are peculiarly adapted to a garden-scene. Yet their number does not render it gay: the dusky hue of the pyramid, the retired situation of the queen's pillar, and the

Principal Residence. the solitary appearance of the rotunda, give it an air of gravity; it is encompassed with wood; and all the external views are excluded; even the opening into the lawn is but an opening into an inclosure.

At the king's pillar, very near to this, is another lovely spot; which is small, but not confined; for no termination appears; the ground one way, the water another, retire under the trees out of sight, but nowhere meet with a boundary. The view is first over some very broken ground, thinly and irregularly planted; then between two beautiful clumps, which feather down to the bottom; and afterwards across a glade, and through a little grove beyond it, to that part of the lake where the thickets, close upon the brink, spread a tranquillity over the surface, in which their shadows are reflected. Nothing is admitted to disturb that quiet: no building obtrudes; for objects to fix the eye are needless in a scene which may be comprehended at a glance; and none would suit the pastoral idea it inspires, of elegance too refined for a cottage, and of simplicity too pure for any other edifice.

The situation of the rotunda promises a prospect more enlarged; and in fact most of the objects on this side of the garden are there visible: but they want both connection and contrast; each belongs peculiarly to some other spot: they all are blended together in this, without meaning; and are rather shown on a map, than formed into a picture. The water only is capital; a broad expanse of it is so near as to be seen under the little groupes on the banks without interruption. Beyond it is a wood, which in one place leaves the lake, to run up behind a beautiful building, of three pavilions joined by arcades, all of the Ionic order: it is called *Kent's Building*. And never was a design more happily conceived: it seems to be characteristically proper for a garden; it is so elegant, so varied, and so purely ornamental: it directly fronts the rotunda, and a narrow rim of the country appears above the trees beyond it. But the effect even of this noble object is fainter here than at other points: its position is not the most advantageous; and it is but one among many other buildings, none of which are principal.

The scene at the temple of Bacchus is in character directly the reverse of that about the rotunda, though the space and the objects are nearly the same in both: but in this, all the parts concur to form one whole. The ground from every side shelves gradually towards the lake; the plantations on the further bank open to show Kent's building, rise from the water's edge towards the knole on which it stands, and close again behind it. That elegant structure, inclined a little from a front view, becomes more beautiful by being thrown into perspective; and though at a greater distance, is more important than before, because it is alone in the view: for the queen's pillar and the rotunda are removed far aside; and every other circumstance refers to this interesting object: the water attracts, the ground and the plantations direct, the eye thither; and the country does but just glimmer in the offscap, but is close and eminent above the wood, and connected by clumps with the garden. The scene all together is a most animated landscape: and the splendor of the building; the reflection in the lake; the transparency

of the water, and picturesque beauty of its form, diversified by little groupes on the brink, while on the broadest expanse no more trees cast their shadows than are sufficient to vary the tints of the surface; all these circumstances, vying in lustre with each other, and uniting in the point to which every part of the scene is related, diffuse a peculiar brilliancy over the whole composition.

The view from Kent's building is very different from those which have been hitherto described. They are all directed down the declivity of the lawn. This rises up the ascent: the eminence being crowned with lofty wood, becomes thereby more considerable; and the hillocks into which the general fall is broken, sloping further out this way than any other, they also acquire an importance which they had not before; that, particularly, on which the rotunda is placed, seems here to be a profound situation; and the structure appears to be properly adapted to so open an exposure. The temple of Bacchus, on the contrary, which commands such an illustrious view, is itself a retired object, close under the covert. The wood rising on the brow, and descending down one side of the hill; is shown to be deep; is high, and seems to be higher than it is. The lawn too is extensive; and part of the boundary being concealed, it suggests the idea of a still greater extent. A small portion only of the lake indeed is visible; but it is not here an object: it is a part of the spot; and neither termination being in sight, it has no diminutive appearance: if more water had been admitted, it might have hurt the character of the place, which is sober and temperate; neither solemn nor gay; great and simple, but elegant; above rusticity, yet free from ostentation.

These are the principal scenes on one side of the gardens. On the other, close to the lawn before the house, is the winding valley abovementioned: the lower part of it is assigned to the Elysian fields. These are watered by a lovely rivulet; are very lightsome, and very airy, so thinly are the trees scattered about them; are open at one end to more water and a larger glade; and the rest of the boundary is frequently broken to let in objects afar off, which appear still more distant from the manner of showing them. The entrance is under a Doric arch, which coincides with an opening among the trees, and forms a kind of vista, through which a Pembroke bridge just below, and a lodge built like a castle in the park, are seen in a beautiful perspective. That bridge is at one extremity of the gardens; the queen's pillar is at another; yet both are visible from the same station in the Elysian fields: and all these external objects are unaffectedly introduced, divested of their own appurtenances, and combined with others which belong to the spot. The temple of Friendship also is in sight, just without the place; and within it, are the temples of ancient Virtue, and of the British worthies; the one in an elevated situation, the other low down in the valley, and near to the water: both are decorated with the effigies of those who have been most distinguished for military, civil, or literary merit; and near to the former stands a rostral column, sacred to the memory of Captain Grenville, who fell in an action at sea: by placing here the meed of valour, and by filling these fields with the representations of those who have deserved

Principal
Residence.

best of mankind, the character intended to be given to the spot is justly and poetically expressed; and the number of the images which are presented or excited, perfectly corresponds with it. Solitude was never reckoned among the charms of Elysium; it has been always pictured as the mansion of delight and of joy; and in this imitation, every circumstance accords with that established idea. The vivacity of the stream which flows through the vale; the glimpses of another approaching to join it; the sprightly verdure of the green sward, and every bust of the British worthies reflected in the water; the variety of the trees; the lightness of the greens; their disposition; all of them distinct objects, and dispersed over gentle inequalities of the ground; together with the multiplicity of objects both within and without, which embellish and enliven the scene; give it a gaiety, which the imagination can hardly conceive, or the heart wish to be exceeded.

Close by this spot, and a perfect contrast to it, is the alder grove; a deep recess in the midst of a shade, which the blaze of noon cannot brighten. The water seems to be a stagnated pool, eating into its banks; and of a peculiar colour, not dirty but clouded, and dimly reflecting the dun hue of the horse-chestnuts and alders which press upon the brink; the stems of the latter, rising in clusters from the same root, bear one another down, and slant over the water. Mishapen elms and ragged firs are frequent in the wood which encompasses the hollow; the trunks of dead trees are left standing amongst them; and the uncouth sumach, and the yew, with elder, nut, and holly, compose the underwood: some limes and laurels are intermixed; but they are not many: the wood is in general of the darkest greens; and the foilage is thickened with ivy, which not only twines up the trees, but creeps also over the falls of the ground: these are steep and abrupt: the gravel-walk is covered with moss; and a grotto at the end, faced with broken flints and pebbles, preserves, in the simplicity of its materials, and the duskiness of its colour, all the character of its situation: two little rotundas near it were better away; one building is sufficient for such a scene of solitude as this, in which more circumstances of gloom concur than were ever perhaps collected together.

Immediately above the alder-grove is the principal eminence in the gardens. It is divided by a great dip into two pinnacles; upon one of which is a large Gothic building. The space before this structure is an extensive lawn: the ground on one side falls immediately into the dip; and the trees which border the lawn, sinking with the ground, the house rises above them, and fills the interval: the vast pile seems to be still larger than it is; for it is thrown into perspective, and between and above the heads of the trees, the upper story, the porticoes, the turrets and ballustrades, and all the slated roofs, appear in a noble confusion. On the other side of the Gothic building, the ground slopes down a long continued declivity into a bottom, which seems to be perfectly irriguous. Divers streams wander about it in several directions: the conflux of that which runs from the Elysian fields with another below it, is full in sight; and a plain wooden bridge thrown over the latter, and evidently designed for a passage, imposes an air of reality on the river. Be-

yond it is one of the Doric porticoes which front the house; but now it is alone; it stands on a little bank above the water, and is seen under some trees at a distance before it: thus grouped, and thus accompanied, it is a happy incident, concurring with many other circumstances to distinguish this landscape by a character of cheerfulness and amenity.

From the Gothic building a broad walk leads to the Grecian valley, which is a scene of more grandeur than any in the gardens. It enters them from the park, spreading at first to a considerable breadth; then winds; grows narrower, but deeper; and loses itself at last in a thicket, behind some lofty elms, which interrupt the sight of the termination. Lovely woods and groves hang all the way on the declivities: and the open space is broken by detached trees; which, near the park, are cautiously and sparingly introduced, lest the breadth should be contracted by them; but as the valley sinks, they advance more boldly down the sides, stretch across or along the bottom, and cluster at times into groupes and forms, which multiply the varieties of the larger plantations. Those are sometimes close coverts, and sometimes open groves: the trees rise in one upon high stems, and feather down to the bottom in another; and between them are short openings into the park or the gardens. In the midst of the scene, just at the bend of the valley, and commanding it on both sides, upon a large, easy, natural rise, is placed the temple of Concord and Victory: at one place its majestic front of six Ionic columns, supporting a pediment filled with bas relief, and the points of it crowned with statues, faces the view; at another, the beautiful colonnade, on the side, of ten lofty pillars, retires in perspective. It is seen from every part; and impressing its own character of dignity on all around, it spreads an awe over the whole: but no gloom, no melancholy, attends it: the sensations it excites are rather placid; but full of respect, admiration, and solemnity: no water appears to enliven, no distant prospect to enrich the view; the parts of the scene are large, the idea of it sublime, and the execution happy; it is independent of all adventitious circumstances, and relies on itself for its greatness.

The scenes which have been described are such as are most remarkable for beauty or character; but the gardens contain many more; and even the objects in these, by their several combinations, produce very different effects, within the distance sometimes of a few paces, from the unevenness of the ground, the variety of the plantations, and the number of the buildings. The multiplicity of the last has indeed been often urged as an objection to Stowe; and certainly, when all are seen by a stranger in two or three hours, twenty or thirty capital structures, mixed with others of inferior note, do seem too many. But the growth of the wood every day weakens the objection, by concealing them one from the other: each belongs to a distinct scene; and if they are considered separately, at different times, and at leisure, it may be difficult to determine which to take away. Yet still it must be acknowledged that their frequency destroys all ideas of silence and retirement. Magnificence and splendor are the characteristics of Stowe: it is like one of those places celebrated in antiquity, which were devoted to the purposes of religion, and filled with sacred groves, hallowed foun-

Residence.

tains,

Principal Residence. tains, and temples dedicated to several deities; the resort of distant nations, and the object of veneration to half the heathen world; this pomp is, at Stowe, blended with beauty; and the place is equally distinguished by its amenity and its grandeur.

In the midst of so much embellishment as may be introduced into this species of garden, a plain field, or a sheep-walk, is sometimes an agreeable relief, and even wilder scenes may occasionally be admitted. These indeed are not properly parts of a garden, but they may be comprehended within the verge of it; and the proximity to the more ornamented scenes is at least a convenience, that the transition from the one to the other may be easy, and the change always in our option. For though a spot in the highest state of improvement be a necessary appendage to a seat; yet, in a place which is perfect, other characters will not be wanting, if they cannot be had on a large scale, they are acceptable on a smaller; and so many circumstances are common to all, that they may often be intermixed; they may always border on each other."

Pract Treat
on Planting
and garden-
ing, p. 615.

But on this head it would be in vain to attempt to lay down particular rules: different places are marked by sets of features as different from each other as are those in mens faces. Much must be left to the skill and taste of the artist; and let those be what they may, nothing but mature study of the natural abilities of the particular place to be improved can render him equal to the execution, so as to make the most of the materials that are placed before him.

Some few general rules may nevertheless be laid down. The approach ought to be conducted in such a manner, that the striking features of the place shall burst upon the view at once; no trick however should be made use of; all should appear to fall in naturally. In leading towards the house, its direction should not be fallen in front, nor exactly at an angle, but should pass obliquely upon the house and its accompaniments; so that their position with respect to each other, as well as the perspective appearance of the house itself, may vary at every step: and having shown the front and the principal wing, or other accompaniment, to advantage, the approach should wind to the back-front, which as has been already observed, ought to lie open to the park or pastured grounds.

The improvements and the room from which they are to be seen should be in unison. Thus the view from the drawing-room should be highly embellished, to correspond with the beauty and elegance within: every thing here should be feminine, elegant, beautiful, such as attunes the mind to politeness and lively conversation. The breakfasting room should have more masculine objects in view: wood, water, and an extended country for the eye to roam over; such as allures us imperceptibly to the ride or the chace. The eating and banqueting rooms need no exterior allurements.

There is a harmony in taste as in music: variety, and even wildness upon some occasions, may be admitted, but discord cannot be allowed. If, therefore, a place so circumstanced as to consist of properties totally irreconcilable, the parts ought, if possible, to be separated in such a manner, that, like the air and the recitative, the adagio and the allegro, in music, they may set off each other's charms by the contrast.

These observations, in the elegant performance whence they are extracted, the author illustrates by the following description and proposed improvement of Persefield, the seat of Mr Morris, near Chepstow in Monmouthshire; a place upon which nature has been peculiarly lavish of her favours, and which has been spoken of by Mr Wheatley, Mr Gilpin, and other writers, in the most flattering terms.

Principal Residence.
Description of Persefield, *ibid.* p. 616, &c

"Persefield is situated upon the banks of the river Wye, which divides Gloucestershire and Monmouthshire, and which was formerly the boundary between England and Wales. The general tendency of the river is from north to south; but about Persefield it describes by its winding course the letter S, somewhat compressed so as to reduce it in length and increase its width. The grounds, of Persefield are lifted high above the bed of the river, shelving, and form the brink of a lofty and steep precipice, towards the south-west.

"The lower limb of the letter is filled with Persewood, which makes a part of Persefield; but is at present an impenetrable thicket of coppice-wood. This dips to the south-east down to the water's edge; and, seen from the top of the the opposite rock, has a good effect.

"The upper limb receives the farms of Llancot: rich and highly cultivated; broken into inclosures, and scattered with groupes and single trees: two well looking farm-houses in the centre, and a neat white chapel on one side: altogether a lovely little paradisaical spot. The lowliness of its situation stamps it with an air of meekness and humility; and the natural barriers which surround it adds that of peacefulness and security. These picturesque farms do not form a low flat bottom, subject to be overflowed by the river; but take the form of a gorget, rising fullest in the middle and falling on every side gently to the brink of the Wye; except on the east-side, where the top of the gorget leans in an easy manner against a range of perpendicular rock; as if to show its disk with advantage to the walks of Persefield.

"This rock stretches across what may be called the *Isthmus*: leaving only a narrow pass down into the fields of Llancot, and joins the principle range of rocks at the lower bend of the river.

"To the north, at the head of the letter, stands an immense rock (or rather a pile of immense rocks heaped one above another) called *Windcliff*; the top of which is elevated as much above the grounds of Persefield as those are above the fields of Llancot.

"These several rocks, with the wooded precipices on the side of Persefield, form a circular inclosure about a mile in diameter, including Persewood, Llancot, the Wye, and a small meadow lying at the foot of Windcliff.

"The grounds are divided into the upper and lower lawn, by the approach to the house: a small irregular building, standing near the brink of the precipice, but facing down the lower lawn, a beautiful ground, falling 'precipately every way into a valley which shelves down in the middle,' and is scattered with groupes and single trees in an excellent style.

"The view from the house is soft, rich, and beautifully picturesque; the lawn and woods of Persefield and the opposite banks of the river; the Wye, near its mouth winding through 'meadows green as emerald,'

Principal Residence.

rald,' in a manner peculiarly graceful; the Severn, here very broad, backed by the wooded and highly cultivated hills of Gloucestershire, Wiltshire, and Somersetshire. Not one rock enters into the composition. The whole view consists of an elegant arrangement of lawn, wood, and water.

"The upper lawn is a less beautiful ground, and the view from it, though it commands the 'cultivated hills and rich valleys of Monmouthshire,' bounded by the Severn and backed by the Mendip-hills, is much inferior to that from the house.

"To give variety to the views from Persefield, to disclose the native grandeur which surrounds it, and to set off its more striking features to advantage, walks have been cut through the woods and on the face of the precipice which border the grounds to the south and east. The viewer enters these walks at the lower corner of the lower lawn.

"The first point of view is marked by an alcove, from which are seen the bridge and the town of Chepstow, with its castle situated in a remarkable manner on the very brink of a perpendicular rock, washed by the Wye; and beyond these the Severn shows a small portion of its silvery surface.

"Proceeding a little farther along the walk, a view is caught which the painter might call a complete landscape: The castle with the serpentine part of the Wye below Chepstow, intermixed in a peculiar manner with the broad waters of the Severn, form the fore-ground; which is backed by distant hills; the rocks, crowned with wood, lying between the alcove and the castle, to the right; and Castlehill farm, elevated upon the opposite banks of the river, to the left, form the two side-screens. This point is not marked, and must frequently be lost to the stranger.

"The grotto, situated at the head of Perse-wood, commands a near view of the opposite rocks; magnificent beyond description! The littleness of human art was never placed in a more humiliating point of view; the Castle of Chepstow, a noble fortress, is, compared with these natural bulwarks, a mere house of cards.

"Above the grotto, upon the isthmus of the Persefield side, is a shrubbery; strangely misplaced! an unpardonable intrusion upon the native grandeur of this scene. Mr Gilpin's observations upon this, as upon every other occasion, are very just. He says, 'It is a pity the ingenious embellisher of these scenes could not have been satisfied with the great beauties of nature which he commanded. The shrubberies he has introduced in this part of his improvements I fear will rather be esteemed paltry.'—'It is not the shrub which offends; it is the formal introduction of it. Wild underwood may be an appendage of the grandest scene; it is a beautiful appendage. A bed of violets or of lilies may enamel the ground with propriety at the foot of an oak; but if you introduce them artificially in a border, you introduce a trifling formality, and disgrace the noble object you wish to adorn.'

"The walk now leaves the wood, and opens upon the lower lawn, until coming near the house it enters the alarming precipice facing Llancot; winding along the face of it in a manner which does great honour to the artist. Sometimes the fragments of rock which fall in its way are avoided, at other times partially removed, so as to conduct the path along a ledge carved

out of the rock; and in one instance, a huge fragment, of a somewhat conical shape and many yards high, is perforated; the path leading through its base. This is a thought which will hand down to future times the greatness of Mr Morris's taste; the design and the execution are equally great; not a mark of a tool to be seen; all appears perfectly natural. The arch-way is made winding, so that on the approach it appears to be the mouth of a cave; and, on a nearer view, the idea is strengthened by an allowable deception; a black dark hole on the side next the cliff, which, seen from the entrance before the perforation is discovered, appears to be the darksome inlet into the body of the cave.

"From this point, that vast inclosure of rocks and precipices which marks the peculiar magnificence of Persefield is seen to advantage. The area, containing in this point of view the fields of Llancot and the lower margin of Perse-wood, is broken in a manner peculiarly picturesque by the graceful winding of the Wye; here washing a low grassy shore, and there sweeping at the feet of the rocks, which rise in some places perpendicular from the water; but in general they have a wooded offset at the base; above which they rise to one, two, or perhaps three or four hundred feet high; exposing one full face, silvered by age, and bearded with ivy, growing out of the wrinkle-like seams and fissures. If one might be allowed to compare the paltry performances of art with the magnificent works of nature, we should say, that this inclosure resembles a prodigious fortress which has lain long in ruins. It is in reality one of nature's strong holds; and as such has probably been frequently made use of. Across the isthmus on the Gloucestershire side there are the remains of a deep intrenchment, called to this day the *Bulwark*; and tradition still teems with the extraordinary warlike feats that have been performed among this romantic scenery.

"From the perforated rock, the walk leads down to the cold-bath (a complete place), seated about the mid-way of the precipice, in this part less steep; and from the cold-bath a rough path winds down to the meadow, by the side of the Wye, from whence the precipice on the Persefield side is seen with every advantage; the giant fragments, hung with shrubs and ivy, rise in a gasty manner from amongst the underwood, and show themselves in all their native savageness.

"From the cold-bath upward, a coach-road (very steep and difficult) leads to the top of the cliff, at the upper corner of the upper lawn. Near the top of the road is a point which commands one of the most pleasing views of Persefield: The Wye sweeping through a grassy vale which opens to the left:—Llancot backed by its rocks, with the Severn immediately behind them; and, seen in this point of view, seems to be divided from the Wye by only a sharp ridge of rock, with a precipice on either side; and behind the Severn, the vale and wooded hills of Gloucestershire.

"From this place a road leads to the top of Wind-cliff—astonishing sight! The face of nature probably affords not a more magnificent scene! Llancot in all its grandeur, the grounds of Persefield, the castle and town of Chepstow, the graceful windings of the Wye below, and its conflux with the Severn; to the left the forest of Dean; to the right, the rich marshes and picturesque

Principal Residence.

Principal Residence.

picturesque mountains of South Wales; a broad view of the Severn, opening its sea-like mouth; the conflux of the Avon, with merchant ships at anchor in King-road, and vessels of different descriptions under sail; Aust-Cliff, and the whole vale of Berkely, backed by the wooded swells of Gloucestershire, the view terminating in clouds of distant hills, rising one behind another, until the eye becomes unable to distinguish the earth's billowy surface from the clouds themselves."

The leading principle of the improvement proposed by our author is, to "separate the sublime from the beautiful; so that in viewing the one, the eye might not so much as suspect that the other was near."

"Let the hanging walk be conducted entirely along the precipices, or through the thickets, so as to disclose the natural scenery, without once discovering the lawn or any other acquired softness. Let the path be as rude as if trodden only by wild beasts and savages, and the resting places, if any, as rustic as possible."

"Erase entirely the present shrubbery, and lay out another as elegant as nature and art could render it before the house, swelling it out into the lawn towards the stables; between which and the kitchen-garden make a narrow winding entrance."

"Convert the upper lawn into a deer-paddock, suffering it to run as wild, rough, and forest-like as total negligence would render it."

"The viewer would then be thus conducted: He would enter the hanging-walk by a sequestered path at the lower corner of the lawn, pursuing it through the wood to beneath the grotto, and round the head-land, or winding through Perfewood, to the perforated rock and the cold-bath, without once conceiving an idea (if possible) that art, or at least that much art, had been made use of in disclosing the natural grandeur of the surrounding objects; which ought to appear as if they presented themselves to his view, or at most as if nothing was wanted but his own penetration and judgment to find them out. The walk should therefore be conducted in such a manner, that the breaks might be quite natural; yet the points of view obvious, or requiring nothing but a block or a stone to mark them. A stranger at least wants no seat here; he is too eager, in the early part of his walk, to think of lounging upon a bench."

"From the cold-bath he would ascend the steep, near the top of which a commodious bench or benches might be placed: the fatigue of ascending the hill would require a resting-place; and there are few points which afford a more pleasing view than this; it is grand, without being too broad and glaring."

"From these benches he would enter the forest part. Here the idea of Nature in her primitive state would be strengthened: the roughnesses and deer to the right, and the rocks in all their native wildness to the left. Even Llancot might be shut out from the view by the natural shrubbery of the cliff. The Lover's Leap, however (a tremendous peep), might remain; but no benches, nor other work of art, should here be seen. A natural path, deviating near the brink of the precipice, would bring the viewer down to the lower corner of the park; where benches should be placed in a happy point, so as to give a full view of the rocks and native wildnesses, and at the same time hide the farm-houses, fields, and other acquired beauties of Llancot."

"Having satiated himself with this savage scene, he

would be led, by a still rustic path, through the labyrinth—when the shrubbery, the lawn, with all its appendages, the graceful Wye, and the broad silver Severn, would break upon the eye with every advantage of ornamental nature: the transition could not fail to strike.

"From this soft scene he would be shown to the top of Windcliff, where in one vast view he would unite the sublime and beautiful of Persefield."

Only one other particular remains to be noticed before closing this article. A place which is the residence of a family all the year is very defective, if some portion of it be not set apart for the enjoyment of a fine day, for air, and exercise, in winter. To such a spot shelter is absolutely essential; and evergreens being the thickest covert, are therefore the best: their verdure also is then agreeable to the eye; and they may be arranged so as to produce a beautiful mixture of greens, with more certainty than deciduous trees, and with almost equal variety: they may be collected into a wood; and through that wood gravel-walks may be led along openings of a considerable breadth, free from large trees which would intercept the rays of the sun, and winding in such a manner as to avoid any draft of wind, from whatever quarter it may blow. But when a retreat at all times is thus secured, other spots may be adapted only to occasional purposes; and be sheltered towards the north or the east on one hand, while they are open to the sun on the other. The few hours of cheerfulness and warmth which its beams afford are so valuable as to justify the sacrifice even of the principles of beauty to the enjoyment of them; and therefore no objections of sameness or formality can prevail against the pleasantness of a straight walk, under a thick hedge or a south wall. The eye may, however, be diverted from the skreen by a border before it, where the acornite and the snowdrop, the crocus and hepatica, brought forward by the warmth of the situation, will be welcome harbingers of spring; and on the opposite side of the walk, little tufts of laurustines, and of variegated evergreens, may be planted. The spot thus enlivened by a variety of colours, and even a degree of bloom, may be still further improved by a green-house. The entertainment which exotics afford peculiarly belongs to this part of the year; and if amongst them be interspersed some of our earliest flowers, they will there blow before their time, and anticipate the gaiety of the season which is advancing. The walk may also lead to the stoves, where the climate and the plants are always the same. And the kitchen-garden should not be far off; for that is never quite destitute of produce, and always an active scene: the appearance of business is alone engaging; and the occupations there are an earnest of the happier seasons to which they are preparative. By these expedients even the winter may be rendered cheerful in a place where shelter is provided against all but the bitterest inclemencies of the sky, and agreeable objects and interesting amusements are contrived for every hour of tolerable weather.

For the particular operations in gardening, see PLANTING, PRUNING, GRAFTING, INOCULATING, KITCHEN-GARDEN, ORCHARD, GREEN-HOUSE, HOT-HOUSE, INARCHING, ESPALIER, &c. and the culture and management of different plants under their respective names.

GARDINER,

Principal Residence.

Gardiner
||
Garland.

GARDINER (Stephen), bishop of Winchester, and lord chancellor of England, born at Bury St Edmunds in Suffolk, natural son to Richard Woodville, brother to queen Elizabeth wife to Edward IV. was learned in the canon and civil laws, and in divinity. He signed the divorce of Henry VIII. from Katharine of Spain; abjured the pope's supremacy: and writ *De vera et falsa obedientia*, in behalf of the king; yet in Edward's reign he opposed the reformation, and was punished with imprisonment; but queen Mary coming to the throne, she enlarged him. He drew up the articles of marriage between the queen and Philip of Spain, which were very advantageous to England. He was violent against the reformers; but on his death-bed was dissatisfied with his life, and often repeated these words: *Erravi cum Petro, sed non flevi cum Petro*. He died in 1555.

GARGARISM (from γαργαραζω, "to wash the mouth;") a gargle. Its use is for washing the mouth and throat with, when inflammations, ulcerations, &c. are there. A small quantity may be taken into the mouth, and moved briskly about, and then spit out; or if the patient cannot do this to any advantage, the liquor may be injected by a syringe. When gargles are required, their use should be more frequently repeated than is done in common practice.

GARGET, a disease of cattle, consisting in a swelling of the throat and the neighbouring parts: to prevent which bleeding in the spring is recommended.

GARGIL, a distemper in geese, which by stopping the head frequently proves mortal. Three or four cloves of garlic, beaten in a mortar with some sweet butter, and made into little balls, and given the creature fasting, are the ordinary cure.

GARIDELLA, in botany: A genus of the triginia order, belonging to the decandria class of plants; and in the natural method ranking under the 26th order, *Multisiliquæ*. The calyx is pentaphyllous, with leaves resembling flower-petals; there are five bilabiate and bifid nectaria; the capsules are polyspermous, and adhering together.

GARIZIM, **GERIZIM**, or *Gerisim*, (anc. geog.) a mountain of Samaria, at the foot of which stood Sichem; so near, that Jotham could be heard by the Sichemites from its top. (Judges ix. 7.) Famous for the temple built on it by Sanballet, in favour of his son-in-law Manasseh, by the permission of Alexander the Great, and 200 years after destroyed by John Hyrcanus, son of Simon, the fourth in succession of the Asmoneans (Josephus).

GARLAND, a sort of chaplet made of flowers, feathers, and sometimes precious stones, worn on the head in manner of a crown.—The word is formed of the French *guirlande*, and that of the barbarous Latin *garlanda*, or Italian *ghirlande*. Menage traces its origin from *gyrus*, through *gyrulus*, to *gyrulare*, *gyrlandum*, *ghirlandum*; and at length *ghirlanda* and *guirlande*; so that *guirlande* and *garland* are descended the sixth or seventh degree from *gyrus*.—Hicks rejects this derivation, and brings the word from *gardel handa*, which in the northern languages signify a *nosegay*, *artfully wrought with the hand*.

GARLAND also denotes ornaments of flowers, fruits, and leaves, intermixed; anciently much used at the gates of temples, where feasts and solemn rejoicings

were held; or at any other place where marks of public joy or gaiety were required, as at triumphal arches, tournaments, &c.

GARLIC. See **ALIU**M.

GARMENT, that wherewith any person is clothed. See **DRESS** and **HABIT**.

GARNET, in natural history, a very beautiful gem, of a red colour, with an admixture of blue. See **GRANATE**.

When pure and free from blemishes, it is little inferior in appearance to the oriental ruby, though only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter.

Among our lapidaries and jewellers, genuine garnets are known by different names according to their different degrees of colour. 1. The garnet, simply so called, is the finest and most valuable kind, being of a very deep blood-red, with a faint admixture of blue. 2. The rock-ruby; a name very improperly given to the garnet when it is of a very strong but not deep red, and has a fairer cast of the blue: this is a very beautiful gem. 3. The forane or serain garnet; that of a yet brighter red, approaching to the colour of native cinnabar, with a faint blue tinge. 4. The almandine, a garnet only a little paler than that called the *rock-ruby*.

GARNET-Colour. See *Colouring of GLASS*.

To imitate GARNETS. The making the counterfeit garnet in paste is done as follows.—Take prepared crystal two ounces, common red-lead six ounces, manganese 16 grains, zaffre three grains; mix all well, put them into a crucible, cover it with lute, and set it in a potter's kiln for 24 hours. Or take crystal two ounces, minium five ounces and a half, manganese 15 grains, zaffre four grains: mix them well together; and let all be baked, in a pot well luted, in a potter's kiln 24 hours.

GARONNE, a large river of France, which taking its rise in the Pyrenean mountains, runs north west by the city of Thoulouse, divides the provinces of Guienne and Gascony, and, visiting the city of Bourdeaux, falls into the Bay of Biscay, about 60 miles below that city. It has also a communication with the Mediterranean, by means of the royal canal of Louis XIV. The tide flows up this river 20 miles above Bourdeaux.

GARRICK (David), Esq; the great Roscius of Britain and this age, who for near 40 years hath shone the brightest luminary in the hemisphere of the stage, was born at the Angel Inn at Hereford, in the year 1716. His father, Captain Peter Garrick, was a French refugee, and had a troop of horse which were then quartered in that city. This rank he maintained in the army for several years, and had a majority at the time of his death; that event, however, prevented him from ever enjoying it. Mr Garrick received the first rudiments of his education at the free-school at Lichfield; which he afterwards completed at Rochester, under the celebrated Mr Colson, since mathematical professor at Cambridge. Dr Johnson and he were fellow-students at the same school: and it is a curious fact, that these two celebrated geniuses came up to London, with the intention of pushing themselves into active life, in the same coach. On the 9th of March 1736, he was entered

Garlic
||
Garrick.

Garrick, entered at the honourable society of Lincoln's-Inn. The study of the law, however, he soon quitted; and followed for some time the employment of a wine-merchant: but that too disgusting him, he gave way at last to the irresistible bias of his mind, and joined a travelling company of comedians at Ipswich in Suffolk, where he went by the name of *Lyddle*. Having in this poor school of Apollo got some acquaintance with the theatrical art, he burst at once upon the world, in the year 1740-1, in all the lustre of perfection, at the little theatre in Goodman's Fields, then under the direction of Henry Giffard.

The character he first performed was Richard III. in which, like the sun-bursting from behind a cloud, he displayed in the earliest dawn a somewhat more than meridian brightness. His excellence dazzled and astonished every one; and the seeing a young man, in no more than his 24th year, and a novice in reality to the stage, reaching at one single step to that height of perfection which maturity of years and long practical experience had not been able to bestow on the then capital performers of the English stage, was a phenomenon that could not but become the object of universal speculation and of as universal admiration. The theatres at the west end of the town were deserted; Goodman's Fields, from being the rendezvous of citizens and citizens wives alone, became the resort of all ranks of men; and Mr Garrick continued to act till the close of the season.

Having very advantageous terms offered him for the performing in Dublin during some part of the summer (1741), he went over thither, where he found the same just homage paid to his merit which he had received from his own countrymen. To the service of the latter, however, he esteemed himself more immediately bound; and therefore, in the ensuing winter, engaged himself to Mr Fleetwood, then manager of Drury-Lane: in which theatre he continued till the year 1745, when he again went over to Ireland, and continued there the whole season, joint manager with Mr Sheridan in the direction and profits of the theatre-royal in Smock-Alley. From thence he returned to England, and was engaged for the season of 1746 with Mr Rich at Covent-Garden. This was his last performance as an hired actor: for in the close of that season, Mr Fleetwood's patent for the management of Drury-Lane being expired, and that gentleman having no inclination further to pursue a design by which, from his want of acquaintance with the proper conduct of it, or some other cause, he had considerably impaired his fortune; Mr Garrick, in conjunction with Mr Lacy, purchased the property of that theatre, together with the renovation of the patent; and in the winter of 1747, opened it with the greatest part of Mr Fleetwood's company, and with the great additional strength of Mr Barry, Mrs Prichard, and Mrs Cibber, from Covent-Garden.

Were we to trace Mr Garrick through the several occurrences of his life,—a life so active, so busy, and so full of occurrence as his, we should swell this account to many pages. Suffice it to say, he continued in the unmolested enjoyment of his fame and unrivalled excellence to the moment of his retirement. His universality of excellence was never once attacked by competition. Tragedy, comedy, and farce, the lover and

Garrick, the hero, the jealous husband who suspects his wife without cause, and the thoughtless lively rake who attacks it without design, were all alike his own. Rage and ridicule, doubt and despair, transport and tenderness, compassion and contempt: love, jealousy, fear, fury, and simplicity; all took in turn possession of his features, while each of them in turn appeared to be the sole possessor of his heart. In the several characters of Lear and Hamlet, Richard, Dorilas, Romeo, and Lufignane; in his Ranger, Bayes, Drugger, Kite-ly, Brute, and Benedick, you saw the muscular conformation that your ideas attached to them all. In short, Nature, the mistress from whom alone this great performer borrowed all his lessons, being in herself inexhaustible, this her darling son, marked out for her truest representative, found an unlimited scope for change and diversity in his manner of copying from her various productions. There is one part of theatrical conduct which ought unquestionably to be recorded to Mr Garrick's honour, since the cause of virtue and morality, and the formation of public manners, are considerably dependent upon it; and that is, the zeal with which he aimed to banish from the stage all those plays which carry with them an immoral tendency, and to prune from those which do not absolutely, on the whole, promote the interests of vice, such scenes of licentiousness and liberty, as a redundancy of wit, and too great liveliness of imagination have induced some of our comic writers to indulge themselves in, and which the sympathetic disposition of our age of gallantry and intrigue has given sanction to. The purity of the English stage has certainly been much more fully established during the administration of this theatrical minister, than it had ever been during preceding managements. He seems to have carried his modest, moral, chaste, and pious principles with him into the very management of the theatre itself, and rescued performers from that obloquy which stuck on the profession. Of those who were accounted blackguards, unworthy the association of the world, he made gentlemen, united them with society, and introduced them to all the domestic comforts of life. The theatre was no longer esteemed the receptacle of all vice; and the moral, the serious, the religious part of mankind, did not hesitate to partake the rational entertainment of a play, and pass a cheerful evening undisgusted with the licentiousness, and uncorrupted by the immorality, of the exhibition.

Notwithstanding the numberless and laborious avocations attendant on his profession as an actor, and his station as a manager; yet still his active genius was perpetually bursting forth in various little productions in the dramatic and poetical way, whose merit cannot but make us regret his want of time for the pursuance of more extensive and important works. It is certain, that his merit as an author is not of the first magnitude: but his great knowledge of men and manners, of stage-effect, and his happy turn for lively and striking satire, made him generally successful: and his prologues and epilogues in particular, which are almost innumerable, possess such a degree of happiness, both in the conception and execution, as to stand unequalled. His Ode on the death of Mr Pelham run through four editions in less than six weeks. His Ode on Shakespeare is a masterly piece of poetry; and when delivered

Garrick ed by himself, was a most capital exhibition. His alterations of Shakespeare and other authors have been at times successful, and at times exploded. The cutting out the grave-diggers scene from Hamlet will never be forgot to him by the inhabitants of the gallery at Drury. Though necessary to the chasteness of the scene, they cannot bear to lose so much true sterling wit and humour; and it must be owed, that exuberances of that kind, though they hurt the uniformity, yet increase the luxuriance of the tree. Among his alterations the following are part: Every Man in his Humour, altered from Ben Johnson; Romeo and Juliet, Winter's Tale, Catherine and Petruchio, Cymbeline, Hamlet, &c. altered and made up from Shakespeare: Gamesters, a comedy, from Shirley; Isabella, from Southerne. To these we add, as original productions, the Farmer's Return, and Linco's Travels, interludes; Guardian, Lethe, Lying Valet, Miss in her Teens, Male Coquet, Irish Widow, and other comedies in two acts; Enchanter, a musical entertainment; Lilliput; the Christmas Tale is ascribed to him, and many others.

We now bring him to the period of his retirement in the spring of 1776; when, full of fame, with the acquirement of a splendid fortune, and growing into years, he thought proper to seek the vale of life, to enjoy that dignified and honourable ease which was compatible with his public situation, and which he had so well earned by the activity and the merits of his dramatic reign. But very short indeed was the period allotted to him for this precious enjoyment: for on the 20th of January 1779, he departed this life; leaving no one rival in excellence upon earth to compensate for his loss, or a hope of our ever meeting with his like again.

GARRISON, in the art of war, a body of forces, disposed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection; or even to be subsisted during the winter season: hence *garrison* and *winter-quarters* are sometimes used indifferently for the same thing; and sometimes they denote different things. In the latter case, a garrison is a place wherein forces are maintained to secure it, and where they keep regular guard, as a frontier town, a citadel, castle, tower, &c. The garrison should be always stronger than the townsmen.

Du Cange derives the word from the corrupt Latin *garnisio*, which the latter writers use to signify all manner of munition, arms, victuals, &c. necessary for the defence of a place, and sustaining of a siege.

Winter-quarters signify a place where a number of forces are laid up in the winter season, without keeping the regular guard.

GARSTANG, a town in Lancashire, 223 miles from London; in the post road between Preston and Lancaster. It is a large populous place, near a mile in length, but built in a very irregular manner, with dirty streets, and very indifferent houses. The church is a stately Gothic structure. By the late inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Westmoreland, Chester, Stafford, Warwick, Leicester, Oxford, Worcester, &c.

GARTER, a ligature for tying up the stocking; but particularly used for the badge of a noble order of knights, hence denominated the

Order of the GARTER, a military order of knighthood, the most noble and ancient of any lay-order in the world, instituted by Edward III. The knights-companions are generally princes and peers; and the king of England is the sovereign or chief of the order. The number of knights was originally 26; but six were added in 1786, on account of the increase of the royal family. They are a college or corporation, having a great and little seal.

Their officers are a prelate, chancellor, register, king at arms, and usher of the black rod. They have also a dean, with 12 canons, and petty canons, vergers, and 26 pensioners or poor knights. The prelate is the head. This office is vested in the bishop of Winchester, and has ever been so. Next the prelate is the chancellor; which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the register, who by his oath is to enter upon the registry, the scrutinies, elections, penalties, and other acts of the order with all fidelity: The dean of Windsor is always register *ex officio*. The fourth officer is Garter and king-at-arms, being two distinct offices united in one person. Garter carries the rod and sceptre at the feast of St George, the protector of this order, when the sovereign is present. He notifies the elections of new knights, attends the solemnity of their installations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See *KING-at-Arms*.

All these officers except the prelate hath fees and pensions. The college of the order is seated in the castle of Windsor, within the chapel of St George, and the charter-house, erected by the founder for that purpose. The habit and ensign of the order are, a garter, mantle, cape, george, and collar. The three first were assigned to the knights companions by the founder; and the george and collar by Henry VIII.

The garter challenges pre-eminence over all the other parts of the dress, by reason that from it the noble order is denominated; that it is the first part of the habit presented to foreign princes and absent knights, who, and all other knights-elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investiture with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, HONI SOIT QUI MAL Y PENSE; i. e. *Shame to him that thinks evil hereof*: The meaning of which is, that king Edward having laid claim to the kingdom of France, retorted shame and defiance upon him that should dare to think amiss of the just enterprise he had undertaken, for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order, was such as would enable him to maintain the quarrel against those that thought ill of it.

The mantle is the chief of these vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights-companions. To the collar of

the

Garter.

the mantle is fixed a pair of long strings, anciently wove with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe, with knobs or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large garter, with the device, *HONI SOIT*, &c. Within this is the cross of the order, which was ordained to be worn at all times by king Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver.

The collar is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold.

When the knights wear not their robes, they are to have a silver star on the left side; and they commonly bear the picture of St George, enamelled on gold, and beset with diamonds, at the end of a blue ribbon, crossing the body from the left shoulder. They are not to appear abroad without the garter, on penalty of 6s. 8d. paid to the register.

The manner of electing a knight-companion into this most noble order, and the ceremonies of investiture, are as follow. When the sovereign designs to elect a companion of the garter, the chancellor belonging to this order draws up the letters, which, passing both under the sovereign's sign-manual and signet of the order, are sent to the person by Garter principal king at arms; and are in this manner or to the same effect: "We, with the companions of our most noble order of the garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shown, and the honourable exploits you have done in our service, by vindicating and maintaining our right, &c, have elected and chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the ensigns thereof, and be ready for your installation upon the — day of this present month, &c."

The garter, which is of blue velvet bordered with fine gold-wire, having commonly the letters of the motto of the same, is, at the time of election, buckled upon the left leg, by two of the senior companions, who receive it from the sovereign, to whom it was presented upon a velvet cushion, by Garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes: "To the honour of God omnipotent, and in memorial of the blessed martyr St George, tie about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous; and having undertaken a just war, in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successively conquer." The princely garter being then buckled on, and the word of its signification pronounced, the knight-elect is brought before the sovereign, who puts about his neck, kneeling, a dark blue ribbon, whereunto is appendant, wrought in gold within the garter, the image of St George on horseback, with his sword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ St George,

VOL. VII.

Garter.

by whose imitation provoked, thou mayest so overpass both prosperous and adverse adventures, that having stoutly vanquished thy enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory." Then the knight elected kisses the sovereign's hand; thanks his majesty for the great honour done him; rises up, and salutes all the companions severally, who return their congratulations. See a representation of the above insignia, among others, on the plate belonging to *Orders of KNIGHTHOOD*.

Since the institution of this order, there have been eight emperors and twenty-eight kings, besides numerous sovereign princes, enrolled as companions thereof. Its origin is somewhat differently related. The common account is, that the countess of Salisbury at a ball happening to drop her garter, the king took it up and presented it to her with these words, "*Honi soit qui maly pense*;" i. e. Evil to him that evil thinks. This accident, it is said, gave rise to the order and the motto; it being the spirit of the times to mix love and war together: but as in the original statutes of this order there is not the least conjecture to countenance such a feminine institution, credit cannot be given to this tradition. Camden, Fern, &c. take it to have been instituted on occasion of the victory obtained by Edward over the French at the battle of Cressy: that prince, say some historians, ordered his garter to be displayed, as a signal of battle: in commemoration whereof, he made a garter the principal ornament of the order erected in memory of this signal victory, and a symbol of the indissoluble union of the knights.

It appears from Rastel's chronicle, lib. vi. quoted by Granger in the supplement to his Biographical History, that this order was devised by Richard I. at the siege of the city of Acres, when he caused twenty-six knights, who firmly stood by him, to wear thongs of blue leather about their legs, and that it was perfected in the nineteenth year of Edward III.

In 1551, Edward VI. made some alterations in the ritual of this order: that prince composed it in Latin, the original whereof is still extant in his own hand-writing. He there ordained, that the order should no longer be called the order of St George, but that of the garter; and, instead of the George, hung at the collar, he substituted a cavalier, bearing a book on the point of his sword, with the word *protectio* graven on the sword, and *verbum Dei* on the book; with a buckle in the left hand, and the word *fides* thereon. Larrey.

GARTER, principal King at Arms. This office was instituted by Henry V.

Garter, and principal king at arms, are two distinct offices united in one person: Garter's employment is to attend the service of the order of the garter; for which he is allowed a mantle and badge, a house in Windsor-Castle, and pensions both from the sovereign and knights, and, lastly, fees. He also carries the rod and sceptre at every feast of St George, when the sovereign is present, and notifies the election of such as are new chosen; attends the solemnity of their installations, and takes care of placing their arms over their seats; and carries the garter to foreign kings and

4 D

princes;

Garter,
Garth.

princes, for which service it has been usual to join him in commission with some peer, or other person of distinction.

Garter's oath relates only to services being performed within the order, and is taken in chapter before the sovereign and knights. His oath, asking at arms, is taken before the earl marshal.

GARTER is also a term in heraldry, signifying the moiety or half of a bend.

GARTH is used in some parts of England for a little backside or clove. It is an ancient British word. Gardd, in that language, signifies *garden*, and is pronounced, and written *garth*. This word is also used for a dam or wear, &c.

GARTH-men is used in the English statutes for those who catch fish by means of fish-garths, or wears. By statute it is ordained that no fisher, nor garth-man, shall use any nets or engines to destroy the fry of fish, &c. 17 Ric. II. cap. 9. The word is supposed by some to be derived from the Scotch word *gart*, which signifies *forced or compelled*; because fish are forced by the wear into a loop, where they are taken.

GARTH (Sir Samuel), an excellent English poet and physician, was descended from a good family in Yorkshire. He was admitted into the college of physicians at London in 1693. He at that time zealously promoted and encouraged the erecting of the dispensary for the relief of the sick poor, by giving them advice gratis, and medicines at low rates. This work of charity having exposed him and many other physicians to the envy and resentment of several persons of the same faculty as well as apothecaries, he ridiculed them, with peculiar spirit and vivacity, in a poem called the *Dispensary*, in six cantos, highly esteemed. He was one of the most eminent members of the famous society called the *Kit-Kat Club*, which consisted of noblemen and gentlemen distinguished by their excellent parts and affection to the house of Hanover. Upon the accession of George I. he was knighted, and made physician in ordinary to his majesty, and physician-general to the army. Nor were these more than just rewards even of his physical merit. He had gone through the office of censor of the college in 1702; and had practised always with great reputation, and a strict regard to the honour and interest of the faculty, never stooping to prostitute the dignity of his profession, through mean and sordid views of self-interest, to any even the most popular and wealthy apothecaries. In a steady adherence to this noble principle, he concurred with the much celebrated Dr Radcliffe, with whom he was also often joined in physical consultations. He had a very extensive practice, but was very moderate in his views of advancing his own fortune; his humanity and good-nature inclining him more to make use of the great interest he had with persons in power, for the support and encouragement of other men of letters. He chose to live with the great in that degree of independency and freedom which became a man possessed of a superior genius, whereof he was daily giving fresh proofs to the public. One of his last performances in polite letters, was his translation of the whole fourteenth book, and the story of Cinnus in the fifteenth book, of Ovid's *Metamorphoses*. These, together with an English version of the rest, were published in 1717; and he

has prefixed an excellent preface to the whole wherein he not only gives an idea of the work, and points out its principal beauties, but shows the uses of the poem, and how it may be read to most profit. The distemper which seized him the ensuing year, and ended not but with his life, caused a general concern; which was particularly testified by lord Lansdown, a brother-poet, though of a different party, in some admirable verses written on the occasion. He died, after a short illness, which he bore with great patience, in January 1719.

GARUMNA, a noble and navigable river of Gaul, which rising from the Pyrenees, formerly bounded Aquitain on the north (Cæsar;) but by the new regulation of Augustus divided it in the middle, emptying itself, to the north of Burdegala, into the Aquitanic ocean. Now the *Garonne*. Mela observes concerning it, that unless it is swelled by winter rains, or the melting of the snow, it is for a great part of the year shoaly and scarce navigable: but when increased by the meeting tide, whereby its waters are repelled, it is somewhat fuller, and the farther the river advances, it is broader, till at length it resembles a large frith or arm of the sea; not only bearing large vessels, but also swelling like a raging sea, tosses them extremely, especially if the direction of the wind be one way and that of the current another.

GAS, a general name for all fluids of the aerial kind, excepting the common air we breathe. It is derived from the German *gascht* or *gast*, signifying an eruption of wind, or the ebullition attending the expulsion of elastic fluids from substances in a state of fermentation or effervescence. It was originally given by Van Helmont to the vapour of charcoal, the same with the fluid now called *fixed air*, and some other factitious airs; and from him has been employed by modern philosophers as a general term for all the fluids about which aerology is conversant.

Under the article AEROLOGY, the nature and properties of these fluids are explained at large; here, however, for the more easy comprehension of the subject, we shall give a list of these fluids, with a general account of the most remarkable particulars hitherto discovered concerning them. The gases, or permanently elastic fluids, as yet known, are,

1. Common or atmospheric air.
2. Fixed air.
3. Inflammable air.
4. Nitrous air.
5. Dephlogisticated air.
6. Vitriolic-acid air.
7. Marine-acid air.
8. Nitrous-acid air.
9. Fluor-acid air.
10. Vegetable-acid air.
11. Alkaline air.
12. Dephlogisticated nitrous air.
13. Sulphurated inflammable air.
14. Hepatic air.
15. Phlogisticated air.

The most remarkable properties of these are as follow.

1. *Atmospherical air* supports both animal and vegetable life; and surrounding the whole globe to a considerable height, is one of the great agents employed by nature for executing her most important purposes.

It

Garumna,
Gas.

Gas.

It is composed of one part of dephlogisticated air, and three or more of phlogisticated air.

2. *Fixed air* is produced in great plenty in all kinds of combustion. If the combustible body be set on fire in pure dephlogisticated air, the fixed air is proportionably pure; but if in the common atmosphere the produce is contaminated by the whole quantity of phlogisticated air contained in that portion of the atmosphere by which the combustion was supported, it proves fatal to animals in a very short time, but is favourable to vegetation. It is absorbed in considerable quantities by water, to which it communicates an agreeable acidulous taste, and a power of dissolving iron; and is the principal ingredient in mineral waters. It is taken up in great quantity by pure alkaline salts whether fixed or volatile; by calcined magnesia, lime, or calcareous earth; all of which it neutralizes, and forms with them salts of different kinds. Lime absorbs it more readily either when quite dry or entirely dissolved in water than when exposed to it in a moist mass, and lime-water is readily precipitated by it; but magnesia attracts it more readily when in a moist mass; and the fixed alkalies equally well in either case, unless when violently heated.

Fixed air is contained in great quantity in fermented liquors, to which it gives their agreeable taste and briskness; and by impregnating them with it, they may be recovered from a vapid state and rendered brisk and agreeable as before. It has a considerable antiseptic power; and notwithstanding its pernicious qualities when taken into the lungs, has been found serviceable in putrid diseases when swallowed, or when injected by way of glyster. Being a natural product of combustion, it is met with in great quantities in the neighbourhood of volcanoes, or mountains which have formerly been volcanoes, where it often produces mischievous effects. It is also met with in mines, where it often proves fatal to the workmen. In the artificial way it is procured from fermenting liquors; from the calcination of magnesia and calcareous earths by heat; and from a mixture of these earths with acids, chiefly the vitriolic. When procured from large quantities of fermenting liquors, it lies in a large body on the surface of the liquor, generally nine inches or a foot thick, and affords an amusing appearance on extinguishing lighted candles or chips of wood in it. In these experiments the smoke readily unites with the gas, so that little or none of it can disperse itself into the atmosphere: and it is remarkable, that the upper surface of this smoke which floats in the fixed air is smooth and well defined, but the under part is ragged, and sometimes even collecting itself into balls connected with the upper surface by slender threads. Sometimes the smoke will form itself into broad flakes parallel to the surface of the liquor, and at different distances from it, exactly like clouds; and these appearances will continue for upwards of an hour with very little variation. Dr Priestley tried the smoke of gun-powder, rosin, sulphur, and other electric substances; and found them all retained equally by the fixed air, as well as the smoke of vitriolic acid raised by putting a burning coal in it.

Fixed air does not very readily unite with common air. It is near twice as heavy as atmospheric air, and acquires a proportionably greater elasticity by heat. It

is composed of dephlogisticated air and phlogiston; which two ingredients are partly separated by the electric spark. It may be kept for any length of time in vessels inverted into quicksilver, or even into water, with a coat of oil about half an inch thick on its surface.

3. *Inflammable air* is composed of phlogiston and water rarefied by heat. It is the lightest fluid known in nature, being 10 or 12 times specifically lighter than the common atmosphere. It is pernicious to animals, but supports vegetable life. By itself it extinguishes flame; but when mixed with a certain quantity of common air, the whole explodes violently, and a small portion of nitrous acid is produced. If dephlogisticated air be used instead of common air, the explosion is much more violent; Dr Priestley says 50 times. It is very readily absorbed by the calces of some metals, particularly lead, to which it restores its metallic form; and is even decomposed by keeping it long in a tube made of white glass, to which it communicates a black colour by its attraction for the lead in its composition. It is produced naturally in coal pits and other mines: where, being mixed with common air, and frequently inflamed by the lights which the miners have along with them, it explodes with prodigious violence, and often produces much mischief. Sometimes it rises out of the marshes, or from the mud at the bottom of springs and rivers; in which case the water will seem to take fire on holding a lighted candle to its surface. It is produced from the vapours of rancid oil; whence it has sometimes been collected in the large bellows used in founderies, and burst them with explosion. It seems also to be a natural product of putrefaction of every kind, being sometimes met with in jakes and privies, where it has exploded as usual on the approach of a candle. When mixed with common air it may be fired by an electric spark, but less readily by one from flint and steel; though there are instances of its taking fire in this manner also. In the artificial way, it is most usually procured from iron-filings and diluted vitriolic acid; and lately from the steam of water conveyed over iron filings through a red-hot tube. It is likewise obtained by distillation of wood, coal, &c. and by dissipating charcoal with the heat of a burning glass *in vacuo*. Dr Pennington of Philadelphia informs us, that it resists putrefaction; but its virtues in this way have not been particularly examined.

4. *Nitrous air* is produced from inflammable substances combined with the nitrous acid; and, according to that class of philosophers styled *Phlogistians*, consists of nitrous acid super-saturated with phlogiston; according to the *Antiphlogistians*, it consists of the same acid, deprived of a part of its oxygenous principle, the same with what the other party call the basis of dephlogisticated air. This is the most noxious of all the kinds of air hitherto discovered; being not only instantly fatal to animal life, but to vegetables also, as well as extinguishing flame in the most perfect manner. It has a strong offensive smell; and when mixed with a quantity of dephlogisticated or common atmospheric air, a very considerable diminution of the latter takes place, attended with heat, red fumes, and the production of nitrous acid. The diminution is greatest of all when pure dephlogisticated air is made use of; and with atmospheric air is greater or less, according to its degree of purity or the quantity of dephlogisticated air it contains. This

Gas.

Gas.

kind of air is a most powerful antiseptic; and has been tried, but without success, to preserve meat fresh for a long time; though for a week or two it might perhaps be useful. It is heavier than common air.

5. *Dephlogisticated air* supports animal life and flame in the most perfect manner, but is less friendly to vegetables; though it seems not to possess any property absolutely detrimental to them, further than as it contains none, or only a small quantity, of that phlogistic matter, which is now found to be the proper food of plants. The heat produced by it in burning bodies seems to be very little if at all inferior to that of a large burning mirror. It unites with water but in small quantity; but attaches itself strongly to iron when fired in it, causing the metal to burn with a bright flame, and being diminished by this combustion to a surprising degree. With other inflammable matters it produces fixed air. It is naturally found in sea-water, and rises in some waters through the earth. It is produced in the day-time by the leaves of many plants; but not in the night. It is also produced from water exposed to the sun's light, especially if certain substances be put into it, of which a particular account is given under the article AEROLOGY. It is also produced by the distillation of nitre, manganese, and other substances.

6. *Vitriolic-acid air* is not essentially different from the fumes of burning sulphur, only that the latter are always mixed with common air. It is very heavy, and destructive both to animal and vegetable life; extinguishing flame also; and uniting in large quantity with water, from which, however, it is easily expelled by heat. By virtue of its properties as an acid, it readily unites with alkaline salts. It dissolves also camphor, reducing it to a transparent liquor; from which, however, the camphor separates on the affusion of water. It is produced by distilling oil of vitriol mixed with inflammable substances with a gentle heat.

7. *Marine-acid air* is no other than the vapour of marine acid, which may be procured either by distilling the marine acid with a very gentle heat, or the mixture of vitriolic acid, and common salt usually made use of for procuring that acid. It is absorbed largely by water: so that a very strong and smoking acid liquor can thus be obtained. It is pernicious to animal and vegetable life, but less so than the two former. It likewise extinguishes flame: but a candle will burn in common air, though mixed with a large proportion of it; in which case the flame appears of a most beautiful blue or green colour.

8. *Nitrous-acid air* has been but little examined on account of its extreme corrosive property, by which it destroys all kinds of liquids wherewith we attempt to confine it. By the addition of a certain quantity of phlogiston it is converted into phlogisticated air, as Dr. Priestley found on attempting to confine it by means of whale oil. It is absorbed by water, and forms nitrous acid; being the vapour of that, as the marine acid air is the vapour of the concentrated marine acid.

9. The *fluor-acid air* is not distinct from the vapour of that acid loaded with siliceous earth, which it plentifully dissolves. A full account of its properties is given under the article CHEMISTRY.

10. *Vegetable-acid air* was procured from an exceedingly concentrated acetous acid, but with more diffi-

Gas.

culty than the others on account of the volatility of the liquid. It extinguishes flame, unites with alkalies, and performs every other thing that could be expected from the acetous acid, manifesting its inferior acid power even in its aerial state. It is very readily imbibed by water and by charcoal. It is likewise absorbed pretty readily by olive oil, on which it has a remarkable effect. The oil takes up about ten times its bulk of the air; and, from being of a yellowish colour, turns almost as clear as water, losing also somewhat of its viscosity, and approaching to the consistence of an essential oil.

A singular appearance was observed by Dr Priestley on attempting to determine how much of this air a certain quantity of water would imbibe. Having put the liquid into a glass tube closed at one end, and introduced it to the vegetable acid air, a small bubble of common air which appeared at the bottom began to expand, and continued to do so till all the water was thrown out of the tube. The same effect took place when the tube was hermetically sealed at the end. With spirit of wine it was the same, and with oil of turpentine the effect took place more quickly; but with olive oil it was more slow.

11. *Alkaline air* is lighter than that of the common atmosphere, and much more expansible by heat. It is now found to be composed of inflammable and phlogisticated air. It has all the properties of caustic volatile spirits, uniting with acids and forming neutral salts. It is obtained from a mixture of sal ammoniac and lime by distillation with a very gentle heat; or it may be had in great quantity by distilling spirit of wine with volatile alkaline spirit. It is inflammable when mixed with common air, but burns without any explosion.

12. *Dephlogisticated-nitrous air* is produced from the nitrous kind exposed to liver of sulphur, or for a longer time to iron. It may also be produced directly in the operation for making nitrous air from the acid and iron. After a great quantity of nitrous air has been extricated from this mixture without heat, the dephlogisticated nitrous air will come over by the application of heat. It is remarkable for being able to sustain flame, without supporting animal life. In this kind of air a candle burns sometimes naturally, and sometimes with an enlarged flame of a blue or green colour. It is less proper as a test for the purity of the atmosphere than common nitrous air.

13. *Sulphurated inflammable air* is a late discovery of Dr Priestley's, and seems to be composed of inflammable and hepatic air mixed together.

14. *Hepatic air* is the steam which arises from liver of sulphur on the addition of water, but still more copiously on the addition of an acid. It is fatal to animal life, and burns without explosion. Its effect on vegetables is not well known; it is remarkable for the property of giving a black colour to some metallic calces, whence it has the property of rendering sympathetic ink visible.

15. *Phlogisticated air* is one of the component parts of the atmosphere; and is produced in great plenty by all the processes of putrefaction, calcination of metals, and many cases of combustion. It is very destructive to animal life, and likewise extinguishes flame; but it is exceedingly proper for the support of vegetables, which

Gas.

which thrive much better in it than in the common air. There are disputes concerning its composition; The Antiphlogistians supposing it to be a primary element, and their antagonists that it is composed in great part of phlogiston; though they have not been able to prove this part of their doctrine either by reviving the calces of metals, or purifying it in such a manner as to make it respirable. It is somewhat lighter than atmospherical air. Mixed with dephlogisticated and inflammable air, it produces nitrous acid by detonation. Inflammable, nitrous, and alkaline air, may be partly converted into it.

Having thus briefly recapitulated the properties of the different gases hitherto discovered, we shall next proceed to consider the apparatus necessary for making the various experiments with these gases, which have been for some time in so much repute among modern philosophers. These experiments may be reduced to the following classes. 1. The production and preservation of the gases themselves. 2. The impregnating water or other fluids with them. 3. Trying their effects upon animals and vegetables. 4. The effects produced on them by electricity. 5. Their capacities for conducting heat.

Where one can have access to large quantities of fermenting liquor, fixed air may be easily procured of tolerable purity, by filling a vial or tumbler with water, and then emptying it below the surface of the mephitic atmosphere which floats above the surface of the liquor, the fixed air occupying the place of the water as it is discharged from the vessel. It may then be preserved by stopping the mouth of the vial with a cork; or, if it is a wide-mouthed vessel, by inverting it in quicksilver, or in water covered with oil. In most cases, however, the different kinds of air may be for a short time preserved in vessels inverted in water alone without any oil. For experiments, therefore, on those kinds of airs which may be preserved in water, Dr Priestley made use of an oblong trough of wood, such as is represented, Plate CCVII. fig. 1. The dimensions were generally two feet in length, 18 inches in breadth, and 11 inches in depth. About an inch below the top is a wooden shelf all round, for the purpose of setting the inverted vials or jars of air upon it. The vessels he commonly made use of were such jars as he had been accustomed to use in his electrical batteries, about 10 inches long and $2\frac{1}{2}$ wide; though for different experiments he had them of various shapes and sizes. When he had occasion to remove vessels of air from the large trough, he put them into pots or dishes of the form represented fig. 2; these dishes being first put under water, and the jars then slid off the shelf upon them. For the mere removal of jars of air from one place to another, where they are to stand only for a few days, he makes use of common tea-dishes, which hold water enough, unless the air be in a state of diminution by any process going on in the vessel. When any thing, as a gallipot, is to be supported in a jar full of air, wire-stands, such as are represented fig. 3. may be conveniently made use of. They answer better than any others, on account of their taking up less room, and being easily bent into any shape. When there is occasion to pour a quantity of air from one vessel to another, a funnel, fig. 4. must be made use of. Thus the operation is rendered exceedingly

easy, by first filling the vessel in which the air is to be conveyed with water, and holding the mouth of it together with the funnel both under water with one hand, while the other is employed in pouring the air; which, ascending through the funnel up into the vessel, makes the water descend, and takes its place. It will be convenient to have several of these funnels of different sizes. They are best made of glass. An improvement on this part of the apparatus was made by the Duke de Chaulnes, and consists in having the under part of the shelf hollowed out into the shape of a funnel, with an hole over the middle, on which the vial is to be placed, and the air ascends without any trouble. When there is occasion to transfer air from a jar standing in the trough of water to a vessel standing in quicksilver, or any other situation whatever, the apparatus represented fig. 5. may be made use of. It consists of a bladder furnished at one end with a small glass-tube bent, and at the other with a cork perforated in such a manner as just to admit the small end of the funnel. When the common air is carefully pressed out of this bladder, and the funnel thrust tightly into the cork, it may be filled with any kind of air as easily as a glass jar. A string being then tied above the cork in which the funnel is inserted, and the orifice in the other cork closed by pressing the bladder against it, it may be carried any where; and if the tube be carefully wiped, the air may be conveyed quite free from moisture through a body of quicksilver or any thing else. When it is wanted to try whether a candle will burn in any kind of air, a cylindrical glass vessel, fig. 6. may be used, with a bit of a wax candle *a* fastened to the end of a wire *b*, and turned up in such a manner as to be let down into the vessel with the flame upwards. The vessel should be kept carefully covered till the moment the candle is admitted. In this manner, the Doctor tells us, he has frequently extinguished a candle more than 20 times successively; though it is impossible to dip the candle into it without giving the external air an opportunity of mixing more or less with that in the inside. The candle *c* at the other end is very convenient for holding under a jar standing in water, in order to burn as long as the inclosed air can supply it; for the moment that it is extinguished, it may be drawn through the water before any smoke can have mixed with the air. To draw the air out of a vessel which has its mouth immersed in water, and thereby to raise the liquid to any height, that may be required, a glass syphon is very convenient, such as is represented, fig. 8. putting one of the legs up into the vessel, and drawing the air out at the other end by the mouth, or rather, as most of the gases have a noxious quality, by a syringe properly fastened to it. Dr Hales sometimes made use of a valve at the top of the vessel; but Dr Priestley does not think this can be altogether depended upon. If, however, a very small hole be made at the top of a glass vessel, it may be filled to any height by holding it under water while the air is issuing out at the hole, which is then to be closed with wax or cement. When the gas employed in the experiments is of such a nature that it will neither be absorbed by water, nor diminish common air, it may be convenient to put part of the materials which generate the gas into a cup, as at *f*, fig. 1. Then having, by means of a syphon,

Gas.

Fig. 7.

drawn

Gas: drawn the air to a convenient height, the small glass vessel may be easily pushed into the cup by a wire introduced through the water. The contents of the small vessel may be discharged into the larger by a variety of contrivances; and the distance between the boundary of air and water, before and after the operation, will show the quantity of the generated air. The effect of such substances as diminish air may also be tried by this apparatus. When air is to be admitted to any thing that will not bear wetting, and yet cannot be conveniently put into a vial, and especially if it be in the form of powder, and must be placed upon a stand (as in those experiments in which the focus of a burning mirror is to be thrown upon it), the receiver in which it is to be placed must first be exhausted; then having a glass tube bent for the purpose, as in fig. 9. it is screwed to the transfer of an air-pump on which the receiver had been exhausted; and introducing it through the water into a jar of air of that kind with which the receiver is to be filled, the purpose is gained by only turning the cock: but in this way, unless a great deal of care be taken, some common air is apt to get into the receiver. If it is wished to try the goodness of any particular kind of air, two measures of it must be put into a jar standing in water; and having marked on the glass the exact place of the boundary of the air and water, a measure of nitrous air is put to it; and after waiting a proper time, the quantity of its diminution is to be noted. If two kinds of air nearly alike are to be compared together after mixing them in a large jar, the mixture is transferred into a long glass tube, by which the scale can be lengthened as much as we please. When the quantity of air, the goodness of which we wish to ascertain, happens to be so small that it is contained in a portion of a glass tube from which water will not run out, as *a* fig. 10. the length of the column of air in the tube is first to be measured with a pair of compasses, the remaining part being filled with water. The length of the column is then to be laid down upon a scale; and then thrusting into the tube a wire of a proper thickness *b*, it is drawn out again by means of a thin plate of iron bent to a sharp angle *c*, when the whole of this little apparatus has been introduced through the water into a jar of nitrous air, and the wire being drawn out, the air from the jar must supply its place. The length of this column of nitrous air is then to be measured, and laid down upon the scale, so as to know the exact length of both the columns. After this, holding the tube under water, the two columns of air are to be forced into contact by means of a small wire; and when they have been a sufficient time together, the length of the whole is measured and compared with the length of both columns taken together.

In many experiments, the matters from which air is to be expelled must be subject to a very considerable degree of heat. In these cases Dr Priestley frequently made use of a gun-barrel, fig. 11. Into this he put the substance from which the air was to be extracted; then filling it up with dry sand so that very little air could be lodged in the barrel, and having also previously burned the sand, so that no air could come from it, he luted to the open end the stem of a tobacco-pipe or small glass tube. Then having put the closed

end of the tube which contains the materials into the fire, the generated air, issuing through the tube, may be received into a vessel of quicksilver, with its mouth inverted into a basin of the same, suspended all together by wires as represented in the figure. Any other fluid substance may be used instead of quicksilver.

The best method, however, of procuring air from several substances by means of heat, is to put them into vials full of quicksilver, with their mouths immersed in the same, and then throwing the focus of a burning mirror upon them. For this purpose the vials should have round bottoms very thin, that they may not be liable to break on any sudden application of heat. If it is wanted to expel air from any liquid, a vial is to be nearly filled with it; then having a cork perforated, a bent glass-tube is put through it and secured with cement, represented at *e*, fig. 1. The vial is then put into a kettle of water, which is set upon the fire and made to boil. The air expelled by the heat issues through the tube, and is received in the basin of quicksilver, fig. 11. But instead of this suspended basin, the simple apparatus of a flaccid bladder, tied to the end of the tube in order to receive the generated air, may sometimes be advantageously made use of. To produce air by the solution of metals, or any similar process, the materials are to be put into a vial prepared in the manner represented at *e*, fig. 1. and the end of the glass-tube put under the mouth of any vessel into which it is wanted to convey the air. Heat may be easily applied while it hangs in this position, by means of a candle or red-hot poker.

In making experiments on such kinds of air as are readily imbibed by water, quicksilver must always be made use of, as represented fig. 12. where *a* is the basin of quicksilver, *b* a glass vessel containing quicksilver with its mouth immersed in it, *c* a vial containing the ingredients from which the air is to be produced, and *d* a small recipient or glass vessel to intercept any liquor that may come over along with the air, which must be transmitted as free from moisture as possible into the vessel *b*. If there be no danger of moisture, however, the glass-tube only is made use of in the manner represented at *a*, fig. 1. To invert the vessel *b*, fig. 12. it must first be filled with quicksilver, and its mouth then carefully covered with a piece of soft leather; after which it may be turned upside down without any danger of admitting the air; and the leather may be withdrawn when it is plunged into the quicksilver.

The figures *aaa*, fig. 13. represent a kind of vials much used by Dr Priestley in all his experiments. They are made round and very thin at the bottom, and the mouth is to be ground smooth, so that they may be either used with a cork, or will stand firm when inverted after being filled with quicksilver or any other fluid. When used as common vials with corks, they will bear the application of a sudden heat without breaking, much better than the common vials which are thickest at the bottom. These vessels are particularly useful in extracting air from any substance confined by quicksilver: for, standing with their mouths downwards, and the substances with which the experiment is made lying upon the surface of the metal, just under the thinnest part of the glass, they are easily subjected to the action of a burning-glass without any danger of breaking the vial which contains them. Care must be taken,

Gas.

Gas

taken, however, not to put them at once into the very focus, lest the glass should give way. In most cases this moderate heat will produce a considerable quantity of air; by which means there will be some space left between the glass and the substance from which the air is to be extracted, so that the greatest heat of the glass may easily be directed upon the substance itself, independent of the glass which contains it; whence the latter is in no danger of being broken or melted. "A skilful operator (says Dr Priestley) will be able to fill his vessel with the newly generated air by this means: but in general, he will do well to content himself with getting it half-full, or less; for as the glass is necessarily thicker towards the mouth, there will be some danger of breaking it when the rays are transmitted near that place, and of losing the air that has been perhaps with great trouble and difficulty procured. If the substance on which the experiment is made be in form of a powder, such as red-lead, and even many very light substances, it will be most convenient to put them into the vessel first; and the quicksilver may, with care, be poured upon them afterwards, so as to keep the substance at the bottom; and yet when the vessel is inverted it will remain uppermost. When the light matter will not lie close, it will not be difficult sometimes to intercept it in the strait part of that vial at the neck; but it will often be most convenient to form these light matters into small balls, and put them into the vessel through the quicksilver with which it has been previously filled. I would observe with respect to this process, and every other in which vessels are to be filled with quicksilver, and then to be placed inverted in basons of the same, that no operation is easier (unless the mouth of the vessel be exceedingly wide) when the mouth of it is covered with soft leather, and, if necessary, tied on with a string, before it be turned upside down; and the leather may be drawn from under it when it is plunged in the quicksilver. If the mouths of the vessels be very narrow, it will be sufficient, and most convenient, to cover them with one's finger. In this process there remains less doubt of the generated air coming from the materials on which the experiment is made, than when the focus of the lens is thrown upon them in vacuo; because there will often be room to suspect, that common air may get into the receiver in the course of a long process, at some place not sufficiently guarded; and besides it is a great satisfaction to see the quantity of air that is generated at any particular time, during the course of a process, that the operator may stop when he sees he has got a quantity sufficient for his purpose, whereas unless he has a gage connected with his transferer (which may be inconvenient), he must admit water into his receiver before he can certainly tell whether he has obtained any air or not; and then it will be liable to be affected by the water, or by the air contained in the water, and which will be set loose very copiously on its first admission into the receiver. But in cases where the air is apt to corrode the quicksilver, which always happens when the nitrous acid is concerned, recourse must then be had to the vacuum: and for this purpose it is necessary to have the receivers made as thin as possible, the thick ones being very apt to break by the heat of the lens. Care must be taken in those experiments to place the materials or

a crucible, a piece of glass, or some substance of that kind which yields no air."

Gas

A vial, with a ground-stopper, having the latter perforated with a number of small holes, will be found of excellent use to convey any liquid, or even any kind of air contained in it, through the water into a jar standing with its mouth inverted in the liquid, without admitting any mixture of common air or even of the water, and yet the generated air will have a sufficient outlet. Fig. 14. *c*, represents a kind of vial of the same form with those shown at *aaa*, fig. 13. but fitted with a ground stopper terminating in a tube, and which is occasionally to be used instead of that marked *e*, fig. 1. In most cases this is preferable to the corks and tubes the Doctor formerly employed; but in some the latter are still to be preferred, particularly where the fluor acid is to be used, which would soon corrode any of those thin vials. For experiments with this acid, therefore, the Doctor recommends the use of common vials made very thick, especially as no great degree of heat or sudden application of it is ever wanted. The vial *e* will be found sufficient for any purpose that does not require more heat than can be given by the flame of a candle held close to the bottom of it; but if there be occasion to place the vial in a sand-heat, and consequently if it must be put into a crucible placed on the fire, it will be necessary to have the tube in which the ground-stopper terminates made as long as possible, that the vessel which receives the air may not be too near the fire. Nine or twelve inches will be a sufficient length for the purpose. In such experiments, however, as are not worth the expence of these vials and stoppers, and yet where gun-barrels cannot be safely trusted, the Doctor has recourse to a vial made narrower at the open end than the other, of about 9 or 12 inches in length, and of an equal thickness throughout. When these vials are put into a crucible with sand, the bottom may be made red-hot, while the top is so cold that a common cork into which a glass tube is inserted will not be affected by the heat. When the materials are put into this vessel, it must be filled up to the mouth with fine sand that will give no air by the application of heat; and the cork must be thrust close down upon the sand. The air is to be received in the same manner as directed for the gun-barrel.

For the purpose of making a quantity of air pass through a body of water or any other fluid, it is convenient to have a number of vials of the form represented fig. 15. the tube which conveys the air into the vial going nearly to the under part, and that which delivers it perforating only the upper part. Thus the air is forced to go through the whole body of the water or powder with which the vial may be filled. These vessels may be of various sizes, from a pint down to half an ounce; the larger end may generally be stopped with a cork, though in some cases it will be necessary to have this stopper also of glass, with only two perforations for inserting the tubes. Sometimes he had occasion to use a number of these vessels placed together, as represented fig. 16. that the same air might pass through them all; and sometimes it was found improper to use any kind of lute or cement, so that all the stoppers, large as well as small, were fitted by grinding; which made the apparatus very expensive.

Gas.

penfive. The long vial annexed to this apparatus was chiefly made use of where the nitrous acid was concerned. It was made deep in order to admit of a sudden and violent effervescence without any danger of the liquid being thrown over; and the tube proceeding from it ought to be long enough to go to the bottom of any vessel in which the vapour is to be delivered.

Plate
CCVIII.

Fig. 17. represents a simple apparatus, being no other than a frame of wood so disposed about a vessel containing quicksilver, that the latter may admit of several glass tubes which support themselves against its sides, and thus may be employed in experiments all at the same time.

Fig. 18. shows a cylindrical vessel of tin perforated with holes, and enclosing another of iron wire. A charcoal fire may be made in the outer one, while a vial containing any quantity of air which it is wished to heat may be put within the frame of iron wire. Thus an equable heat will be produced on every part of the glass, without heating the bottom more than the rest; which in many cases is greatly to be wished for.

Fig. 19. shows the apparatus by which were made the principal experiments relating to the apparent conversion of water into air, on which Dr Priestley bestowed considerable attention, though he found it at last to be a mistake*. It consists of an earthen vessel; the bulb of which, containing moistened clay, is fixed in the inside of a glass vessel, through which the heat of a burning lens may be thrown upon it; while the inside has a communication with a basin of water or of quicksilver, in which vessels may be placed to receive the air that is forced through the body of the earthen vessel, while the water or mercury in the basin in which the glass stands rises to supply its place.

* See Water.

Fig. 20. shows the apparatus for transmitting steam through a red-hot tube containing iron or other substances. The contrivance is evident from an inspection of the figure; only the vessel which receives the air must be much larger in proportion than is here represented. Instead of the small furnace, one of Argand's lamps may be advantageously used. Fig. 21. shows a method of receiving the air under a funnel, when large balloons are to be filled for the purposes of aerostation.

These are the principal parts of the apparatus used by Dr Priestley in his numerous experiments for the production of airs, of all different kinds, from a vast variety of substances, and for preserving, transferring, or mingling them with one another as occasion required. On this part of his apparatus no improvement of any consequence has ever been made. It has been otherwise, however, with the method he proposed for impregnating water with the various gases, especially fixed air, which for some time engrossed a considerable share of the public attention. In this operation a principal requisite is to expose as large a surface of the water as possible to the action of the air; for it is only in proportion to the expanded surface, and not to the depth of the liquid, that the air is taken up. It is also requisite to save the air as much as possible, by stopping every outlet, and at the same time to prevent the vessels from bursting, which they might otherwise be apt to do. The first apparatus invented by Dr Priest-

Gas.

ley, and which seems to have also been the first ever made use of by any person, is represented fig. 22. It consists of a glass vessel *a*, with a pretty narrow neck, but so formed that it will stand with its mouth downwards; and having filled it with water, lay a slip of clean paper or thin pasteboard upon it: then if they be pressed close together, the vessel may be turned upside down without danger of admitting common air into it; and when it is thus inverted, it must be placed in another vessel in the form of a bowl or basin *b*, with a little water in it, so much as to permit the slip of paper or pasteboard to be withdrawn, and the end of the pipe *c* introduced. The pipe used by the Doctor was at first made of leather, that by means of its flexibility he might be able to shake the vessel *d* containing the effervescing mixture; but afterwards he found it more convenient to use one of glass, making use of two bladders instead of the one represented in the figure at *d*. These two are joined together by a perforated cork, and give room enough for shaking the vessel, which one would scarcely admit of. Having put the oil of vitriol to the calcareous earth in the bottle *e*, the fixed air will very soon distend the bladder or bladders *d*, which must then be pressed out into the vessel *a*, but will not suddenly be absorbed by it. A quantity proportionable to the bulk of the air will therefore descend into the basin; and after the bottle *a* has thus been about half emptied, it will be necessary to shake it briskly; when the agitation will cause the air to be imbibed, and the water will reascend into the bottle. This is to be repeated till the water will not take up any more; after which it ought to be put into a bottle well corked and cemented; the air being very apt to escape after being once taken up.

Though this apparatus must evidently answer the purpose of impregnating water with fixed air very effectually, yet it is troublesome on account of the attendance required; and objections were also made to the use of bladders in it, as being apt to communicate a disagreeable taste to the liquor. The latter objection was particularly insisted upon by Dr Nooth; who from his own experience declared, that the use of them communicated some degree of urinous flavour to the impregnated water. Dr Priestley made light of this objection, but allowed the validity of that from the attendance necessary during the impregnation. Though he reckoned Dr Nooth's apparatus therefore inferior to his own with regard to its power, and tho' slower in its operation as well as more expensive, he constantly used it himself in his after experiments; and it has now become almost universally employed for the purpose of impregnating small quantities of water with this kind of gas.

Dr Nooth's apparatus, with some improvements in it by Mr Parker, is represented fig. 23. and is all made of crystal glass. The lowermost vessel contains the chalk and diluted oil of vitriol; the middle one the water to be impregnated; and the upper one is designed to give vent to such part of the air as cannot be imbibed. The air is admitted to the water through a number of holes, so small that the water cannot get through them on account of the resistance made by the ascending gas. The uppermost vessel is filled to a certain height with water, which is prevented from descending into the middle vessel by the resistance of the air

Gas.

air in the empty part. As the gas ascends, that part of it which is not condensed compresses the water, and forces it up into the upper vessel, leaving thereby a greater space for the air to expand in; at the same time that a considerable pressure is made by the weight of the incumbent water, which very much promotes the absorption of this or any other gas. The effervescing materials may be renewed, and the water drawn off, by the cocks represented in the figure. Fig. 24. shows a farther improvement upon this apparatus by Mr Blades of Ludgate-hill. The only difference is in the shape of the vessels, and having a glass cock for letting off the impregnated water instead of a tube closed with a cork.

Another apparatus, capable of answering the purpose at least as well as that of Dr Nooth, and much less expensive, was invented by Dr Withering, and is represented fig. 25. A, is a glass-vessel about 10 inches high in the cylindrical part, and $6\frac{1}{2}$ inches diameter. B, a glass-vessel about 12 inches high in the conical part, $1\frac{1}{2}$ in the neck, and 5 inches diameter at the bottom. C, a copper pipe passing through the stopper of the vessel B, and tied fast into the flexible tube D. This tube is made of strong leather, and kept hollow by means of a spiral wire running through its whole length. E, a conical brass-pipe, with a stop-cock fastened to the tube D. F, a conical pipe, with a stop-cock G; having the end of the tube E accurately ground to it so as to be air tight. G, the stop-cock cutting off all communication with the atmosphere when the pipe E is removed. H H, two large hog's bladders, each of which ought to contain two quarts. I, a stop-cock to prevent the water from rising into the bladders when the vessel A is agitated. K, a bladder tied to the crooked tube with the stop-cock L, which occasionally opens or shuts the communication with the vessel B. M, a glass funnel accurately fitted with the glass-stopper N. O, the aperture fitted with a glass-stopper, from which the impregnated water is to be drawn for use; or, instead of the glass-stopper, a silver-cock may be more conveniently applied. P, the tube opening into the vessel A.

To make use of this apparatus, we must, 1. Fill the vessel A with pure water, adding such other ingredients as are necessary along with the gas. The vessel is calculated to hold five quarts conveniently for impregnation. 2. Put into the vessel B as much marble or whiting in small lumps as will cover its bottom to the height of two inches, then pour in water to the height represented by the dotted line. 3. Let all the bladders be tied round their respective tubes, so that they may be perfectly air-tight. 4. Fit the mouth of the vessel A tight with a cork, and through a hole in this pass the tube P; putting on the cork some sealing-wax of the softest kind, or else modelling wax, so that the whole may be made air-tight. 5. Stop the mouth of the vessel B with a piece of mahogany prepared in the following manner. Let the wood be first turned in a lathe of a conical figure, but a little larger than the mouth of the glass will admit. Put this piece of wood into melted bees-wax, and heat the wax until the wood begins to grow black. When cool, turn it again in a lathe until it fits the mouth of the vessel. The tubes C, L, and M, are fitted into holes bored

VOL. VII.

through the wooden stopper previous to its being immersed in the melted bees-wax. 6. Push these tubes through their respective holes in the wooden stopper; press their stopper into the orifice of the vessel B, and cement the whole with sealing or modelling wax. 7. Shut the stop-cocks I and L, having previously pressed the air out of the bladder K; open the stop-cocks G and E; then squeeze the air out of the bladder H H; and afterwards press the conical pipe E into the pipe F. 8. Pour about a large spoonful of oil of vitriol through the funnel M, and stop it with its stopper N: on this the fixed air rising through the tube C passes into the bladders H H, and distends them. 9. When the bladders are distended, open the stop-cock I, and draw off about a quart of water from the aperture at O. The empty space left by the water will quickly be filled with gas, which the remaining water will begin to absorb, and the absorption will still be supplied by fresh gas from the bladders; for which reason these must be kept pretty fully distended, by adding more oil of vitriol when they begin to grow flaccid. 10. If it be required to impregnate the water quickly, turn the stop-cocks at G and E, and open that at E; then separate the pipe E from the tube F, and agitate the vessel A. During this time the fixable air that is produced passes into the bladder K, from whence it may be afterwards pressed into the other bladders when the parts of the apparatus are again united. 11. During the agitation close the stop-cock at I, opening it only occasionally to replace from the bladders H H the air absorbed by the water. 12. If a strong impregnation be desired, the temperature of the room where the operation is carried on ought not to be more than 48° of Fahrenheit. 13. That the cocks may continue perfectly air-tight, it will be necessary to supply them once a-year with a very small quantity of unsalted lard. Modelling wax, of which mention is made in this description, may be made by adding two ounces of tallow and one of turpentine to half a pound of bees-wax. It may be coloured with red-lead or Spanish-brown; and the mixture must be kept stirring till cold.

These are the principal discoveries which have yet been made concerning the method of impregnating water with fixed air, and they may undoubtedly be applied to the impregnation of that fluid with any other kind of gas which it will take up; only it must be observed, that where any of the acids are concerned, that of fluor alone excepted, there is an absolute necessity for having all parts of the apparatus made of glass.

For making experiments on vegetables, the large Plate cylindrical glass, fig. 2. is very proper. When it was wished to try how long a small animal would live in a certain quantity of air, Dr Priestley found a large beer-glass, such as is represented at *d*, fig. 1. very convenient. The animals he most commonly made experiments upon were mice; and in a beer-glass containing between two and three ounces, he found that one of these creatures would live 20 minutes or half an hour. To obtain mice for such experiments, he directs that they should be caught in wire-traps, from whence they may be easily taken. To get them into the air, they must be passed through the water into the vessel containing it. The wet they sustain on this occasion does

4 E

them

Gas.

Gas.

them no hurt; but if the air is of such a quality that it is expected the mouse can live any time, it must have something to sit upon out of the reach of the water. Where this is not the case, it will be proper to hold the animal by the tail, in order to withdraw it as soon as possible; but if the air has been thoroughly noxious, it will be irrecoverable by a single inspiration. The mice are kept in receivers open at top and bottom, standing upon plates of tin perforated with many holes, and covered with others of the same kind to admit the air, kept down with weights, as in fig. 26. A quantity of paper or tow must be put into the vessel, and changed every two or three days in order to clean it; for which purpose it is proper to have another receiver of the same kind ready cleaned to hold them in. These animals must be kept in a place of a moderate temperature, either too much heat or too much cold being prejudicial to them. The place where Dr Priestley kept his had a temperature of about 70° of Fahrenheit. When they had been made to pass through water, it was necessary to give them a considerable degree of heat in order to dry and warm them. In the course of his experiments he found, that mice will live entirely without water; for though he kept them for three or four months, and several times offered them water, they would never taste it; notwithstanding which they continued in perfect health and vigour. Two or three of them will live very peaceably together in the same vessel; though the Doctor had one instance of a mouse tearing another almost in pieces, when there was plenty of provisions for both.

Some difficulty may occur in opening the mouth of a phial containing any kind of substance to which water must not be admitted in a jar of air; but this will easily be overcome, by having a cork cut tapering with a strong wire thrust through it, as in fig. 27. for thus it will easily fit the mouth of any phial; and by holding the phial in one hand, and plunging both into the trough of water, the phial can easily be conveyed through the water into the jar; which must either be held by an assistant, or be fastened by strings with its mouth projecting over the shelf. When the phial is thus conveyed into the jar, the cork may easily be removed, and put in again at pleasure.

Plate
CCVIII.

Fig. 28. represents an apparatus for determining the conducting power of air with regard to heat. It consists only of a jar, which may be filled with any kind of air, with a very sensible thermometer inserted in it, as represented in the figure. The scale of this was so large, that the Doctor could mark upon it 20 divisions, each larger than half an inch, between the mean temperature of the atmosphere and a heat much below that of boiling water. By frequent trials he at last adjusted it in such a manner, that having filled the vessel with any kind of air, he could plunge it first in hot and then in cold water, so that the mercury would rise to the division 20 and fall to that of 6 or 7 in no great time; and thus, by means of a clock which beat seconds, he could not well make a mistake of more than two in noting down any particular division. The hot water was always made to boil, and the cold water was always brought fresh from the same pump. The mouth of the air-vessel was placed in a cup of mercury kept always at the same

height; so that he could thus try any kind of air with as much accuracy as one would think were possible. Notwithstanding this, however, he could not thoroughly satisfy himself with the results; at least he has not yet thought proper to publish fully the results of his experiments. The differences, he says, were less striking than he expected. Inflammable air, however, appeared to conduct heat better than any other; the mercury ascending the same space in half the time in it that it took up in common air. Fixed air, and all the acid airs, were considerably worse than common air. Alkaline air was a little better, and dephlogisticated air a little worse, than common air; but the result of this last experiment was uncertain.

The electric spark is easily taken in any kind of air by filling a small tube with the air desired, with two wires approaching within striking-distance of each other in the middle.

We shall close this account of the apparatus for making experiments on gases with an account of an instrument invented by Dr Pearson of London for collecting air of any kind which escapes in bubbles from the surface of springs or rivers. It consists of a funnel inserted into a phial in such a manner that the gas as it issues through the water may come under the funnel, and thus rise into the phial. For the convenient holding it to receive the air from any place where it may issue copiously, it is furnished with a handle and a ring, to which the funnel is tied by springs, as represented fig. 29.

GASCOIGNE (Sir William), chief justice of the court of king's bench under Henry IV. A most learned and upright judge; who being insulted on the bench by the then prince of Wales, afterwards Henry V. with equal intrepidity and coolness committed the prince to prison; and by this seasonable fortitude laid the foundation of the future glory of that great monarch, who from this event dated his reformation from the licentiousness of his youth. It is not well authenticated that the prince struck Sir William, as recorded by Shakespeare; but all authors agree, that he interrupted the course of justice to screen a lewd servant. Sir William died in 1413.

GASCOIGNE (George), an English poet of some fame in the early part of the reign of queen Elizabeth, was born at Walthamstow in Essex, of an ancient family, and educated at both universities, but principally at Cambridge. From thence he removed to Gray's Inn, and commenced student of the law; but having a genius too volatile for that study, he travelled abroad, and for some time served in the army in the Low Countries. He afterwards went to France: where he became enamoured of a Scottish lady, and married her. Being at length, says Wood, *weary of those vanities*, he returned to England; and settled once more in Gray's Inn, where he wrote most of his dramatic and other poems. The latter part of his life he spent in his native village of Walthamstow, where he died in the year 1573. He had the character of a polite gentleman, an eloquent and witty companion, *et vir inter poetas sui seculi præstantissimus*. His plays, first printed separately, were afterwards, with several other poems, &c. reprinted in two volumes 4to; the first volume in 1577, the second in 1587.

GASCOIN,

Gas,
Gascoigne.

Gascoin
||
Gassendi.

GASCOIN, or **GASCOIGN**, denotes the hinder thigh of a horse, which begins at the stifle, and reaches to the ply or bending of the ham.

GASCONADE, a boast or vaunt of something very improbable. The term has its rise from the Gascons, or people of Gascony in France, who it seems have been distinguished for bragging and rhodomontado.

GASCONY, the most south-west province of France, is bounded by Guienne on the north, by Languedoc on the east, by the Pyrenees which separate it from Spain on the south, and by the Bay of Biscay on the west. It had its name from the ancient inhabitants called *Gascones*, or *Vascones*; by the moderns *Basques*, or *Vasques*. After these were subdued by the Franks, they had for some time dukes of their own, who were subject to the dukes of Aquitaine; but both were at last dispossessed by the kings of France. The country produces corn, wine, fruits, tobacco, hemp, brandy, prunes, &c. The inhabitants are noted for a corrupt and vicious pronunciation of the French tongue, as well as their vain-glorious boasting.

GASSENDI (Peter), one of the most celebrated philosophers France has produced, was born at Chanterrier, about three miles from Digne in Provence, in 1592. When a child, he took a particular delight in gazing at the moon and stars as often as they appeared in clear unclouded weather. This pleasure frequently drew him into bye-places, in order to feast his eye freely and undisturbed; by which means his parents had him often to seek, not without many anxious fears and apprehensions. They therefore put him to school at Digne; where, in a short time, he made such an extraordinary progress in learning, that some persons, who had seen specimens of his genius, resolved to have him removed to Aix, in order to study philosophy under Fesay, a learned minor friar. This proposal was so disagreeable to his father, who intended to breed him up in his own way to country business, as being more profitable than that of a scholar, that he would consent to it only upon condition that he should return home in two years at farthest. Accordingly young Gassendi, at the end of the appointed time, repaired to Chanterrier: but he had not been long there when he was invited to be professor of rhetoric at Digne, before he was quite 16 years of age; and he had been engaged in that office but three years, when his master Fesay dying, he was made professor in his room at Aix. When he had been there a few years, he composed his *Paradoxical Exercitations*; which, coming to the hands of Nicholas Peiresc, that great patron of learning joined with Joseph Walter prior of Valette in promoting him; and he having entered into holy orders, was first made canon of the church of Digne and doctor of divinity, and then obtained the wardenship or rectorship of that church. Gassendi's fondness for astronomy grew up with his years; and his reputation daily increasing, he was in 1645 appointed royal professor of mathematics at Paris. This institution being chiefly designed for astronomy, our author read lectures on that science to a crowded audience. However, he did not hold this place long; for a dangerous cough and inflammation of the lungs obliged him, in 1647, to return to Digne for the benefit of his native air.—Gassendi wrote against the metaphysical meditations of

Des Cartes; and divided with that great man the philosophers of his time, almost all of whom were Cartesian or Gassendians. He joined to his knowledge of philosophy and the mathematics an acquaintance with the languages and a profound erudition. He wrote, 1. Three volumes on Epicurus's Philosophy; and six others, which contain his own philosophy. 2. Astronomical Works. 3. The Lives of Nicholas de Peiresc, Epicurus, Copernicus, Tycho Brahe, Perbachius, and Regiomontanus. 4. Epistles, and other treatises. All his works were collected together, and printed at Lyons in 1658, in six volumes folio. He died at Paris in 1655, aged 63.

GASTEROSTEUS, the **STICKLE-BACK**, in ichthyology, a genus of fishes belonging to the order of thoracici. There are three rays in the membrane of the gills; the body is carinated; and there are some distinct prickles before the back-fin. There are 11 species distinguished by the number of prickles on the back. One of these species, the *aculeatus*, stickleback, bausticle, or sharpling, is common in many of the British rivers. In the fens of Lincolnshire, and some rivers that proceed from them, they are found in prodigious quantities. At Spalding there are once in seven or eight years amazing shoals that appear in the Welland, and come up the river in form of a vast column. They are supposed to be the multitudes that have been washed out of the fens by the floods of several years, and collected in some deep hole, till overcharged with numbers, they are periodically obliged to attempt a change of place. The quantity is so great, that they are used to manure the land, and trials have been made to get oil from them. A notion may be had of this vast shoal, by being informed, that a man being employed by the farmer to take them, has got for a considerable time four shillings a-day by selling them for a half-penny per bushel.—This species seldom reaches the length of two inches; it hath three sharp spines on the back, that can be raised or depressed at pleasure. The colour of the back and sides is an olive-green; the belly white: but in some the lower jaws and belly are of a bright crimson.

GAST-HOUND. See *GAZE-Hound*.

GASTRELL (Francis), bishop of Chester, was born in 1662, appointed preacher to the society of Lincoln's Inn in 1694, and made bishop of Chester in 1714. He preached a course of sermons for Boyle's lectures; engaged in the Trinitarian controversy with Mr Collins and Dr Clarke; and published two excellent pieces, the one, intitled, *Christian Institutes*, and the other, a *Moral Proof of a Future State*. He vindicated the rights of the university of Oxford against the archbishop of Canterbury, in the appointment of the warden of Manchester college; and opposed the violent proceedings against bishop Atterbury in the house of lords, though he disliked the bishop as a man of arbitrary principles. He died in 1725.

GASTRIC, in general, something belonging to the stomach.

GASTRIC-Juice, a thin pellucid liquor, which distills from certain glands in the stomach, for the dilution, &c. of the food. See *ANATOMY*, Sect. XIII.

GASTROCNEMIUS, in anatomy. See *ANATOMY*, *Table of the Muscles*.

GASTROMANCY, or **GASTROMANTIA**, a kind of divination

Gastro-
steus
||
Gastro-
mancy.

Gastro-
raphy
||
Gate.

divination practised among the ancients by means of words coming or seeming to come out of the belly.

The word is Greek, γαστρομαρτεία, composed of γαστρ belly, and μαρτεία divination.

There is another kind of divination called by the same name *gastromancy*, which is performed by means of glasses or other round transparent vessels, within which certain figures appear by magic art. It is thus called, because the figures appear as in the belly of the vessels.

GASTROGRAPHY, in surgery, the operation of sewing up wounds of the abdomen. See **SURGERY**.

GASTROTOMY (of γαστρ, and τεμνω, *I cut*), the operation of cutting open the belly; otherwise called the *Cæsarian section*. See **MIDWIFERY**.

GATAKER (Thomas), a learned critic and divine, was born at London in 1574, and studied at St John's college, Cambridge. He was afterwards chosen preacher at Lincoln's Inn; which he quitted in 1611, for the rectory of Rotherhithe in Surry. In 1629, he made a tour through the Low Countries; and in 1624, published at London a book, intitled, *Transubstantiation declared by the Confession of the Popish Writers to have no necessary foundation in God's Word*: he wrote likewise a defence of this discourse. In 1642, he was appointed one of the assembly of divines, and was engaged with them in writing annotations upon the Bible. He died in July 1654, in the 80th year of his age. Besides the above works, he published, 1. A Dissertation upon the Style of the New Testament. 2. *De nomine tetragrammata*. 3. *De diphongis, sive bivocalibus*. 4. An Edition and Translation of the Emperor Marcus Antoninus's Meditations. 5. A Collection of Sermons, in folio; and many other works. His piety and charity were very exemplary; and his modesty so great, that he declined all ecclesiastical dignity and court-preferments. His extensive learning was admired by Salmasius and other great men abroad; his house was a private seminary for young gentlemen of the nation, and many foreigners resorted to him to receive advice in their studies.

GATE, in architecture, a large door, leading or giving entrance into a city, town, castle, palace, or other considerable building. See **ARCHITECTURE**.

Thebes, in Egypt, was anciently known by the appellation *with a hundred gates*. In ancient Rome there was a triumphal gate, *porta triumphalis*. In modern Rome there is the *jubilee gate*, which is only opened in the year of a grand jubilee.

The gates of London were many of them converted into gaols or prisons, as Ludgate, Newgate, &c. but they are now removed. The lesser or by-gates are called *posterns*. Gates, through which coaches, &c. are to pass, should not be less than 7 feet broad, nor more than 12; the height to be 1½ the breadth.

GATE, or **GAIT**, in the manege, called in French *train*, is used for the going or pace of a horse.

GATE, in a military sense, is made of strong planks, with iron bars, to oppose an enemy. They are generally made in the middle of the curtain, from whence they are seen, and defended by the two flanks of the bastions. They should be covered with a good ravelin, that they may not be seen or enfiladed by the enemy. These gates, belonging to a fortified place,

are passages through the rampart, which may be shut and opened by means of doors and a portcullis. They are either private or public.

Private gates are those passages by which the troops can go out of the town unteed by the enemy, when they pass to and from the relief of the duty in the outworks, or on any other occasion which is to be concealed from the besiegers.

Public gates are those passages through the middle of such curtains, to which the great roads or public ways lead. The dimensions of these are usually about 13 or 14 feet high, and 9 or 10 feet wide, continued through the rampart, with proper recesses for foot passengers to stand in out of the way of wheel carriages.

GATES of Hell. This expression is used in scripture, to denote figuratively either the *grave* or the *powers of darkness*, i. e. the devil and his angels.

The Mahometans use the expression literally, and suppose that hell has seven gates. The first is that where Mussulmans, who incur the guilt of sin, will be tormented. The second is for the Christians. The third is for the Jews. The fourth for the Sabians. The fifth for the Magians or worshippers of fire. The sixth for Pagans and idolaters. And the seventh for hypocrites, who make an outward show of religion, but have none.

GATESHEAD, in the county of Durham, is as it were the suburbs of Newcastle, though it lies in another county, being divided by the river Tyne; over which there is a fine stone-bridge, with an iron-gate in the middle, having the arms of Durham on one side, and those of Newcastle on the other, which is the boundary between the bishoprick and Northumberland. The church is a fine building, with a very high tower, seen at a great distance; and in the church-yard are several ancient monuments. There are few traces left of its ancient monastery, except a stone gateway, or rather a modern erection. The house covered two acres and a half of land. Here live the coal-pit men.

GATH, or **GETH** (anc. geog.), a celebrated city of the Philistines, and one of their five principalities. It is famous for having given birth to Goliath. David made a conquest of it in the beginning of his reign over all Israel; and it continued subject to the kings his successors till the declension and decay of the kingdom of Judah. Rehoboam rebuilt or fortified it; king Uzziah retook it, and Hezekiah once more reduced it under his subjection.

Gath stood about five or six miles from Jamnia, about 14 south of Joppa, and 32 west of Jerusalem. Hence some authors (among whom is F. Calmet) have committed an egregious mistake in making Gath the most southern; and Ekron the most northern, of the Philistine cities; as if these two had been the two boundaries of their dominions, whereas these two cities are not above five miles asunder; and Gaza is the last of the five satrapies south. And Josephus (in the place already quoted) expresses himself plainly enough, when he says, that Hezekiah took all the Philistine cities from Gaza to Gath; there being many more cities of that name, which signifies in the Hebrew a *wine-press*. Several more of the name of Geih or Gath are mentioned in Eusebius and St Jerom, whose situation,

situation, according to them, plainly shows them to have been different places from this, and from each other; besides those which had an adjunct to distinguish them.

This city recovered its liberty and lustre in time of the prophets Amos and Micah; but was afterwards demolished by Hazael king of Syria, since which it became of but little consideration till the time of the holy war, when Fulk king of Jerusalem built a castle on its ruins.

GATH-Opher, *GATH-Epher*, or *Gath*, in the canton of Opher, in Galilee, was the birth place of the prophet Jonah. Joshua makes this city to be part of the tribe of Zebulun; and St Jerom, in his preface upon Jonah, says, that it was two miles from Sephoris, otherwise called *Diocæsarea*.

GATH-Rimmon, a city belonging to the tribe of Dan. St Jerom places it ten miles from Diospolis on the way from Eleutheropolis. It was given to the Levites of Kohath's family.

GATH-Rimmon, was also a city in the half-tribe of Manasseh, on this side Jordan, and was also given for a place of abode in the Levites of Kohath's family.

GATH-Rimmon, was likewise a city in the tribe of Ephraim, given to the Kohathites.

GATTON, a borough in the county of Surry, 19 miles from London. It lies under the side of a hill going to Reigate; and is supposed to have been known to the Romans by reason of their coins and other antiquities that have been found here. It is a borough by prescription; and has sent members to parliament ever since the 29th of Henry VI. It was formerly a large town; but is now a mean village, with a small church, and without either fair or market. The members are returned by its constable, who is annually chosen at the lord of the manor's court.

GAUBIUS (Hieronymus David), a celebrated physician of Holland. He studied under the illustrious Boerhaave; and became so much the favourite of his professor, that he resigned the chemical chair in his favour. He taught at Leyden with great applause for 40 years. In the year 1775 he laid down his office, as being no longer able to support the fatigues of it. He was succeeded by John David Hahus, then professor at Utrecht. His reputation was extended all over Europe by several valuable publications, and particularly by his *Institutiones Pathologiae Medicinalis*, and his *Adversaria*, which have contributed not a little to the improvement both of the theory and practice of medicine. He died at Leyen 29th November 1780, in the 76th year of his age.

GAUDEN (Dr Joseph), son of John Gauden vicar of Mayfield in Essex, was born there in 1605. At the commencement of the civil war, he was chaplain to Robert earl of Warwick; who taking part with the parliament against the king, was followed by his chaplain. Upon the establishment of the presbyterian model of church-government, he complied with the ruling powers, and was nominated one of the assembly of divines who met at Westminster in 1643, and took the covenant; yet having offered some scruples and objections to it, his name was afterwards struck out of the list. Nor did he espouse the parliament cause any longer than they adhered to their first avowed principles of reforming only, instead of destroying, mo-

narchy and episcopacy. In this spirit he was one of those divines who signed a protestation to the army, against the violent proceedings that affected the life of the king: and a few days after his execution published the famous *ΕΙΚΩΝ ΒΑΣΙΛΙΚΗ*, *A Portraiture of his Sacred Majesty in his Solitude and Sufferings*; which ran through 50 editions in the course of a year. Upon the return of Charles II. he was promoted to the see of Exeter; and in 1662 was removed to Worcester, much to his regret; having flattered himself with the hopes of a translation to Winchester; and his death happened the same year. He wrote many controversial pieces suited to the circumstances of the times, and to his own views from them. The *Εικων Βασιλικη* abovementioned he published as the king's private meditations: though on this point there has been a long controversy. After the bishop's death, his widow, in a letter to one of her sons, calls it *The Jewel*: and said her husband had hoped to make a fortune by it; and that she had a letter of a very great man's, which would clear up that he writ it. This assertion, as the earl of Clarendon had predicted, was eagerly espoused by the anti-royalists, in the view of disparaging Charles I. But it has been observed, that Gauden had too luxuriant an imagination, which betrayed him into a rankness of style in the Asiatic way; and from thence, as bishop Burnet argues with others, it may be certainly concluded, that not he, but the king himself, was the true author of the *ΕΙΚΩΝ ΒΑΣΙΛΙΚΗ*: in which there is a nobleness and justness of thought, with a greatness of style, that made it be looked on as the best written book in the English language.

GAVEL, or **GABEL**, among builders. See **GABEL**.

GAVEL, in law: tribute, toil, custom, or yearly revenue; of which there was in old time several kinds. See **GABEL**.

GAVEL-Kind, a tenure or custom belonging to lands in the county of Kent. The word is said by Lambard to be compounded of three Saxon words, *gyfe*, *eal*, *kyn*, "*omnibus cognatione proximis data*." Vertegan calls it *gavelkind*, quasi "give all kind," that is, to each child his part: and Taylor, in his history of *gavelkind*, derives it from the British *gavel*, i. e. a hold or tenure, and *cenned*, "*generatio aut familia*;" and so *gavel cenned* might signify *tenuragenerationis*.—It is universally known what struggles the Kentish men made to preserve their ancient liberties, and with how much success those struggles were attended. And as it is principally here that we meet with the custom of *gavelkind* (though it was and is to be found in some other parts of the kingdom), we may fairly conclude, that this was a part of these liberties; agreeable to Mr Selden's opinion, that *gavelkind*, before the Norman conquest, was the general, custom of the realm. The distinguishing properties of this tenure are various: some of the principal are those. 1. The tenant is of age sufficient to alienate his estate by feoffment, at the age of 15. 2. The estate does not escheat in case of an attainder and execution for felony; their maxim being, "the father to the bough, the son to the plough." 3. In most places he had a power of devising lands by will, before the statute for that purpose was made. 4. The lands descend, not to the eldest, youngest, or any one son only, but to all the sons together; which was indeed anciently the most usual course of descent all

Gavelet all over England, though in particular places particular customs prevailed.

Gauging.

GAVELET, in law an ancient and special cessavit used in Kent, where the custom of gavelkind continues, by which the tenant, if he withdraws his rent and services due to the lord, forfeits his lands and tenements.

The process of the gavelet is thus. The lord is first to seek by the steward of his court, from three weeks to three weeks, to find some distress upon the tenement, till the fourth court; and if at that time he find none, at this fourth court it is awarded, that he take the tenement in his hand in name of a distress, and keep it a year and a day without manuring; within which time, if the tenant pay his arrears, and make reasonable amends for the withholding, he shall have and enjoy his tenement as before: if he come not before the year and day be past, the lord is to go to the next county-court, with witnesses of what had passed at his own court, and pronounce there his process, to have further witnesses; and then by the award of his own court, he shall enter and manure the tenements as his own: so that if the tenant desired afterwards to have and hold it as before, he must agree with the lord; according to this old saying: "Has he not since any thing given, or any thing paid, then let him pay five pound for his were, e're he be come heald again." Other copies have the first part with some variations; "Let him nine times pay, and nine times repay."

GAVELET, in London, is a writ used in the hustings, given to lords of rents in the city of London. Here the parties, tenant and demandant appear by *scire facias*, to show cause why the one should not have his tenant again on payment of his rent, or the other recover the lands on default thereof.

GAUGAMELA, (anc. geog.), a village of Aturia, lying between the rivers Lycus and Tygris; famous for Alexanders's victory over Darius. It is said to have been allowed to Darius Hystaspes for the maintenance of a camel; and hence the name. It was not far from a more considerable place called *Arbela*; whence the latter gave the name to the victory. See **ARBELA**.

GAGUE-POINT of a solid measure the diameter of a circle whose area is equal to the solid content of the same measure.

GAUGER, an officer who is appointed to examine all tuns, pipes, hogsheds and barrels, of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

GAUGING. See **GEOMETRY**.

GAUGING-Rod, an instrument used in gauging or measuring the contents of any vessel. That usually employed is the four foot gauging-rod. It is commonly made of box, and consists of four rules, each a foot long and about three-eighths of an inch square, joined together by three brass joints; by which means the rod is rendered four feet long when the four rules are quite opened, and but one foot when they are all folded together. On the first face of this rod, marked 4, are placed two diagonal lines; one for beer and the other for wine; by means of which the content of any common vessel in beer or wine gallons may be readily found, by putting the rod in at the bung-hole of

the vessel till it meets the intersection of the head of the vessel with the staves opposite to the bung-hole. For distinction of this line, there is written thereon, *beer and wine gallons*. On the second face, 5, are a line of inches and the gauge-line; which is a line expressing the areas of circles, whose diameters are the correspondent inches in ale-gallons. At the beginning is written, *ale area*. On the third face, 6, are three scales of lines; the first, at the end of which is written *hogshhead*, is for finding how many gallons there are in a hogshhead when it is not full, lying with its axis parallel to the horizon. The second line, at the end of which is written *B. L.* signifying a *butt lying*, is for the same use as that for the hogshhead. The third line is to find how much liquor is wanting to fill up a butt when it is standing: at the end of it is written *B. S.* signifying a *butt standing*. In the half of the fourth face of the gauging-rod, 7, there are three scales of lines, to find the wants in a firkin, kilderkin, and barrel lying with their areas parallel to the horizon. They are distinguished by letters *F. K. B.* signifying a *firkin, kilderkin, and barrel*.

Use of the diagonal lines on this rod. To find the content of a vessel in beer or wine gallons, put the braised end of the gauging-rod into the bung-hole of the cask, with the diagonal lines upwards, and thrust this braised end to the meeting of the head and staves; then with chalk make a mark at the middle of the bung hole of the vessel, and also on the diagonal lines of the rod, right against, over one another, when the braised end is thrust home to the head and staves: then turn the gauging-rod to the other end of the vessel, and thrust the braised end home to the end as before. Lastly, see if the mark made on the gauging-rod come even with the mark made on the bung-hole when the rod was thrust to the other end; which if it be, the mark made on the diagonal lines will, on the same lines, show the whole content of the cask in beer or wine gallons.

If the mark made on the bung-hole be not right against that made on the rod when you put it the other way, then right against the mark made on the bung-hole make another in the diagonal lines; and the division on the diagonal line between the two chalks will show the vessel's whole contents in beer or wine gallons. Thus *e. gr.* if the diagonal line of a vessel be 28 inches four-tenths, its contents, in beer gallons will be near 51, and in wine gallons 62

If a vessel be open, as a half barrel, tun, or copper, and a measure from the middle on one side to the head and staves be 38 inches, the diagonal line gives 122 beer gallons; half of which, *viz.* 61, is the content of the open half tub.

If you have a large vessel, as a tun or copper, and the diagonal line taken by a long rule proves 70 inches; the content of that vessel may be found thus: Every inch at the beginning-end of the diagonal line call ten inches. Thus ten inches becomes 100 inches; and every tenth of a gallon call 100 gallons; and every whole gallon call 1000 gallons.

Example. At 44.8 inches on the diagonal beer-line is 200 gallons; so that 4 inches 8 parts, now called 44 inches 8-tenths, is just two-tenths, of a gallon, now called 200 gallons: so also if the diagonal line be 76 inches and 7 tenths, a close cask of such diagonal will

Gauging.

Plste
CCV.

will

Gauge,
Gaul.

will hold 1000 beer-gallons; but an open cask but half so much, viz. 500 beer-gallons.

Use of the GAUGE-Line. To find the content of any cylindrical vessel in ale-gallons; seek the diameter of the vessel in inches, and just against it on the gauge-line is the quantity of ale gallons contained in one inch deep; this multiplied by the length of the cylinder will give its content in ale-gallons.

For example, suppose the length of the vessel 32.06, and the diameter of its base 25 inches; to find what is the content in ale-gallons? Right against 25 inches on the gauge-line is one gallon and 745, of a gallon; which multiplied by 32.06 the length gives 55.9447 gallons for the content of the vessel.

The bung diameter of a hoghead being 25 inches, the head diameter 22 inches, and the length 32.06 inches; to find the quantity of ale-gallons contained in it?—Seek 25, the bung-diameter, on the line of inches; and right against it on the gauge-line you will find 1.745; take one-third of it, which is .580, and set it down twice: seek 22 inches in the head-diameter, and against it you will find on the gauge-line 1.356; one-third of which added to twice .580, gives 1.6096; which multiplied by the length 32.06, the product will be 51.603776, the content in ale-gallons. Note, this operation supposes, that the aforesaid hoghead is in the figure of the middle frustrum of a spheroid.

The use of the lines on the two other faces of the rod is very easy; you need only put it down-right into the bung-hole; (if the vessel you desire to know the quantity of ale-gallons contained therein be lying) to the opposite staves; and then where the surface of the liquor cuts any one of the lines appropriated to that vessel, will be the number of gallons contained in that vessel.

GAUL, the name given by the Romans to the country that now forms the kingdom of France.—The original inhabitants were descended from the Celtes or Gomerians by whom the greatest part of Europe was peopled; the name of *Galli* or *Gauls*, being probably given them long after their settlement in that country. See **GALLIA**.

The ancient history of the Gauls is entirely wrapped up in obscurity and darkness; all we know concerning them for a long time is, that they multiplied so fast, that their country being unable to contain them, they poured forth in vast multitudes into other countries, which they generally subdued, and settled themselves in. It often happened, however, that these colonies were so molested by their neighbours, that they were obliged to send for assistance to their native country. This was always very easily obtained. The Gauls were, upon every occasion, ready to send forth great numbers of new adventurers; and as these spread desolation wherever they came, the very name of *Gauls* proved terrible to most of the neighbouring nations.—The earliest excursion of these people, of which we have any distinct account, was into Italy, under a famed leader, named *Bellovesus*, about 622 years before Christ. He crossed the Rhone and the Alps, till then unattempted; defeated the *Hetrurians*; and seized upon that part of their country, since known by the name of *Lombardy* and *Piedmont*.—The second grand expedition was made by the *Cœuomani*, a people dwelling between the rivers *Seine* and *Loire*, under a general named *Elitonis*. They settled in those parts of Italy now known by the names of *Bresciano*, *Gremio-*

excursions
into Italy.

nese, *Mantuan*, *Carniola*, and *Venetian*.—In a third excursion, two other Gaulish nations settled on both sides of the river *Po*; and in a fourth, the *Boii* and *Lingones* settled in the country between *Ravenna* and *Bologna*. The time of these three last expeditions is uncertain.

The fifth expedition of the Gauls was more remarkable than any of the former, and happened about 200 years after that of *Bellovesus*. The *Senones*, settled between *Paris* and *Meux*, were invited into Italy by an *Hetrurian* lord, and settled themselves in *Umbria*. *Brennus* their king laid siege to *Clusium*, a city in alliance with *Rome*; and this produced a war with the *Romans*, in which the latter were at first defeated, and their city taken and burnt; but at length the whole army was cut off by *Camillus*, inasmuch that not a single person escaped.

Some other expeditions the Gauls undertook against the *Romans*: in which, though they always proved unsuccessful, by reason of their want of military discipline; yet their fierceness and courage made them so formidable to the republic, that, on the first news of their march, extraordinary levies of troops were made, sacrifices and public supplications offered to the gods, and the law which granted an immunity from military service to priests and old men, was, for the time, abolished.

Against the *Greeks*, the expeditions of the Gauls were very little more successful than against the *Romans*. The first of these we hear of was about 279 years before Christ, in the year after *Pyrrhus* had invaded Italy. At this time, the Gauls finding themselves greatly overstocked at home, sent out three great colonies to conquer new countries for themselves. One of these armies was commanded by *Brennus*, another by *Cerethrius*, and the third by *Belgius*. The first entered *Pannonia*, or *Hungary*; the second *Thrace*; and the third marched into *Illyricum* and *Macedonia*. Here *Belgius* at first met with great success; and enriched himself by plunder to such a degree, that *Brennus* envying him, resolved to enter the same countries, in order to share the spoil. In a short time, however, *Belgius* met with such a total defeat, that his army was almost entirely destroyed: upon which *Brennus* hastened to the same place. His army at first consisted of 150,000 foot and 15,000 horse: but two of his principal officers revolted, and carried off 20,000 men, with whom they marched into *Thrace*; where having joined *Cerethrius*, they seized on *Byzantium* and the western coast of *Propontis*, making the adjacent parts tributary to them.—To retrieve this loss, *Brennus* sent for fresh supplies from *Gaul*; and having increased his army to 150,000 foot, and upwards of 60,000 horse, he entered *Macedonia*, defeated the general who opposed him, and ravaged the whole country. He next marched towards the straits of *Thermopylæ*, with a design to invade *Greece*; but was stopped by the forces sent to defend that pass against him. He passed the mountains, however, as *Xerxes* had formerly done; upon which the guards retired, to avoid being surrounded. *Brennus* then, having ordered *Acichorius*, the next to him in command, to follow at a distance with part of his army, marched with the bulk of the forces to *Delphi*, in order to plunder the rich temple there. This enterprise proved exceedingly unfortunate: a great number of his men were destroyed

army.

by a dreadful storm of hail, thunder, and lightning; another part of his army was destroyed by an earthquake; and the remainder, some how or other, imagining themselves attacked by the enemy, fought against each other the whole night, so that in the morning scarce one-half of them remained. The Greek forces then poured in upon them from all parts; and that in such numbers, that though Acichorius came up in due time with his forces, Brennus found himself unable to make head against the Greeks, and was defeated with great slaughter. He himself was desperately wounded; and so disheartened by his misfortune, that, having assembled all his chiefs, he advised them to kill all the wounded and disabled, and to make the best retreat they could; after which he put an end to his own life. On this occasion, it is said that 20,000 of these unhappy people were executed by their own countrymen. Acichorius then set out with the remainder for Gaul; but by being obliged to march through the country of their enemies, the calamities they met with by the way were so grievous, that not one of them reached their own country. A just judgement, say the Greek and Roman authors, for their sacrilegious intentions against Delphi.

4
Gaul in-
vaded by
the Ro-
mans.

The Romans having often felt the effects of the Gaulish ferocity and courage, thought proper at last, in order to humble them, to invade their country. Their first successful attempt was about 118 years before Christ, under the command of Quintus Marcius, surnamed *Rex*. He opened a way betwixt the Alps and the Pyrenees, which laid the foundation for conquering the whole country. This was a work of immense labour of itself, and rendered still more difficult by the opposition of the Gauls, especially those called the *Stæni*, who lived at the foot of the Alps. These people finding themselves overpowered by the consular army, set fire to their houses, killed their wives and children, and then threw themselves into the flames. After this Marcius built the city of Narbonne, which became the capital of a province. His successor Scaurus also conquered some Gaulish nations; and in order to facilitate the sending troops from Italy into that country, he made several excellent roads between them, which before were almost impassable. These successes gave rise to the invasion of the *Cimbri* and *Teutones*; an account of whose unfortunate expedition is given under the articles *CIMBRI*, *ROME*, *TEUTONES*, &c.

5
Surprising
success of
Julius Cæ-
sar.

From this time, the Gauls ceased to be formidable to the Romans, and even seem to have been for some time on good terms with them. At last, however, the *Helvetii* kindled a war with the republic, which brought Cæsar over the Alps, and ended in the total subjection of the country. *Orgetorix* was the first cause of it; who had engaged a vast number of his countrymen to burn their towns and villages, and to go in search of new conquests. *Julius Cæsar*, to whose lot the whole country of Gaul had fallen, made such haste to come and suppress them, that he was got to the *Rhone* in eight days; broke down the bridge of *Genèva*, and, in a few days more, finished the famed wall between that city and mount *Jura*, now *St Claude*, which extended seventeen miles in length, was sixteen feet high, fortified with towers and castles at proper distances, and a ditch that run the whole length of it. If his own account of it may be relied upon, he

did not set out till the beginning of April; and yet this huge work was finished by the ides or 13th of the month: so that, subtracting the eight days he was coming, it must have been all done in about five days; a prodigious work, considering he had but one legion there, or even though the whole country had given him assistance. Whilst this was doing, and the reinforcements he wanted were coming, he amused the *Helvetii*, who had sent to demand a passage through the country of the *Ailobroges*, till he had got his reinforcements; and then flatly refused it to them; whereupon a dreadful battle ensued; in which they lost one hundred and thirty thousand men, in spite of all their valour; besides a number of prisoners, among whom was the wife and daughter of *Orgetorix*, the leader of this unfortunate expedition. The rest submitted, and begged they might be permitted to go and settle among the *Ædii*, from whom they originally sprung; and, at the request of these last, were permitted to go.

The Gauls were constantly in a state of variance with one another; and Cæsar, who knew how to make the most of these intestine broils, soon became the protector of the oppressed, a terror to the oppressor, and the umpire of all their contentions. Among those who applied to him for help, were his allies the *Ædii*; against whom *Ariovistus*, king of the *Germans*, joined with the *Averni*, who inhabited the banks of the *Loire*, had taken the country of the *Sequanj* from them, and obliged them to send hostages to him. Cæsar, forthwith sent to demand the restitution of both, and, in an interview which he soon after obtained of that haughty and treacherous prince, was like to have fallen a sacrifice to his perfidy; upon which he bent his whole power against him, forced him out of his strong entrenchments, and gave him a total overthrow. *Ariovistus* escaped with difficulty over the *Rhine*; but his two wives, and a daughter, with a great number of *Germans* of distinction, fell into the conqueror's hand. Cæsar, after this signal victory, put his army into winter-quarters, whilst he went over the Alps to make the necessary preparations for the next campaign. By this time all the *Belgæ* in general were so terrified at his success, that they entered into a confederacy against the Romans as their common enemy. Of this, *Labienus*, who had been left in Gaul, sent Cæsar notice; upon which he immediately left Rome, and made such dispatch, that he arrived on their confines in about fifteen days. On his arrival the *Remi* submitted to him; but the rest, appointing *Galba*, king of the *Suessones*, general of all their forces, which amounted to one hundred and fifty thousand men, marched directly against him. Cæsar, who had seized on the bridge of the *Axona*, now *Aisne*, led his light horse and infantry over it; and whilst the others were encumbered in crossing the river, made such a terrible slaughter of them, that the river was filled with their dead, insomuch that their bodies served for a bridge to those who escaped. This new victory struck such terror into the rest, that they dispersed themselves; immediately after which the *Suessones*, *Bellovaci*, *Ambiones*, and some others, submitted to him. The *Nervii*, indeed, joined with the *Atrebatæ* and *Veromandui* against them; and having first secured their wives and children, made a vigorous resistance for some time;

The Gauls
defeated
with great
slaughter.

Gaul.

but were at length defeated, and the greatest part of them slain. The rest, with their wives and old men, surrendered themselves, and were allowed to live in their own cities and towns as formerly. The Aduatici were next subdued; and, for their treachery to the conqueror, were sold for slaves, to the number of fifty thousand. Young Crassus, the son of the triumvir, subdued likewise seven other nations, and took possession of their cities; which not only completed the conquest of the Belgæ, but brought several nations from beyond the Rhine to submit to the conqueror. The Veneti, or ancient inhabitants of Vannes in Brittany, who had been likewise obliged to send hostages to the conqueror, were, in the mean time, making great preparations by sea and land to recover their liberty. Cæsar, then in Illyricum, was forced to equip a fleet on the Loire; and having given the command of it to Brutus, went and defeated them by land, as Brutus did by sea; and having put their chief men to death, sold the rest for slaves. The Unelli, with Veridorix their chief, together with the Lexovii and Aulercii, were about the same time subdued by Sabinus, and the Aquitani by Crassus, with the loss of thirty thousand men. There remained nothing but the countries of the Morini and Menapii to be conquered of all Gaul. Cæsar marched himself again them: but he found them so well entrenched in their inaccessible fortresses, that he contented himself with burning and ravaging their country; and having put his troops into winter-quarters, again passed over the Alps, to have a more watchful eye on some of his rivals there. He was, however, soon after obliged to come to defend his Gaulish conquests against some nations of the Germans, who were coming to settle there, to the number of four hundred thousand. These he totally defeated, and then resolved to carry his conquering arms into Germany: but for an account of his exploits there, see the article GERMANY.

8
The Gauls
revolt, but
are sub-
dued.

Upon his return into Gaul, he found it labouring under a great famine, which had caused a kind of universal revolt. Cotta and Sabinus, who were left in the country of the Eubrones, now Liege, were betrayed into an ambush by Ambiorix, one of the Gaulish chiefs, and had most of their men cut off. The Aduatici had fallen upon Q. Cicero, who was left there with one legion, and had reduced him to great straits: at the same time Labienus, with his legion, was attacked by Indutiomarus, at the head of Rheni and Senones; but had better luck than the rest, and, by one bold sally upon them, put them to flight, and killed their general. Cæsar acquired no small credit by quelling all these revolts; but each victory lost the lives of so many of his troops, that he was forced to have recourse to Pompey for a fresh supply, who readily granted him two of his own legions to secure his Gaulish conquests.

9
A second
revolt.

But it was not long before the Gauls, ever restless under a foreign yoke, raised up a new revolt, and obliged him to return thither. His fear lest Pompey should gain the affections of the Roman people, had obliged him to strip the Gauls of their gold and silver, to bribe them over to his interest; and this gave no small handle to those frequent revolts which happened during his absence. He quickly, however, reduced the Nervii, Aduatici, Menapii, and Treviri; the last of whom had raised the revolt, under the command of Ambiorix: but he found the flame spread much far-

VOL. VII.

Gaul.

ther, even to the greatest part of the Gauls, who had chosen Vercingetorix their generalissimo. Cæsar was forced to leave Insurbria, whither he had retired to watch the motions of Pompey, and, in the midst of winter and snow, to repass the Alps into the province of Narbonne. Here he gathered his scattered troops with all possible speed; and, in spite of the hard weather, besieged and took Noviodunum, now Noyons; and defeated Vercingetorix, who was come to the relief of that place. He next took the city of Avaricum, now Bourges, one of the strongest in Gaul, and which had a garrison of forty thousand men; of whom he made such a dreadful slaughter, that hardly eight hundred escaped. Whilst he was besieging Gergovia, the capital of the Arverni, he was informed that the Nitiobriges, or Agenois, were in arms; and that the Ædui were sending to Vercingetorix ten thousand men, which they were to have sent to reinforce Cæsar. Upon this news, he left Fabius to carry on the siege, and marched against Ædui. These, upon his approach, submitted, in appearance, and were pardoned; but soon after that whole nation rose up in arms, and murdered all the Italian troops in their capital. Cæsar, at this, was in great straits what measures to take; but resolved at length to raise the siege of Gergovia, and at once attack the enemy's camp, which he did with some success; but when he thought to have gone to Noviodunum, or Noyons, where his baggage, military chest, &c. were left, he heard that the Ædui had carried it off, and burnt the place. Labienus, justly thinking that Cæsar would want his assistance in the condition he now was, went to join him, and in his way defeated a Gaulish general named *Camulogeno*, who came to oppose his march: but this did not hinder the revolt from spreading itself all over the Celtic Gaul, whether Vercingetorix had sent for fresh supplies, and, in the mean time, attacked Cæsar; but was defeated, and forced to retire to Alesia, a strong place, now Alise in Burgundy, as is supposed. Hither Cæsar hastened, and besieged him; and, having drawn a double circumvallation, with a design to starve him in it, as he was likely to have done, upon that account refused all offers of a surrender from him. At length, the long expected reinforcement came, consisting of 160,000 men, under four generals: these made several fruitless attacks on Cæsar's trenches; but were defeated in three several battles, which at length obliged Vercingetorix to surrender at discretion. Cæsar used all his prisoners with great severity, except the Ædui and Arverni, by whose means he hoped to gain their nations, which were the most potent of the Celtic Gaul; nor was he disappointed; for both of them submitted to him, and the former received him into the capital, where he spent the winter, after he put his army into winter-quarters. This campaign as it proved one of the hardest he ever had, so he gained more glory by it than any Roman general had done before: yet could not at all by this procure from the servile senate, now wholly dedicated to his rival, a prolongation of his proconsulship; upon which he is reported to have laid his hand upon his sword, and said, that that should do it.

10
They are
again sub-
dued.

He was as good as his word; and the Gauls, upon their former ill success, resolving to have as many separate armies as provinces, in order to embarrass him

4 F

the

Gaul.

the more, Cæsar, and his generals Labienus and Fabius were forced to fight them one after another; which they did however, with such success, that, notwithstanding the hardness of the season, they subdued the Bituriges, Carnuti, Rhemi, and Bellovaci, with their general Correcus, by which he at once quieted all the Belgic provinces bordering on Celtic Gaul. The next who followed were the Treveri, the Eburones, and the Andes, under their general Dunmarus. The last place which held out against him was Uxellodunum; which was defended by the two last acting generals of the Gauls. Drapes, the Senonian, and Luterius the Cadurcean. The place being strong, and well garrisoned, Cæsar was obliged to march thither, from the farthest part of Belgic Gaul; and soon after reduced it, for want of water. Here again he caused the right hands of all that were fit to bear arms to be cut off, to deter the rest from revolting afresh. Thus was the conquest of Gaul finished from the Alps and Pyrenees to the Rhine, all which vast tract was now reduced to a Roman province under the government of a prætor. During his several expeditions into Gaul, Cæsar is said to have taken 800 cities; to have subdued 300 different nations; and to have defeated in several battles, three millions of men, of whom one million were killed, and another taken prisoners.—The history of the country, from the time of its conquest by the Romans to the present, is given under the article **ROME** and **FRANCE**.

11
Gaul reduced to a Roman province.

12
Character, &c. of the ancient Gauls:

The Gauls anciently were divided into a great number of different nations, which were continually at war with one another, and at variance among themselves. Cæsar tells us, that not only all their cities, cantons, and districts, but even almost all families, were divided and torn by factions; and thus undoubtedly facilitated the conquest of the whole. The general character of all these people was an excessive ferocity and love of liberty. This last they carried to such an extreme, that either on the appearance of servitude, or incapacity of action through old age, wounds, or chronic diseases, they put an end to their own lives, or prevailed upon their friends to kill them. In cities, when they found themselves so straitly besieged that they could hold out no longer, instead of thinking how to obtain honourable terms of capitulation, their chief care very often was to put their wives and children to death, and then to kill one another, to avoid being led into slavery. Their excessive love of liberty and contempt of death, according to Strabo, very much facilitated their conquest by Cæsar; for pouring their numerous forces upon such an experienced enemy as Cæsar, their want of conduct very soon proved the ruin of the whole.

The chief diversion of the Gauls was hunting; and indeed, considering the vast forests with which their country abounded, and the multitude of wild beasts which lodged in them, they were under an absolute necessity to hunt and destroy them, to prevent the country from being rendered totally uninhabitable. Besides this, however, they had also their hippodromes, horse and chariot races, tilts and tournaments; at all of which the bards assisted with their poems, songs, and musical instruments.—For an account of their religion, see the article **DRUID**.

The Gauls were excessively fond of feasting, in

which they were very profuse; as like all other northern nations, they were great lovers of good eating and drinking. Their chief liquors were beer and wine. Their tables were very low. They ate but little bread, which was baked flat and hard, and easily broken in pieces: but devoured a great deal of flesh, boiled, roasted, or broiled; and this they did in a very slovenly manner, holding the piece in their hands, and tearing it with their teeth. What they could not part by this way, they cut with a little knife which hung at their girdle. When the company was numerous, the *Coryphee*, or chief of the feast, who was either one of the richest, or noblest, or bravest, sat in the middle, with the master of the house by his side; the rest took their places next according to their rank, having their servants holding their shields behind them. These feasts seldom ended without bloodshed, but if by chance the feast proved a peaceable one, it was generally accompanied not only with music and songs, but likewise with dances, in which the dancers were armed cap-a-pee, and beat time with their swords upon their shields. On certain festivals they were wont to dress themselves in the skins of beasts, and in that attire accompany the processions in honour of their deities or heroes. Others dressed themselves in masquerade habits, some of them very indecent, and played several antic and immodest tricks. This last custom continued long after their conversion to Christianity.

Gaulanitis
||
Gauntlope.

GAULANITIS, or **GAULONITIS**, (Josephus); (anc. geog.) according to the different manner of writing the capital, *Galon* or *Gaulon*; the extreme part of Bashan to the south, and bordering on the tribe of Gad. It was divided into the Superior, which to the east extended to Arabia; and into the Inferior, which lay on the lake of Genesareth, (Josephus).

GAULON, or **GOLAN**, the capital of the Gaulanitis Superior; a Levitical city and place of refuge, (Moses, Joshua.)

GAULOS, (anc. geog.) a small island of Sicily, in the African sea, adjoining to Melite or Malta; with commodious harbours; a colony of Phœnicians, with a cognominal town. Gaulonitæ, the people, (Inscription). Now called *Gozo*, five miles to the west of Malta.

GAULTHERIA, in botany: A genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 18th order, *Bicornes*. The exterior calyx is diphyllous, the interior quinquefid; the corolla ovate; the nectarium consists of ten subulated points. The capsule is quinquelocular, covered with the interior calyx formed in the shape of a berry.

GAUNT-BELLIED, in the manege, is said of a horse whose belly shrinks up towards his flanks.

GAUNTLET. See **GANTLET**.

GAUNTLOPE, pronounced *Gauntlet*, a military punishment for felony, or some other heinous offence.

In vessels of war, it is executed in the following manner. The whole ship's crew is disposed in two rows, standing face to face on both sides of the deck, so as to form a line whereby to go *forward* on one side, and return *ast* on the other; each person being furnished with a small twisted chord, called a *knittle*, having two or three knots upon it. The delinquent is then stripped naked above the waist, and ordered to pass forward between

Gavies
||
Gause.

between the two rows of men, and aft on the other side, a certain number of times, rarely exceeding three; during which every person gives him a stripe as he runs along. In his passage through this painful ordeal, he is sometimes tripped up, and very feverely handled while incapable of proceeding. This punishment, which is called *running the gauntlet*, is seldom inflicted, except for such crimes as will naturally excite a general antipathy among the sea-men; as, on some occasions, the culprit would pass without receiving a single blow, particularly in cases of mutiny and sedition, to the punishment of which the sailors seem to have a constitutional aversion.

In the land-service, when a soldier is sentenced to run the gauntlope, the regiment is drawn out in two ranks facing each other; each soldier, having a switch in his hand, lashes the criminal as he runs along naked from the waist upwards. While he runs, the drums beat at each end of the ranks. Sometimes he runs three, five, or seven times, according to the nature of the offence. The major is on horseback, and takes care that each soldier does his duty.

GAVIES, or GAURS. See GABRES.

GAVOTTA, or GAVOTTE, is a kind of dance, the air of which has two brisk and lively strains in common time, each of which strains is twice played over. The first has usually four or eight bars; and the second contains eight, twelve, or more. The first begins with a minim, or two crotchets, or notes of equal value, and the hand rising; and ends with the fall of the hand upon the dominant or mediant of the mode, but never upon the final, unless it be a rondeau: and the last begins with the rise of the hand, and ends with the fall upon the final of the mode.

Tempi di Gavotta, is when only the time or movement of a gavotte is imitated, without any regard to the measure or number of bars or strains.—Little airs are often found in sonatas, which have this phrase to regulate their motions.

GAURA, in botany: A genus of the monogynia order, belonging to the octandria class of plants; and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is quadrid and tubular; the corolla pentapetalous, with the petals rising upwards. The nut is inferior, monospermous, and quadrangular.

GAUSE, or GAWSE, in commerce, a very thin, slight, transparent kind of stuff, woven sometimes of silk, and sometimes only of thread.—To warp the silk for making of gause, they use a peculiar kind of mill, upon which the silk is wound: this mill is a wooden machine about six feet high, having an axis perpendicularly placed in the middle thereof, with six large wings, on which the silk is wound from off the bobbins by the axis turning round. When all the silk is on the mill, they use another instrument to wind it off again on two beams: this done, the silk is passed through as many little beads as there are threads of silk; and thus rolled on another beam to supply the loom.

The gause-loom is much like that of the common weavers, though it has several appendages peculiar thereto. See LOOM.

There are figured gausfes; some with flowers of gold

and silver, on a silk ground: these last are chiefly brought from China.

GAY (John), a celebrated English poet, descended from an ancient family in Devonshire, was born at Exeter, and received his education at the free school of Barnstaple in that county, under the care of Mr William Rayner.—He was bred a mercer in the Strand; but having a small fortune independent of business, and considering the attendance on a shop as a degradation of those talents which he found himself possessed of, he quitted that occupation, and applied himself to other views, and to the indulgence of his inclination for the muses. In 1712 we find him secretary, or rather domestic steward, to the duchess of Monmouth, in which station he continued till the beginning of the year 1714; at which time he accompanied the earl of Clarendon to Hanover, whither that nobleman was dispatched by Queen Anne. In the latter end of the same year, in consequence of the queen's death, he returned to England, where he lived in the highest estimation and intimacy of friendship with many persons of the first distinction both in rank and abilities.—He was even particularly taken notice of by Queen Caroline, then princess of Wales, to whom he had the honour of reading in manuscript his tragedy of the *Captives*; and in 1726 dedicated his *Fables*, by permission, to the Duke of Cumberland.—From this countenance shown to him, and numberless promises made him of preferment, it was reasonable to suppose, that he would have been genteely provided for in some office suitable to his inclination and abilities. Instead of which, in 1727, he was offered the place of gentleman-usher to one of the youngest princesses; an office which, as he looked on it as rather an indignity to a man whose talents might have been so much better employed, he thought proper to refuse; and some pretty warm remonstrances were made on the occasion by his sincere friends and zealous patrons the duke and duchess of Queensberry, which terminated in those two noble personages withdrawing from court in disgust. Mr Gay's dependencies on the promises of the great, and the disappointments he met with, he has figuratively described in his fable of the *Hare with many friends*. However, the very extraordinary success he met with from public encouragement made an ample amends, both with respect to satisfaction and emolument, for those private disappointments.—For, in the season of 1727-8, appeared his *Beggar's Opera*; the vast success of which was not only unprecedented, but almost incredible.—It had an uninterrupted run in London of 63 nights in the first season, and was renewed in the ensuing one with equal approbation. It spread into all the great towns of England; was played in many places to the 30th and 40th time, and at Bath and Bristol 50; made its progress into Wales, Scotland, and Ireland, in which last place it was acted for 24 successive nights; and last of all it was performed at Minorca. Nor was the fame of it confined to the reading and representation alone, for the card-table and drawing-room shared with the theatre and closet in this respect; the ladies carried about the favourite songs of it engraven upon their fan-mounts, and screens and other pieces of furniture were decorated with the same. In short, the satire of this piece was so striking,

Gay.

Gay,
Gaza.

king, so apparent, and so perfectly adapted to the taste of all degrees of people, that it overthrew the Italian opera, that Dagon of the nobility and gentry, which had so long seduced them to idolatry, and which Dennis, by the labours and outcries of a whole life, and many other writers by the force of reason and reflection, had in vain endeavoured to drive from the throne of public taste. The profits of this piece were so very great, both to the author and Mr Rich the manager, that it gave rise to a quibble, which became frequent in the mouths of many, viz. *That it had made Rich gay, and Gay rich*; and it has been asserted, that the author's own advantages from it were not less than 2000*l*. In consequence of this success, Mr Gay was induced to write a second part to it, which he intitled *Polly*. But the disgust subsisting between him and the court, together with the misrepresentations made of him as having been the author of some disaffected libels and seditious pamphlets, occasioned a prohibition and suppression of it to be sent from the lord chamberlain, at the very time when every thing was in readiness for the rehearsal of it. A very considerable sum, however, accrued to him from the publication of it afterwards in quarto—Mr Gay wrote several other pieces in the dramatic way, and many very valuable ones in verse. Among the latter, his *Trivia*, or the *Art of walking the streets of London*, tho' his first poetical attempt, is far from being the least considerable, and is what recommended him to the esteem and friendship of Mr Pope: but as, among his dramatic works, his *Beggars Opera* did at first, and perhaps ever will, stand as an unrivalled master-piece, so, among his poetical works, his *Fables* hold the same rank of estimation, the latter having been almost as universally read as the former was represented, and both equally admired. Mr Gay's disposition was sweet and affable, his temper generous, and his conversation agreeable and entertaining. But he had one foible, too frequently incident to men of great literary abilities, and which subjected him at times to inconveniences which otherwise he needed not to have experienced, viz. an excess of indolence, without any knowledge of economy. So that, though his emoluments were, at some periods of his life, very considerable, he was at others greatly straitened in his circumstances; nor could he prevail on himself to follow the advice of his friend Dean Swift, whom we find in many of his letters endeavouring to persuade him to the purchasing of an annuity, as a reserve for the exigencies that might attend on old age.—Mr Gay chose rather to throw himself on patronage, than secure to himself an independent competency by the means pointed out to him; so that, after having undergone many vicissitudes of fortune, and being for some time chiefly supported by the liberality of the duke and duchess of Queensberry, he died at their house in Burlington-gardens, in December 1732. He was interred in Westminster-abbey, and a monument erected to his memory, at the expence of his aforementioned noble benefactors, with an inscription expressive of their regards and his own deserts, and an epitaph in verse by Mr Pope.

GAZA (Theodore), a famous Greek in the 15th century, was born in 1398. His country being invaded by the Turks, he retired into Italy; where he

at first supported himself by transcribing ancient authors, an employment the learned had frequent recourse to before the invention of printing. His uncommon parts and learning soon recommended him to public notice; and particularly to cardinal Bessarion, who procured him a benefice in Calabria. He was one of those to whom the revival of polite literature in Italy was principally owing. He translated from the Greek into Latin, Aristotle's History of Animals, Theophrastus on Plants, and Hippocrates's Aphorisms; and put into Greek, Scipio's Dream, and Cicero's Treatise on Old Age. He wrote several other works in Greek and Latin; and died at Rome in 1475.

GAZA, (anc. geog.), a principal city and one of the five satrapies of the Philistines. It was situated about 100 stadia from the Mediterranean, on an artificial mount, and strongly walled round. It was destroyed by Alexander the Great, and afterwards by Antiochus. In the time of the Maccabees it was a strong and flourishing city; but was destroyed a third time by Alexander Jannæus. At present it has a miserable appearance. The buildings are mean, both as to the form and matter. Some remains of its ancient grandeur appear in the handsome pillars of Parian marble which support some of the roofs; while others are disposed of here and there, in different parts of almost every beggarly cottage. On the top of the hill, at the north east corner of the town, are the ruins of large arches sunk low into the earth, and other foundations of a stately building, from whence some of the bashaws have carried off marble pillars of an incredible size. The castle is a contemptible structure, and the port is ruined. E. Long. 34. 55. N. Lat. 31. 28.

GAZE-HOUND, or *Cast-hound*, one that makes more use of his sight than of his nose. Such dogs are much used in the north of England: they are fitter in an open champaign country than in bushy and woody places. If at any time a well-taught gaze-hound takes a wrong way, he will return upon a signal and begin the chace afresh. He is also excellent at spying out the fattest of a herd; and having separated it from the rest, will never give over the pursuit till he has worried it to death.

GAZEL, in zoology, a species of CAPRA.

GAZETTE, a newspaper, or printed account of the transactions of all the countries in the known world in a loose sheet or half-sheet. This name is in England confined to that paper of news published by authority. The word is derived from *gazetta*, a Venetian coin, which was the usual price of the first newspaper printed there, and which was afterwards given to the paper itself.

The first gazette in England was published at Oxford, the court being there, in a folio half-sheet, Nov. 7. 1665. On the removal of the court to London, the title was changed to the *London Gazette*. The Oxford gazette was published on Tuesdays, the London on Saturdays: and these have continued to be the days of publication ever since.

GAZNA, a city of Asia, once much celebrated, and the capital of a very extensive empire; but which is now either entirely ruined, or become of so little consideration, that it is not taken notice of in our books

Gaza
Gazna.

Gazna.

books of geography.—This city was anciently an empery and fortrefs of Sableftan, not far from the confines of India. During the vast and rapid conquests of the Arabs, all this country had been reduced under their fubjection. On the decline of the power of the khalifs, however, the vast empire established by Mahomet and his fucceffors was divided into a number of independent principalities, moft of which were but of fhort duration. In the year of the Hegira 384, answering to the 994th of the Christian era, the city of Gazna, with fome part of the adjacent country, was governed by Mahmud Gazni; who became a great conqueror, and reduced under his fubjection a confiderable part of India, and moft of Perfia.

This empire continued in the family of Mahmud Gazni for upwards of 200 years. None of his fucceffors, however, were poffeffed of his abilities; and therefore the extent of the empire, inftead of increafing, was very confiderably diminished foon after Mahmud's death. The Seljuks made themfelves mafters of Khorafan, and could not be driven out; the greateft part of the Perfian dominions alfo fell off; and in the 547th year of the Hegira, the race of Gazni fultans were entirely fet afide by one Gauri, who conquered Khofru Shah the reigning prince, and beftowed his dominions on his own nephew Gayathoddin Mohammed. Thefe new fultans proved greater conquerors than the former, and extended their dominions farther than even Mahmud Gazni himfelf had done. They did not, however, long enjoy the fovereignty of Gazna; for in 1218, Jenghiz Khan having conquered the greateft part of China and almoft all Tartary, began to turn his arms weftward; and fet out againft the fultan of Gazna at the head of 700,000 men.

To oppofe this formidable army, Mohammed, the reigning fultan, could mufter only 400,000 men; and, in the firft battle, 160,000 of his troops are faid to have perifhed. After this victory, Jenghiz Khan advanced; Mohammed not daring to risk a fecond battle, the lofs of which would have been attended with the entire ruin of his kingdom. He therefore diftributed his army among the ftrongeft fortified towns he had in his dominions; all of which Jenghiz Khan took one after another. The rapid progrefs of his conquests, indeed, almoft exceeds belief. In 1219 and 1220, he had reduced Zarnuk, Nur, Bokhara, Otrar, Saganak, Uzkant, Alhafh, Jund Tonkat, Khojend, and Samarcand.—Mohammed, in the mean time, fled firft to Bokhara; but on the approach of Jenghiz Khan's army, quitted that place, and fled to Samarcand. When this laft city was alfo in danger of being invefted, the fultan did not think proper to truft himfelf in it more than in the other, though it was garrifoned by 110,000 of his braveft troops; and therefore fled through byways into the province of Ghilan in Perfia, where he took refuge in a ftrong fortrefs called *Eftabad*. But being alfo found out in this retreat, he fled to an ifland in the Cafpian fea called *Abifkum*; where he ended his days, leaving his empire, fuch as it was, to his fon Jaloloddin.

The new fultan was a man of great bravery and experience in war; but nothing was able to flop the progrefs of the Moguls. In 1220 and 1221, they made themfelves mafters of all the kingdoms of Karazim and Khorafan, committing every where fuch mafacres as

were never heard of before or fince that time. In the mean time Jaloloddin affembled his forces with the utmoft diligence, and defeated two detachments of the Mogul army. This happened while Jenghiz Khan was befieging Bamiyan; but answered little other purpofe, than ferving to bring upon that city the terrible defftruction, of which an account is given under the article BAMIYAN. Immediately after the reduction of that city, Jenghiz Khan marched towards Gazna; which was very ftrongly fortified, and where he expected to have found Jaloloddin. But he had left the place 15 days before; and, as Jenghiz Khan's army was much reduced, he might perhaps have ftood his ground, had it not been for an accident. He had been lately joined by three Turkish commanders, each of whom had a body of 10,000 men under his command. After his victories over the Moguls, thefe officers demanded the greateft fhare of the fpoils; which being refufed, they feparated themfelves from the fultan. He ufed his utmoft endeavours to make them hearken to reafon; and fent feveral meffages and letters to them, representing the inevitable ruin which muft attend their feparation, as Jenghiz Khan was advancing againft them with his whole army. At laft they were perfuaded to lay afide their animofities: but it was now too late; for Jenghiz Khan, being informed of what paffed, detached 60,000 horfe to prevent their joining the fultan's army; who, finding himfelf deprived of this powerful aid, retired towards the river Indus. When he was arrived there, he ftopped in a place where the fream was moft rapid and the place confined, with a view both to prevent his foldiers from placing any hopes of fafety in flight, and to hinder the whole Mogul army from attacking him at once. Ever fince his departure from Gazna he had been tormented with a colic: yet, at a time when he fuffered moft, hearing that the enemy's vanguard was arrived at a place in the neighbourhood called *Herder*, he quitted his litter, and, mounting a horfe, marched with fome of his chofen foldiers in the night; furprifed the Moguls in their camp; and having cut them almoft all in pieces, without the lofs of a fingle man on his fide, returned with a confiderable booty.

Jenghiz Khan, finding by this that he had a vigilant enemy to deal with, proceeded with great circumfpection. When he came near the Indus, he drew out his army in battalia: to Jagatay, one of his fons, he gave the command of the right wing; to Oktay, another fon, he gave the command of the left: and put himfelf in the centre, with 6000 of his guards. On the other fide, Jaloloddin prepared for battle like one who had no resource but in victory. He firft fent the boats on the Indus farther off; referving only one to carry over his mother, wife, and children: but unluckily the boat fplit when they were going to embark, fo that they were forced to remain in the camp. The fultan took to himfelf the command of the main body of the army. His left wing, drawn up under fhelter of a mountain which hindered the whole right wing of the Moguls from engaging at once, was commanded by his vizir; and his right by a lord named *Amin Malek*. This lord began the fight; and forced the enemy's left wing, notwithstanding the great disparity of numbers, to give ground. The right wing of the

Gazna.

Mo.

Gazna. Moguls likewise wanting room to extend itself, the sultan made use of his left as a body of reserve, detaching from thence some squadrons to the assistance of the troops who stood in need of them. He also took one part of them with him when he went at the head of his main body to charge that of Jenghiz Khan; which he did with so much resolution and vigour, that he not only put it in disorder, but penetrated into the place where Jenghiz Khan had originally taken his station: but that prince, having had a horse killed under him, was retired from thence, to give orders for all the troops to engage.

This advantage had like to have lost the Moguls the battle; for a report being immediately spread that the enemy had broken through the main body, the troops were so much discouraged, that they would certainly have fled had not Jenghiz Khan encouraged them by riding from place to place in order to show himself. At last, however, Jaloloddin's men, who were in all but 30,000, having fought a whole day with ten times their number, were seized with fear, and fled. One part of them retired to the rocks which were on the shore of Indus, where the enemy's horse could not follow them; others threw themselves into the river, where many were drowned, though some had the good fortune to cross over in safety; while the rest, surrounding their prince, continued the fight through despair. The sultan, however, considering that he had scarce 7000 men left, began to think of providing for his own safety: therefore, having bidden a final adieu to his mother, wife, and children, he mounted a fresh horse, and spurred him into the river, which he crossed in safety, and even stopped in the middle of it to insult Jenghiz Khan, who was now arrived at the bank. His family fell into the hands of the Moguls; who killed all the males, and carried the women into captivity.

Jaloloddin being now securely landed in India, got up into a tree, in order to preserve himself from wild beasts. Next day, as he walked melancholy among the rocks, he perceived a troop of his soldiers, with some officers, three of whom proved to be his particular friends. These, at the beginning of the defeat, had found a boat in which they had sailed all night, with much danger from the rocks, shelves, and rapid current of the river. Soon after, he saw 300 horse coming towards him; who informed him of 4000 more that had escaped by swimming over the river; and these also soon after joined the rest. In the mean time an officer of his household, named *Jamalarrazad*, knowing that his master and many of his people were escaped, ventured to load a very large boat with arms, provisions, money, and stuff to clothe the soldiers; with which he crossed the river. For this important service Jaloloddin made him steward of his household, and surnamed him the *Chosen*, or the *Glory of the faith*. For some time after, the sultan's affairs seemed to go on prosperously: he gained some battles in India; but the princes of that country, envying his prosperity, conspired against him, and obliged him to repass the Indus. Here he again attempted to make head against the Moguls; but was at last defeated and killed by them, and a final end put to the once mighty empire of Gazna.

The metropolis was reduced by Oktay; who no sooner entered the country in which it was situated, than he committed the most horrid cruelties. The city was well provided with all things necessary for sustaining a siege; had a strong garrison, and a brave and resolute governor. The inhabitants, expecting no mercy from Jenghiz Khan, who they knew had sworn their ruin, were resolved to make a desperate defence. They made frequent sallies on the besiegers, several times overthrew their works, and broke above 100 of their battering rams. But one night, after an obstinate fight, part of the city walls fell down; and a great number of Moguls having filled up the ditch, entered the city sword in hand. The governor perceiving all was lost, at the head of his bravest soldiers rushed into the thickest of his enemies, where he and his followers were all slain. However, Gazna was not entirely destroyed, nor were the people all killed; for after the massacre had continued four or five hours, Oktay ordered it to cease, and taxed those who were left alive at a certain rate, in order to redeem themselves and the city. It does not, however, appear that after this time the city of Gazna ever made any considerable figure.—It was taken by the Moguls in the year 1222.

GEBRES. See GABRES.

GECCO, in natural history, a name given by the Indians to their terrible poison, which kills when mixed with the blood in ever such a small quantity. They say that this gecco is a venomous froth or humour vomited out of the mouths of their most poisonous serpents; which they procure in this fatal strength, by hanging up the creatures by the tails, and whipping them to enrage them: they collect this in proper vessels as it falls, and when they would use it, they either poison a weapon with it, or wounding any part of the flesh introduce the smallest quantity imaginable into it; and this is said to be immediate death.

GECKO. See LACERTA.

GED (William), an ingenious though unsuccessful artist, who was a goldsmith in Edinburgh, deserves to be recorded for his attempt to introduce an improvement in the art of printing. The invention, first practised by Ged in 1735, was simply this. From any types of Greek or Roman, or any other character, he formed a plate for every page, or sheet, of a book, from which he printed, instead of using a type for every letter, as is done in the common way. This was first practised, but on blocks of wood, by the Chinese and Japanese, and pursued in the first essays of Coster the European inventor of the present art. "This improvement (says James Ged the inventor's son) is principally considerable in three most important articles, viz. expence, correctness, beauty and uniformity." But these improvements were controverted.

In July 1729, William Ged entered into partnership with William Fenner, a London stationer, who was to have half the profits, in consideration of his advancing all the money requisite. To supply this, Mr John James, then an architect at Greenwich (who built Sir Gregory Page's house, Bloomsbury church, &c.) was taken into the scheme, and afterwards his brother Mr Thomas James, a letter-founder, and James Ged the inventor's son. In 1730, these partners applied to the university of Cambridge for printing bibles and

Geddes and common-prayer books by blocks instead of single types; and, in consequence, a lease was sealed to them April 23d 1731. In their attempt they sunk a large sum of money, and finished only two prayer-books; so that it was forced to be relinquished, and the lease was given up in 1738. Ged imputed his disappointments to the villainy of the pressmen and the ill treatment of his partners (which he specifies at large), particularly Fenner, whom John James and he were advised to prosecute, but declined it. He returned to Scotland in 1733, where he gave his friends a specimen of his performance, by an edition of Sallust. But being still unsuccessful, and having failed in obtaining redress from Fenner, who died insolvent, he was preparing again to set out for London, in order to join with his son James as a printer there, when he died October 19. 1749. Thus ended his life and project; which, ingenious as it seems, is not likely to be revived, if, as Mr Mores suggests, "it must, had it first succeeded, have soon sunk under its own burden," for reasons here needless to recapitulate.

GEDDES (James), born of a respectable family in Scotland in 1610, was educated for and practised at the bar several years; but died of a consumption before he arrived at the age of 40. He published *An essay on the composition and manner of writing of the ancients*; and left behind him several other tracts.

GEHENNA, a scripture term, which has given some pain to the critics. It occurs in St Mathew v. 22. 29. 30. x. 28. xviii. 9. xxiii. 15. 33. Mark ix. 43. 45. 47. Luke xii. 5. James iii. 6.

The authors of the Louvain and Geneva versions retain the word *gehenna* as it stands in the Greek; the like does M. Simon: the English translators render it by *hell* and *hell fire*, and so do the translators of Mons and father Bohours.

The word is formed from the Hebrew *gehinnom*, i. e. "valley of Hinnom." In that valley, which was near Jerusalem, there was a place named *Tophet*, where some Jews sacrificed their children to Moloch, by making them pass through the fire. King Josias, to render this place for ever abominable, made a cloaca or common sewer thereof, where all the filth and carcases in the city were cast.

The Jews observe further, that there was a continual fire kept up there, to burn and consume, these carcases; for which reason, as they had no proper term in their language to signify *hell*, they made use of that of *gehenna* or *gehinnom*, to denote a fire unextinguishable.

GELA (anc. geog.), a city of great extent on the south of Sicily, taking its name from the river Gelas, which washes it. It was built by colonists from Rhodes and Crete, 45 years after the building of Syracuse, or in the third year of the 22d Olympiad, 690 before Christ; originally called *Lindii*, from the colonists of *Lindus*, a city of Rhodes, who settled there first. Now *Terranuova*, and the river called *Fiume di Terranuova*. The people were called *Geloi*, *Gelenses*, and *Gelani*. The City Gela, after having stood 408 years, was destroyed by Phintias, the tyrant of Agrigentum; and the inhabitants were removed to a new city, called *Phintias* after his name.

GELATINA, JELLY. See **JELLY**.

GELATINOUS, among the physicians, is applied

to any thing approaching to the glutinous consistence of a jelly.

GELD, in the English old customs, a Saxon word signifying *money*, or *tribute*. It also denoted a compensation for some crime committed: Hence *wergeld*, in their ancient laws, was used for the value of a man slain; and *orfgeld*, of a beast.

GELDENHAUR (Gerard), in Latin *Geldenkarius*, an historian and Protestant divine in the 16th century. He was a native of Nimeguen, and studied classical learning at Deventer. He went through his course of philosophy at Louvaine, where he contracted a very strict friendship with several learned men, and particularly with Erasmus. He became reader and historian to Charles of Austria, and afterwards to Maximilian of Burgundy. At length he embraced the Protestant religion; taught history at Marburg; and afterwards divinity till his death, in 1542. He wrote, 1. History of Holland. 2. History of the Low Countries; 3. History of the Bishops of Utrecht: and other works.

GELDERLAND. See **GUELDERLAND**.

GELDERS. See **GUELDERLAND**.

GELDING, the operation of castrating any animal, particularly horses.

If the operation is to be performed on a colt, he may be gelded at nine or fifteen days old, if the testicles be come down: in regard the sooner he is gelt the better it will be for his growth, shape, and courage; though a horse may be gelt at any age, if proper care is taken in the cure.

The manner of gelding is as follows. The beast being cast down on some soft place, the operator takes the stones between his foremost and his great finger, and slitting the cod presses the stones forth; then taking a pair of nippers made very smooth, either of steel, box, or brazil-wood, he claps the strings of the stones between them, very near to where the stones are set on, and presses them so hard that there may be no flux of blood; then with a thin, drawing, cauterising iron, sears away the stone. This done, he takes a hard plaster made of rosin, wax, and washed turpentine, well dissolved together, and melts it on the head of the strings: he then sears them, and melts more of the salve, till such time as he has laid a good thickness of it upon the strings.

When is this done to one stone, the nippers are loosened, and the like is done to the other; and the two slits of the cod are then filled with white salt, and the outside of the cod is anointed with hog's grease: and thus they let him rise, and keep him in a warm stable, without tying him up. If he swells much in his cods or sheath, they chase him up and down, and make him trot for an hour in a day, which soon recovers him.

The manner of gelding a hog is as follows: The operator, after having made two cross slits or incisions on the midst of the stones, presses them out, and anoints the sore with tar. But another general method, yet somewhat more dangerous if not well done, is, first to cut the stone on the top, and after having drawn that one forth, the operator puts in his fingers at the same slit, and with a lancet cuts the skin between the two stones, and by that slit presses out the other.

other stone. Then having cleansed out the blood, he anoints the part with fresh grease: and thus there is but one incision made in the cod. Boar-pigs ought to be gelt about six months old; yet they are commonly gelded about three weeks or a month old.

GELE'E (Claude). See CLAUDE.

GELENHAUSEN, a small imperial town of Wetteravia in Germany, with a castle built by the emperor Frederic I. E. Long. 8. 13. N. Lat 50. 20.

GELENIUS (Sigismund), a learned and excellent man born of a good family at Prague, about the year 1498. Erasmus conceiving an esteem for him at Basil, recommended him to John Frobenius as a corrector for his printing-house; which laborious charge he accepted, and had a great number of Hebrew, Greek, and Latin books to correct: he also translated many works himself from the Greek into Latin; and published a dictionary in four languages, Greek, Latin, German, and Slavonian. Profitable and honourable employments were offered him in other places, but nothing could tempt him to quit his peaceful situation at Basil. He died in 1555. All his translations are highly esteemed.

GELINOTTE, or GRUS, in ornithology. See TETRAO.

GELLERT (Christian), one of the finest geniuses Germany has produced, was born at Hænichen, near Freyburgh in Saxony, in 1715, and studied at Leipzig; at which university he was for many years professor of philosophy and the belles lettres. He early distinguished himself by his talent for poetry; and contracted a strict friendship with the most learned and polite writers in Germany. All his works are filled with sentiment, and bear the impression of the sweetness of his disposition. The most considerable of them are his comedies, his spiritual songs, and moral poems, and particularly his sacred odes, his fables, and his tales. He died in 1769, much lamented.

GELLI (John Baptist), an eminent Italian writer, was born of mean parents at Florence, in the year 1498. He was bred a taylor: but had such an extraordinary genius, that he acquired several languages, and made an uncommon progress in the belles lettres; and though he continued always to work at his trade, became acquainted with all the wits and learned men at Florence, and his merit was universally known. He was chosen a member of the academy there, and the city made him a burges. He acquired the highest reputation by his works, which are. 1. *I. Caprici del Bottaino*, quarto; which contains ten dialogues. 2. *La Circe*, octavo. This, which also contains ten dialogues, and treats of human nature, has been translated into Latin, French, and English. 3. Dissertations in Italian on the poems of Dante and Petrarch. 4. The comedies of *La Sporta* and *La Errore*; and other works. He died in 1563.

GELLIBRAND (Henry) a laborious astronomer of the last century, was born in 1597. Though he was not without good views in the church, yet he became so enamoured with mathematical studies, that on the death of his father he became a student at Oxford, contented himself with his private patrimony, and devoted himself solely to them. On the death of Mr Gunter, he was recommended by Mr Briggs to the trustees of Gresham college, for the astronomical professorship there; to which he was elected in 1627.

His friend Mr Briggs dying in 1630, before he had finished his *Trigonometrica Britannica*, it was finished by Gellibrand at his request. He wrote several other things chiefly tending to the improvement of navigation: and died in 1636.

GELLIUS (Aulus), a celebrated grammarian, who lived in the 2d century under Marcus Aurelius and some succeeding emperors. He wrote a collection of observations on authors, for the use of his children; and called it *Noctes Atticae*, because composed in the evenings of a winter he spent at Athens. The chief value of it, is for preserving many facts and monuments of antiquity not to be found elsewhere. Critics and grammarians have bestowed much pains on this writer.

GELLY. See JELLY.

GELO, or GELON, a son of Dinomenes who made himself absolute at Syracuse 484 years before the Christian era. He conquered the Carthaginians at Himera, and made his oppression popular by his great equity and moderation. He reigned seven years, and his death was universally lamented at Syracuse. He was called the father of his people, and the patron of liberty, and honoured as a demigod. His brother Hiero succeeded him. See SYRACUSE.

GEM, in natural history, a common name for all precious stones; of which there are two classes, the pellucid and semipellucid.

The bodies composing the class of pellucid gems are bright, elegant, and beautiful fossils, naturally and essentially compound, ever found in small detached masses, extremely hard, and of great lustre.

The bodies composing the class of semipellucid gems, are stones naturally and essentially compound, not inflammable nor soluble in water, found in detached masses, and composed of crystalline matter debased by earth: however, they are but slightly debased, and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

The knowledge of gems depends principally on observing their hardness and colour. Their hardness is commonly allowed to stand in the following order: The diamond the hardest of all; then the ruby, sapphire, jacinth, emerald, amethyst, garnet, carneol, chalcedony, onyx, jasper, agate, porphyry, and marble. This difference, however, is not regular and constant, but frequently varies. Good crystals may be allowed to succeed the onyx; but the whole family of metallic glassy fluors seem to be still softer.—In point of colour, the diamond is valued for its transparency, the ruby for its purple, the sapphire for its blue, the emerald for its green, the jacinth for its orange, the amethyst carneol for its carnation, the onyx for its tawny, the jasper, agate, and porphyry, for their vermilion, green, and variegated colours, and the garnet for its transparent blood-red.

All these gems are sometimes found coloured and spotted, and sometimes quite limpid and colourless. In this case the diamond-cutter or polisher knows how to distinguish their different species by their different degrees of hardness upon the mill. For the cutting or polishing of gems, the fine powder of the fragments of those that are next in degree of hardness is always required to grind away the softer; but as none of them are harder than the diamond, this can only be polished by its own powder.

Gellius
||
Gems.

Gem.

Cronstedt observes of gems in general, that the colour of the ruby and emerald are said to remain in the fire, while that of the topaz flies off: hence it is usual to burn the topaz, and thence substitute it for the diamond. "Their colours (says our author) are commonly supposed to depend upon metallic vapours; but may they not more justly be supposed to arise from a phlogiston united with a metallic or some other earth? because we find that metallic earths which are perfectly well calcined give no colour to any glass; and that the manganese, on the other hand, gives more colour than can be ascribed to the small quantity of metal which is to be extracted from it." M. Magellan is of opinion, that their colour is owing chiefly to the mixture of iron which enters their composition; but approves the sentiment of Cronstedt, that phlogiston has a share in their production, it being well known that the calces of iron when dephlogisticated produce the red and yellow colours of marble, and when phlogisticated to a certain degree produce the blue or green colours.

With regard to the texture of gems, M. Magellan observes, that all of them are foliated or laminated, and of various degrees of hardness. Whenever the edges of these laminæ are sensible to the eye, they have a fibrous appearance, and reflect various shades of colour, which change successively according to their angular position to the eye. These are called by the French *chatoyantes*; and what is a blemish in their transparency, often enhances their value on account of their scarcity. But when the substance of a gem is composed of a broken texture, consisting of various sets of laminæ differently inclined to each other, it emits at the same time various irradiations of different colours, which succeed one another according to their angle of position. This kind of gems has obtained the name of *opals*, and are valued in proportion to the brilliancy, beauty, and variety of their colours. Their crystallization, no doubt, depends on the same cause which produces that of salts, earths, and metals, which is treated of under the article CRYSTALLIZATION: but as to the particular configuration of each species of gems, we can hardly depend upon any individual form as a criterion to ascertain each kind; and when we have attended with the utmost care to all that has been written on the subject, we are at last obliged to appeal to chemical analysis, because it very often assumes various forms. The following table shows the component parts of gems according to the analysis of Bergman and M. Achard; the letter B prefixed to each denoting Bergman's analysis, and A that of Achard.

VOL. VII.

Gem.

The chrysopease from Koscinitz in Silesia was likewise analysed by M. Achard; who found that it contained 456 grains of siliceous earth, 13 of calcareous, 6 of magnesia, 3 of copper, and 2 of iron. "This (says M. Magellan) seems to be the only gem that contains no argillaceous earth."

Imitation or Counterfeiting of GEMS in Glass. The art of imitating gems in glass is too considerable to be passed without notice: some of the leading compositions therein we shall mention upon the authority of Neri and others.

These gems are made of pastes; and are noway inferior to the native stones, when carefully made and well polished, in brightness or transparency, but want their hardness.

The general rules to be observed in making the pastes are these: 1. That all the vessels in which they are made be firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels be chosen for the work as will bear the fire well. 3. That the powders be prepared on a porphyry stone; not in a metal mortar, which would communicate a tinge to them. 4. That the just proportion in the quantity of the several ingredients be nicely observed. 5. That the materials be all well mixed; and, if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot: for if this be not observed, they will be full of blisters and air-bladders. 6. That a small vacuity be always left at the top of the pot, to give room to the swelling of the ingredients.

To make paste of extreme hardness, and capable of all the colours of the gems, with great lustre and beauty.—Take of prepared crystal ten pounds: salt of pulverine, six pounds; sulphur of lead, two pounds; mix all these well together into a fine powder; make the whole with common water into a hard paste; and make this paste into small cakes of about three ounces weight each, with a hole made in their middle; dry them in the sun, and afterwards calcine them in the straitest part of a potter's furnace. After this, powder them, and levigate them to a perfect fineness on a porphyry-stone, and set this powder in pots in a glass-furnace to purify for three days: then cast the whole into water, and afterwards return it into the furnace; where let it stand 15 days, in which time all foulness and blisters will disappear, and the paste will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brass thrice calcined; for a sea-green, brass simply calcined to a redness; for a sapphire, add zaffer, with manganese; and for a topaz, manganese and tartar. All the gems are thus imitated in this, by the same way of working as the making of coloured glasses: and this is so hard, that they very much approach the natural gems.

The colour of all the counterfeit gems made of the several pastes, may be made deeper or lighter, according to the work for which the stones are designed; and it is a necessary general rule, that small stones for rings, &c. require a deeper colour, and large ones a paler. Besides, the colours made from manganese, verdegris, and zaffer, which are the ingredients commonly used, there are other very fine ones which care and skill

4 G

may

Gem. may prepare. Very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from brass or copper; a sky-colour from silver, and a much finer one from the granates of Bohemia.

A very singular and excellent way of making the paste to imitate the coloured gems in this: Take a quantity of saccharum saturni, or sugar of lead, made with vinegar in the common way; set it in sand, in a glass body well luted from the neck downwards; leave the mouth of the glass open, and continue the fire 24 hours; then take out the salt, and if it be not red but yellowish, powder it fine, and return it into the vessel, and keep it in the sand-heat 24 hours more, till it becomes as red as cinnabar. The fire must not be made so strong as to melt it, for then all the process is spoiled. Pour distilled vinegar on this calcined salt, and separate the solution from the dregs; let the decanted liquor stand six days in an earthen vessel, to give time for the finer sediment to subside; filter this liquor, and evaporate it in a glass body, and there will remain a most pure salt of lead; dry this well, then dissolve it in fair water; let the solution stand six days in a glazed pan; let it subside, then filter the clear solution, and evaporate it to a yet more pure white and sweet salt; repeat this operation three times; put the now perfectly pure salt into a glass vessel, set it in a sand-heat for several days, and it will be calcined to a fine impalpable powder, of a lively red. This is called *the sulphur of lead*.

Take all the ingredients as in the common composition of the pastes of the several colours, only instead of red lead, use this powder; and the produce will well reward the trouble of the operation, as experience has often proved.

A paste proper for receiving colours may be readily made by well-pounding and mixing six pounds of white sand cleansed, three pounds of red lead, two pounds of purified pearl-ashes, and one pound of nitre. A softer paste may be made in the same manner, of six pounds of white sand cleansed; red lead, and purified pearl-ashes, of each three pounds; one pound of nitre, half a pound of borax, and three ounces of arsenic. For common use a pound of common salt may be substituted for the borax. This glass will be very soft, and will not bear much wear if employed for rings, buckles, or such imitations of stones as are exposed to much rubbing; but for ear-rings, ornaments worn on the breast, and those little used, it may last a considerable time.

In order to give paste different colours, the process is as follows. For

Amethyst. Take ten pounds of either of the compositions described under *Colouring of GLASS*, one ounce and a half of manganese, and one dram of zaffer; powder and fuse them together.

Black. Take ten pounds of either of the compositions just referred to, one ounce of zaffer, six drams of manganese, and five drams of iron, highly calcined; and proceed as before.

Blue. Take of the same composition ten pounds; of zaffer six drams; and of manganese two drams; and proceed as with the foregoing.

Chrysolite. Take of either of the compositions for paste above described, prepared without saltpetre, ten

pounds, and of calcined iron five drams; and pursue the same process as with the rest.

Red Cornelian. Take of the compositions mentioned under *Colouring of GLASS* two pounds; of glass of antimony one pound; of the calcined vitriol called *scarlet oker* two ounces; and of manganese one dram. Fuse the glass of antimony and manganese with the composition; then powder them, and mix them with the other, by grinding them together, and fuse them with a gentle heat.

White Cornelian. Take of the composition just referred to two pounds; and of yellow oker well washed two drams; and of calcined bones one ounce. Mix them, and fuse them with a gentle heat.

Diamond. Take of the white sand six pounds; of red-lead four pounds; of pearl ashes purified three pounds; of nitre two pounds; of arsenic five ounces; and of manganese one scruple. Powder and fuse them.

Eagle-marine. Take ten pounds of the composition under *GLASS*; three ounces of copper highly calcined with sulphur; and one scruple of zaffer. Proceed as before.

Emerald. Take of the same composition with the last nine pounds; three ounces of copper precipitated from aquafortis; and two drams of precipitated iron. See *EMERALD*.

Garnet. Take two pounds of the composition under *GLASS*; two pounds of the glass of antimony, and two drams of manganese. For vinegar garnet, take of the composition for paste, described in this article, two pounds; one pound of glass of antimony, and half an ounce of iron, highly calcined; mix the iron with the uncoloured paste, and fuse them; then add the glass of antimony powdered, and continue them in the heat till the whole is incorporated.

Gold or full yellow. Take of the composition for paste ten pounds, and one ounce and a half of iron strongly calcined; proceeding as with the others.

Deep purple. Take of either of the compositions for paste ten pounds; or manganese one ounce; and of zaffer half an ounce.

Ruby. Take one pound of either of the compositions for paste, and two drams of *calx cassii*, or precipitation of gold by tin; powder the paste, and grind the calx of gold with it in a glass, flint, or agate mortar, and then fuse them together. A cheaper ruby paste may be made with half a pound of either of the above compositions, half a pound of glass of antimony, and one dram and a half of the calx of gold; proceeding as before.

Sapphire. Take of the composition for paste ten pounds: of zaffer three drams and one scruple; and of the *calx Cassii* one dram. Powder and fuse them. Or the same may be done, by mixing with the paste one-eighth of its weight of smalt.

Topaz. Take of the compositions under *GLASS* ten pounds, omitting the saltpetre; and an equal quantity of the *Gold-coloured hard GLASS*. Powder and fuse them. See *TOPAZ*.

Turquoise. Take of the composition for blue paste already described, ten pounds; of calcined bone horn, or ivory, half a pound. Powder and fuse them.

Opake white. Take of the composition for paste ten pounds; and one pound of calcined horn, ivory, or bone; and proceed as before.

Semitransparent white, like opal. See *OPAL*.

Gem.

Gem.

To the above we shall add the following receipts and processes, contained in a Memoir by M. Fontanieu of the Royal Academy of Sciences at Paris, and said to have met with much approbation.

I. *Of the Bases.* Although the different calces of lead are all adapted to produce the same effect in vitrification; yet M. Fontanieu prefers lead in scales, and next to that minium, as being the most constantly pure. It is necessary to sift through a silk sieve the preparations of lead one wishes to make use of in the vitrification, in order to separate the grosser parts, as also the lead found in a metallic state when white lead in scales is employed.

The base of factitious gums is calx of lead and rock-crystal, or any other stone vitrifiable by the calces already mentioned. Pure sand, flint, and the transparent pebbles of rivers, are substances equally fit to make glass: but as it is first necessary to break the masses of crystal, stones, or pebbles, into smaller parts; so by this operation particles of iron or copper are frequently introduced, and to these dust or greasy matters are also apt to adhere. Our author therefore begins by putting the pounded crystal or pebbles into a crucible, which he places in a degree of heat capable of making the mass red-hot; he then pours it into a wooden bowl filled with very clear water; and shaking the bowl from time to time, the small portions of coals furnished by the extraneous bodies swim on the surface of the water, and the vitrifiable earth, with the iron, &c. rests on the bottom. He then decants the water; and having dried the mass, he pounds it, sifts the powder through the finest silk sieve: he then digests the powder during four or five hours with marine acid, shaking the mixture every hour. After having decanted the marine acid from the vitrifiable earth, he washes the latter until the water no longer reddens the tincture of tournsol. The said earth being dried, is passed through a silk sieve, and is then fit for use. Nitre, salt of tartar, and borax, are the three species of salts that enter with quartz and the several calces of lead into M. Fontanieu's vitrifications.

Much of the success in the art of making coloured stones depends on the accurate proportion of the substances made use of to form the crystal which serves as a base to the factitious stones. After having tried a great variety of receipts, our author found they might be reduced to the following.

1. Take two parts and a half of lead in scales, one part and a half of rock-crystal or prepared flints, half a part of nitre, as much borax, and a quarter part of glass of arsenic. These being well pulverised and mixed together, are to be put into a Hessian crucible, and submitted to the fire. When the mixture is well melted, pour it into cold water: then melt it again a second and a third time; taking care, after each melting, to throw it into fresh cold water, and to separate from it the lead that may be revived. The same crucible should not be used a second time, because the glass of lead is apt to penetrate it in such a manner as to run the risk of losing the contents. One must also be careful to cover the crucible well, to prevent any coals getting into it, which would reduce the calx of lead, and spoil the composition.

2. Take two parts and a half of white ceruss, one

part of prepared flints, half a part of salt of tartar, and a quarter part of calcined borax: melt the mixture in a Hessian crucible, and then pour it into cold water; it is then to be melted again, and washed a second and a third time, the same precautions being observed as for the first base.

3. Take two parts minium, one part rock-crystal, half a part of nitre, and as much salt of tartar: this mixture being melted, must be treated as the former.

4. Take three parts of calcined borax, one part of prepared rock-crystal, and one part of salt of tartar; these being well mixed and melted together, must be poured into warm water: the water being decanted and the mass dried; an equal quantity of minium must be added to it; it is then to be melted and washed several times as directed above.

5. That called by our author the *Mayence base*, and which he considers as one of the finest crystalline compositions hitherto known, is thus composed: Take three parts of fixed alkali of tartar, one part of rock-crystal or flint pulverized: the mixture to be well baked together, and then left to cool. It is afterwards poured into a crucible of hot water to dissolve the fritt; the solution of the fritt is then received into a stone-ware pan, and aquafortis added gradually to the solution till it no longer effervesces: this water being decanted, the fritt must be washed in warm water till it has no longer any taste: the fritt is then dried, and mixed with one part and a half of fine ceruss or white lead in scales; and this mixture must be well levigated with a little distilled water. To one part and a half of this powder dried add an ounce of calcined borax: let the whole be well mixed in a marble mortar, then melted and poured into cold water as the other bases already described. These fusions and lotions having been repeated, and the mixture dried and powdered, a 12th part of nitre must be added to it, and then melted for the last time; when a very fine crystal will be found in the crucible.

6. As a composition for furnishing very fine white stones: Take eight ounces of ceruss, three ounces of rock-crystal pulverised, two ounces of borax finely powdered, and half a grain of manganese; having melted and washed this mixture in the manner directed above, it will produce a very fine white crystal.

II. *Of the Colours.* The calces of metals, as already observed, are the substances employed to colour factitious gems; and on the preparation of these calces depends the vividness of their colours.

a, *From Gold.*] To obtain the mineral purple known by the name of *precipitate of Cassius*, M. Fontanieu employs the following processes.

1. Dissolve some pure gold in aqua regia, prepared with three parts of precipitated nitrous acid and one part of marine acid; and to hasten the dissolution, the matras should be placed in a sand-bath. Into this solution pour a solution of tin in aqua regia. The mixture becomes turbid, and the gold is precipitated with a portion of the tin, in the form of a reddish powder; which, after being washed and dried, is called *precipitate of Cassius*.—The aqua regia employed to dissolve the tin is composed of five parts nitrous acid and one part of marine acid: to eight ounces of this aqua regia are added sixteen ounces of

Gem.

Gem.

distilled water. Some leaves of Malacca tin, about the size and thickness of a sixpence, are then put into this diluted aqua regia, till it will dissolve no more of them: which operation, our author observes, requires commonly twelve or fourteen days; though it might probably be hastened by beating the tin still thinner, and then rolling it into the form of a hollow cylinder, or turning it round into spiral convolutions, and thus exposing a greater extent of surface to the action of the menstruum. In order to prepare more readily the precipitate of Cassius, M. Fontanieu puts into a large jug eight ounces of solution of tin, to which he adds four pints of distilled water: he afterwards pours into this metallic lye some solution of gold, drop by drop, taking care to stir the whole with a glass tube: when the mixture becomes of a deep purple colour, he ceases dropping the solution of gold; and in order to hasten the precipitation of the mineral purple, pours into the mixture a pint of fresh urine. Six or seven hours after, the precipitate is collected at the bottom of the vessel: the fluid is then decanted; and the precipitate, washed once or twice, is dried till it becomes a brown powder.

2. Pour into a vessel of fine tin with a thick bottom four ounces of the solution of gold; three minutes after add two pints of distilled water. Let this mixture stand in the tin vessel during seven hours, taking care to stir it every hour with a glass tube; afterwards pour it into a conical glass jug, and add to it a pint of new urine: the mineral purple is soon precipitated, and then is to be washed and dried.

3. Distil in a glass cornute placed in a bath of ashes, some gold dissolved in aqua regia, made with three parts nitrous and one part marine acid; when the acid is passed over and the gold contained in the cornute appears dry, leave the vessel to cool, then pour into it some new aqua regia, and proceed to distil as before. Replace the aqua regia twice upon the gold and distil the same. After these four operations, pour by little and little into the cornute some oil of tartar *per deliquium*, which will occasion a brisk effervescence: when this ceases, distil the mixture till it becomes dry, and then put some warm water into the cornute. Shake the whole, and put it into a cucurbit, when a precipitate is deposited the colour of which is sometimes brown and sometimes yellow: After having washed this precipitate, dry it. Our author says, this mineral purple was much superior to the foregoing, since two grains of it only were sufficient to an ounce of the base, whilst it required of the other two a 20th part of the base. And he adds; that he found a means of exalting the colour of the precipitate of Cassius, by putting to it a sixth part of its weight of glass of antimony finely powdered, and of nitre in the proportion of a dram to eight ounces of the base.

b, From Silver.] The calx of silver, being vitrified, produces a yellowish grey colour. This calx enters only into the composition of the yellow artificial diamond and the opal. M. Fontanieu introduces it into the base in the form of luna cornea.

In order to prepare it, he directs to dissolve the silver in precipitated nitrous acid, and afterwards to pour it into a solution of sea-salt: a white precipitate is obtained; which, being washed and dried, melts very readily in the fire, and is soon volatilized if not

mixed with vitrifiable matters. To make the yellow diamond, 25 grains of this luna cornea are put to an ounce of the fourth base: the dose of silver may be diminished according to the shade of yellow that one wishes to procure.

c, From Copper.] The calx of copper imparts to white glass the finest green colour; but if this metal be not exactly in a state of calx, it produces a brownish red colour. *Mountain blue, verdegris*, and the residue of its distillation, are the different preparations of copper which our author employs to make the artificial emeralds.

d, From Iron.] Although it has been asserted, that the calces of iron introduce a very fine transparent red colour into white glass, M. Fontanieu could only obtain from it a pale red a little opaque. The calx of iron that he employed was in the proportion of the 20th part of the base.

There are several ways of preparing the calx of iron called *crocus Martis*, or *saffron of Mars*. In general, it is necessary that this metal be so far deprived of its phlogiston, that the magnet ceases to attract it: thus one may use the scales of iron found upon the bars of the furnaces, which serve to distil aquafortis. By digesting filings of steel with distilled vinegar, then evaporating and replacing the vinegar 10 or 12 times upon these filings and drying them alternately, a calx of iron is obtained, which must be sifted through a silk sieve, and then calcined. The calx of iron thus obtained by the vinegar; our author says, only introduced into his bases a green colour inclining to a yellow.

By the following process a saffron of Mars of the finest red colour is obtained: Let an ounce of iron filings be dissolved in nitrous acid in a glass cornute, and distilled over a sand-bath to dryness. After having replaced the acid or the dry calx, and re-distilled it a second and a third time, it is thenedulcorated with spirits of wine, and afterwards washed with distilled water.

e, From the Magnet.] It is necessary to calcine the magnet before it be introduced into the vitrifications. Having therefore torrifed the magnet during two hours, it must be washed and dried. It is only employed in the composition of the opal.

f, From Cobalt.] The calx of cobalt is only proper to introduce a blue colour into glass; but this femimetal is rarely found free from iron and bismuth, and therefore it is first necessary to separate them from it. This is done by calcining the ore of cobalt in order to disengage the arsenic: afterwards the calx must be distilled in a cornute with sal ammoniac, and the iron and the bismuth are found sublimed with this salt. The distillation must be repeated with the sal ammoniac till this salt is no longer coloured yellow. The cobalt which remains in the cornute is then calcined in a potsherd, and becomes a very pure calx; which being introduced into the base, in the proportion of a goodth part, gives it a very fine blue colour, the intensity of which may be increased at discretion by the addition of calx of cobalt. In order to prepare *black enamel* resembling that which is called *black agate* of Iceland; melt together a pound and a half of one of the bases, two ounces of the calx of cobalt, two ounces of

crocus

Gem.

Gem. *crocus Martis*, prepared with vinegar, and two ounces of manganese.

g, From *Tin*.] The calx of tin is not vitrifiable alone, and when deprived of phlogiston is of a white colour; it renders opaque the glass with which it is melted, and forms white enamel. For this purpose, calcine the putty of tin; then wash and dry it, and sift it through a silk sieve. Take six pound of the second base, the same quantity of the calcined putty of tin, and 48 grains of manganese.

h, From *Antimony*.] Antimony is only susceptible of vitrification when its calx contains phlogiston, and then it produces a reddish or hyacinth coloured glass; but if the antimony be in a state of absolute calx, such as the diaphoretic antimony, then it is no longer vitrifiable and may be substituted for calx of tin to make white enamel. M. Fontanieu introduces the glass of antimony in the composition of artificial topazes. For the *oriental topaz*, he takes 24 ounces of the first base and five drachms of the glass of antimony. To imitate the *topaz of Saxony*, he adds to each ounce of the base five grains of the glass of antimony. For the *topaz of Brazil*, he takes 24 ounces of the first base, one ounce 24 grains of glass of antimony, and 8 grains of the *precipitate of Cassius*.

i, From *Manganese*.] This mineral, employed in a small quantity, renders the glass whiter: a larger quantity produces a very fine violet colour, and a still larger dose of it renders the glass black and opaque.

There are two ways of preparing manganese, 1. The most simple consists in exposing it to a red heat, and then quenching it with distilled vinegar; it is afterwards dried and powdered, in order to pass it through a silk sieve. 2. Haudiquier de Blancour describes the second manner of preparing the manganese, proper to furnish a red colour, and names it *fusible manganese*. Take of manganese of Piedmont one pound; torrefy and pulverize it; then mix it with a pound of nitre, and calcine the mixture during 24 hours; afterwards wash it repeatedly in warm water, till the water of the lyes has no longer any taste; dry the manganese, and mix with it an equal weight of sal ammoniac; levigate this mixture on a slab of porphyry with oil of vitriol diluted with water to the strength of vinegar. Dry the mixture, and introduce it into a cornute; distil by a graduated fire; and when the sal ammoniac is sublimed, weigh it, and add to the mixture an equal quantity. Then distil and sublime as before, and repeat the operation six times, being careful at each time to mix the sal ammoniac and the manganese upon the porphyry with diluted oil of vitriol.

At Tournhault in Bohemia, there is sold a fusible glass of a yellow colour, very like that of the topaz of Brazil, which, when exposed to a degree of fire in a cupel sufficient to redden it, becomes of a very fine ruby colour, more or less deep according to the degree of fire to which it has been exposed. Our author assayed this glass, and found it to contain a great deal of lead, but was not able to discover any gold in it.

III. *Of the different degrees of fire necessary for factitious Gems.* Our author observes, that there are three degrees of heat very different in their energy. The fire kept up in the wind furnaces in the laboratories of chemists, is

less active than that whose effect is accelerated by the means of bellows; and a fire supported by wood, and kept up during 60 hours, without interruption, produces singular effects in vitrification, and renders the glass finer and less alterable.

When recourse is had to the forge, in order to operate a vitrification, it is necessary to turn about the crucible from time to time, that the mass may melt equally. Some coal also should be replaced, in proportion as it consumes towards the nozzle of the bellows; for without this precaution, we should run the risk of cooling the crucible opposite to the flame, and probably of cracking it, when all the melted mass running among the coals would be totally lost. Though this is the readiest way of melting, it should not be employed out of choice; for the crucible often breaks, or coals get into it, and reduce the calyx of lead to a metallic state.

The wind-furnace is either square or round. A small cake of baked clay or brick, of the thickness of an inch, is placed upon the grate; and upon this cake is placed the crucible, surrounded with coal. The degree of heat produced by this furnace is much less than that of the forge: but in order to succeed in the vitrification, M. Fontanieu recommends the use of a furnace described by Kunckle, which, with some necessary alterations, is represented on Plate CCXX. The interior part is so disposed, that we may place crucibles at three different heights; and the name of *chambers* is given to those steps upon which the crucibles are placed. Fig. 4. is a plan of the kiln at the first chamber, and fig. 5. a plan of the kiln where the fire is placed. Fig. 6. exhibits the elevation; A the ash-pit; B the door to put in the wood; C the door of the first chamber; D the door of the second chamber; E the third chamber; F the flue or chimney; GG iron hoops which surround the kiln to strengthen it. Fig. 7. is a section of the kiln: H the ash-pit with its air-hole; I the chamber for the fire with an air-hole; K the first chamber for the crucibles; L the second chamber; M the dome; N the chimney; OO air-holes.

It is obvious, that the degree of heat cannot be equal in the said three chambers. The chamber K is that where the heat is greatest, afterwards in that of L, and lastly, in that of M. We should begin by placing the crucibles according to their size, in these different chambers; by which means the best effect in vitrification is produced.

In order to conduct the fire well, only three billets of white wood should be put into the furnace at a time for the first 20 hours, four billets at a time for the next 20 hours, and six billets for the last 20 hours; in all 60 hours. The furnace is then left to cool, care being taken to stop the air-holes with some lute; and in about 48 hours after, when the kiln is quite cold, the crucible is to be withdrawn.

IV. *The Compositions.* 1. For the white diamond: Take the base of Mayence. This crystal is very pure, and has no colours.

2. For the yellow diamond: to an ounce of the fourth base, add for colour 25 grains of luna cornea or 10 grains of glass of antimony.

3. For the emerald: 1. To 15 ounces of either of the bases, add for colour one dram of mountain-blue and six grains

Gem. grains of glass of antimony ; or, 2. To an ounce of the second base, add for colour 20 grains of glass of antimony and three grains of calx of cobalt.

4. For the sapphire : To 24 ounces of the Mayence base, add for colour two drams 46 grains of the calx of cobalt.

5. For the amethyst : To 24 ounces of the Mayence base, add for colour four drams of prepared manganese and four grains of precipitate of Cassius.

9. For the beril : To 24 ounces of the third base, add for colour 96 grains of glass of antimony and four grains of calx of cobalt.

7. For the black agate : To 24 ounces of either of the bases, add two ounces of the mixture directed above in par. f.

8. For the opal : To an ounce of the third base, add for colour 10 grains of luna cornea, two grains of magnet, and 26 grains of absorbent earth.

9. For the oriental topaz : To 24 ounces of the first or third base, add for colour five drams of glass of antimony.

10. For the topaz of Saxony : To 24 of the same base, add for colour six drams of the glass of antimony.

11. For the topaz of Brasil : To 24 ounces of the second or third base, add for colour one ounce 24 grains of the glass of antimony and eight grains of precipitate of Cassius.

12. For the hyacinth : To 24 ounces of the base made with rock-crystal, add for colour two drams 48 grains of glass of antimony.

13. For the oriental ruby : 1. To 16 ounces of the Mayence base, add for colour a mixture of two drams 48 grains of the precipitate of Cassius, the same quantity of crocus Martis prepared in aquafortis, the same of golden sulphur of antimony and of fusible manganese, with the addition of two ounces of mineral crystal ; or, 2. To 20 ounces of the base made with flint, add half an ounce of fusible manganese and two ounces of mineral crystal.

14. For the balais ruby : 1. To 16 ounces of the Mayence base, add the above colouring powder, but diminished a fourth part ; or, 2. To 20 ounces of the base made with flints, add the same colouring powder but with a fourth less of the manganese.

The *factitious* gems are easily distinguished from the *natural*, by their softness and fusibility ; by their solubility in acids ; by their causing only a single refraction of the rays of light ; and, in many cases, by their specific gravity, which exceeds 2.76 in all precious gems of the first order, as the diamond, ruby, sapphire, &c.

Imitation of Antique GEMS. There has been at different times a method practised by particular persons of taking the impressions and figures of antique gems, with their engravings, in glass of the colour of the original gem. This has always been esteemed a very valuable method, and greatly preferable to the more ordinary ones of doing it on sealing-wax or brimstone : but, to the misfortune of the world, this art being a secret only in the hands of some particular persons who got their bread by it, died with them, and every new artist was obliged to re-invent the method ; till at length Mr Homberg, having found it in great perfection, gave the whole process to the world to be no

more forgotten or lost ; and since that time it has been very commonly practised in France, and sometimes in other places.
