Mr Homberg was favoured in his attempts with all the engraved gems of the king's cabinet ; and took such elegant impressions, and made such exact resemblances of the originals, and that in glasses so artfully tinged to the colour of the gems themselves, that the nicest judges were deceived in them, and often took them for the true antique stones. These counterfeit gems also serve, as well as the original ones, to make more copies from afterwards : so that there is no end of the numbers that may be made from one ; and there is this farther advantage, that the copy may be easily made perfect, though the original should not be so, but should have sustained some damage from a blow or otherwise.

The great care in the operation is to take the impression of the gem in a very fine earth, and to press down upon this a piece of proper glass, softened or half melted at the fire, so that the figures of the impression made in the earth may be nicely and perfectly expressed upon the glass. In general, the whole process much resembles that of the common founders. But when it is brought to the trial, there is found a number of difficulties which were not to be foreseen, and which would not at all affect the common works of the founder. For this purpose, every earth will serve that is fine enough to receive the impressions, and tough enough not to crack in the drying : these all serve for their use, because the metals which they cast are of a nature incapable of mixing with earth, or receiving it into them, even if both are melted together so that the metal always easily and perfectly separates itself from the mould ; but it is very difficult in these casts of glass. They are composed of a matter which differs in nothing from that of the mould, but that it has been run into this form by the force of fire, and the other has not yet been so run, but is on any occasion ready to be so run, and will mix itself inseparably with the glass in a large fire : consequently, if there be not great care used, as well in the choice of the glass as in the manner of using it, when the whole is finished there will be found great difficulty in the separating the glass from the mould, and often this cannot be done without wholly destroying the impression.

All earths run more or less easily in the fire as they are more or less mixed with saline particles in their natural formation. As all salts make earths run into glass, and as it is necessary to use an earth on this occasion for the making a mould, it being also necessary to the perfection of the experiment that this earth should not melt or run, it is our business to search out for this purpose some earth which naturally contains very little salt. Of all the species of earth which Mr Homberg examined on this occasion, none proved so much divested of salts, or so fit for the purpose, as the common tripela, or TRIPOLI, used to polish glass and stones. Of this earth there are two common kinds ; the one reddish, and composed of several flakes or strata ; the other yellowish, and of a simple structure. These are both to be had in the shops. The latter kind is from the Levant ; the former is found in England, France, and many other places. This tripela must be chosen soft and smooth to the touch, and not mixed with

Gem.

with sandy or other extraneous matter. The yellowish kind is the best of the two, and is commonly called *Venetian tripoli*. This receives the impressions very beautifully; and never mixes with the glass in the operation, which the red kind sometimes does. Mr Homberg usually employed both kinds at once in the following manner: first, powder a quantity of the red tripela in an iron mortar, and sifting it through a fine sieve set it by for use; then scrape with a knife a quantity of the yellow tripela into a sort of powder, and afterwards rub it till very fine in a glass mortar with a glass pestle. The finer this powder is, the finer will be the impression, and the more accurately perfect the cast. The artificer might naturally suppose, that the best method to obtain a perfect fine powder of this earth, would be by washing it in water; but he must be cautioned against this. There is naturally in this yellowish tripoli a sort of unctuousity, which when it is formed into a mould keeps its granules together, and gives the whole an uniform glossy surface: now the washing the powder takes away this unctuousity; and though it renders it much finer, it makes it leave a granulated surface, not this smooth one, in the mould; and this must render the surface of the cast less smooth.

When the two tripelas are thus separately powdered, the red kind must be mixed with so much water as will bring it to the consistence of paste, so that it may be moulded like a lump of dough between the fingers: this paste must be put into a small crucible of a flat shape, and about half an inch or a little more in depth, and of such a breadth at the surface as is a little more than that of the stone whose impression is to be taken. The crucible is to be nicely filled with this paste lightly pressed down into it, and the surface of the paste must be strewed over with the fine powder of the yellow tripela not wetted. When this is done, the stone, of which the impression is to be taken, must be laid upon the surface, and pressed evenly down into the paste with a finger and thumb, so as to make it give a strong and perfect impression; the tripela is then to be pressed nicely even to its sides with the fingers, or with an ivory knife. The stone must be thus left a few moments, for the humidity of the paste to moisten the dry powder of the yellow tripela which is strewed over it: then the stone is to be carefully raised by the point of a needle fixed in a handle of wood; and the crucible being then turned bottom upwards, it will fall out, and the impression will remain very beautifully on the tripela.

If the sides of the cavity have been injured in the falling out of the stone, they may be repaired; and the crucible must then be set, for the paste to dry, in a place where it will not be incommoded by the dust.

The red tripoli being the more common and the cheaper kind, is here made to fill the crucible only to save the other, which alone is the substance fit for taking the impression. When the stone is taken out, it must be examined, to see whether any thing be lodged in any part of the engraving, because if there be any of the tripela left there, there will certainly be so much wanting in the impression. When the crucible and paste are dry, a piece of glass must be chosen of a proper colour, and cut to a size proper for the figure; this must be laid over the mould, but in such a manner that it does not touch the figures, otherwise it would spoil them. The crucible is then to be brought

near the furnace by degrees, and gradually heated till it cannot be touched without burning the fingers; then it is to be placed in the furnace under a muffle, surrounded with charcoal. Several of these small crucibles may be placed under one muffle; and when they are properly disposed, the aperture of the muffle should have a large piece of burning charcoal put to it, and then the operator is to watch the process, and see when the glass begins to look bright: this is the signal of its being fit to receive the impression. The crucible is then to be taken out of the fire; and the hot glass must be pressed down upon the mould with an iron instrument, to make it receive the regular impression: as soon as this is done, the crucible is to be set at the side of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glass is to be taken out, and its edges should be grated round with pincers, which will prevent its flying afterwards, which is an accident that sometimes happens when this caution has been omitted, especially when the glass is naturally tender. The different coloured glasses are of different degrees of hardness, according to their composition; but the hardest to melt are always the best for this purpose, and this is known by a few trials.

If it be desired to copy a stone in relief which is naturally in creux, or to take one in creux which is naturally in relief; there needs no more than to take an impression first in wax or sulphur, and to mould that upon the paste of tripela instead of the stone itself: then proceeding in the manner before directed, the process will have the desired success.

A more simple and easy method than the above, is by taking the casts in gypsum, or Plaster of Paris as it is commonly called. For this purpose, the gypsum must be finely pulverised, and then mixed with clear water to the consistence of thick cream. This is poured upon the face of the gem or seal of which the impression is wanted, and which must be previously moistened with oil to facilitate the separation of the cast; and in order to confine the liquid plaster, it is only necessary to pin a slip of oiled paper round the sides of the seal by way of a cap or rim. When the plaster is dry, it is to be taken off, and set before the mouth of the furnace, in order to free it entirely from moisture; when it is fit to be used as a matrix in the same way as that formed with the tripoli earths. Only no crucible or other receptacle is at all necessary; the casts being formed like so many small cakes half an inch thick, and thus put into the furnace with the bits of glass upon them. The glass, after coming to a proper heat, is pressed down upon the mould with an iron spatula to receive the desired impression, the pressure requisite being more or less according to the size of the stone. This method has been long practised very successfully, and with no small emolument, by that ingenious seal-engraver Mr Deuchar of Edinburgh. The only respect in which it is inferior to the other more operose and expensive methods, consists in the chance of air-bubbles arising in pouring on the plaster; which chance, however, is less in proportion to the fineness of the gypsum employed. When air-bubbles do occur, the casts may be laid aside, as it is so easy to replace them.

The application of pastes to multiply and preserve the impressions of cameaux and intaglios, is an object very interesting to artists and to antiquaries, as well as to men of learning and taste in the fine arts.

This

Gem.

This art, though only lately restored to any degree of perfection, is of very considerable antiquity. The great prices which the ancients paid for the elegant gems engraved by the celebrated Greek artists, could not but early suggest to them the idea of multiplying their numbers, by taking off their impressions in wax, in sulphur, in plaster, or in clay; but more particularly in coloured glass, or that vitrified substance commonly called *paste*.

As the impressions on *paste* are durable, and imitate the colours and brilliancy of the original stones, they serve the same purposes as the gems themselves. This art was therefore practised not only by the Greeks, but by all the nations who cultivated Grecian taste.

Many of the finest gems of antiquity are now lost, and their impressions are to be found only on ancient pastes. Great therefore is the value of these pastes. Numerous collections of them have been formed by the curious. Instances of this are found in the Florentine Musæum, in Stofch's work on ancient gems with inscriptions, in Winckelmann's description of Stofch's cabinet, and in the noble collection of Mr Charles Townley in London.

The art of taking impressions of gems seem not to have been altogether lost even in the Gothic ages; for Heraclius, who probably lived in the ninth century, and wrote a book *De coloribus et artibus Romanorum*, teaches in very plain though not elegant terms how to make them. Indeed, some of the few persons who then possessed this art, taking advantage of the ignorance of the times, sold pastes for original gems. Thus the famous emerald of the abbey of Reichnaw near Constance, although a present made by Charlemain, is now found to be a piece of glass. And thus the celebrated emerald vase in the cathedral of Genoa is likewise found to be a *paste* (A). The Genoese got this vase at the taking of Cesarea in the year 1101 as an equivalent for a large sum of money; nor was any imposition then suspected, for in the year 1319 they pawned it for 1200 marcs of gold.

But this ingenious art, revived indeed in Italy in the time of Laurence of Medici and Pope Leo X. was not cultivated in an extensive manner till the beginning of the present century, when M. Homberg restored it, as already mentioned. In this he is said to have been greatly assisted and encouraged by the then duke of Orleans regent of France, who used to amuse himself with that celebrated chemist in taking off impressions in *paste* from the king of France's, from his own, and other collections of gems.

According to the French Encyclopedists, M. Clanchant the elder, an engraver of some note, who died at Paris in 1781, learned this art from his royal highness, to whose household his father or he seems to have belonged. Mademoiselle Feloix next cultivated this art, and it is believed still carries it on. She had been taught by her father, who in quality of *garçon de chambre* to the regent had often assisted in the laboratory of his master, where he acquired this knowledge. Her collection consists of 1800 articles.

Baron Stofch, a Prussian, who travelled over Europe

I

Gem.

in quest of original engraved stones and impressions of ancient gems, for the elegant work which he published and Picart engraved (B), was well acquainted with this art. He had taught it to his servant Christian Dehn, who settled at Rome, where he made and sold his well known sulphur impressions and pastes. He had collected 2500 articles. Dolce has arranged them in a scientific order, and given a descriptive catalogue of them.

It was chiefly from Dehn's collection that the taste for sulphurs and pastes has become so universal. They are great objects of study, and often require much learning to explain them: They have unquestionably served to extend and improve the art of engraving on stones; and have been of infinite use to painters, to statuaries, and to other artists, as well as to men of classical learning and fine taste.

It is very difficult to take off impressions, and perfectly to imitate various coloured cameos. It cannot be properly done in wax, sulphur, plaster, or glass of one colour only. The difficulties arising from their size and form, and from the various nature of the different sorts of glass, which do not well unite into different strata, are very numerous: nor could the completest success in this chemical and mechanical branch of the art produce a tolerable cameo. Impressions or imitations, if unassisted by the tool of the engraver, do not succeed; because the undercutting and deep work of most of the originals require to be filled up with clay or wax, that the moulds may come off safe without injuring them. Hence the impressions from these moulds come off hard and destitute of delicacy, sharpness, and precision of outline, till the underworking of the moulder, is cut away. But Mr Reiffenstein at Rome, by his genius, perseverance, and the assistance of able artists, has overcome these difficulties; and has had the satisfaction of succeeding, and producing variegated cameos which can hardly be distinguished from the originals.

Mr Lippart of Dresden, an ingenious glazier, and an enthusiast in the fine arts, practised this branch not unsuccessfully; but not finding sufficient encouragement for his pastes of coloured glass, or perhaps from local difficulties in making them well and cheap, he abandoned this art. He substituted in its place impressions of fine white alabaster or selenite plaster. Such impressions, when carefully soaked in a solution of white Castile soap, then dried, and rubbed over with a soft brush, take a very agreeable polish. They show the work perhaps to better advantage than red or white sulphurs do; but they are not so durable, and are liable to be defaced by rubbing.

Of these impressions Mr Lippart published three different collections, each of them containing 1000 articles; and to the merit of having increased the number of Mademoiselle Feloix and Christiano Dehn's collections, which are all inserted in his, he added that of employing two learned Germans to arrange and describe them. The first thousand were arranged and described by the late professor Christ at Leipzig, and the second and third thousand by professor Heine

(A) See M. de la Condamine's Diff. in Memoir. de l'Acad. Roy. de Paris, 1757.

(B) Gemmæ antiquæ coloratæ, sculptorum nominibus insignitæ, re incisæ, per Bernardum Picart. Amstelodam: 1724, folio.

Gem. Heine at Goettingen. Nor did Mr Lippart stop here: but to make the study of antiquity more easy and acceptable to artists, he selected out of the whole collection of 3000, a smaller one of 2000 of the best and most instructive subjects, of which he himself drew up and published a description in German.

But of all the artists and ingenious men who have taken impressions of engraved gems in sulphur and in paste, no one seems to have carried that art to such perfection as Mr James Tassie, a native of Glasgow but who has resided in London since the year 1766. His knowledge in various branches of the fine arts, particularly in that of drawing, naturally led him to it. The elegant portraits which he models in wax, and afterwards moulds and casts in paste, which entirely resemble cameos, are well known to the public.

Mr Tassie, profiting of all the former publications of this sort, and by expence, industry, and access to many cabinets in England and other kingdoms to which former artists had not obtained admission, has now increased his collection of impressions of ancient and modern gems to the number of above 15,000 articles. It is the greatest collection of this kind that ever existed; and serves for all the purposes of artists, antiquaries, scholars, men of taste, and even philosophers. The great demand for his pastes was perhaps owing in the beginning to the London jewellers, who introduced them into fashion by setting them in rings, seals, bracelets, necklaces, and other trinkets.

The reputation of this collection having reached the empress of Russia, she was pleased to order a complete set; which being accordingly executed in the best and most durable manner, were arranged in elegant cabinets, and are now placed in the noble apartments of her imperial majesty's superb palace at Czar'sk Zelo.

Mr Tassie, in executing the commission, availed himself of all the advantages which the improved state of chemistry, the various ornamental arts, and the knowledge of the age, seemed to afford. The impressions were taken in a beautiful white enamel composition, which is not subject to shrink or form air-bladders; which emits fire when struck with steel, and takes a fine polish; and which shows every stroke and touch of the artist in higher perfection than any other substance. When the colours, mixed colours, and nature of the respective originals, could be ascertained, they were imitated as completely as art can imitate them; inasmuch that many of the paste intaglios and cameos in this collection are such faithful imitations, that artists themselves have owned they could hardly be distinguished from the originals. And when the colour and nature of the gems could not be authenticated, the pastes were executed in agreeable, and chiefly transparent, colours; constant attention being bestowed to preserve the outlines, extremities, attributes, and inscriptions.

It was the learned Mr Raspe (from whom this account (c) is taken) who arranged this great collection, and made out the descriptive catalogue. His arrangement is nearly the same with that of the late Abbé Winkelmann, in his description of the gems which be-

VOL. VII.

longed to Baron Stofsch. But as modern works were inserted in this collection, he found it necessary to make a few alterations, and added some divisions to those of M. Winkelmann, as will appear from the following conspectus, with which we shall conclude this detail.

I. Ancient Art and Engravings.

Egyptian. Hieroglyphics, sacred animals, divinities, priests.

Basilidian, Gnostic, and other talismans, &c.

Oriental and barbarous ancient and modern engravings.

Greek and Roman originals, copies, and imitations (the Etruscan are classed with the Greek works.)

A, Mythology or fabulous age. Gods, inferior divinities, religious ceremonies.

B, Heroic age before the siege of Troy.

C, Siege of Troy.

D, Historic age. Of Carthage, Greece, Rome, subjects unknown.

E, Fabulous animals and chimeras.

F, Vases and urns.

II. Modern Art and Engravings.

A, Religious subjects.

B, Portraits of kings and sovereigns.

C, Portraits of illustrious men in alphabetical order.

D, Portraits unknown.

E, Devices and emblems.

F, Cyphers, arms, supporters, and medley of modern history.

GEMARA, or GHEMARA, the second part of the TALMUD.

The word גמרה, *gemara*, is commonly supposed to denote a supplement; but in strictness it rather signifies complement, perfection: being formed of the Chaldee גמר, *gemar* or *ghemar*, "to finish, perfect, or complete any thing."

The rabbins call the Pentateuch simply the *law*: the first part of the Talmud, which is only an explication of that law, or an application thereof to particular cases, with the decisions of the ancient rabbins thereon, they call the *Mischna*, i. e. "second law:" and the second part, which is a more extensive and ample explication of the same law, and a collection of decisions of the rabbins posterior to the *Mischna*, they call *Gemara*, q. d. "perfection, completion, finishing;" because they esteem it the finishing of the law, or an explication beyond which there is nothing farther to be desired.

The Gemara is usually called simply *Talmud*, the common name of the whole work. In this sense we say, there are two Gemaras or Talmuds; that of Jerusalem and that of Babylon: though in strictness the Gemara is only an explication of the *Mischna*, given by the Jewish doctors in their schools; much as the commentaries of our school-divines on St Thomas, or the master of the sentences, are an explication of the writings of those authors.

A commentary, Monf. Tillemont observes, was wrote on the *Mischna*, by one Jochanan, whom the Jews place about the end of the second century: but Fa-

4 H

Morin

(c) Account of the present state and arrangement of Mr James Tassie's collection of pastes and impressions from ancient and modern gems, by R. C. Raspe, London, 1786, 8vo.

Gemini, Morin proves, from the work itself, wherein mention is made of the Turks, that it was not wrote till the time of Heraclius, or about the year 620; and this is what is called the *Gemara*, or *Talmud of Jerusalem*, which the Jews do not use or esteem much because of its obscurity.

They set a much greater value on the *Gemara*, or *Talmud of Babylon*, begun by one Afa; discontinued for 73 years, on occasion of the wars with the Saracens and Persians; and finished by one Jofa, about the close of the seventh century. See TALMUD.

Though the name *Talmud*, in its latitude, includes both the *Mischna* and the two *Gemaras*, yet it is properly that of Afa and Jofa alone which is meant under that name. This the Jews prize above all their other writings, and even set it on a level with scripture itself: in effect, they conceive it as the word of God, derived by tradition from Moses, and preserved without interruption to their time. R. Jehuda, and afterwards R. Johanan, R. Afa, and R. Jofa, fearing the traditions should be lost in the dispersion of the Jews, collected them into the *Mischna* and the *Gemara*. See CARAITES and RABBINISTS.

GEMINI, in astronomy, the TWINS; a constellation or sign of the zodiac, the third in order, representing Castor and Pollux; and it is marked thus, ♊. The stars in the sign Gemini, in Ptolemy's catalogue, are 25; in Tycho's, 25; in Hevelius's, 38; in the Britannic Catalogue, 85.

GEMINIANI, a celebrated musician and composer, was born at Lucca in the year 1680. He received his first instructions in music from Alessandro Scarlatti; and after that became a pupil of Carlo Ambrosio Lunati, surnamed *Il Gobbo*, a most celebrated performer on the violin; after which he became a disciple of Corelli, and under him finished his studies on that instrument. In the year 1714, he came to England; where in a short time he so recommended himself by his exquisite performance, that all who professed to love and understand music were captivated with hearing him. Many of the nobility laid claim to the honour of being his patrons; but he seemed chiefly to attach himself to Baron Kilmansegge, chamberlain to king George I. as elector of Hanover, and a favourite of that prince. In 1716, he published and dedicated to his patron 12 sonatas *a violino violone e cembalo*: the first six with fugues and double stops as they are vulgarly called; the last with airs of various measures, such as allemandes, courants, and jiggs. This publication was so well relished by the baron, that he mentioned Geminiani to the king as an excellent performer; in consequence of which our musician had the honour to perform before his majesty, in concert with the celebrated Handel, who played on the harpsichord. But though Geminiani was exceedingly admired, yet he had not a talent at associating music with poetry, nor do we find that he ever became a public performer: he was therefore obliged to depend for his subsistence on the friendship of his patrons, and the profits which accrued to him from teaching. He had also the misfortune to be an enthusiast in painting; and the versatility of his temper was such, that, in order to gratify this passion, he not only suspended his studies, and neglected to exercise his talents, but involved himself in debts. In 1727, he was offered the place of

master and composer of the state-music in Ireland; but this could not be conferred on a Catholic, and Geminiani refused to change his religion: upon which it was given to Matthew Dubourg, a young man who had been one of his pupils, and was a celebrated performer on the violin. Geminiani then set himself to compose parts to the *opera quinta* of Corelli; or, in other words, to make concertos of the first six of his solos. This work he completed, and, with the help of a subscription, at the head of which were the names of the royal family, published in 1726. In 1732, he published his *opera seconda*, which contains a celebrated minuet that goes by his name. He published many other pieces, the profits of which did not much mend his circumstances; but this perhaps was owing to his rambling disposition and enthusiastic fondness of painting. He was also an utter stranger to the business of an orchestra, and had no idea of the labour and pains necessary in the instruction of singers for the performance of music to which they were strangers. The consequence of this was, that a *concerto spirituale*, which he had advertised for his own benefit in 1748, failed in the performance. The audience, however, compassionated his distress, and sat very silent till the books were changed; when the performance was continued with compositions of the author's own, and which he executed in such a manner as was never forgot. The profits arising from this performance enabled him to take a journey to Paris; where he staid long enough to get plates engraven for a score of solos, and the parts of two operas of concertos. About the year 1755 he returned to England, and advertised them for sale. In 1761, Geminiani went over to Ireland; and was kindly entertained there by Mr Matthew Dubourg, who had been his pupil, and was then master of the king's band in Ireland. This person through the course of his life had ever been disposed to render him friendly offices; and it was but a short time after Geminiani's arrival at Dublin that he was called upon to do him the last. It seems that Geminiani had spent many years in compiling an elaborate treatise on music, which he intended for publication; but soon after his arrival at Dublin, by the treachery of a female servant, who, it was said, was recommended to him for no other end than that she might steal it, it was conveyed away, and could not be recovered. The greatness of this loss, and his inability to repair it, made a deep impression on his mind; and, as is conjectured, hastened his end; at least he survived it but a short time, ending his days on the 17th of September 1762. The following list comprises the whole of his publications, except two or three articles of small account. Twelve solos for a violin, *opera prima*; six concertos in seven parts, *opera seconda*; six concertos in seven parts, *opera terza*; twelve solos for a violin, *opera quarta*; six solos for a violoncello, *opera quinta*; the same made into solos for a violin; six concertos from his *opera quarta*; six concertos in eight parts, *opera settima*; rules for playing in taste; a treatise on good taste; the art of playing the violin, 12 sonatas from his first solos, *opera undecima*; Ripieno parts to ditto; lessons for the harpsichord; *Guida Armonica*; supplement to ditto; the art of accompaniment, two books; his first two operas of concertos in score; and the enchanted forest.—Of his solos the *opera prima* is esteem-

Gemma. ed the best. Of his concertos some are excellent, others of them scarce pass the bounds of mediocrity. The sixth of the third opera not only surpasses all the rest, but, in the opinion of the best judges of harmony, is the finest instrumental composition extant.

GEMMA, or BUD, in botany; a compendium or epitome of a plant, seated upon the stem and branches, and covered with scales, in order to defend the tender rudiments inclosed from cold and other external injuries, till their parts being unfolded, they acquire strength, and render any further protection unnecessary.

Buds, together with bulbs, which are a species of buds generally seated upon or near the root, constitute that part of the herb called by Linnæus *hybernacula*; that is the winter-quarters of the future vegetable: a very proper appellation, as it is during that severe season that the tender rudiments are protected in the manner just mentioned.

Plants considered in analogy to animals, may properly enough be reckoned both viviparous, and oviparous. Seeds are the vegetable eggs; buds, living fetuses, or infant plants, which renew the species as certainly as the seed.

Buds are placed at the extremity of the young shoots, and along the branches, being fixed with a short footstalk upon a kind of brackets, the remainder of the leaves, in the wings or angles of which the buds in question were formed the preceding year. They are sometimes placed single; sometimes two by two, and those either opposite or alternate; sometimes collected in greater numbers in whirls or rings.

With respect to their construction, buds are composed of several parts artificially arranged. Externally, we find a number of scales that are pretty hard, frequently armed with hairs, hollowed like a spoon, and placed over each other like tiles. These scales are fixed into the inner plates of the bark, of which they appear to be a prolongation. Their use is to defend the internal parts of the bud; which being unfolded, will produce some flowers, leaves, and stipulæ; others, footstalks and scales. All these parts, while they remain in the bud, are tender, delicate, folded over each other, and covered with a thick clammy juice, which is sometimes resinous and odoriferous, as in the taca-hamac-tree. This juice serves not only to defend the more tender parts of the embryo-plant from cold, the assaults of insects, and other external injuries; but likewise from excessive perspiration, which, in its young and infant state, would be very destructive. It is conspicuous in the buds of horse-chestnut, poplar, and willow trees.

In general, we may distinguish three kinds of buds; that containing the flower, that containing the leaves, and that containing both flower and leaves.

The first, termed *gemma florifera*, and by the French *bouton a fleur* or *a fruit*, contains the rudiments of one or several flowers, folded over each other, and surrounded with scales. In several trees, this kind of bud is commonly found at the extremity of certain small branches, which are shorter, rougher, and less garnished with leaves, than the rest. The external scales of this species of bud are harder than the internal; both are furnished with hairs, and in general more swelled than those of the second sort. The bud containing the flower too is commonly thicker, shorter, al-

most square, less uniform, and less pointed; being generally terminated obtusely. It is called by Pliny *oculus gemma*; and is employed in that species of grafting called *inoculation*, or *budding*.

The second species of bud, *viz.* that containing the leaves, termed *gemma folifera*, and by the French *bouton a feuilles* or *a bois*, contains the rudiments of several leaves, which are variously folded over each other, and outwardly surrounded by scales, from which the small stipulæ that are seated at the foot of the young branches are chiefly produced. These buds are commonly more pointed than the former sort. In the hazel-nut, however, they are perfectly round; and in horse-chestnut, very thick.

The third sort of bud is smaller than either of the preceding; and produces both flowers and leaves, tho' not always in the same manner. Sometimes the flowers and leaves are unfolded at the same time. This mode of the flower and leaf bud is termed by Linnæus *gemma folifera & florifera*. Sometimes the leaves proceed or emerge out of this kind of bud upon a small branch, which afterwards produces flowers. This mode of the flower and leaf bud is termed by Linnæus *gemma folifera-florifera*, and is the most common bud of any.

Such buds as produce branches adorned only with leaves are called *barren*; such as contain both leaves and flowers, *fertile*. From the bulk of the bud we may often with ease foretel whether it contains leaves only, or leaves and flowers together, as in cherry and pear trees.

Neither the buds produced on or near the root, called by some authors *turiones*, nor those produced on the trunk, and from the angles or wings of the leaves, contain, in strict propriety, an entire delineation of the plant; since the roots are wanting; and in various buds, as we have seen, shoots are contained with leaves only, and not with flowers: but as a branch may be considered as a part similar to the whole plant, and, if planted, would in process of re-vegetation exhibit or produce roots and flowers, we may in general allow, that the bud contains the whole plant, or the principles of the whole plant, which may be unfolded *ad libitum*; and thus resembles the seed in containing a delineation of the future plant in embryo: for although the bud wants a radicle, or plumula, of which the seed is possessed, yet it would undoubtedly form one, if planted in the earth. But as the medullary part adhering to the bud is too tender, and by the abundance of juice flowing into it from the earth would be disposed to putrefaction, the buds are not planted in the soil, but generally inserted within the bark of another tree; yet placed so that the production of the marrow, or pith, adhering to them, may be inserted into the pith of the branch in which the fissure or cleft is made; by which means there is a large communication of juice. This propagation by gems or buds, called *inoculation*, is commonly practised with the first sort of buds above described.

From the obvious uses of the buds, we may collect the reason why the supreme Author of nature has granted this sort of protection to most of the trees that are natives of cold climates: and, on the other hand, denied it to such as, enjoying a warm benign atmosphere, have not the tender parts of their embryo-

Gemma, shoots exposed to injuries and depredations from the severities of the weather. Of this latter kind are the plants of the following list; some of them very large trees; others smaller woody vegetables, of the shrub and under-shrub kind; Citron, orange, lemon, cassava, mock-orange, blad-apple, shrubby swallow-wort, alaternus, shrubby geraniums, berry-bearing alder, Christ's-thorn. Syrian mallow, baobab or Ethiopian four-gourd, justicia, mild sena, the acacias and sensitive plant, coral-tree, stinking bean-trefoils, medicago, oleander, viburnum, sumach, ivy, tamarisk, heath, Barbadoes cherry, lavatera, rue, shrubby nightshades, Guinea henweed, cypress, lignum vitæ, and sagine a species of juniper.

On annual plants, whose root as well as stalk perishes after a year, true buds are never produced; in their stead, however, are protruded small branches, like a little feather, from the wings of the leaves, which wither without any farther expansion if the plants climb and have no lateral branches; but if, either by their own nature or from abundance of sap, the plants become branched, the ramuli just mentioned obtain an increase similar to that of the whole plant.

The same appearance obtains in the trees of warm countries, such as those enumerated in the above list, in which a plumula, or small feather, sends forth branches without a scaly covering; as, in such countries, this tender part requires no defence or protection from cold. A scaly covering then is peculiar to buds, as it protects the tender embryo inclosed from all external injuries. When we therefore speak of trees having buds that are naked or without scales, our meaning is the same as if we had said that they have no buds at all.

The buds that are to be unfolded the following year, break forth from the evolved buds of the present year, in such a manner as to put on the appearance of small eminences in the wings or angles of the leaves. These eminences or knots grow but little during the summer: as, in that season, the sap is expended on the increase of the parts of the plant: but in autumn, when the leaves begin to wither and fall off, the buds, placed on the wings, increase; and the embryo-plant contained in the bud is so expanded, that the leaves and flowers, the parts to be evolved the following year, are distinctly visible. Thus in horse-chestnut the leaves, and in cornel-tree the flowers, are each to be observed in their respective buds.

As each bud contains the rudiments of a plant, and would, if separated from its parent vegetable, become every way similar to it; Linnæus, to show the wonderful fertility of nature, has made a calculation, by which it appears, that, in a trunk scarce exceeding a span in breadth, 10,000 buds (that is, herbs) may be produced. What an infinite number, then, of plants might be raised from a very large tree!

GEMMATIO, from *gemma*, "a bud;" a term used by Linnæus, expressive of the form of the buds, their origin, and their contents. It includes both those properly called *buds*, and those which are seated at the roots, styled *bulbs*.

As to the origin of buds, they are formed either of the footstalks of the leaves, of stipulæ, or of scales of the bark. Their contents have been already discovered, in the preceding article, to be either flowers, leaves, or both.

GEMONIÆ SCALE, or *Gradus GEMONII*, among the Romans, was much the same as gallows or gibbet in England.—Some say they were thus denominated from the person who raised them; others, from the first criminals that suffered on them; and others, from the verb *gemo*, "I sigh or groan."

The *gradus gemonii*, according to Publius Victor or Sextus Rufus, was a place raised on several steps, from whence they precipitated their criminals; others represent it as a place whereon offenders were executed, and afterwards exposed to public view. The *gemoniæ scalæ* were in the tenth region of the city, near the temple of Juno. Camillus first appropriated the place to this use, in the year of Rome 358.

GENDARMES, or GEN D'ARMES, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour; (see *Scots GENDARMES, infra.*) These troops were commanded by captain-lieutenants, the king and the princes of the blood being their captains: the king's troop, besides a captain-lieutenant, has two sublieutenants, three ensigns, and three guidons.

Grand GENDARMES, latterly were a troop composed of 250 gentlemen; the king himself was their captain, and one of the first peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers.

Small GENDARMES, were the Scots gendarmes, the queen's, the dauphin's, the gendarmes of Anjou, Burgundy, the English and Flemish gendarmes, having each a captain-lieutenant, sub-lieutenant, ensign, guidon, and quarter-master.

Scots GENDARMES, were originally instituted by Charles VII. of France, about the middle of the 5th century, and formed a part of his guard; in which station also they acted under other princes. It was their prerogative to take precedence of all the companies of the gendarmerie of France; and, on particular occasions, they even preceded the two companies of the king's mousquetaires. The sons of the Scottish monarchs were the usual captains of this company; and after Mary's accession to the throne, its command belonged to them as a right. It was thence that James VI. made a claim of it for his son prince Henry. This honour, and its emoluments, were also enjoyed by Charles I. and the next in command to this prince was Louis Stuart duke of Lennox. George Gordon marquis of Huntly succeeded the duke of Lennox in the year 1624, and took the title of captain or commander in chief when Charles I. mounted the English throne. It is not certain whether Charles II. was ever captain of this company; but it was conferred on his brother the duke of York, who was captain of the Scots gendarmes till the year 1667, when he resigned his commission into the hands of the French king. Since that time no native of Great Britain has enjoyed this command. See *Scots GUARDS*.

All the different gendarmeries are now abolished, in consequence of the reforming systems that have lately taken place in France.

GENDER, among grammarians, a division of nouns, or names, to distinguish the two sexes.

This was the original intention of gender: but afterwards

Gemoniæ
||
Gender.

Stuart's
Constit. of
Scotland.

Gendre ||
Genep. wards other words, which had no proper relation either to the one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor* in Latin is feminine, but *arbre* in French is masculine; and *dens* in Latin is masculine, but *dent* in French is feminine.

The oriental languages frequently neglect the use of genders, and the Persian language has none at all.

The Latins, Greeks, &c. generally content themselves to express the different genders by different terminations; as *bonus equus*, "a good horse;" *bona equa*, "a good mare," &c. But in English we frequently go further, and express the difference of sex by different words: as boar, sow; boy, girl; buck, doe; bull, cow; cock, hen; dog, bitch, &c.—We have only about 24 feminines, distinguished from the males, by the variation of the termination of the male into *es*; of which number are abbot, abbess; count, countess; actor, actress; heir, heiress; prince, princess, &c. which is all that our language knows of any thing like genders.

The Greek and Latin, besides the masculine and feminine, have the neuter, common, and the doubtful gender; and likewise the epicene, or promiscuous, which under one single gender and termination includes both the kinds.

GENDRE (Louis le), an esteemed historian, born at Roan. He became canon of Notre Dame at Paris, subchanter of the same church, and abbot of Notre Dame at Claire Fontaine in the diocese of Chartres. He wrote a great number of works; the principal of which are: 1. The Manners and Customs of the French, in the different times of that monarchy. 2. An History of France, in three volumes folio, and in seven volumes duodecimo. 3. The life of Cardinal d'Amboise. He died in 1733, aged 78.

GENDRE (Gilbert Charles le), marquis of St Aubin, counsellor in the parliament of Paris, and afterwards master of requests in the king's household. He wrote several works; but is chiefly distinguished by his *Traite de l'opinion*, 9 vols 12mo; a curious performance proving, by historic examples, the empire of opinion over the works of art and science. He died at Paris in 1746, aged 59.

GENEALOGY, an enumeration of a series of ancestors; or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

The word is Greek γενεαλογια; which is formed of γενεα, "race or lineage," and λογια, "discourse."

In divers chapters and military orders, it is required that the candidates produce their genealogy, to show that they are noble by so many descents.

GENEALOGICA ARBOR, or *TREE of Consanguinity*, signifies a genealogy or lineage drawn out under the figure of a tree, with its root, stock, branches, &c. The genealogical degrees are usually represented in circles, ranged over, under, and aside each other. This the Greeks called *stemmata*, a word signifying crown, garland, or the like. See the articles **CONSANGUINITY** and **DESCENT**, and the plates there referred to.

GENEP, a strong town of Germany, in the circle of

Westphalia, subject to the king of Prussia. E. Long. 4. 29. N. Lat. 51. 42.

GENERAL, an appellation given to whatever belongs to a whole genus.

GENERAL Assembly. See **ASSEMBLY**.

GENERAL Charge in law. See *CHARGE to enter Heir*.

GENERAL Terms, among logicians, those which are made the signs of general ideas. See **LOGIC** and **METAPHYSICS**.

GENERAL Warrant. See **WARRANT**.

GENERAL of an Army, in the art of **WAR**, he who commands in chief. See the article **WAR**, where his office and duties are particularly explained.

GENERAL of the Artillery. See **ORDNANCE**.

GENERAL of Horse, and *GENERAL of Foot*, are posts next under the general of the army, and these have upon all occasion an absolute authority over all the horse and foot in the army.

Adjutant GENERAL, one who attends the general, assists in council, and carries the general's orders to the army. He distributes the daily orders to the majors of brigade. He is likewise charged with the general detail of the duty of the army. The major of brigade sends every morning to the adjutant-general an exact return, by batallion and company, of the men of his brigade. In a day of battle the adjutant-general sees the infantry drawn up; after which, he places himself by the general, to receive any orders which may regard the corps of which he has the detail. In a siege, he orders the number of workmen demanded, and signs the warrant for their payment. He receives the guards of the trenches at their rendezvous, and examines their condition; he gives and signs all orders for parties. He has an orderly serjeant from each brigade of infantry in the line, to carry such orders as he may have occasion to send from the general.

Lieutenant-GENERAL, is the next in command after the general; and provided he should die or be killed, the order is, that the oldest lieutenant-general shall take the command. This office is the first military dignity after that of a general. One part of their function is, to assist the general with their counsel: they ought therefore, if possible, to possess the same qualities with the general himself; and the more, as they often command armies in chief.

The number of lieutenant-generals have been multiplied of late in Europe, in proportion as the armies have become numerous. They serve either in the field, or in sieges, according to the dates of their commissions. In battle the oldest commands the right wing of the army, the second the left wing, the third the centre; the fourth the right wing, of the second line, the fifth the left wing, the sixth the centre; and so on. In sieges, the lieutenant-generals always command the right of the principal attack, and order what they judge proper for the advancement of the siege during the 24 hours they are in the trenches; except the attacks, which they are not to make without an order from the general in chief.

Lieutenant-GENERAL of the Ordnance. See **ORDNANCE**.

Lieutenant-GENERAL of the Artillery, is, or ought to be, a very great mathematician, and an able engineer; to know all the powers of artillery; to understand the attack and defence of fortified places, in all its differ-

General
||
Generate.

rent branches; how to dispose of the artillery in the day of battle to the best advantage; to conduct its march and retreat; as also to be well acquainted with all the numerous apparatus belonging to the train, and to the laboratory, &c.

Major-GENERAL, the next officer to the lieutenant-general. His chief business is to receive orders from the general, or in his absence from the lieutenant general of the day; which he is to distribute to the brigade-majors, with whom he is to regulate the guards, convoys, detachments, &c. On him the whole fatigue and detail of duty of the army roll. It is the major-general of the day who is charged with the encampment of the army, who places himself at the head of it when they march, who marks out the ground of the camp to the quarter master-general, and who places the new guards for the safety of the camp.

The day the army is to march, he dictates to the field-officers the order of the march, which he has received from the general, and on other days gives them the parole.

In a fixed camp he is charged with the foraging, with reconnoitring the ground for it, and posting the escorts, &c.

In sieges, if there are two separate attacks, the second belongs to him; but if there is but one, he takes, either from the right or left of the attack, that which the lieutenant-general has not chosen.

When the army is under arms, he assists the lieutenant-general, whose orders he executes.

If the army marches to an engagement, his post is at the head of the guards of the army, until they are near enough to the enemy to rejoin their different corps; after which he retires to his own proper post: for the major-generals are disposed on the order of battle as the lieutenant-generals are; to whom, however, they are subordinate, for the command of their divisions. The major-general has one aid-de-camp, paid for executing his orders.

GENERAL is also used for a particular march, or beat of drum; being the first which gives notice, commonly in the morning early, for the infantry to be in readiness to march.

GENERAL is likewise an appellation by which officers in law, in the revenues, &c. are distinguished; as, *attorney-general, solicitor-general, &c. receiver-general, comptroller-general, &c.* See ATTORNEY, &c.

GENERAL is also used for the chief of an order of monks; or of all the houses and congregations established under the same rule. Thus we say, the general of the Franciscans, Cistercians, &c.

GENERALISSIMO, called also *captain-general*, and simply *general*, is an officer who commands all the military powers of a nation; who gives orders to all the other general officers, and receives no orders himself but from the king.

Mons. Balzac observes, that the cardinal de Richelieu first coined this word, of his own absolute authority, upon his going to command the French army in Italy.

GENERATE, in music, is used to signify the operation of that mechanical power in nature, which every sound has in producing one or more different sounds. Thus any given sound, however simple, produces along with itself, its octave, and two other sounds extremely sharp, viz. its twelfth above, that is

to say, the octave of its fifth; and the other the seventeenth above, or in other words, the double octave of its third major.

Whether we suppose this procreation of sounds to result from an aptitude in the texture and magnitude of certain particles in the air, for conveying to our ears vibrations that bear those proportions one to another, as being determined at once by the partial and total oscillations of any musical string: or from whatever economy of nature we choose to trace it; the power of one sound thus to produce another, when in action, is said to *generate*. The same word is applied, by Signior Tartini and his followers, to any two sounds which, simultaneously heard, produce a third.

GENERATED, or GENITED, is used, by some mathematical writers, for whatever is produced, either in arithmetic, by the multiplication, division, or extraction of roots; or in geometry, by the invention of the contents, areas, and sides; or of extreme and mean proportionals, without arithmetical addition and subtraction.

GENERATING LINE, or FIGURE, in geometry, is that which, by its motion of revolution, produces any other figure, plane or solid. See GENESIS.

GENERATION, in physiology, the act of procreating and producing a being similar to the parent. See ANATOMY, n^o 109, 110.

GENERATION of Fishes. See COMPARATIVE ANATOMY, n^o 154. and ICHTHYOLOGY.

GENERATION of Plants. See BOTANY, sect. v.

GENERATION of Insects. See COMPARATIVE ANATOMY, p. 274. and ENTOMOLOGY, sect. ii.

Parts of GENERATION. See ANATOMY, n^o 107, 108.

GENERATION, in mathematics, is used for formation or production. Thus we meet with the generation of equations, curves, solids, &c.

GENERATION, in theology. The Father is said by some divines to have produced his Word or Son from all eternity, by way of generation; on which occasion the word *generation* raises a peculiar idea; that procession, which is really effected in the way of understanding, is called *generation*, because in virtue thereof, the Word becomes like to him from whom he takes this original; or as St Paul expresses it, is the figure or image of his substance, *i. e.* of his being and nature. And hence it is, they say, that the second Person in the Trinity is called the Son.

GENERATION is also used, though somewhat improperly, for genealogy, or the series of children issued from the same stock. That the gospel of St Matthew commences from the book of the generation of Jesus Christ, &c. The latter and more accurate translators, instead of *generation* use the word *genealogy*.

GENERATION is also used to signify a people, race, or nation, especially in the literal translations of the scripture, where the word generally occurs wherever the Latin has *Generatio*, and the Greek γενεαι. Thus, "A wicked and perverse generation seeketh a sign," &c. "One generation passeth away, and another cometh," &c.

GENERATION is also used in the sense of an age, or the ordinary period of man's life. Thus we say, "to the third and fourth generation." In this sense historians usually reckon a generation the space of 33 years or thereabouts. See AGE.

Herodotus

Generated
||
Generation

Generator Herodotus makes three generations in an hundred years; which computation appears from the later authors of political arithmetic to be pretty just.

||
Genesis.

GENERATOR, in music, signifies the principal sound or sounds by which others are produced. Thus the lowest C for the treble of the harpsichord, besides its octave, will strike an attentive ear with its twelfth above, or G in alt, and with its seventeenth above, or E in alt. The C, therefore, is called their *generator*, the G and E its products or harmonics. But in the approximation of chords, for G, its octave below is substituted, which constitutes a fifth from the generator, or lowest C; and for E, is likewise substituted its fifteenth below, which, with the abovementioned C, forms a third major. To the lowest notes, therefore, exchanged for these in alt by substitution, the denominations of products or harmonics are likewise given, whilst the C retains the name of their *generator*. But still according to the system of Tartini, two notes in concord, which when sounded produce a third, may be termed the *concurring generators* of that third. (See *Generation Harmonique, par M. Rameau*; see also that delineation of Tartini's system called *The power and principles of harmony*.)

GENERIC NAME, in natural history, the word used to signify all the species of natural bodies, which agree in certain essential and peculiar characters, and therefore all of the same family or kind; so that the word used as the generical name equally expresses every one of them, and some other words expressive of the peculiar qualities or figures of each are added, in order to denote them singly, and make up what is called the specific name. See **BOTANY** and **ZOOLOGY**.

GENESIS, the first book of the Old Testament, containing the history of the creation, and the lives of the first patriarchs.

The book of Genesis stands at the head of the Pentateuch. Its author is held to be Moses: it contains the relation of 2369 years, viz. from the beginning of the world to the death of Joseph. The Jews are forbidden to read the beginning of Genesis, and the beginning of Ezekiel, before 30 years of age.

The Hebrews called this book *Bereschith*, because it begins with that word, which in their language signifies *in principio*, or "in the beginning." The Greeks gave it the name *Genesis*, *Γενεσις*, *q. d.* production, generation, because it begins with the history of the production or generation of all beings.

This book, besides the history of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the rise of religion; the general defection and corruption of the world; the deluge; the restoration of the world; the division and peopling of the earth; and the history of the first patriarchs to the death of Joseph. It was easy for Moses to be satisfied of the truth of what he delivers in this book, because it came down to him thro' a few hands: for from Adam to Noah there was one man, viz. Methuselah, who lived so long as to see them both: in like manner Shem conversed with Noah and Abraham; Isaac with Abraham and Joseph, from whom the records of this book might easily be conveyed to Moses by Amram, who was contemporary with Joseph.

GENESIS, in geometry, denotes the formation of a line, plane, or solid, by the motion or flux of a point, line, or surface. See **FLUXIONS**.

Genesis.

1
Geneva.

The genesis or formation, *e. gr.* of a globe or sphere, is conceived by supposing a semicircle to revolve upon a right line, drawn from one extreme thereof to the other, called its axis, or axis of circumvolution: the motion or revolution of that semicircle is the genesis of the sphere, &c.

In the genesis of figures, &c. the line or surface that moves is called the *describent*; and the line round which, or, according to which, the revolution or motion is made, the *dirigent*.

GENET, **GENNET**, or *Jennet*, in the manege, denotes a small-sized well-proportioned Spanish horse.

To ride *a la genette*, is to ride after the Spanish fashion, so short, that the spurs bear upon the horses flank.

GENETHLIA, in antiquity, a solemnity kept in memory of some person deceased.

GENETHLIACI, in astrology, persons who credit horoscopes or pretend to foretel what shall befall a man by means of the stars which presided at his nativity. The word is formed of the Greek *γενεθλια*, *origin, generation, nativity*.

The ancients called them *Chaldaei*, and by the general name *mathematici*: accordingly, the several civil and canon laws, which we find made against the mathematicians, only respect the *genethliaci* or astrologers.

They were expelled Rome by a formal decree of the senate; and yet found so much protection from the credulity of the people, that they remained therein unmolested. Hence an ancient author speaks of them as *hominum genus, quod in civitate nostra semper & vegetabitur, & retinebitur*.

GENETTE, in zoology. See **VIVERRA**.

GENEVA, a city of Switzerland, on the confines of France and Savoy, situated in 6° E. Long. and 46° 12' 9" N. Lat. It stands on the banks of the river Rhone, just at the place where the latter issues from the lake which takes its name from the city; and part of it is built on an island in the river. It is handsome, well fortified, and pretty large; the streets in general are clean and well paved, but the principal one is encumbered with a row of shops on each side between the carriage and foot-paths. The latter is very wide, and protected from the weather by great wooden penthouses projecting from the roofs; which, though very convenient, give the street a dark and dull appearance. The houses are generally constructed of freestone, with basements of limestone; the gutters, spouts, ridges, and outward ornaments, being made of tinned iron. Some of them have arched walks or piazzas in front. The place called *Treille* is very agreeable, being planted with linden trees, and commanding a fine prospect of the lake, with several ranges of rocks rising behind one another, some covered with vineyards and herbage, and others with snow, having openings between them. Immediately below Geneva the Rhone is joined by the Arve, a cold and muddy stream rising among the Alps, and deriving a considerable part of its waters from the Glaciers. The Rhone is quite clear and transparent, so that the muddy water of the Arve is distinguished from it even after they have flowed for several miles together. There are four bridges

over

Geneva. over the Rhone before it joins the Arve; and from it the city is supplied with water by means of an hydraulic machine, which raises it 100 Paris feet above its level. The principal buildings are, 1. The Maison de Ville, or town-house, a plain ancient edifice, with large rooms, in which the councils assemble, and public entertainments are held; and in one of them a weekly concert is held by subscription during the winter. The ascent to the upper story is not by steps but a paved activity; which however, is so gentle, that horses and mules can go up to the top. 2. The church of St Peter, formerly the cathedral, is an ancient Gothic building, with a modern portico of seven large Corinthian columns of red and white marble from Roche. The only thing remarkable in the inside is the tomb of Henry duke of Rohan. 3. The arsenal is in good order, and supplied with arms sufficient for 12,000 men. There are many ancient suits of armour; and the scaling ladders, lanthorns, hatchets, &c. used by the Savoyards in their treacherous attempt on the city in the year 1602, to be afterwards noticed, are here preserved. The magazines contain 110 cannons besides mortars. 4. The hospital is a large handsome building, by which and other charities near 4000 poor people are maintained. 5. The fortifications on the side of Savoy are of the modern construction, but are commanded by some neighbouring grounds. On the side of France they are old fashioned, and at any rate are rather calculated to prevent a surprise than to sustain a regular siege. There are three gates, towards France, Savoy and Switzerland; and the access to the lake is guarded by a double jetty and chain.

The territory belonging to this city contains about seven square leagues, and is divided into nine parishes; the town is by far the most populous in Switzerland, having about 30,000 inhabitants, of whom, however, 5000 are generally supposed to be absent. It has a small district dependent upon it, but this does not contain above 16,000. The adjacent country is extremely beautiful, and has many magnificent views arising from the different positions of the numerous hills and mountains with regard to the town and lake. The inhabitants were formerly distinguished into four classes, viz. citizens, burgeses, inhabitants, and natives; and since the revolution in 1782, a fifth class, named *domicilius*, have been added, who annually receive permission from the magistrates to reside in the city. The citizens and burgeses alone, however, are admitted to a share in the government; those called *inhabitants* are strangers allowed to settle in the town with certain privileges; and *natives* are the sons of those inhabitants, who possess additional advantages. The people are very active and industrious, carrying on an extensive commerce.

I
State of
learning in
Geneva.

This city is remarkable for the number of learned men it has produced. The reformed doctrines of religion were very early received in it, being preached there in 1533 by William Farel and Peter Viret of Orbe, and afterwards finally established by the celebrated John Calvin. Of this reformer Voltairne observes that he gave his name to the religious doctrines first broached by others, in the same manner that Americus Vesputius gave name to the continent of America which had formerly been discovered by Columbus. It was by the assiduity of this celebrated reformer, and

Geneva. the influence that he acquired among the citizens, that a public academy was first established in the city, where he, Theodore Beza, and some of the more eminent first reformers, read lectures with uncommon success. The intolerant spirit of Calvin is well known; but little of it now appears in the government of Geneva: on the contrary it is the most tolerating of all the States in Switzerland, being the only one of them which permits the public exercise of the Lutheran religion. The advantages of the academy at Geneva are very conspicuous among the citizens at this day, even the lower class of them being exceedingly well informed; so that, according to Mr Coxe, there is not a city in Europe where learning is so generally diffused. "I received great satisfaction (says he) in conversing even with several tradesmen upon topics both of literature and politics; and was astonished to find in this class of men so uncommon a share of knowledge; but the wonder ceases when we are told that all of them were educated at the public academy." In this seminary the industry and emulation of the students are excited by the annual distribution of prizes to those who distinguish themselves in each class. The prizes consist of small medals, but are conferred with such solemnity as cannot fail to produce a striking effect on the minds of youth. There is also a public library to which the citizens have access, and which undoubtedly tends greatly to that universal diffusion of learning so remarkable among the inhabitants. It was founded by Bonnivard; remarkable for his sufferings in the cause of the liberties of his country. Having been a great antagonist of the dukes of Savoy, against whom he asserted the independence of Geneva, he had the misfortune at last to be taken prisoner, and was imprisoned for six years in a dungeon below the level of the lake, in the castle of Chillon, which stands on a rock in the lake, and is connected with the land by a drawbridge. In 1536 this castle was taken from Charles III. of Savoy by the canton of Berne, assisted by the Genevans, who furnished a frigate (their whole naval force) to besiege it by sea. Bonnivard was now taken from his dungeon, where by constant walking backwards and forward, his only amusement, he had worn a hollow in the floor which consisted of solid rock. Bonnivard considered the hardships he had endured as ties which endeared him to the city, and became a principal promoter of the reformation by the mild methods of persuasion and instruction. He closed his benefactions by the gift of his books and manuscripts, and bequeathing his fortune towards the establishment and support of the seminary. His works, which chiefly relate to the history of Geneva, are still preserved with great care and reverence. The library contains 25,000 volumes, with many curious manuscripts, of which an account has been published by the reverend H. Sennebier the librarian, who has likewise distinguished himself by several literary works. Messrs Bonnet, Saussure, Mallet, and de Luc are the other most distinguished literary geniuses of which Geneva can boast. The last is particularly remarkable for the perfection to which he has brought the barometer, and which is now so great, that very little seems possible to be done by any body else. His cabinet merits the attention of naturalists, as containing many rare and curious specimens of fossils, which serve to illustrate the theory of the globe.

2
Account of
de Luc's
cabinet.

Geneva. It may be divided into three parts: 1. Such as enable the naturalist to compare the petrifications of animals and vegetables with the same bodies which are still known to exist in our parts of the globe. 2. The compare these petrifications of animals with the same bodies which are known to exist in different countries. 3. To consider the petrifications of those bodies which are no longer known to exist. The second part comprehends the stones under three points of view: 1. Those of the primitive mountains, which contain no animal bodies; 2. Those of the secondary mountains, which contain only marine bodies; 3. Those which contain terrestrial bodies. The third part contains the lavas and other volcanic productions; which are distinguished into two classes: 1. Those which come from volcanoes now actually burning; 2. Those from extinguished volcanoes.

³ History and government of Geneva. In the time of Charles the Great, the city and territory of Geneva made part of his empire; and, under his successors, it became subject to the German emperors. By reason of the imbecility of these princes however, the bishops of Geneva acquired such authority over the inhabitants, that the emperor had no other means of counterbalancing it than by augmenting the privileges of the people. In these barbarous ages also the bishops and counts had constant disputes, of which the people took the advantage; and by siding sometimes with one, and sometimes with the other, they obtained an extension of their privileges from both. The house of Savoy at length purchased the territory, and succeeded the counts with additional power: against them therefore the bishops and people united in order to resist their encroachments; and, during this period, the government was strangely complicated by reason of the various pretensions of the three parties. The counts of Savoy, however, had at last the address to dissolve the union between the bishops and citizens, by procuring the episcopal see for their brothers, and even their illegitimate children; by which means their power became gradually so extensive, that towards the commencement of the 16th century, Charles III. of Savoy (though the government was accounted entirely republican) obtained an almost absolute authority over the people, and exercised it in a most unjust and arbitrary manner. Thus violent commotions took place; and the citizens became divided into two parties, one of which, viz. the patriots, were styled *Eidgenossen* or *confederates*; the partisans of Savoy being disgraced by the appellation of *Mamelucs* or *slaves*. The true period of Genevan liberty may therefore be considered as commencing with the treaty concluded with Berne and Friburg in the year 1526; in consequence of which the duke was in a short time deprived of his authority, the bishop driven from the city, and the reformed religion and a republican form of government introduced. A long war commenced with Savoy on this account: but the Genevans proved an overmatch for their enemies by their own bravery and the assistance of the inhabitants of Berne. In 1584, the republic concluded a treaty with Zurich and Berne, by which it is allied to the Swiss cantons. The house of Savoy made their last attempt against Geneva in 1602, when the city was treacherously attacked in the night-time during a profound peace. Two hundred soldiers had scaled the walls, and got into the town before any alarm was given;

VOL. VII.

but they were repulsed by the desperate valour of a few citizens, who perished in the encounter. A petard had been fastened to one of the gates by the Savoyards; but the gunner was killed before it could be discharged. The war occasioned by this treachery was next year concluded by a solemn treaty, which has ever since been observed on both sides; though the independence of Geneva was not formally acknowledged by the king of Sardinia till the year 1754.

The restoration of tranquillity from without in consequence of the above treaty, was however soon followed by the flames of internal discord, so common in popular governments; so that during the whole of the last century the history of Geneva affords little more than an account of the struggles betwixt the aristocratical and popular parties. About the beginning of the present century the power of the Grand Council was become almost absolute; but in order to restrain its authority, an edict was procured in 1707 by the popular party, enacting, that every five years a general council of the citizens and burghers should be summoned to deliberate upon the affairs of the republic. In consequence of this law a general assembly was convened in 1712; and the very first act of that assembly was to abolish the edict by which they had been convened. A proceeding so extraordinary can scarcely be accounted for on the principles of popular fickleness and inconstancy. Rousseau, in his *Miscellaneous Works*, ascribes it to the artifices of the magistrates, and the equivocal terms marked upon the billets then in use. For the question being put, "Whether the opinion of the councils for abolishing the periodical assemblies should pass into a law," the words *approbation* or *rejection*, put upon the billets by which the votes were given, might be interpreted either way. Thus, if the billet was chosen on which the word *approbation* was written, the opinion of the councils which rejected the assemblies was approved; and by the word *rejection*, the periodical assembly was rejected of course. Hence several of the citizens complained that they had been deceived, and that they never meant to reject the general assembly, but only the opinion of the councils.

In consequence of the abolition of the general assemblies the power of the aristocratical party was greatly augmented; till at length the inhabitants exerting themselves with uncommon spirit and perseverance, found means to limit the power of the magistrates, and enlarge their own rights. In 1776, as Mr Coxe informs us, the government might be considered as a mean betwixt that of the aristocratical and popular cantons of Switzerland. The members of the senate, or little council of 25, enjoyed in their corporate capacity several very considerable prerogatives. By them half the members of the great council were named; the principal magistrates were supplied from their own body; they convoked the great and general councils, deliberating previously upon every question which was to be brought before these councils. They were vested also with the chief executive power, the administration of finances, and had in a certain degree the jurisdiction in civil and criminal causes. Most of the smaller posts were likewise filled by them; and they enjoyed the sole privilege of conferring the burghership. These, and other prerogatives, however, were balanced by those of the great council and the privileges of the general

Geneva.

⁴ Sketch of the government in 1776.

Geneva.

neral council. The former had a right to choose the members of the senate from their own body; receiving appeals in all causes above a certain value, pardoning criminals, &c. besides which they had the important privilege of approving or rejecting whatever was proposed by the senate to be laid before the people.

The general council or assembly of the people, is composed of the citizens and burghers of the town; their number in general amounting to 1500, though usually not more than 1200 were present; the remainder residing in foreign countries, or being otherwise absent. It meets twice a-year, chooses the principal magistrates, approves or rejects the laws and regulations proposed by the other councils, imposes taxes, contracts alliances, declares war or peace, and nominates half the members of the great council, &c. But the principal check to the power of the senate arose from the right of *re-election*, or the power of annually expelling four members from the senate at the nomination of the *syndics* or principal magistrates, and from the right of representation. The *syndics* are four in number, chosen annually from the senate by the general council; and three years elapse before the same members can again be appointed. In choosing these magistrates, the senate appointed from its own body eight candidates, from whom the four *syndics* were to be chosen by the general council. The latter, however, had it in their power to reject not only the first eight candidates, but also the whole body of senators in succession: in which case, four members of the senate retired into the great council; and their places were filled by an equal number from that council. With regard to the power of representation, every citizen or burgher had the privilege of applying to the senate in order to procure a new regulation in this respect, or of remonstrating against any act of the magistracy. To these remonstrances the magistrates were obliged to give an explicit answer; for if a satisfactory answer was not given to one, a second was immediately presented. The representation was made by a greater or smaller number of citizens according to the importance of the point in question.

5
Account of
the revolution in
1782.

Since the 1776, however, several changes have taken place. This right of *re-election*, which the aristocratical party were obliged to yield to the people in 1768, soon proved very disagreeable, being considered by the former as a kind of ostracism; for which reason they caught at every opportunity of procuring its abolition. They were now distinguished by the title of *negatives*, while the popular party had that of *representants*; and the point in dispute was the compilation of a new code of laws. This measure the negatives opposed, as supposing that it would tend to reduce their prerogative; while, on the other hand, the representants used their utmost endeavours to promote it, in hopes of having their privileges augmented by this means. At last, in the month of January 1777, the negatives were obliged to comply with the demands of their antagonists; and a committee for forming a new code of laws was appointed by the concurrence of the little, great, and general councils. The committee was to last for two years, and the code to be laid before the three councils for their joint approbation or rejection. A sketch of the first part of the code was presented to the little and great councils on the first of September 1779, that

they might profit by their observations before it was presented to the general council. Great disputes arose; and at length it was carried by the negatives that the code should be rejected and the committee dissolved. The opposite party complained of this as unconstitutional, and violent disputes ensued; the issue of which was, that the great council offered to compile the code, and submit it to the decision of the public. This did not give satisfaction to the popular party, who considered it as insidious: the contentions revived with more fury than ever, until at length the negatives supposing, or pretending to suppose, that their country was in danger, applied to their guarantees, France, Zurich, and Berne, intricating them to protect the laws and constitution. This was productive of no good effect; so that the negatives found no other method of gaining their point than by sowing dissension among the different classes of inhabitants. The *natives* were discontented and jealous on account of many exclusive privileges enjoyed by that class named *citizens*: they were besides exasperated against them for having, in 1773, banished eight of the principal natives, who pretended that the right of burghership belonged to the natives as well as to the citizens, and demanded that this right ought to be gratuitously conferred instead of being purchased. The negatives, in hopes of making such a considerable addition to their party, courted the natives by all the methods they could think of, promising by a public declaration that they were ready to confer upon them those privileges of trade and commerce which had hitherto been confined exclusively to the citizens. The designs of the negatives were likewise openly favoured by the court of France, and dispatches were even written to the French resident at Geneva to be communicated to the principal natives who sided with the aristocratic party. The attorney-general, conceiving this mode of interference to be highly unconstitutional, presented a spirited remonstrance; by which the French court were so much displeased that they procured his deposition from his office; and thus their party was very considerably increased among the natives. The representants were by no means negligent in their endeavours to conciliate the favour of the same party, and even promised what they had hitherto opposed in the strongest manner, viz. to facilitate the acquisition of burghership, and to bestow it as the recompence of industry and good behaviour. Thus two parties were formed among the natives themselves; and the dissensions becoming every day worse and worse, a general insurrection took place on the 5th of February 1781. A dispute, accompanied with violent reproaches, having commenced betwixt two neighbouring and opposite parties of natives, a battle would have immediately taken place, had it not been for the interposition of the *syndics* on the one side, and the chiefs of the representants on the other. The tumult was beginning to subside, when a discharge of musquetry was heard from the arsenal. Some young men who sided with the negatives, having taken possession of the arsenal, had fired by mistake upon several natives of their own party, and had killed one and wounded another. This was considered by the representants as the signal for a general insurrection, on which they instantly took up arms and marched in three columns to the arsenal; but finding

Geneva.

Geneva. finding there only a few young men who had rashly fired without orders, they permitted the rest to retire without molestation. In the opinion of some people, however, this affair was preconcerted, and the representants are said to have been the first aggressors.

The representants having thus taken up arms, were in no haste to lay them down. They took possession of all the avenues to the city; and their committee being summoned next morning by the natives to fulfil their engagements with respect to the burghership, they held several meetings with the principal negatives on that subject, but without any success: for though the latter readily agreed to an augmentation of the commercial privileges of the natives, they absolutely refused to facilitate the acquisition of the burghership. The committee, however, embarrassed and alarmed at the number and threats of the natives, determined to abide by what they had promised; drew up an edict permitting the natives to carry on trade, and to hold the rank of officers in the military associations; and conferred the burghership on more than 100 persons taken from the natives and inhabitants, and even from the peasants of the territory. This was approved by the three councils; the negatives, dreading the power of their adversaries, who had made themselves masters of the city, not daring to make their appearance.

Thus the popular party imagined that they had got a complete victory; but they soon found themselves deceived. They were prevailed upon by the deputies from Zurich and Berne (who had been sent to conciliate the differences) to lay down their arms; and this was no sooner done, than these same deputies declared the edict in favour of the natives to be null and illegal. The senate declared themselves of the same opinion; and maintained, that the assent of the councils had been obtained only through fear of the representants who were under arms, and whom none at that time durst oppose. The representants, exasperated by this proceeding, presented another remonstrance on the 18th of March 1782, summoning the magistrates once more to confirm the edict; but a month afterwards received the laconic answer, that "government was neither willing nor able to confirm it." The natives, now finding themselves disappointed in their favourite object at the very time they had such strong hopes of obtaining it, behaved at first like frantic people; and these transports having subsided, an universal tumult took place. The most moderate of the popular party endeavoured in vain to allay their fury, by dispersing themselves in different quarters of the city; and the citizens, finding themselves at last obliged either to abandon the party of the natives or to join them openly, hastily adopted the latter measure; after which, as none could now oppose them, the officers of the representants took possession of the town, and quelled the insurrection. Various negotiations were carried on with the negatives in order to prevail upon them to ratify the edict, but without success; on which a few of the magistrates were confined by the popular party along with the principal negatives; and as they justly expected the interference of France on account of what they had done, they resolved to prolong the confinement of the prisoners, that they might answer the purpose of hostages for their own safety. In the mean time the body of citizens, decei-

Geneva. ved by the pretences of the popular party, acted as if their power was already established and permanent. In consequence of this, they deposed several members of the great and little councils, appointing in their room an equal number of persons who were favourable to the cause of the representants. The great council thus new modelled, executed the edict for conferring the burghership upon a number of the natives; and appointed a committee of safety, composed of eleven members, with very considerable authority. By this committee the public tranquillity was re-established; after which, the fortifications were ordered to be repaired; and the people were buoyed up by the most dangerous notions of their own prowess, and a confidence that France either durst not attack them or did not incline to do so. In consequence of this fatal error, they refused every offer of reconciliation which was made them from the other party; until at last troops were dispatched against them by the king of Sardinia and the canton of Berne; and their respective generals, Messrs de la Marmora and Lentulus, being ordered to act in concert with the French commander M. de Jaucourt, who had advanced to the frontiers with a considerable detachment. The Genevans, however, vainly puffed up by a confidence in their own abilities, continued to repair their fortifications with indefatigable labour; the peasants repaired from all quarters to the city, offering to mount guard and work at the fortifications without any pay; women of all ranks crowded to the walls as to a place of amusement, encouraging the men, and even assisting them in their labour. The besiegers, however, advanced in such force, that every person of discernment foresaw that all resistance would be vain. The French general Jaucourt, on the 29th of June 1782, dispatched a message to the Syndics; in which he insisted on the following humiliating conditions: 1. That no person should appear on the streets under pain of military punishment. 2. That a certain number of citizens, among whom were all the chiefs of the representants, should quit the place in 24 hours. 3. That all arms should be delivered to the three generals. 4. That the deposed magistrates should be instantly re-established: And, lastly, That an answer should be returned in two hours. By this message the people were thrown into the utmost despair; and all without exception resolved to perish rather than to accept of terms so very disgraceful. They instantly hurried to the ramparts with a view of putting their resolution in force; but in the mean time the Syndics found means to obtain from the generals a delay of 24 hours. During this interval, not only men of all ages prepared for the approaching danger, but even women and children tore the pavement from the streets, carrying the stones up to the tops of the houses, with a view of rolling them down upon the enemy in case they should force their way into the town. About 80 women and girls, dressed in uniforms, offered to form themselves into a company for the defence of their country. The committee of safety accepted their services, and placed them in a barrack secured from the cannon of the besiegers. The negatives were greatly alarmed at this appearance of desperate resistance; and some of the most moderate among them endeavoured, but without success, to effect a reconciliation. At the hour

Geneva.

in which it was expected that the attack would begin, the ramparts were filled with defenders; and though the most zealous of the popular party had calculated only on 3000, upwards of 5000 appeared in the public cause. The French general, however, justly alarmed for the prisoners, who were now in imminent danger, again prolonged the period proposed for the capitulation. By these repeated delays the ardour of the defendants began to abate. The women first began to figure to themselves the horrors of a town taken by assault, and given up to an enraged and licentious soldiery; many timid persons found means not only to disguise their own fears, but to inspire others with them under the pretence of prudence and caution: at last the committee of safety themselves, who had so strenuously declared for hostilities, entirely changed their mind. Being well apprized, however, that it would be dangerous for them to propose surrendering in the present temper of the people, they assembled the citizens in their respective circles, representing, that if the city should be attacked in the night, it would be no longer possible to convene them: for which reason they recommended to them that each circle should nominate several deputies with full authority to decide in their stead; adding that they ought rather to appoint those persons who from their age and respectable character were capable of assisting their country by their advice, while others were defending it by their valour. Thus a new council, composed of about 100 citizens, was formed; in which the chiefs by various manœuvres, first intimidating, and then endeavouring to persuade the members of the necessity of surrendering, at last found means to take the thoughts of the people entirely off the defence of the city, and engage them in a scheme of general emigration. A declaration was drawn up to be delivered to the Syndics with the keys of the city, the chiefs summoned the principal officers from their posts, ordered the cannon of several batteries to be rendered unfit for service, and at last took care of themselves by quitting the town. The people were in the utmost despair; and left the town in such multitudes, that when the Sardinians entered it in the morning, they found it almost deserted. This was followed by the restoration of the former magistrates, a complete subjection of the popular party, and the establishment of a military government.

6

New constitution established.

The changes which took place on this occasion were as follow: 1. An abolition of the right of re-election. 2. The abolition of that right by which the general council nominated half the vacancies in the great council. 3. The right of remonstrating was taken from the citizens at large, and vested in 36 adjuncts, who might be present in the great council the first Monday of every month. They enjoyed a right of representation, and in consequence of that had a deliberate voice; but on the whole were so insignificant, that they were nicknamed *Les Images*, or "The Shadows." 4. The introduction of the grabeau, or annual confirmation of the members of the senate and of the great council, vested entirely in the latter. By this law part of the authority both of the senate and general council was transferred to the great council; and by subjecting the senate to this annual revision, its power was greatly lessened, and it was made in fact depend-

ent upon the general council. 5. The circles or clubs in which it was customary to convene the citizens, and all public assemblies whatever, were prohibited; and so rigorously was this carried into execution, that the society of arts was prohibited from meeting. 6. The militia was abolished; firing at marks, even with bows and arrows, was prohibited; and the town, instead of being guarded by the citizens, was now put under the care of 1000 foreign soldiers, whose colonel and major were both to be foreigners. These troops were to take an oath of fidelity to the republic, and of obedience to the great council and the committee of war; but were under the immediate command and inspection of the latter, and subject to the superior controul of the former. 7. No person was permitted to bear arms, whether citizen, native, or inhabitant. 8. Several taxes were imposed without the consent of the general council; but in time to come it was provided, that every change or augmentation of the revenue should be submitted to that body. 9. Several privileges with regard to trade and commerce, formerly possessed the citizens alone, were now granted both to citizens and inhabitants.

It is not to be supposed that this revolution would be agreeable to people who had such a strong sense of liberty, and had been accustomed to put such a value upon it, as the Genevans. From what has been already related, it might seem reasonable to conclude, that an almost universal emigration would have taken place: but after their resentment had time to subside, most of those who fled at first, thought proper to return; and, in the opinion of Mr Coxe, not more than 600 finally left their country on account of the revolution in 1782. The emigrants principally settled at Brussels and Constance, where they introduced the arts of printing linens and watchmaking. Soon after the revolution, indeed, a memorial, signed by above 1000 persons of both sexes, all of them either possessed of some property or versed in trade or manufactures, was presented to the earl of Temple, then lord lieutenant of Ireland, expressing a desire to settle in that kingdom. The proposal met with general approbation; the Irish parliament voted L. 50,000 towards defraying the expences of their journey, and affording them a proper settlement in the island. Lands were purchased for L. 8000 in a convenient situation near Waterford; part of New Geneva was actually completed at the expence of L. 10,000; a charter was granted with very considerable privileges; the standard of gold was altered for the accommodation of the watch manufacturers; and the foundation of an academy laid upon an useful and liberal plan. Several Genevans landed in Ireland in the month of July 1783; but when the nation had expended near L. 30,000 on the scheme, it was suddenly abandoned. This seems principally to have been owing to the delays necessarily occasioned in the execution of such a complicated plan; and in some degree also by the high demands of the Genevan commissioners, who required many privileges inconsistent with the laws of Ireland. By these delays the Genevans, whose character seems not to be *perseverance*, were induced to abandon the scheme, and return to their former place of residence. Even the few who had already landed, though maintained at the public expence, were discontented at not finding the new town prepared for their

Geneva.

Scheme of settling a number of Genevans in Ireland.

Geneva. their reception; and as these among the proposed emigrants who possessed the greatest share of property had already withdrawn their names, the remainder did not choose to remain in a country where they had not capital sufficient to carry on any considerable trade or manufacture. A petition was then presented by the Genevan commissioners, requesting that L.10,000 of the L.50,000 voted might be appropriated to the forming a capital: but as this had been voted for other purposes, the petition was of course rejected; in consequence of which, the Genevans relinquished the settlement by an address, and soon after quitted the island.

8
New revolution in 1789. The people of Old Geneva, though returned to their former place of abode, were far from being inclined to submit to the yoke with patience. They were obliged to pay heavy taxes for maintaining a military force expressly calculated to keep themselves in subjection; and so intolerable did this appear, that in a few years every thing seemed ready for another revolution. The success of this seemed more probable than that of the former, as France was not now in a condition to interfere as formerly. The general ferment soon rose to such a height, that government was obliged to call in the aid of the military to quell a tumult which happened in the theatre. This produced only a temporary tranquillity; another tumult took place on the 26th of January 1789, on account of the publication of an edict raising the price of bread a farthing per pound. On this the people instantly rose; plundered the bakers shops; and next day a carriage loaded with bread and escorted by soldiers was plundered in its way to the distribution office. The soldiers fired on the populace, by which one man was killed and another wounded: but the tumult still increasing, the soldiers were driven away; and the body of the deceased was carried in a kind of procession before the town-house, as a monument of the violence and oppression of the aristocratic party. The magistrates in the mean time spent their time in deliberation, instead of taking any effectual method of quelling the insurrection. The people made the best use of the time afforded them by this delay of the magistrates: they attacked and carried two of the gates, dangerously wounding the commanding officer as he attempted to allay the fury of both parties. At last the magistrates dispatched against them a considerable body of troops, whom they thought the insurgents would not have the courage to resist; but in this they found themselves deceived. The people had formed a strong barricade, behind which they played off two fire-pumps filled with boiling water and soap lyes against the extremities of two bridges which the military had to cross before they could attack them. The commanding officer was killed and several of his men wounded by the discharge of small arms from windows; and the pavement was carried up to the tops of houses in order to be thrown down upon the troops if they should force the barricades and penetrate into the streets. The tumult in the mean time continued to increase, and was in danger of becoming universal; when the magistrates, finding it would be impossible to quell the insurgents without a great effusion of blood, were reduced to the necessity of complying with their demands. One of the principal magistrates repaired in person to the quarter of St Gervais, pro-

claimed an edict for lowering the price of bread, granted a general amnesty, and released all the insurgents who had been taken into custody. Thus a momentary calm was produced; but the leaders of the insurrection, sensible that the magistrates were either unable or unwilling to employ a sufficient force against them, resolved to take advantage of the present opportunity to procure a new change of government. A new insurrection, therefore, took place on the 29th of the month, in which the soldiers were driven from their posts, disarmed, and the gates seized by the people. The magistrates then, convinced that all opposition was fruitless, determined to comply with the demands of their antagonists in their full extent; and the aristocratical party suddenly changing their sentiments, renounced in a moment that system to which they had hitherto so obstinately adhered. On the application of the solicitor general, therefore, for the recovery of the ancient liberties of the people, the permission of bearing arms, re-establishment of the militia, and of their circles or political clubs, the removal of the garrison from the barracks, and the recall of the representatives who were banished in 1782; these moderate demands were received with complacency, and even satisfaction. The preliminaries were settled without difficulty, and a new edict of pacification was published under the title of *Modifications a l'Edict de 1782*, and approved by the senate, great council, and general council. So great was the unanimity on this occasion, that the modifications were received by a majority of 1321 against 52. The pacification was instantly followed by marks of friendship betwixt the two parties which had never been experienced before; the sons of the principal negatives frequented the circles of the burghers; the magistrates obtained the confidence of the people; and no monument of the military force so odious to the people will be allowed to remain. "The barracks of the town-house (says Mr Coxe) are already evacuated, and will be converted into a public library; the new barracks, built at an enormous expence, and more calculated for the garrison of a powerful and despotic kingdom than for a small and free commonwealth, will be converted into a building for the university. The reformation of the studies, which have scarcely received any alteration since the time of Calvin, is now in agitation. In a word, all things seem at present to conspire for the general good; and it is to be hoped that both parties, shocked at the recollection of past troubles, will continue on as friendly terms as the jealous nature of a free constitution will admit.

GENEVA Lake. This lake is in the shape of a crescent; along the concave side of which Mr Coxe travelled 54 miles. Switzerland forms the hollow, and Savoy the convex part; the greatest breadth being about 12 miles. The country on the side of Savoy is full of high and craggy mountains; but from Geneva to the environs of Lausanne it slopes to the margin of the lake, and is very rich and fertile. The banks rise considerably in the neighbourhood of Lausanne, and form a most beautiful terrace, with a rapid descent a few miles beyond the town. A plain begins in the neighbourhood of Vevey, which continues for a great way beyond the end of the lake, but contracting towards the water by the approach of the mountains.

The

Geneva
|
Geneva
Lake.

Geneva,
Genial.

The lake itself appears at a distance of a beautiful blue colour, and the water is very clear and transparent. Near Geneva the coast of the lake abounds with pebbles; between that city and Laufanne it is sandy; from thence to Chillon it is bounded by hard calcareous rocks; and the extremity of the shore is a marsh formed by mud collected from the river Rhone. The greatest depth of this lake found by M. de Luc is 160 fathoms. Here the birds called *tippet grebes* make their appearance in December, and retire in February to other places where they breed. They make floating nests of reeds; but as the lake of Geneva affords none of these, they are obliged to migrate to other places where they grow. Their skins are much esteemed, and sell for 12 or 14s. each. The lake of Geneva, like all others situated between mountains, is subject to sudden storms.

GENEVA, or *Gin*, among distillers, an ordinary malt spirit, distilled a second time, with the addition of some juniper berries.

Originally, the berries were added to the malt in the grinding; so that the spirit thus obtained was flavoured with the berries from the first, and exceeded all that could be made by any other method. At present, they leave out the berries entirely, and give their spirits a flavour by distilling them with a proper quantity of oil of turpentine; which, though it nearly resembles the flavour of juniper-berries, has none of their valuable virtues.

GENEVIEVE, fathers or religious of; the name of a congregation of regular canons of the order of St Augustine, established in France.

The congregation of St Genevieve is a reform of the Augustine canons. It was begun by St Charles Faure, in the abbey of St Vincent de Senlis, of which he was a member in the year 1618.

In the year 1634, the abbey was made elective; and a general chapter, composed of the superiors of 15 houses who had now received the reform, chose F. Faure coadjutor of the abbey of St Genevieve, and general of the whole congregation. Such were its beginnings.

It has since increased very much, and it now consists of above a hundred monasteries; in some whereof the religious are employed in the administration of the parishes and hospitals; and in others in the celebration of divine service, and the instruction of ecclesiastics in seminaries for the purpose.

The congregation takes its name from the abbey of St Genevieve, which is the chief of the order, and whose abbot is the general thereof. The abbey itself took its name from St Genevieve, the patroness of the city of Paris, who died in the year 512. Five years after her death, Clovis erected the Church of St Genevieve, under the name and invocation of St Peter, where her relics are still, or were till lately, preserved, her shrine visited, and her image carried with great processions and ceremonies upon extraordinary occasions, as when some great favour is to be intreated of heaven.

GENGISKHAN, the renowned sovereign of the Moguls, a barbarous and bloody conqueror. See JENGHIZ KHAN, and (*History of the*) MOGULS.

GENIAL, an epithet given by the Pagans to cer-

tain gods who were supposed to preside over generation.

The genial gods, says Festus, were earth, air, fire, and water. The twelve signs, together with the sun and moon, were sometimes also ranked in the number.

GENII, a sort of intermediate beings, by the Mahometans believed to exist, between men and angels. They are of a grosser fabric than the latter, but much more active and powerful than the former. Some of them are good, others bad, and they are capable of future salvation or damnation like men. The Orientals pretend that these genii inhabited the world many thousand years before the creation of Adam, under the reigns of several princes, who all bore the common name of Solomon: that falling at length into an almost general corruption, Eblis was sent to drive them into a remote part of the earth, there to be confined; and that some of the generation still remaining were by Tahmurath, one of the ancient kings of Persia, forced to retreat into the famous mountain of *Kaf*; of whose successions and wars they have many fabulous and romantic stories. They also made several ranks and degrees among this kind of beings (if they are not rather different species); some being absolutely called *Fin*; some *Peri*, or fairies; some *Div*, or giants; and other *Tacwins*, or fates.

GENIOGLOSSI, in anatomy. See ANATOMY, *Table of the Muscles*.

GENIOHYOIDÆUS, in anatomy. *Ibid.*

GENOSTOMA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants. The calyx is a turbinated quinquefid perianthium; the corolla monopetalous and tubular; the stamina five short filaments; the antheræ oblong; the seeds very numerous and subangulated, placed on a filiform receptacle.

GENIPPA, in botany: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order, *Contora*. The corolla is wheel-shaped; the stigma club-shaped; the berry bilocular; the seeds nestling in a carnosus heart-shaped substance.

GENISTA, BROOM, OR DYERS-WEED: A genus of the decandria order, belonging to the diadelphica class of plants; and in the natural method ranking under the 32d order *Papilionacæ*. The calyx is bilabiate, the upper lip bidentate, the under one tridentate; the vexillum is oblong and reflected, or turned back from the pistil and stamina. There are several species; of which the most remarkable are, the cytho-genista, or common broom; and the tinctoria, or dyers weed—The first is too well known to need description. Its young flowers are sometimes preserved as pickles; and the plant, when burnt, affords a tolerably pure alkaline salt. Dr Mead relates the case of a dropsical patient that was cured by taking half a pint of a decoction of green broom tops, with a spoonful of whole white mustard seed, every morning and evening. The patient had been tapped three times, and tried the usual remedies before. An infusion of the seeds, drank freely, has been known to produce similar happy effects; but these are by no means to be expected in every instance. Cows, horses, and sheep, refuse the plant.—2. The tinctoria is also a native of Britain.

It

Genii
||
Genista.

Genital
||
Genitus.

It rises with shrubby stalks three feet high, garnished with spear-shaped leaves placed alternate, and terminated by several spikes of yellow flowers, succeeded by pods. The branches of the plant are used by dyers for giving a yellow colour; from whence it is called *dyers-broom*, *green-wood*, *wood-waxen* or *dyers-wæd*. A dram and an half of the powdered seeds operate as a mild purgative. A collection of the plant is diuretic; and, like the former, has proved serviceable in dropical cases. Horses, cows, goats, and sheep eat it.

GENITAL, an appellation given to whatever belongs to the parts of generation. See ANATOMY, n° 107, 108.

GENITES, among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of *genites* such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in grammar, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns called the *genitive case*; but in the vulgar tongues they make use of a sign to express the relation of this case. In English they prefix the article *of*, in French *de* or *du*, &c. Though in strictness there are no cases in either of these languages; inasmuch as they do not express the different relations of things by different terminations, but by additional prepositions, which is otherwise in the Latin.

GENIUS, a good or evil spirit or dæmon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and to be his guard. See DÆMON.

Among the Romans, Festus observes, the name *genius* was given to the god who had the power of doing all things, *deum qui vim obtineret rerum omnium genendarum*; which Vossius, *de Idol.* rather chooses to read *genendarum*, who has the power of producing all things; by reason Censorius frequently uses *gerere* for *gignere*.

Accordingly, St. Augustin *de Civitat. Dei*, relates, from Varro, that the genius was a god who had the power of generating all things; and presided over them produced.

Festus adds, that Anuscius spake of the genius as the Son of God, and the Father of men, who gave them life; others, however, represented the genius as the peculiar or tutelary god of each place: and it is certain, the last is the most usual meaning of the word. The ancients had their *genii* of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals, GENIUS POPULI ROM. "the genius of the Roman people;" or GENIO POP. ROM. "to the genius of the Roman people." In this sense, *genius* and *lar* were the same thing; as, in effect, Censorius and Apulius affirm they were. See LARES and PENATES.

The Platonists, and other eastern philosophers, supposed the *genii* to inhabit the vast region or extent of air between earth and heaven. They were a sort of intermediate powers, who did the office of mediators

between gods and men. They were the interpreters and agents of the gods; communicated the wills of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into such trifling concerns; this became the lot of the *genii*, whose nature was a mean between the two; who derived immortality from the one, and passions from the other; and who had a body framed of an aërial matter. Most of the philosophers, however, held, that the *genii* of particular men were born with them, and died; and Plutarch attributes the ceasing of oracles partly to the death of the *genii*. See ORACLE.

The heathens, who considered the *genii* as the guardians of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befel their wards. They never, or very rarely, appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the *genii* of different men; and that some were much more powerful than others: on which principle it was, that a wizard in *Ap-pian* bids Anthony keep at a distance from Octavius, by reason Anthony's genius was inferior to and stood in awe of that of Octavius. There were also evil *genii*, who took a pleasure in persecuting men, and bringing them evil tidings: such was that in *Paterculus*, &c. which appeared to Brutus the night before the battle of Philippi. These were also called *larvæ*, and *lemures*. See LARVÆ and LEMURES.

GENIUS, in matters of literature, &c. a natural talent or disposition to do one thing more than another; or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently and with a great deal of pains.

To know the bent of nature is the most important concern. Men come into the world with a genius determined not only to a certain art, but to certain parts of that art, in which alone they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules; whilst another displeases though he observes them, because he has not the happiness of being born with a genius for painting.

A man born with a genius for commanding an army, and capable of becoming a great general by the help of experience, is one whose organical conformation is such, that his valour is no obstruction to his presence of mind, and his presence of mind makes no abatement of his valour. Such a disposition of mind cannot be acquired by art: it can be possessed only by a person who has brought it with him into the world. What has been said of these two arts may be equally applied to all other professions. The administration of great concerns, the art of putting people to those employments for which they are naturally formed, the study of physic, and even gaming itself, all require a genius. Nature has thought fit to make a distribution of her talents among men, in order to render them necessary to one another; the wants of men being the very first link of society: she has therefore pitched upon particular persons, to give them aptitude to perform rightly
some

Genius.

Genius,
Genoa.

some things which she has rendered impossible to others; and the latter have a greater facility granted them for other things, which facility has been refused to the former. Nature, indeed, has made an unequal distribution of her blessings among her children; yet she has disinherited none; and a man divested of all kinds of abilities, is as great a phenomenon as an universal genius.

From the diversity of genius, the difference of inclination arises in men, whom nature has had the precaution of leading to the employments for which she designs them, with more or less impetuosity in proportion to the greater or lesser number of obstacles they have to surmount in order to render themselves capable of answering this vocation. Thus the inclinations of men are so very different, because they follow the same mover, that is, the impulse of their genius. This, as with the painter, is what renders one poet pleasing, even when he trespasses against rules; while others are disagreeable, notwithstanding their strict regularity.

The genius of these arts, according to the abbe du Bos consists in a happy arrangement of the organs of the brain; in a just conformation of each of these organs; as also in the quality of the blood, which disposes it to ferment, during exercise, so as to furnish plenty of spirits to the springs employed in the functions of the imagination. Here he supposes that the composer's blood is heated; for that painters and poets cannot invent in cool blood; nay, that it is evident they must be wrapt into a kind of enthusiasm when they produce their ideas. Aristotle mentions a poet who never wrote so well as when his poetic fury hurried him into a kind of phrenzy. The admirable pictures we have in Tasso of Armida and Clorinda, were drawn at the expence of a disposition he had to real madness into which he fell before he died. "Do you imagine (says Cicero), that Pacuvius wrote in cold blood? No, it was impossible. He must have been inspired with a kind of fury, to be able to write such admirable verses."

GENOA, a city of Italy, and capital of a republic of the same name, situated in E. Long. 9. 30. N. Lat. 44. 30.—By the Latin authors it is very frequently, though corruptly, called *Janua*; and its present territories made part of the ancient Liguria. The era of its foundation is not known. In the time of the second Punic war it was a celebrated emporium; and having declared for the Romans, was plundered and burnt by Mago the Carthaginian. It was afterwards rebuilt by the Romans; and with the rest of Italy continued under their dominions till the decline of the western empire in 476. Soon after, it fell under the power of Theodoric the Ostrogoth; who having defeated the usurper Odoacer, became king of Italy. This happened in the year 498; and in a short time, the Goths being almost entirely subdued by Belisarius the emperor Justinian's general, Genoa was reannexed to the Roman empire. In 1638, it was plundered and burnt by the Lombards, whose king Protharis erected it into a provincial dukedom.

The Lombards continued masters of Genoa till the year 774, when they were conquered by Charles the Great, son to Pepin king of France. He reduced Liguria to the ancient bounds settled by Augustus,

and erected it into a marquisate; appointing his relation *Audemarus* the first count or margrave. Genoa at this time being distinguished for its wealth and populousness, began to give its name to the whole coast; and continued under the dominion of these counts for about 100 years, till the race of the Pepins became entirely extinct in Italy, and the empire was transferred to the German princes.—In the year 935 or 936, while the Genoese forces were absent on some expedition, the Saracens surprised the city, which they plundered and burnt, putting to death a great number of the inhabitants, and carrying others into captivity. Having embarked their captives, together with an immense booty, they set sail for Africa: but the Genoese immediately returning, pursued the invaders; and having entirely defeated them, recovered all the captives and booty, and took a great many of the enemy's ships.

About the year 950, the Franks having lost all authority in Italy, the Genoese began to form themselves into a republic, and to be governed by their own magistrates, who were freely elected, and took the name of *Consuls*. In order to support their independence, they applied themselves with great assiduity to commerce and navigation; and being apprehensive that some of the German emperors, who frequently entered Italy as invaders, might renew their pretensions to their state, they consented to acknowledge Berengarius III. duke of Friuli, who had been elected emperor by a party of Italian nobles. Berengarius, who had much ado to maintain himself in his new dignity, endeavoured by his concessions to enlarge the number of his friends and adherents; and accordingly made no difficulty to confirm the new republic in all its rights and privileges. After this the Genoese began to extend their commerce from Spain to Syria, and from Egypt to Constantinople; their vessels, according to the custom of these times, being fitted for fighting as well as merchandize. Having thus acquired great reputation, they were invited in 1017, by the Pisans, who had likewise formed themselves into republic, to join with them in an expedition against Sardinia, which had been conquered by the Moors. In this expedition they were successful; the island was reduced; but from this time an enmity commenced between the two republics, which did not end but with the ruin of the Pisans.

The first war with Pisa commenced about 30 years after the Sardinian expedition, and lasted 18 years; when the two contending parties having concluded a treaty of peace, jointly sent their forces against the Moors in Africa, of whom they are said to have killed 100,000. The Genoese were very active in the time of the crusades, and had a principal share in the taking of Jerusalem. They also waged considerable war with the Moors in Spain, of whom they generally got the better. They also prevailed against the neighbouring states; and, in 1220, had enlarged their territories beyond the skirts of the Appenines, so that the rest of Italy looked upon them with a jealous eye: but in 1311 the factions which had for a long time reigned in the city, notwithstanding all its wealth and power, induced the inhabitants to submit themselves for 20 years to the dominion of Henry VII. emperor of Germany. That emperor, however, died in August 1312; and the vicar he had left, soon after went to Pisa, upon

Genoa.

Genoa. on which the dissensions in Genoa revived with greater fury than ever. In 1317, a quarrel happened between the families of Spinola and Doria; which came to such an height, that both parties fought in the streets for 24 days without intermission, raised battering engines against each others houses, and filled the city with blood. At last the Spinolæ quitted the city, and retired to their territories in the Appenine mountains. The civil war continued till the year 1331; when, by the mediation of the king of Naples, it was concluded, that all exiles should return to the city; that the republic should be governed by the king's vicar; and all the offices of the state be equally divided between the Guelfs and the Gibellines, the two contending parties.

By this ruinous war, the coast of Genoa, formerly adorned with palaces and vineyards, was now reduced to the appearance of a barren waste. So great was the general desolation, that, according to Petrarch, the spectators who sailed along were struck with astonishment and horror. Villani, a cotemporary author, relates, that it was supposed by the learned, that greater exploits had not been performed at the siege of Troy; and that the losses each party had sustained would have been sufficient to have purchased a kingdom, the Genoese republic being in his time the richest and most powerful state in Christendom. The annalist Stella informs us, that, before the war, the most extravagant profusion and luxury prevailed among the Genoese: but that, towards the end, many noble families were reduced to indigence and poverty; so that, about 100 years after, it became fashionable for the nobles to live in a plain manner, without any show or magnificence.

In 1336, both parties, suspending their mutual animosities, sent two fleets of 20 galleys each into the German ocean, to the assistance of the king of France, who was engaged in a war with Edward III. king of England. This naval expedition proved the cause of a most remarkable revolution in the Genoese government. The sailors of the fleet, thinking themselves injured by their officers, whom they accused of defrauding them of their pay, proceeded to an open mutiny; and, having expelled the admiral, and other commanders, seized the galleys. The king of France being chosen arbitrator, decided in favour of the officers, and imprisoned 16 of the chiefs of the mutineers. Upon this several of the sailors left the fleet, and returned to Genoa; where they went round the coasts, repeating their ruinous complaints, which were greatly hearkened to, upon a false report that the mutineers who had been imprisoned were broke upon the wheel. The factious spirit increased; and at last the Genoese insisted in a tumultuous manner for having an abbot of their own choosing, and 20 of the people with the consent of the captains of the republic assembled for that purpose. While the mob were impatiently expecting their decision, a mechanic, generally accounted a fool, mounted a wooden bench, and called out that one Simon Bucanigree should be chosen abbot. This being instantly echoed by the populace, he was first declared *abbot*, then *lord*, and at last *duke* of Genoa.

This new expedient did not at all answer the purpose. The dissensions continued as violent as ever, notwithstanding the power of the new magistrates;

VOL. VII.

and by these perpetual divisions the republic was at last so much weakened, that in 1390 the king of France was declared Lord of Genoa. Under the French government, however, they soon became exceedingly impatient; and, in 1422, the duke of Milan obtained the sovereignty. With this situation they were equally displeased, and therefore revolted in 1436. Twenty-two years after, finding themselves pressed by a powerful fleet and army sent by Alphonso king of Naples, they again conferred the sovereignty of their state upon the king of France. In 1460, they revolted from the French; and, four years after, put themselves again under the protection of the duke of Milan; from whom they revolted in 1478. He was again declared sovereign of the republic in 1488; and, 11 years after, the city and territories of Genoa were conquered by Louis XII. of France.

The almost unparalleled fickleness of the Genoese disposition was not to be corrected by this misfortune. They revolted in 1506; but next year were again subdued by Louis. Six years after, they again revolted; and in 1516, the city was taken and plundered by the Spaniards. In 1528, Andrew Doria, a Genoese admiral in the service of the French, undertook to rescue his country from the dominion of foreign princes, and restore it to its liberty. Knowing well the fickle disposition of his countrymen, he took all occasions of exciting discontents among them against the government. He persuaded them, that the French (who had again obtained the sovereignty) had left them only a shadow of liberty, while they pretended to protect them from their enemies. To the nobility he represented the disgrace of suffering the government to be vested in the hands of foreigners less worthy of authority than themselves. Thus he soon formed a strong faction, and formed his plan; for the execution of which he took the most proper time, namely, when almost three-fourths of the French garrison had been carried off by the plague. He advanced with 500 men; and his friends having opened the gates of the city to him, he seized the principal posts, and thus became master of it without drawing his sword. The garrison retired to the forts, where they soon after capitulated, and being driven out of the city, Doria re-established the ancient form of government. See DORIA.

The republic hath since continued to preserve her liberty, though greatly fallen from her ancient splendor, and now become a very inconsiderable state. In 1684, the Genoese had the misfortune to fall under the resentment of Louis XIV. at which time the city was almost destroyed by a formidable bombardment. In the year 1688, it was bombarded by admiral Byng, and forced to capitulate; but there were at that time no views of making a permanent conquest of the city. In 1730, the island of Corsica revolted from the Genoese, and could never afterwards be reduced by them; for which reason it was sold to the French, who in the year 1770 totally reduced it.

The Genoese territories extend along that part of the Mediterranean sea, commonly called the *gulf of Genoa*, about 152 miles; but their breadth is very unequal, being from eight to about 20 miles. When they are not bounded by the sea, the following states and countries, taking them from west to east, are their

Genoa. boundaries, *viz.* Piedmont, Montferat, Milan, Placentia, Parma, the dukedom of Tuscany, and the republic of Lucca. This tract, though a great part of it is mountainous, and some of that barren enough, yet produces plenty of excellent fruit, good pasture, wood, garden-stuff, and mulberry-trees, with some wine and oil, but little corn. What they want of the last, they have either from Lombardy, Sicily, or Naples.

Genoa stands on the coast of the Mediterranean sea, at the bottom of a little gulph, partly on the flat, and partly on the declivity of a pleasant hill; in consequence of which, it appears to great advantage from the sea. It is defended on the land-side by a double wall, which in circumference is about ten Italian miles. Two of the streets consist entirely of a double straight row of magnificent palaces. The others, though clean and well paved, are crooked and narrow. The palaces of the nobility are almost all of marble, and many of them are painted on the outside. That there should be such a profusion of marble here, is not to be wondered at, as the neighbouring hills abound with it. The city contains a vast number of palaces, churches, and convents, and several hospitals. The palace where the doge resides, and where the great and little council, and the two colleges of the procuratori and governatori assemble, is a large stone building in the centre of the city: but it contains some fine paintings in fresco; two statues of Andrew and John Doria in white marble; and an arsenal, in which are said to be arms for thirty-four thousand men, with a shield, containing one hundred and twenty pistol-barrels, and thirty-three coats of mail, which, it is pretended, were worn by as many Genoese heroes in a crusade. Of the churches, the finest are those of the Annunciation, St Mary Carignan, St Dominic, and St Martha. In the cathedral is a dish made of a single emerald. All the inhabitants here, except the principal ladies, who are carried in chairs, walk on foot, on account of the narrowness or steepness of the streets. The fortifications of the city, towards the sea, are remarkably strong. There are two fine stone-bridges over the rivers Bonzevera and Bisagno, the first whereof washes the west, and the other the east side of the city, within which there is also a surprising stone-bridge joining two hills. The harbour, though large, is far from being safe; but no care or expence have been spared to render it as safe and commodious as possible. The wind to which it is most exposed, is that called *Labeccio*, or the south-west. The place where the republic's galleys lie, is called the *Darsena*, where are a great number of Turkish slaves. On a rock, on the west side of the harbour, is the fanal or light-house, a high tower, on the top of which is a lanthorn, containing thirty-six lamps. The trade of Genoa is chiefly in velvets, damasks, plush, and other silks, brocades, lace, gloves, sweetmeats, fruits, oil, Parmesan cheese, anchovies, and medicinal drugs from the Levant; but the badness of the harbour, and the high price of commodities, greatly check its commerce. In 1751, Genoa was declared a free port for ten years, under certain restrictions: in that called *Porto Franco*, any merchant may have a ware-house, and import or export goods duty-free; but such as are disposed of in the city, or on the continent, are taxed pretty high. The nobility are allowed to trade in the wholesale way; to carry

on velvet, silk, and cloth manufactures; and to have shares in merchant-ships: and some of them, as the Palavacini, are actually the greatest merchants in Genoa. Another very profitable article of trade carried on by them is banking, and dealing in bills of exchange. A new academy of painting, sculpture, civil and military architecture, was instituted here in 1751. One may walk the streets of Genoa in the night with the greatest safety, which is more than can be said of many cities in Italy. Excessive splendor and luxury are, in several respects, restrained by salutary laws. No beggars are permitted to ask alms in Genoa, and the inns are better than those at Turin. When a single person is buried, a kind of garland of all sorts of artificial flowers is placed on the coffin. The Genoese in general are esteemed crafty, industrious, and inured to labour above the other Italians.

GENSING. See PANAX.

GENTIANA, GENTIAN, in botany: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 20th order, *Rotaceæ*. The corolla is monopetalous; the capsule bivalved and unilocular; there are two longitudinal receptacles. The most remarkable species are the following:

1. The lutea, or common gentian of the shops. It is a native of the mountainous parts of Germany; from whence the roots, the only part used in medicine, are brought to Britain. These have a yellowish-brown colour, and a very bitter taste. The lower leaves are of an oblong oval shape, a little pointed at the end, stiff, of a yellowish green, and have five large veins on the back of each. The stalk rises four or five feet high, garnished with leaves growing by pairs at each joint, almost embracing the stalk at their base. They are of the same form with the lower, but diminish gradually in their size to the top. The flowers come out in whirls at the joints on the upper part of the stalks, standing on short foot-stalks, whose origin is in the wings of the leaves. They are of a pale yellow colour.—The roots of this plant are very frequently used in medicine as stomachic bitters. In taste they are less exceptionable than most of the substances of this class. Infusions of gentian-root flavoured with orange-peel, are sufficiently grateful. Some years ago a poisonous root was discovered among the gentian brought to London; the use of which occasioned violent disorders, and in some cases death. This root is easily distinguished from the gentian, by its being internally of a white colour, and void of bitterness.

2. The centaureum, or lesser centaury of the shops, is a native of many parts of Britain. It grows on dry pastures; and its height is commonly proportioned to the goodness of the soil, as in rich soils it will grow to the height of a foot, but in poor ones not above three or four inches. It is an annual plant, with upright branching stalks, garnished with small leaves, placed by pairs. The flowers grow in form of an umbel at the top of the stalk, and are of a bright purple colour. They come out in July, and the seed ripens in autumn. The plant cannot be cultivated in gardens. The tops are an useful aperient bitter, in which view they are often used in the present practice of medicine.

GEN-

Gensing,
Gentiani.

Gentile
||
Gentilis.

GENTILE, in matters of religion, a Pagan, or worshipper of false gods.

The origin of this word is deduced from the Jews, who called all those who were not of their name גוים *gojim*, i. e. *gentes*, which in the Greek translations of the old Testament is rendered *ἔθνη*; in which sense it frequently occurs in the New Testament; as in Matth. vi. 32. "All these things the nations or Gentiles seek." Whence the Latin church also used *gentes* in the same sense as our *Gentiles*, especially in the New Testament. But the word *gentes* soon got another signification, and no longer meant all such as were not Jews; but those only who were neither Jews nor Christians, but followed the superstitions of the Greeks and Romans, &c. In this sense it continued among the Christian writers, till the manner of speech, together with their religion, was publicly and by authority received in the empire; when *gentiles*, from *gentes*, came into use: and then both words had two significations, viz. in treatises or laws concerning religion, they signified Pagans, neither Jews nor Christians; and in civil affairs, they were used for all such as were not Romans.

GENTILE, in the Roman law and history, a name which sometimes expresses what the Romans otherwise called *barbarians*, whether they were allies of Rome or not: but this word was used in a more particular sense for all strangers and foreigners not subject to the Roman empire.

GENTILESCHI (Horatio), an Italian painter, was born at Pisa in 1563. After having made himself famous at Florence, Rome, Genoa, and other parts of Italy, he removed to Savoy; from whence he went to France, and at last, upon the invitation of Charles I. went over to England. He was well received by that king, who appointed him lodgings in his court, together with a considerable salary; and employed him in his palace at Greenwich, and other public places. The most remarkable of his performances in England, were the ceilings of Greenwich and York-house. He did also a Madona, a Magdalen, and Lot with his two daughters, for King Charles; all which he performed admirably well. After the death of the king, when his collection was exposed to sale, nine pictures of Gentileschi were sold for 600*l.* and are now said to be the ornaments of the hall in Marlborough-house. His most esteemed piece abroad was the portico of cardinal Bentivoglio's palace at Rome. He made several attempts in face-painting, but with little success; his talent lying altogether in histories, with figures as big as the life. He was much in favour with the duke of Buckingham, and many others of the nobility. After 12 years continuance in England, he died there at 84 years of age, and was buried in the queen's chapel at Somerset-house. His print is among the heads of Vandyke, he having been drawn by that great master. He left behind him a daughter, *Artemisia Gentileschi*, who was but little inferior to her father in history-painting, and excelled him in portraits.

GENTILIS (Albericus), professor of civil law at Oxford; an Italian by birth. He had quitted Italy with his father, on account of religion. He wrote several works; three books, in particular *De jure belli*,

which have not been unserviceable to Grotius. He died at London in 1608.

GENTILIS (Scipio), brother to the former, and as celebrated a civilian as he, forefook his native country that he might openly profess the Protestant religion. He was counsellor of the city of Nuremberg, and professor of law with uncommon reputation. He was a great humanist; and in his lectures, as well as books, mixed the flowers of polite learning with the thorns of the law. He died in 1616.

GENTLEMAN. Under this denomination are comprehended all above the rank of yeomen*, where-
* See Com-
monalty.

A gentleman is usually defined to be one, who, without any title, bears a coat of arms, or whose ancestors have been freemen: and by the coat that a gentleman giveth, he is known to be, or not to be, descended from those of his name that lived many hundred years since.

The word is formed of the French *gentilhomme*; or rather of *gentil*, "fine, fashionable, or becoming;" and the Saxon *man*, q. d. *honestus*, or *honesto loco natus*.—The same signification has the Italian *gentilhuomo*, and the Spanish *hidalgo*, or *hijo dalgo*, that is, the son of somebody, or of a person of note.—If we go farther back, we shall find *gentleman* originally derived from the Latin *gentilis homo*; which was used among the Romans for a race of noble persons of the same name, born of free or ingenuous parents, and whose ancestors had never been slaves or put to death by law. Thus Cicero in his *Topics*, "*Gentiles sunt, qui inter se eodem sunt nomine, ab ingenuis oriundi, quorum majorum nemo servitutem servavit, qui capite non sunt diminuti*, &c.—Some hold that it was formed from *gentile*, i. e. pagan; and that the ancient Franks, who conquered Gaul, which was then converted to Christianity, were called *gentiles* by the natives, as being yet heathens.—Others relate, that towards the declension of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of brave soldiers, the one called *gentilium*, and the other *scutariorum*; and that it was hence we derive the names *gentleman* and *esquire*. See **ESQUIRE**.—This sentiment is confirmed by Pasquiere, who supposes the appellation *gentiles* and *ecuyers* to have been transmitted to us from the Roman soldiery; it being to the *gentiles* and *scutarii*, who were the bravest of the soldiery, that the principal benefices and portions of lands were assigned. See **BENEFICE**.—The Gauls observing, that during the empire of the Romans, the *scutarii* and *gentiles* had the best tenements or appointments of all the soldiers on the frontiers of the provinces, became insensibly accustomed to apply the same names, *gentilhommes* and *ecuyers*, to such as they found their kings gave the best provisions or appointments to.

GENTLEMAN *Usher of the Black Rod*. See **ROD**.

GENTLEMEN *of the Chapel*; officers whose duty and attendance is in the royal chapel, being in number 32. Twelve of them are priests; the other 20, commonly called *clerks of the chapel*, assist in the performance of divine service. One of the first 12 is chosen for confessor of the household; whose office is to read prayers every morning to the household servants, to visit the sick, examine and prepare communicants, and administer

Gentoo.

nister the sacrament. One of 20 clerks, well versed in music, is chosen first organist, who is master of the children; to instruct them in music, and whatever else is necessary for the service of the chapel; a second is likewise an organist; a third a lutanist; and a fourth a violist. There are likewise three vergers, so called from the silver rods they carry in their hands; being a serjeant, a yeoman, and groom of the vestry: the first attends the dean and sub-dean, and finds surplices and other necessaries for the chapel; the second has the whole care of the chapel, keeps the pews, and seats the nobility and gentry; the groom has his attendance within the chapel-door, and looks after it.

GENTOOS, in modern history, according to the common acceptation of the term, denote the professors of the religion of the bramins or brachmans, who inhabit the country called *Hindostan*, in the East Indies, from the word *stan*, a "region," and *hind* or *hindoo*; which Ferishteh, as we learn from colonel Dow's translation of his history, supposes to have been a son of Ham the son of Noah. It is observed, however, that Hindoo is not the name by which the inhabitants originally styled themselves; but according to the idiom of the *schan scrit* which they use, *jumbodeep*, from *jumboo*, "a jackall," an animal common in their country; and *deep*, a large portion of land surrounded by the sea; or *bhertekhunt*, from *khunt*, i. e. "a continent," and *bherrhur*, the name of one of the first Indian rajahs. It is also to be observed, that they have assumed the name of *Hindoos* only since the era of the Tartar government, to distinguish themselves from their conquerors the Mussulmen. The term *Gentoo* or *Gent*, in the *Schan scrit* dialect, denotes *animal* in general, and in its more confined sense *mankind*, and is never appropriated particularly to such as follow the doctrines of Brhima. These are divided into four great tribes, each of which has its own separate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word *Gentoo*. Mr Halhed, in the preface to his translation of the Code of Gentoo Laws, conjectures, that the Portuguese, on their first arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domestic appellation of the Indians themselves, or perhaps their bigotry might force from the word *Oentoo* a fanciful allusion to Gentile or Pagan. The *Hindoos*, or *Gentoo*s, vie with the Chinese as to the antiquity of their nation. They reckon the duration of the world by four jogues, or distinct ages: the first is the *Suttee jogue*, or age of purity, which is said to have lasted about 3,200,000 years; during which the life of man was 100,000 years, and his stature 21 cubits: the second, the *Tirtah jogue*, or the age in which one-third of mankind were reprobate; which consisted of 2,400,000 years, when men lived to the age of 10,000 years: the third, the *Dwapar jogue*, in which half of the human race became depraved; which endured to 600,000 years, when men's lives were reduced to 1000 years: and fourthly, the *Collee jogue*, in which all mankind were corrupted, or rather diminished, which the word *collee* imports. This is the present era, which they suppose will subsist for 400,000 years, of which near 5000 are

Gentoo.

already past; and man's life in this period is limited to 100 years. It is supposed by many authors, that most of the *Gentoo shasters*, or scriptures, were composed about the beginning of the *Collee jogue*: but an objection occurs against this supposition, viz. that the *shasters* take no notice of the deluge; to which the bramins reply, that all their scriptures were written before the time of Noah, and the deluge never extended to Hindostan. Nevertheless, it appears from the *shasters* themselves, that they claim a much higher antiquity than this; instances of which are recited by Mr Halhed.

The doctrine of transmigration is one of the distinguishing tenets of the *Gentoo*s. With regard to this subject, it is their opinion, according to Mr Hollwell, that those souls which have attained to a certain degree of purity, either by the innocence of their manners or the severity of their mortifications, are removed to regions of happiness proportioned to their respective merits; but that those who cannot so far surmount the prevalence of bad example, and the powerful degeneracy of the times, as to deserve such a promotion, are condemned to undergo continual punishment in the animation of successive animal forms, until, at the stated period, another renovation of the four jogues shall commence, upon the dissolution of the present. They imagine six different spheres above this earth; the highest of which, called *suttee*, is the residence of Brhima and his particular favourites. This sphere is also the habitation of those men who never uttered a falsehood, and of those women who had voluntarily burned themselves with their husbands; the propriety of which practice is expressly enjoined in the code of the *Gentoo* laws. This code, printed by the East-India Company in 1776, is a very curious collection of *Hindoo* jurisprudence, which was selected by the most experienced pundits or lawyers, from curious originals in the *Schan scrit* language, who were employed for this purpose from May 1773 to February 1775; afterwards translated into the Persian idiom, and then into the English language by Mr Halhed.

The several institutes contained in this collection are interwoven with the religion of the *Gentoo*s, and revered as of the highest authority. The curious reader will discover an astonishing similarity between the institutes of this code and many of the ordinances of the Jewish law; between the character of the bramins or priests, and the Levites; and between the ceremony of the scape-goat under the Mosaic dispensation, and a *Gentoo* ceremony called the *ashunned jug*, in which a horse answers the purpose of the goat. Many obsolete customs and usages alluded to in many parts of the Old Testament, may also receive illustrations from the institutes of this code. It appears from the code, that the bramins, who are the priests and legislators of the country, have resigned all the secular and executive power into the hands of another cast or tribe; and no bramin has been properly capable of the magistracy since the time of the *suttee jogue*. The only privilege of importance which they have appropriated to themselves, is an exemption from all capital punishment: they may be degraded, branded, imprisoned for life, are sent into perpetual exile; but it is every where expressly ordained, that a bramin shall not be put to death on any account whatever.

We

Genu-
flexion,
Genus.

We have already observed, that the Hindoos are divided into four great and original tribes, which, according to the Gentoo theology, proceeded from the four different members of Brhima, the supposed immediate agent of the creation under the spirit of the Almighty. These tribes are the bramins, which proceeded from his mouth, and whose office is to pray, read, and instruct; the Chehteree, which proceed from his arms, whose office is to draw the bow, to fight, and to govern; the Bice, proceeding from the belly or thighs, who are to provide the necessaries of life by agriculture and traffic; and the Sooder, from the feet, which are ordained to labour, serve, and travel.

Few Christians, says the translator of the Gentoo code, have expressed themselves with a more becoming reverence of the grand and impartial designs of Providence in all its works, or with a more extensive charity towards all their fellow-creatures of every profession, than the Gentoos. It is indeed an article of faith among the bramins, that God's all merciful power would not have permitted such a number of different religions, if he had not found a pleasure in beholding their varieties.

GENUFLEXION, (of *genu*, "knee," and *flecto* "I bend,") the act of bowing or bending the knee; or rather of kneeling down.

The Jesuit Rosweyd, in his *Onomasticon*, shows, that genuflexion, or kneeling, has been a very ancient custom in the church, and even under the Old Testament dispensation; and that this practice was observed throughout all the year, excepting on Sundays, and during the time from Easter to Whitsuntide, when kneeling was forbid. by the council of Nice.

Others have shown, that the custom of not kneeling on Sundays had obtained from the time of the apostles; as appears from St Irenæus, and Tertullian; and the Ethiopic church, scrupulously attached to the ancient ceremonies, still retains that of not kneeling at divine service. The Russians esteem it an indecent posture to worship God on the knees. Add, that the Jews usually prayed standing. Rosweyd gives the reasons of the prohibition of genuflexion on Sundays, &c. from St Basil, Anastasius, St Justin, &c.

Baronius is of opinion, that genuflexion was not established in the year of Christ 58, from that passage in Acts xx. 36. where St Paul is expressly mentioned to kneel down at prayer; but Saurin shows, that nothing can be thence concluded. The same author remarks, also, that the primitive Christians carried the practice of genuflexion so far, that some of them had worn cavities in the floor where they prayed: and St Jerome relates of St James, that he had contracted a hardness on his knees equal to that of camels.

GENUS, among metaphysicians and logicians, denotes a number of beings which agree in certain general properties common to them all: so that a genus is nothing else but an abstract idea, expressed by some general name or term. See LOGIC and METAPHYSICS.

GENUS, is also used for a character or manner applicable to every thing of a certain nature or condition: in which sense it serves to make capital divisions in divers sciences, as medicine, natural history, &c.

GENUS, in rhetoric. Authors distinguish the art of rhetoric, as also orations or discourses produced

thereby, into three genera or kinds, demonstrative, deliberative, and judiciary. To the demonstrative kind belong panegyrics, genealogies, epithalamiums, funeral harrangues, &c. To the deliberative kind belong persuasions, dissuasions, commendations, &c. To the judiciary kind belong defences and accusations.

GENUS, in medicine. See MEDICINE, under the *Nosology*.

GENUS, in natural history, a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters. See BOTANY and ZOOLOGY.

GENUS, in music, by the ancients called *genus melodia*, is a certain manner of dividing and subdividing the principles of melody; that is, the consonant and dissonant intervals, into their concinnous parts.

The moderns considering the octave as the most perfect of intervals, and that whereon all the concords depend, in the present theory of music, the division of that interval is considered as containing the true division of the whole scale.

But the ancients went to work somewhat differently: the diatessaron, or fourth, was the least interval which they admitted as concord; and therefore they sought first how that might be most conveniently divided; from whence they constituted the diapente and diapason.

The diatessaron being thus, as it were, the root and foundation of the scale, what they called the *genera*, or kinds, arose from its various divisions; and hence they defined the *genus modulari* to be the manner of dividing the tetrachord and disposing its four sounds as to succession.

The genera of music were three, the enharmonic, chromatic, and diatonic. The two first were variously subdivided: and even the last, though that is commonly reckoned to be without any species, yet different authors have proposed different divisions under that name, without giving any particular names to the species as was done to the other two.

For the characters, &c. of these several genera, see ENHARMONIC, CHROMATIC, and DIATONIC.

GEOCENTRIC, in astronomy, is applied to a planet, or its orbit, to denote it concentric with the earth, or as having the earth for its centre, or the same centre with the earth.

GEOFFRÆA, in botany: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is quinquefid, the fruit an oval plum; the kernel compressed. There is only one species, viz. the inermis, or cabbage-bark tree, which is a native of Brasil and Jamaica. The wood of this tree is used in building; but it is chiefly valued for its bark, which is administered as an anthelmintic medicine. From this medical property it is also called the *worm-bark tree*. This bark is of a grey colour externally, but black and furrowed on the inside. It has a mucilaginous and sweetish taste, and a disagreeable smell. It is given in cases of worms, in form of powder, decoction, syrup, and extract. The decoction is preferred; and is made by slowly boiling an ounce of the fresh dried bark in a quart of water, till it assume

Geoffrey. fume the colour of Madeira wine. This sweetened the syrup; evaporated, it forms an extract. It commonly produces some sickness and purging; sometimes violent effects, as vomiting, delirium, and fever. These last are said to be owing to an over-dose, or to drinking cold water; and are relieved by the use of warm-water, castor oil, or a vegetable acid. It should always be begun in small doses. But when properly and cautiously administered, it is said to operate as a very powerful anthelmintic, particularly for the expulsion of the lumbrici, which are a very common cause of disease in the West-India islands; and there it is very frequently employed. But it has we believe been but little used in Britain.

GEOFFREY of MONMOUTH, bishop of St Asaph, called by the ancient biographers *Gallofridus Monumetensis*. Leland conjectures that he was educated in benedictine convent at Monmouth, where he was born; and that he became a monk of that order. Bale, and after him Pits call him archdeacon of Monmouth; and it is generally asserted that he was made bishop of St Asaph in the year 1151 or 1152, in the reign of king Stephen. His history was probably finished after the year 1138. It contains a fabulous account of British kings, from the Trojan Brutus to the reign of Cadwallader in the year 690. But Geoffrey, whatever censure he may deserve for his credu-

lity, was not the inventor of the stories he relates. It is a translation from a manuscript written in the British language, and brought to England from Armórica by his friend Gualter, archdeacon of Oxford. But the achievements of king Arthur, Merlin's prophecies, many speeches and letters, were chiefly his own addition. In excuse for this historian, Mr Wharton judiciously observes, that fabulous histories were then the fashion, and popular traditions a recommendation to his book.

GEOFFROY (Stephen Francis), a celebrated physician, botanist, and chemist, born at Paris in 1672. After having finished his studies, he travelled into England, Holland, and Italy. In 1704, he received the degree of doctor of physic at Paris; and at length became professor of chemistry, and physician of the Royal College. He was a member of the Royal Society of London, and of the Academy of Sciences. He wrote, 1. Several very curious Theses in Latin, which were afterwards translated into French, 2. An excellent treatise intitled *Tractatus de Materia Medica, sive de Medicamentorum simplicium historia, virtute, delectu, et usu*. He died at Paris, in 1731.

GEOGRAPHICAL MILE, the same with the sea mile; being one minute, or the 60th part of a degree of a great circle on the earth's surface.

Geoffrey,
Geogra-
phical.

G E O G R A P H Y.

GEOGRAPHY (*γεωγραφία*, from *γη terra*, and *γραφω scribo*); the doctrine or knowledge of the earth, but as in itself, and as to its affections; or a description of the terrestrial globe, and particularly of the known and inhabitable parts thereof, with all its different divisions. See EARTH and ASTRONOMY.

SECT. I. History of the Science.

AT what time the Science of geography began first to be studied among mankind is entirely uncertain. It is generally agreed, that the knowledge of it was derived to the Greeks, who first of the European nations cultivated this science, from the Egyptians or Babylonians; but it is impossible to determine which of these two nations had the honour of the invention. Herodotus tells us, that the Greeks first learned the pole, the gnomon; and the 12 divisions of the day, from the Babylonians. By Pliny, and Diogenes Laertius, however, we are told, that Thales of Miletus first found out the passage of the sun from tropic to tropic; which he could not have done without the assistance of a gnomon. He is said to have been the author of two books, the one on the tropic, and the other on the equinox; both of which he probably determined by the gnomon; and by this he was led to the discovery of the four seasons of the year, which are determined by the solstices and equinoxes.

Thales divided the year into 365 days; which was undoubtedly a method discovered by the Egyptians, and communicated by them to him. It is said to have been invented by the second Mercury, surnamed *Trismegistus*, who, according to Eusebius, lived about 50 years after the *Exodus*. Pliny tells us expressly,

that this discovery was made by observing when the shadow returned to its marks; a clear proof that it was done by the gnomon. Thales also knew the method of determining the height of bodies by the length of their shadows, as appears by his proposing this method for measuring the height of the Egyptian pyramids. Hence many learned men have been of opinion, that as the use of the gnomon was known in Egypt long before the dawn of learning in Greece, the pyramids and obelisks, which to common travellers appeared only to be buildings of magnificence, were in reality as many sun-dials on a very large scale, and built with a design to ascertain the season of the year, by the variation of the length of their shadows; and, in confirmation of this opinion, it was found by M. Chazelles in 1694, that the two sides, both of the larger and smaller pyramids, stood exactly north and south; so that, even at this day, they form true meridian lines.

From the days of Thales, who flourished in the sixth century before Christ, very little seems to have been done towards the establishment of geography for 200 years. During this period, there is only one astronomical observation recorded; namely, that of Meton and Euctemon, who observed the summer solstice at Athens, during the archonship of Apseudes, on the 21st of the Egyptian month Phamenoth, in the morning, being the 27th of June 432 B. C. This observation was made by watching narrowly the shadow of the gnomon, and was done with a design to fix the beginning of their cycle of 19 years.

Timocharus and Aristillus, who began to observe about 295 B. C. seem to have been the first who attempted

Conjecture concerning the use of the Egyptian pyramids and obelisks.

3
Longitudes and latitudes determined,

1
Seasons of the year discovered by Thales,

History. attempted to fix the longitudes and latitudes of the fixed stars, by considering their distances from the equator. One of their observations gave rise to the discovery of the precession of the equinoxes, which was first observed by Hipparchus about 150 years after; and he made use of Timocharis and Aristillus's method, in order to delineate the parallels of latitude, and the meridians on the surface of the earth; thus laying the foundation of the science of geography as we have it at present.

But though the latitudes and longitudes were thus introduced by Hipparchus, they were not attended to by any of the intermediate astronomers till the days of Ptolemy. Strabo, Vitruvius, and Pliny, have all of them entered into a minute geographical description of the situation of places, according to the length of the shadows of the gnomon, without taking the least notice of the degrees and minutes of longitude and latitude.

The discovery of the longitudes and latitudes immediately laid a foundation for making maps, or delineations of the surface of the earth *in plano*, on a very different plan from what had been attempted before.

4 Formerly the maps were little more than rude outlines and topographical sketches of different countries. The earliest were those of Sesostris, mentioned by Eustathius; who says, that "this Egyptian king, having traversed great part of the earth, recorded his march in maps, and gave copies of his maps not only to the Egyptians, but to the Scythians, to their great astonishment."—Some have imagined, that the Jews made a map of the Holy Land, when they gave the different portions to the nine tribes at Shiloh; for Joshua tells us, that they were sent to walk through the land, and that they *described it in seven parts in a book*; and Josephus tells us, that when Joshua sent out people from the different tribes to measure the land, he gave them, as companions, persons well skilled in geometry, who could not be mistaken in the truth.

The first Grecian map on record is that of Anaximander, mentioned by Strabo, lib. i. p. 7. It has been conjectured by some, that this was a general map of the then known world, and is imagined to be the one referred to by Hipparchus under the designation of the *ancient map*. Herodotus minutely describes a map made by Aristagoras tyrant of Miletus, which will serve to give us some idea of the maps of those ages. He tells us, that Aristagoras showed it to Cleomenes king of Sparta, with a view of inducing him to attack the king of Persia, even in his palace at Susa, in order to restore the Ionians to their ancient liberty. It was traced upon brass or copper, and contained the intermediate countries which were to be traversed in that march. Herodotus tells us, that it contained "the whole circumference of the earth, the whole sea or ocean, and all the rivers:" but these words must not be understood literally. From the state of geography at that time, it may be fairly concluded that by the *sea* was meant no more than the Mediterranean; and therefore, the earth or land signified the coasts of that sea, and more particularly the Lesser Asia, extending towards the middle of Persia. The rivers were the Halys, the Euphrates, and Tigris, which Herodotus mentions as necessary to be crossed in that expedition. It contained one straight line, called the *Royal High-*

way, which took in all the stations or places of encampment from Sardis to Susa. Of these there were 111 in the whole journey, containing 13,500 stadia, or 1687 $\frac{1}{4}$ Roman miles of 5000 feet each.

These itinerary maps of the places of encampment, were indispensably necessary in all armies. Athenæus quotes Bæton as author of a work intitled, *The encampments of Alexander's march*; and likewise Amyntas to the same purpose. Pliny tells us, that Diognetus and Bæton were the surveyors of Alexander's marches, and then quotes the exact number of miles according to their mensuration; which he afterwards confirms by the letters of Alexander himself. It likewise appears, that Alexander was very careful in examining the measures of his surveyors, and took care to employ the most skilful in every country for this purpose. The same author also acquaints us, that a copy of this great monarch's surveys was given by Xenocles his treasurer to Patrocles the geographer, who, as Pliny informs us, was admiral of the fleets of Selencus and Antiochus. His book on geography is often quoted both by Strabo and Pliny; and it appears, that this author furnished Eratosthenes with the principal materials for constructing his map of the oriental part of the world.

Eratosthenes was the first who attempted to reduce geography to a regular system, and introduced a regular parallel of latitude. This was traced over certain places where the longest day was of the same length. He began it from the straits of Gibraltar; and it thence passed through the Sicilian sea, and near the southern extremities of Peloponnesus. From thence it was continued through the Island of Rhodes and the bay of Issus; and there entering Cilicia, and crossing the rivers Euphrates and Tigris, it was extended to the mountains of India. By means of this line, he endeavoured to rectify the errors of the ancient map, supposed to be that of Anaximander. In drawing this parallel, he was regulated by observing where the longest day was fourteen hours and an half, which Hipparchus afterwards determined to be the latitude of 36 degrees.

The first parallel through Rhodes was ever afterwards considered with a degree of preference, like the foundation stone of all ancient maps; and the longitude of the then known world was often attempted to be measured in stadia and miles, according to the extent of that line, by many succeeding geographers. Eratosthenes soon after attempted not only to draw other parallels of latitude, but also to trace a meridian at right angles to these, passing through Rhodes and Alexandria, down to Syene and Meroë; and as the progress he thus made tended naturally to enlarge his ideas, he at last undertook a still more arduous task, namely, to determine the circumference of the globe, by an actual measurement of a segment of one of its great circles. To find the measure of the earth is indeed a problem which has probably engaged the attention of astronomers and geographers ever since the globular figure of it was known. Anaximander is said to have been the first among the Greeks who wrote upon this subject. Archytas of Tarentum, a Pythagorean, famous for his skill in mathematics and mechanics, is said also to have made some attempts in this way; and Dr Long conjectures, that these are the

History.

5 Parallel of latitude how drawn at first.

6 Attempts to determine the extent of the earth's circumference.

History.
7
Most ancient opinions on this subject.

the authors of the most ancient opinion that the circumference of the earth is 400,000 stadia. Aristarchus of Samos is thought to have considered the magnitude of the earth as well as of the sun and moon. Archimedes makes mention of the ancients who held the circumference of the earth to be 30,000 stadia; but it does not appear what methods were made use of by these very ancient geographers to solve the problem. Probably they attempted it by observations of stars in the zenith or in the horizon, and actual mensuration from some part of the circumference of the earth. A proof of this we have from what Aristotle writes in his treatise *De Cælo*; that we have different stars pass through our zenith, according as our situation is more or less northerly; and that in the southern parts of the earth we have stars come above our horizon, which if we go northward will no longer be visible to us. Hence it appears, that there are two ways of measuring the circumference of the earth; one by observing stars which pass through the zenith of one place, and do not pass through that of another; the other, by observing some stars which come above the horizon of one place, and are observed at the same time to be in the horizon of another. Eratosthenes at Alexandria in Egypt made use of the former method. He knew that at the summer solstice the sun was vertical to the inhabitants of Syene, a town on the confines of Ethiopia, under the tropic of Cancer, where they had a well built for that purpose, on the bottom of which the rays of the sun fell perpendicularly the day of the summer solstice: he observed by the shadow of a wire set perpendicularly in an hemispherical basin, how much the sun was on the same day at noon distant from the zenith of Alexandria; and found that distance to be one-50th part of a great circle in the heavens. Supposing then Syene and Alexandria to be under the same meridian, he concluded the distance between them to be the 50th part of a great circle upon the earth; and this distance being by measure 5000 stadia, he concluded the circumference of the earth to be 250,000 stadia; but as this number divided by 360 would give $694\frac{2}{3}$ stadia to a degree, either Eratosthenes himself or some of his followers assigned the round number 700 stadia to a degree; which multiplied by 360, makes the circumference of the earth 252,000 stadia; whence both these measures are given by different authors as that of Eratosthenes.

8
Method used by Eratosthenes.

In the time of Pompey the Great, Posidonius made an attempt to measure the circumference of the earth by the method of horizontal observations. He knew that the star called *Ganopus* was but just visible in the horizon of Rhodes, and that at Alexandria its meridian height was the 48th part of a great circle in the heavens, or $7\frac{1}{2}$ deg., which shows what part of a great circle upon the earth the distance between those places amounts to. Supposing them both to be under the same meridian, and the distance between them to be 5000 stadia, the circumference of the earth will be 240,000 stadia; which is the first measure of Posidonius. According to Strabo, Posidonius made the measure of the earth to be 180,000 stadia, at the rate of 500 stadia to a degree. The reason of this difference is thought to be, that Eratosthenes measured the distance between Rhodes and Alexandria, and found it to be but 3750 stadia: taking this for a 48th part of the

earth's circumference, which is the calculation of Posidonius, the whole circumference will be 180,000 stadia. This measure was received by Marinus of Tyre, and is usually ascribed to Ptolemy. Posidonius's method, however, is found to be exceedingly erroneous, on account of the uncertainty of refraction in the stars which are near the horizon. Cassini remarks, that taking exactly the mean betwixt the last dimensions of Eratosthenes and Posidonius, a degree of a great circle upon the earth will be 600 stadia, and a minute of a degree 10 stadia, which is just a mile and a quarter of the ancient Roman measure and a mile of the modern measure.

History.

Several geographers after the time of Eratosthenes and Posidonius have made use of the different heights of the pole in distant places under the same meridian to find the dimensions of the earth. About the year 800, the khalif Almamun had the distance measured of two places two degrees asunder, and under the same meridian, in the plains of Sirjar near the Red Sea. The result of the matter was, that the mathematicians employed found the degree at one time to consist of 56 miles, at another of $56\frac{1}{2}$, or, as some will have it, $56\frac{2}{3}$ miles.

10
By the khalif Almamun.

The next attempt to find the circumference of the earth was in 1525 by Fernelius, a learned French physician. To attain his purpose, he took the height of the pole at Paris, going from thence directly northwards, until he came to the place where the height of the pole was one degree more than at the city. The length of the way was measured by the number of revolutions made by one of the wheels of his carriage; and after proper allowances for the declivities and turnings of the road, he concluded that 68 Italian miles were equal to a degree on the earth.

11
By Fernelius.

Snellius, an eminent Dutch mathematician, succeeded Fernelius in his attempts to measure the circumference of the earth. Having taken the heights of the pole at Alcaer and at Bergen-op-zoom, he found the difference to be $1^{\circ} 11' 30''$. He next measured the distance betwixt the parallels of these two places, by taking several stations and forming triangles; by means of which he found the degree to consist of 341,676 Leyden feet. Having measured the distance betwixt the parallels of Alcaer and Leyden, which differ only half a degree in their latitude, the calculation came out 342,120 Leyden feet to a degree. Hence he assigned the round number 342,000 Leyden feet to a degree; which, according to Picard, amounts to 55,021 French toises.

12
By Snellius.

In 1635, Mr Norwood, an Englishman, took the elevations of the pole at London and at York; and having measured the distance betwixt the two parallels, assigned $69\frac{1}{2}$ miles and two poles to a degree; each pole being reckoned $16\frac{1}{2}$ feet.

13
Mr. Norwood's calculation.

After the year 1654, Ricciolus made use of several methods to determine the circumference of the earth; from all which he concluded, that one degree contained 64,363 Bologna paces, which are equivalent to 61,650 French toises. The most remarkable attempt, however, was that of the French mathematicians, who employed telescopic sights for the purpose, which had never been done before. These are much the best; as by them the view may be directed to an object at a greater distance, and towards any point with more

14
Calculations by Ricciolus.

15
By the French academicians.

certainty;

History. certainly; whence the triangles for measuring distances may be formed with greater accuracy than otherwise can be done. In consequence of this improvement, the fundamental base of their operations was much longer than that made use of by Snellius or Ricciolus. The distance measured was between the parallels of Sourdon and Malvoisine; between which the difference of the polar altitude is somewhat more than one degree; and the result of the whole was, that one degree contained 57,060 French toises. As this problem can be the more accurately determined in proportion to the length of the meridian line measured, the members of the Royal Academy prolonged theirs quite across the kingdom of France, measuring it trigonometrically all the way. This work was begun in the year 1683, but was not finished till 1718. They made use of Picard's fundamental base, as being measured with sufficient accuracy; and an account of the whole was published by Cassini in the year 1720. In this work some mistakes were detected in the calculations of Snellius; and it was likewise shown, that there are errors in those of Ricciolus, owing principally to the latter having taken too short a fundamental base, and not having paid sufficient attention to the effects of refraction. Though Snellius, however, had made some mistakes in his calculations, there is no reason to doubt the accuracy of his observations. Holland, by reason of its flatness, is the fittest country in Europe for measuring an arc of the meridian; and Snellius had an uncommon opportunity of observing the exactness of his fundamental base, *viz.* the distance betwixt one tower at Leyden and another at Souterwode. A frost happened just after the country round Leyden had been overflowed; by which means he was enabled to take two stations upon the ice; the distance between which he carefully measured, three times over; and then from these stations he observed the angles which the visual rays pointing at those towers made with the straight line upon the ice. From these considerations professor Muschenbroek, was induced to make new calculations and form triangles upon the fundamental base of Snellius, which he did in the year 1700; and from these he assigns 57,033 toises to a degree, which is only 27 less than had been done by the academicians.

16
Inaccuracy
of the an-
cient maps.

The investigation of this problem of the circumference of the earth was essentially necessary for determining the radical principles of all maps; that of Eratosthenes, though the best of which antiquity can boast, was nevertheless exceedingly imperfect and inaccurate. It contained little more than the states of Greece, and the dominions of the successors of Alexander, digested according to the surveys abovementioned. He had seen, indeed, and has quoted; the voyages of Pytheas into the great Atlantic ocean, which gave him some faint idea of the western parts of Europe: but so imperfect, that they could not be realised into the outlines of a chart. Strabo tells us, that he was extremely ignorant of Gaul, Spain, Germany, and Britain. He was equally ignorant of Italy, the coasts of the Adriatic, Pontus, and all the countries towards the north. We are also told by the same author, that Eratosthenes made the distance between Epidamnus or Dyrrhachium on the Adriatic, and the bay of Thermæ on the Ægean sea, to be only 900 stadia, when in rea-

lity it was above 2000; and in another instance, he had enlarged the distance from Carthage to Alexandria to 15,000 stadia, when in reality it was no more than 9000.

History.

Such was the state of geography and the nature of the maps prior to the time of Hipparchus; who made a closer connection between geography and astronomy, by determining the longitudes and latitudes from celestial observations. It must be owned, however, that the previous steps to this new projection of the sphere had been in a great measure made easy by Archimedes, upwards of 50 years before the time of Hipparchus, when he invented his noble theorems for measuring the surface of a sphere and its different segments.

It appears that war has been generally the occasion of making the most accurate maps of different countries; and therefore geography made great advances from the progress of the Roman arms. In all the provinces occupied by that people, we find that camps were every where constructed at proper intervals, and roads were raised with substantial materials, for making an easier communication between them; and thus civilization and surveying were carried on according to system throughout the extent of that large empire. Every new war produced a new survey and itinerary of the countries where the scenes of action passed; so that the materials of geography were accumulated by every additional conquest. Polybius tells us, that at the beginning of the second Punic war, when Hannibal was preparing his expedition against Rome, the countries through which he was to pass were carefully measured by the Romans. Julius Cæsar caused a general survey of the Roman empire to be made, by a decree of the senate. Three surveyors, Zonodorus, Thecodotus, and Polyclitus, had this task assigned them, and are said to have completed it in 25 years. The Roman itineraries that are still extant, also show what care and pains they had been at in making surveys in all the different provinces of their empire; and Pliny has filled the third, fourth, and fifth books of his Natural History with the geographical distances that were thus measured. We have likewise another set of maps still preserved to us, known by the name of the *Peutingarian Tables*, published by Welfer and Bertius, which give a sufficient specimen of what Vegetius calls the *Itinera Picta*, for the clearer direction of their armies in their march.

The Roman empire had been enlarged to its greatest extent, and all its provinces well known and surveyed, when Ptolemy, in the reign of Antoninus Pius, about 150 years after Christ, composed his system of geography. The principal materials he made use of for compiling this work, were *the proportions of the gnomon to its shadow*, taken by different astronomers at the times of the equinoxes and solstices; calculations founded upon the length of the longest days; the measures or computed distance of the principal roads contained in their surveys and itineraries; and the various reports of travellers and navigators, who often determined the distances of places by hearsay and conjecture. All these were compared together, and digested into one uniform body or system: and afterwards were translated by him into a new mathematical language, expressing the different degrees of longitude and latitude, according to the invention of Hip-

History.

Hipparchus, but which Ptolemy had the merit of carrying into full practice and execution, after it had been neglected for upwards of 250 years. With such imperfect and inaccurate materials, it is no wonder to find many errors in Ptolemy's system. Neither were these errors such as had been introduced in the more distant extremities of his maps, but even in the very centre of that part of the world which was the best known to the ancient Greeks and Romans, and where all the famed ancient astronomers had made their observations.—Yet this system, with all its imperfections, continued in vogue till the beginning of the present century. The improvements in geography which at that time, and since, have taken place, were owing to the great progress made in astronomy by several eminent men who lived during that period. More correct methods and instruments for observing the latitude were found out; and the discovery of Jupiter's satellites afforded a much easier method of finding the longitudes than was formerly known. The voyages made by different nations also, which were now become much more frequent than formerly, brought to the knowledge of the Europeans a vast number of countries utterly unknown to them before. The late voyages of Captain Cooke, made by order of his Britannic Majesty, have contributed more to the improvement of geography than any thing that has been done during the present century; so that now the geography of the utmost extremities of the earth is in a fair way of being much better known to the moderns than that of the most adjacent countries was to the ancients. This, however, must be understood only of the sea-coasts of these countries; for, as to their internal geography, it is less known now than before, except in a very few places.

17
Geography
still imper-
fect.

On the whole, it may be observed, that geography is a science even yet far from perfection. The maps of America and the eastern parts of Asia are, perhaps, more unfinished than any of the rest. Even the maps of Great Britain and Ireland are very imperfect and unsatisfactory; and the numbers we have of them, varied, and republished, without any real improvement, justly confirm an observation made by Lord Bacon, namely, that an opinion of plenty is one of the causes of want. The late Dr Bradley was of opinion, that there were but two places in England whose longitude might be depended upon as accurately taken; and that these were the observatory at Greenwich, and Serburn-castle the seat of the earl of Macclesfield in Oxfordshire; and that their distance was one degree in space, or four minutes in time. Even this was found to be inaccurate, the distance in time being observed by the late transit of Venus to be only three minutes and 47 seconds. It were well, however, if there were no greater errors with regard to other places: but if we examine the longitude of the Lizard, we shall find scarce any two geographers that agree concerning it; some making it $4^{\circ} 40'$ from London; others 5° , and $5^{\circ} 14'$; while some enlarge it to 6° . Our best maps are therefore still to be considered as unfinished works, where there will always be many things to be added and corrected, as different people have an opportunity.

SECT. II. *Principles and Practice of Geography.*

Principles
and
Practice.

THE fundamental principles of geography are, the spherical figure of the earth; its rotation on its axis; its revolution round the sun; and the position of the axis or line round which it revolves, with regard to the celestial luminaries. That the earth and sea taken together constitute one vast sphere, is demonstrable by the following arguments. 1. To people at sea, the land disappears, though near enough to be visible were it not for the intervening convexity of the water. 2. The higher the eye is placed, the more extensive is the prospect; whence it is common for sailors to climb up to the tops of the masts to discover land or ships at a distance. But this would give them no advantage were it not for the convexity of the earth; for, upon an infinitely extended plane objects would be visible at the same distance whether the eye were high or low; nor would any of them vanish till the angle under which they appeared became too small to be perceptible. 3. To people on shore, the mast of a ship at sea appears before the hull; but were the earth an infinite plane, not the highest objects, but the biggest, would be longest visible; and the mast of a ship would disappear by reason of the smallness of its angle long before the hull did so. 4. The convexity of any piece of still water of a mile or two extent may be perceived by the eye. A little boat, for instance, may be perceived by a man who is any height above the water; but if he stoops down and lays his eye near the surface, he will find that the fluid appears to rise and intercept the view of the boat entirely. 5. The earth has been often sailed round; as by Magellan, Drake, Dampier, Anson, Cook, and many other navigators; which demonstrates that the surface of the ocean is spherical; and that the land is very little different, may easily be proved from the small elevation of any part of it above the surface of the water. The mouths of rivers which run 1000 miles are not more than one mile below their sources; and the highest mountains are not quite four miles of perpendicular height: so that, though some parts of the land are elevated into hills, and others depressed into valleys, the whole may still be accounted spherical. 6. An undeniable and indeed ocular demonstration of the spherical figure of the earth is taken from the round figure of its shadow which falls upon the moon in the time of eclipses. As various sides of the earth are turned towards the sun during the time of different phenomena of this kind, and the shadow in all cases appears circular, it is impossible to suppose the figure of the earth to be any other than spherical. The inequalities of its surface have no effect upon the earth's shadow on the moon; for as the diameter of the terraqueous globe is very little less than 8000 miles, and the height of the highest mountain on earth not quite four, we cannot account the latter any more than the 2000th part of the former; so that the mountains bear no more proportion to the bulk of the earth, than grains of dust bear to that of a common globe.

A great many of the terrestrial phenomena depend upon the globular figure of the earth, and the position of its axis with regard to the sun; particularly the rising

rising and setting of the celestial luminaries, the length of the days and nights, &c. A general explanation of these is given under the article ASTRONOMY; but still it belongs to geography to take notice of the difference betwixt the same phenomena in different parts of the earth. Thus, though the sun rises and sets all over the world, the circumstances of his doing so are very different in different countries. The most remarkable of these circumstances is the duration of the light not only of the sun himself, but of the twilight before he rises and after he sets. In the equatorial regions, for instance, darkness comes on very soon after sun-set; because the convexity of the earth comes quickly in between the eye of the observer and the luminary, the motion of the earth being much more rapid there than any where else. In Britain the twilight always continues two hours or thereabouts, and during the summer-season it continues in a considerable degree during the whole night. In countries farther to the northward or southward, the twilight becomes brighter and brighter as we approach the pole, until at last the sun does not appear to touch the horizon, but goes in a circle at some distance above it for many days successively. In like manner, during the winter, the same luminary sinks lower and lower, until at last he does not appear at all; and there is only a dim twinkling of twilight for an hour or two in the middle of the day. By reason of the refraction of the atmosphere, however, the time of darkness, even in the most inhospitable climates, is always less than that of light; and so remarkable is the effect of this property, that in the year 1682, when some Dutch navigators wintered in Nova Zembla, the sun was visible to them 16 days before he could have been seen above the horizon had there been no atmosphere, or had it not been endowed with any such power. The reason of all this is, that in the northern and southern regions only a small part of the convexity of the globe is interposed betwixt us and the sun for many days, and in the high latitudes none at all. In the warmer climates the sun has often a beautiful appearance at rising and setting, by reason of the refraction of his light through the vapours which are copiously raised in those parts. In the colder regions, halos, parhelia, aurora borealis, and other meteors, are frequent; the two former owing to the great quantity of vapour continually flying from the warm regions of the equator to the colder ones of the poles. The aurora borealis is owing to the electrical matter imbibed by the earth from the sun in the warm climates, and going off through the upper regions of the atmosphere to the place from whence it came. In the high northern latitudes, thunder and lightning are unknown, or but seldom heard of; but the more terrible phenomena of earthquakes, volcanoes, &c. are by no means unfrequent. These, however, seem only to affect islands and the maritime parts of the continent. See the articles EARTHQUAKE and VOLCANO.

Notwithstanding the seeming inequality in the distribution of light and darkness, however, it is certain, that throughout the whole world there is nearly an equal proportion of light diffused on every part, abstracting from what is absorbed by clouds, vapours, and the atmosphere itself. The equatorial regions have indeed the most intense light during the day,

but the nights are long and dark; while, on the other hand, in the northerly and southerly parts, though the sun shines less powerfully, yet the length of time that he appears above the horizon, with the greater duration of the twilight, makes up for the seeming deficiency.

Were the earth a perfect plane, the sun would appear to be vertical in every part of it: For in comparison with the immense magnitude of that luminary, the diameter of this globe itself is but very small: and as the sun, were he near to us, would do much more than cover the whole earth; so, though he were removed to any distance, the whole diameter of the latter would make no difference in the apparent angle of his altitude. By means of the globular figure of the earth also, along with the great disparity between the diameters of the two bodies, some advantage is given to the day over the night: for thus the sun, being immensely the larger of the two, shines upon more than one half of the earth; whence the unenlightened part has a shorter way to go before it again receives the benefit of his rays. This difference is greater in the inferior planets Venus and Mercury than the earth.

To the globular figure of the earth likewise is owing the long moon-light which the inhabitants of the polar regions enjoy, the general reason of which is given under the article ASTRONOMY, n^o 373. The same thing likewise occasions the appearance and disappearance of certain stars at some seasons of the year in some countries; for were the earth flat, they would all be visible in every part of the world at the same time. Hence most probably has arisen the opinion of the influence of certain stars upon the weather and other sublunary matters. In short, on the globular figure of the earth depends the whole present appearance of nature around us; and were the shape of the planet we inhabit to be altered to any other, besides the *real* differences which would of consequence take place, the *apparent* ones would be so great that we cannot form any idea of the face which nature would then present to us.

In geography the circles which the sun apparently describes in the heavens are supposed to be extended as far as the earth, and marked on its surface; and in like manner we may imagine as many circles as we please to be described on the earth, and their planes to be extended to the celestial sphere, till they mark concentric ones on the heaven. The most remarkable of these supposed by geographers to be described in this manner are the following.

1. *The Horizon.* This is properly a double circle, one of the horizons being called the *sensible*, and the other the *rational*. The former comprehends only that space which we can see around us upon any part of the earth; and which is very different according to the difference of our situation. The other, called the *rational*, is a circle parallel to the former, and passing through the centre of the earth supposed to be continued as far as the celestial sphere itself. To the eyes of spectators, there is always a vast difference between the sensible and rational horizons; but by reason of the immense disparity betwixt the size of the earth and celestial sphere, planes of both circles may be considered as coincident. Hence, in geography, when the horizon, or plane of the horizon is spoken of, the rational

20
Circles supposed to be drawn on the earth's surface

21
Horizon.

Principles
and
Practice.

22

Vertical
circles or
azimuths.

tional is always understood, when nothing is said to the contrary. By reason of the round figure of the earth, every part has a different horizon. The poles of the horizon, that is, the points directly above the head, and opposite to the feet of the observer, are called the *zenith* and *nadir*.

2. A great circle described upon the sphere of the heaven, and passing through the two vertical points, is called a *vertical circle*, or an azimuth; and of these we may suppose as many as we please all round the horizon. Sometimes they are also called *secondaries* of the horizon; and in general any great circle, drawn through the poles of another, is called its *secondary*. In geography every circle obtains the epithet of *great* whose plane passes through the centre of the earth; in other cases they are called *lesser circles*. The altitudes of the heavenly bodies are measured by an arch of the azimuth or vertical circle intercepted between the horizon and the body itself. The method of taking them is explained under the article *ASTRONOMY*, n^o 379; but a more accurate method with regard to the sun and moon, is for two persons to make their observations at the same time; one of them to observe the altitude of the upper limb, the other of the lower limb of the luminary; the mean betwixt these two giving the true height of the centre. The same thing may also be done accurately by one observer, having the apparent diameter of the luminary given. For, having found the height of the upper edge of the limb by the quadrant, take from it half his diameter, the remainder is the height of his centre; or having found the altitude of his lower edge, add to it half the diameter, and the sum is the height of the centre as before. When the observations are made with a large instrument, it will be convenient to use a sextant, or sixth part of a circle, rather than a quadrant, as being less unwieldy.

24

Almucantars.

3. *Almucantars* are circles supposed to be drawn upon the sphere parallel to the horizon, and grow less and less as they approach the vertical points, where they entirely vanish. The apparent distances betwixt any two celestial bodies are measured by supposing arches of great circles drawn through them, and then finding how many degrees, minutes, &c. of these circles are intercepted between them. The apparent diameter of the sun's disk is found by a circle of distance drawn through the centre of it; and the number of minutes continued between the two opposite points of that part of the circle which passes through the centre is the measure of the apparent diameter. The apparent diameter of the sun may be found by two observers, one taking the altitude of the upper, and the other of the lower edge of the limb; the difference betwixt the two being the diameter required; or,

26

Sensible
horizon de-
fined.

4. Sometimes the visible horizon is considered only with regard to the objects which are upon the earth itself; in which case we may define it to be a lesser circle on the surface of the earth, comprehending all such objects as are at once visible to us; and the higher the eye, the more is the visible horizon extended. It is most accurately observed, however, on the sea, on account of the absence of those inequalities which at land render the circle irregular; and for this reason it is called sometimes the horizon of the sea; and may be observed by looking through the sights of a quadrant at the most distant part of the sea then visible.

In making this observation, the visual rays AD and AE, fig. 2. will, by reason of the spherical surface of the sea, always point a little below the true sensible horizon SS; and consequently below the rational horizon which is parallel to it, and supposed to be coincident with it. The quadrant shows the depression of the horizon of the sea below the true horizon; and it is obvious from the figure, that the higher the eye is, the greater must this depression be. The depression of the horizon of the sea, however, is not always the same, even though there be no variation in the height of the eye. The difference indeed is but small, amounting only to a few seconds, and is owing to a difference in the atmosphere, which sometimes refracts more than at others. Without refraction, the visual ray would be AE, and in that case E is the most distant point which could be seen; but by refraction, the ray FG, coming from the point G, may be seen at F, so as to go on from thence in the line FA; and then the view is extended as far as G, and the depression of the horizon of the sea is in the line AF, which points higher than AE, but extends the view farther. From an inspection of the figure it is evident, that if the refraction were greater, the view would be extended still farther, as to M; though the depression of the horizon of the sea would then be less, as is shown by the line ALM: whence also it appears, that by reason of the difference of refraction in the air, our horizon is sometimes more extensive than at others.

5. The *equator* is a great circle upon the earth, every part of which is equally distant from the poles or extremities of the imaginary line on which the earth revolves. In the sea-language it is usually called the *line*, and when people sail over it they are said to cross the line.

28

Equator.

6. The *meridian* of any place is a great circle on the earth drawn through that place and both poles of the earth. It cuts the horizon at right angles, marking upon it the true north and south points; dividing also the globe into two hemispheres called the *eastern* and *western* from their relative situation to that place and to one another. The poles divide the meridians into two semicircles; one of which is drawn through the place to which the meridian belongs, the other through that point of the earth which is opposite to the place. By the meridian of a place geographers and astronomers often mean that semicircle which passes through the place; and which may therefore be called the *geographical meridian*. All places lying under this semicircle are said to have the same meridian; the semicircle opposite to this is called the *opposite meridian*. The meridians are thus immoveably fixed to the earth as much as the places themselves on its surface; and are carried along with it in its diurnal rotation. When the geographical meridian of any place is, by the rotation of the earth, brought to point at the sun, it is noon or mid-day at that place; in which case, were the plane of the circle extended, it would pass through the middle of the luminary's disk. Supposing the plane of the meridians to be extended to the sphere of the fixed stars, in that case, when by the rotation of the earth the meridian comes to any point in the heavens, then, from the apparent motion of the heavens, that point is said to come to the meridian. The rotation of the earth is from west to east; whence the celestial bodies appear to move the con-

29
Meridians.

trary

Principles and Practice

30 True east and west points.

31 Longitude and first meridian.

trary way. East and west, however, are terms merely relative; since a place may be west from some part of the earth, and east from another; but the true east and west points from any place are those where its horizon cuts the equator.

7. All places lying under the same meridian are said to have the same *longitude*, and those which lie under different meridians to have different longitudes; the difference of longitude being reckoned eastward or westward on the equator. Thus if the meridian of any place cuts the equator in a point 15 degrees distant from another, we say there is a difference of 15° longitude betwixt these two places. Geographers usually pitch upon the meridian of some remarkable place for the first meridian; and reckon the longitude of all others by the distance of their meridians from that which they have pitched upon as the first; measuring sometimes eastward on the equator all round the globe, or sometimes only one half east and the other west; according to which last measurement, no place can have more than 180° longitude either east or west. By the ancient Greek geographers the first meridian was placed in *Hera* or *Junonia*, one of the *Fortunate Islands* as they were then called; which is supposed to be the present island of *Teneriffe*, one of the *Canaries*. These islands being the most westerly part of the earth then known, were on that account made the seat of the first meridian, the longitude of all other places being counted eastward from them. The Arabians, ambitious of having the first meridian taken from them, fixed it at the most westerly part of the continent of *Africa*. Some later geographers placed the first meridian in the island of *Corvo*, one of the *Azores* (A); because at that time the magnetic needle on the island just mentioned pointed due north without any variation; and it was not then known that the needle itself was subject to variation, as has since been discovered. *Bleau* replaced the first meridian in the isle of *Teneriffe*; and to ascertain the place more exactly, caused it to pass through the famous mountain of that island, called the *peak* from *el-pico*, 'a bird's beak.' Among modern geographers, however, it is now become customary for each to make the first meridian pass through the capital of his own country; a practice, however, which is certainly improper, as it is thus impossible for the geographers of one nation to understand the maps of another without a troublesome calculation, which answers no purpose. By the British geographers the royal observatory at *Greenwich* is accounted the place of the first meridian.

32 Hour circles.

8. If we suppose 12 great circles, one of which is the meridian to a given place, to intersect each other at the poles of the earth, and divide the equator into 24 equal parts, these are the *hour-circles* of that place. These are by the poles divided into 24 semicircles, corresponding to the 24 hours of the day and night. The distance betwixt each two of these semicircles is 15°, being the 24th part of 360; and by the rotation of the earth, each succeeding semicircle points at the sun one hour after the preceding; so that in 24 hours all the semicircles point successively at the sun. Hence

it appears that such as have their meridian 15° east from any other, have likewise noon one hour sooner, and the contrary; and in like manner every other hour of the natural day is an hour sooner at the one place than at the other. Hence, from any instantaneous appearance in the heavens observed at two distant places, the difference of longitude may be found, if the hour of the day be known at each place. Thus the beginning of an eclipse of the moon, when the luminary first touches the shadow of the earth, is an instantaneous appearance, as also the end of an eclipse of this kind when the moon leaves the shadow of the earth, visible to all the inhabitants on that side of the globe. If therefore we find, that at any place an eclipse of the moon begins an hour sooner than at another, we conclude that there is a difference of 15° of longitude between the two places. Hence also were a man to travel or sail round the earth from west to east, he will reckon one day more to have passed than they do who stay at the place from whence he set out; so that their Monday will be his Tuesday, &c. On the other hand, if he sails westward, he will reckon a day less or be one day in the week later, than those he leaves behind.

Principles and Practice.

9. The equator divides the earth into two hemispheres called the *northern* and *southern*: all places lying under the equator are said to have no latitude; and all others to have north or south latitude according to their situation with respect to the equator. The *latitude* itself is the distance from the equator measured upon the meridian, in degrees, minutes, and seconds. The complement of latitude is the difference between the latitude itself and 90°, or as much as the place itself is distant from the pole; and this complement is always equal to the elevation of the equator above the horizon of the place. The elevation of the pole of any place is equal to the latitude itself.

33 Of the latitude.

An inhabitant of the earth who lives at either of the poles, has always one of the celestial poles in his zenith and the other in his nadir, the equator coinciding with the horizon: hence all the celestial parallels are also parallel to the horizon; whence the person is said to live in a parallel sphere, or to have a parallel horizon.

34

Of a parallel sphere.

Those who live under the equator have both poles in the horizon, all the celestial parallels cutting the horizon at right angles; whence they are said to live in a right-sphere, or to have a right horizon.

35

Right sphere.

Lastly, those who live between either of the poles and the equator are said to live in an oblique sphere, or to have an oblique horizon; because the celestial equator cuts his horizon obliquely, and all the parallels in the celestial sphere have their planes oblique to that of the horizon. In this sphere some of the parallels intersect the horizon at oblique angles, some are entirely above it, and some entirely below it; all of them, however, so situated, that they would obliquely intersect the plane of the horizon extended.

36

Oblique sphere.

The largest parallel which appears entire above the horizon of any place in north latitude is called by the ancient astronomers the *arctic circle* of that place; within

37

Arctic and antarctic circle.

(A) These islands had their name from the number of goshawks found there; the word *azor* in Spanish signifying a "goshawk."

Principles
and
Practice.

within this circle, *i. e.* between it and the arctic pole, are comprehended all the stars which never set in that place, but are carried perpetually round the horizon in circles parallel to the equator. The largest parallel which is hid entire below the horizon of any place in north latitude was called the *antarctic circle* of that place by the ancients. This circle comprehends all the stars which never rise in that place, but are carried perpetually round below the horizon in circles parallel to the equator. In a parallel sphere, however, the equator may be considered as both *arctic* and *antarctic* circle; for being coincident with the horizon, all the parallels on one side are entirely above it, and those on the other entirely below it. In an oblique sphere, the nearer any place is to either of these poles, the larger are the arctic and antarctic circles, as being nearer to the celestial equator, which is a great circle. In a right sphere, the arctic and antarctic circles have no place; because no parallel appears either entirely above or below it. By the arctic and antarctic circles, however, modern geographers in general understand two fixed circles at the distance of $23\frac{1}{2}$ degrees from the pole. These are supposed to be described by the poles of the ecliptic, and mark out the space all round the globe where the sun appears to touch the horizon at midnight in the summer time, and to be entirely sunk below it in the winter. These are also called the *polar circles*. By the ancients the arctic circle was called *maximus semper apparentium*, and *circulus perpetuæ apparitionis*; the antarctic circle, on the other hand, being named *maximus semper occultorum*, and *circulus perpetuæ occultationis*.

38
Appearances to the inhabitants of a parallel, right, and oblique sphere.

According to the different positions of the globe with regard to the sun, the celestial bodies will exhibit different phenomena to the inhabitants. Thus, in a parallel sphere, they will appear to move in circles round the horizon; in a right sphere, they would appear to rise and set as at present, but always in circles cutting the horizon at right angles; but in an oblique sphere, the angle varies according to the degree of obliquity, and the position of the axis of the sphere with regard to the sun. The phenomena thence arising will be sufficiently understood from what is said under the article *ASTRONOMY*, n^o 345, &c. From thence we will easily perceive the reason of the sun's continual change of place in the heavens: but though it is certain that this change takes place every moment, the vast distance of the luminary renders it imperceptible for some time, unless to very nice astronomical observers. Hence we may generally suppose the place of the sun to be the same for a day or two together, though in a considerable number of days it becomes exceedingly obvious to every body. When he appears in the celestial equator, his motion appears for some time to be in the plane of that circle, though it is certain that his place there is only for a single moment; and in like manner, when he comes to any other point of the heavens, his apparent diurnal motion is in a parallel drawn throughout. Twice a-year he is in the equator, and then the days and nights are nearly equal all over the earth. This happens in the months of March and September; after which the sun proceeding either northward or south, according to the season of the year and the position of the observer, the days become longer or shorter than the nights, and

summer or winter come on, as is fully explained under the article *ASTRONOMY*. The secession of the sun from the equator either northward or southward is called his *declination*, and is either north or south according to the season of the year; and when this declination is at its greatest height, he is then said to be in the tropic, because he begins to turn back (the word *tropic* being derived from the Greek *τροπος* *verto*). The space between the two tropics, called the *torrid zone*, extends for no less than 47 degrees of latitude all round the globe; and throughout the whole of that space the sun is vertical to some of the inhabitants twice a-year, but to those who live directly under the tropics only once. Throughout the whole torrid zone also there is little difference between the length of the days and nights. The ancient geographers found themselves considerably embarrassed in their attempts to fix the northern tropic; for though they took a very proper method, namely, to observe the most northerly place where objects had no shadow on a certain day, yet they found that on the same day no shadow was cast for a space of no less than 300 stadia. The reason of this was, the apparent diameter of the sun; which being about half a degree, seemed to extend himself over as much of the surface of the earth, and to be vertical every where within that space.

Principles
and
Practice.

39
Sun's declination.

40
Of the tropics, &c.

When the sun is in or near the equator, he seems to change his place in the heavens most rapidly; so that about the equinoxes one may very easily perceive the difference in a day or two; but as he approaches the tropics this apparent change becomes gradually slower; so that for a number of days he scarce seems to move at all. The reason of this may be easily be understood from any map on which the ecliptic is delineated: for by drawing lines through every degree of it parallel to the equator, we shall perceive them gradually approach nearer and nearer each other, until at last, when we approach the point of contact betwixt the ecliptic and tropic, they can for several degrees scarce be distinguished at all.

From an observation of the diversity in the length of the days and nights, the rising and setting of the sun, with the other phenomena already mentioned, the ancient geographers divided the surface of the earth into certain districts which they called *climates*; and instead of the method of describing the situation of places by their latitude and longitude as we do now, they contented themselves with mentioning the climate in which they were situated. When more accuracy was required, they mentioned also the beginning, middle, and ending of the climates. This distinction, however, was certainly very vague and inaccurate: for the only method they had for determining the difference was by the length of the day; and a climate according to them, was such a space as had the day in its most northerly part half an hour longer than in the most southerly. For the beginning of their first climate they took that parallel under which the day is twelve hours and three quarters long, those parts of the world which lie nearer the equator not being supposed to be in any climate; either because in a loose sense they may be considered as in a right sphere, or because they were unknown, or thought to be uninhabitable by reason of the heat. The northern climates were generally supposed to be seven; which must have

41
Division of the earth's surface into climates.

Principles
and
Practice.

Principles
and
Practice.

have an equal number of southern climates corresponding with them. The names of the northern climates, according to the ancients, were as follow: 1. Meroe. 2. Syene in Egypt. 3. Alexandria in Egypt. 4. Rhodes. 5. Rome; or, according to others, a parallel drawn through the Hellespont. 6. The parallel passing through the mouth of the river Boristhenes. 7. The Riphean mountains.—Each of these places was supposed to be in the middle of the climate; and as the southern parts of the globe were then very little known, the climates to the southward of the equator were supposed to be as far distant from that circle as the northern ones; in consequence of which they took their names from the latter.

A parallel was said to pass through the middle of a climate when the day under that parallel is a quarter of an hour longer than that which passes through the most southerly part. Hence it does not divide the space into two equal parts, but that part next the equator will always be the larger of the two; because the farther we recede from that circle, the less increase of latitude will be sufficient to lengthen the day a quarter of an hour. Thus, in every climate there are three parallels; one making the beginning, the second, the middle, and the third the ending of the climate; the ending of one being always the beginning of another. Some of the ancients divided the earth by these parallels; others by a parallel did not mean a mere line, but a space of some breadth: and hence the parallel may be understood as the same with half a climate.

This method of dividing the surface of the earth into climates, though now very much disused, has been adopted by several modern geographers. Some of these begin their climates at the equator, reckoning them by the increase of half an hour in the length of the day northward. Thus they go on till they come to the polar circles, where the longest day is 24 hours: betwixt these and the poles they count the climates by the increase of a natural day in the length of time that the sun continues above the horizon, until they come to one where the longest day is 15 of ours, or half a month; and from this to the pole they count by the increase of half months or whole months, the climates ending at the poles where the days are six months long. The climates betwixt the equator and the polar circles are called *hour-climates*, and those between the polar circles and the poles are called *month-climates*.—In common language, however, we take the word *climate* in a very different sense; so that, when two countries are said to be in different climates, we understand only that the temperature of the air, seasons, &c. are different.

42
Different
names given to people from the position of their shadows.

From the difference in the length and positions of the shadows of terrestrial substances, ancient geographers have given different terms to the inhabitants of certain places of the earth; the reason of which will be easily understood from the following considerations. 1. Since the sun in his apparent annual revolution never removes farther from the equator than 23½ degrees, it follows, that none of those who live without that space, or beyond the tropics, can have the luminary vertical to them at any season of the year. 2. All who live between the tropics have the sun vertical twice a-year, though not all at the same time.

Thus, to those who live directly under the equator, he is directly vertical in March and September at the time of the equinox. If a place is in 10° north latitude, the sun is vertical when he has 10° north declination; and so of every other place. 3. All who live between the tropics have the sun at noon sometimes north and sometimes south of them. Thus, they who live in a place situated in 20° north latitude, have the sun at noon to the northward when he has more than 20 degrees north declination, and to the southward when he has less. 4. Such of the inhabitants of the earth as live without the tropics, if in the northern hemisphere, have the sun at noon to the southward of them, but to the northward if in the southern hemisphere. 5. When the sun is in the zenith of any place, the shadow of a man or any upright object falls directly upon the place where they stand, and consequently is invisible; whence the inhabitants of such places were called *Afcii*, or without shadows: those who live between the tropics, and have the sun sometimes to the north and sometimes to the south of them, have of consequence their shadows projecting north at some seasons of the year and south at others; whence they were called *Araphiscii*, or having two kinds of shadows. They who live without the tropics have their noon shadows always the same way; and are therefore called *Heteroscii*, that is, having only one kind of shadow. If they are in north latitude, the shadows are always turned towards the north; and if in the southern hemisphere, towards the south. When a place is so far distant from the equator that the days are 24 hours long or longer, the inhabitants were called *Periscii*, because their shadows turn round them.

Names have likewise been imposed upon the inhabitants of different parts of the earth from the parallels of latitude under which they live, and their situation with regard to one another. Thus, when two places are so near each other that the inhabitants have only one horizon, or at least that there is no perceptible difference between them, the inhabitants were called *Synæci*, that is, near neighbours; the seasons, days, nights, &c. in both places being perfectly alike. Those who lived at distant places, but under the same parallel, were called *Periæci*, that is, living in the same circle. Those who are on the same side of the equator have the seasons of the year at the same time; but if on different sides, the summer season of the one is the winter of the other, as is fully explained under the article ASTRONOMY. Some writers, however, by the name of *Periæci*, distinguish those who live under opposite points of the same parallel, where the noon of one is the midnight of the other. When two places lie under parallels equally distant from the equator, but in opposite hemispheres, the inhabitants were called *Antæci*. These have a similar increase of days and nights, and similar seasons, but in opposite months of the year. According to some, the Antæci were such as lived under the same geographical meridian, and had day and night, at the same time. If two places are in parallels equally distant from the equator, and in opposite meridians, the inhabitants were called *Antichthones* with respect to one another, that is, living on opposite sides of the earth; or *Antipodes*, that is, having their feet opposite to one another. When two persons are Antipodes, the zenith of the one is the nadir

nadir of the other. They have a like elevation of the pole, but it is of different poles: they have also days and nights alike, and similar seasons of the year; but they have opposite hours of the day and night, as well as seasons of the year. Thus, when it is mid-day with us, it is midnight with our Antipodes; when it is summer with us, it is winter with them, &c.

From the various appearances of the sun, and the effects of his light and heat upon different parts of the earth, the division of it into *zones* has arisen. These are five in number. 1. The torrid zone, lying between the two tropics for a space of 47° of latitude. This is divided into two equal parts by the equator; and the inhabitants have the sun vertical to them twice a-year, excepting only those who dwell under the tropics, to whom he is vertical only once, as has already been explained. 2. The two temperate zones lie between the polar circles and the tropics, containing a space of 45° of latitude. And, 3. The two frigid zones lie between the polar circles and the poles. In these last the longest day is never below 24 hours, in the temperate zones it is never quite so much, and in the torrid zone it has never above 14. The zones are named from the degree of heat they were supposed to be subjected to. The torrid zone was supposed by the ancients to be uninhabitable by reason of its heat; but this is now found to be a mistake, and many parts of the temperate zones are more intolerable in this respect than the torrid zone itself. Towards the polar circles, also, these zones are intolerably cold during the winter season. Only a small part of the northern frigid zone, and none of the southern, is inhabited. Some geographers reckoned six zones, dividing the torrid zone into two by the equator.

When any parts of the heaven or earth are said to be on the right or left, we are to understand the expression differently according to the position of the person who makes use of it; because according to that his face is supposed to be turned towards a certain quarter. A geographer is supposed to stand with his face to the north, because the northern part of the world is best known. An astronomer looks towards the south, to observe the celestial bodies as they come to the meridian. The ancient augurs, in observing the flight of birds, looked towards the east; while the poets look towards the *Fortunate Isles*. In books of geography, therefore, by the right hand we must understand the east; in those of astronomy, the west; in such as relate to augury, the south; and in the writings of poets, the north.

Under the article *ASTRONOMY*, n^o 376, *et seq.* the method of drawing a meridian line is fully explained; the knowledge of which is absolutely necessary both for geographers and astronomers. To what is mentioned there we shall only add further, that the time for drawing a line of this kind is when the sun is nearly at the summer solstice; because the difference of declination is then scarce perceptible for several days, and in the few hours requisite for the operation may be totally disregarded. The winter solstice would do equally well, were it not that the sun is then so low in the heavens that a difference in the refraction might cause a considerable error in the result. The motion of the luminary above the horizon is likewise so oblique, that he changes his vertical faster than his alti-

tude, which is inconvenient in an operation where we are to determine the vertical by the altitude. A clear day must be chosen for the purpose; and the ground on which the shadow falls ought to be white, that the shadow may be the better defined. The stile ought not to be too high, because then the top of the shadow will be indistinct; neither ought it to terminate in a point, for the same reason. Dr Long recommends the top of it to be about an eighth of an inch thick. Having drawn a meridian line upon one plane, we may draw one upon another by the following method: Hang a thread with a plummet exactly over the south end of the meridian line given, and another on the plane on which the meridian line is to be drawn. Let one person observe at noon the moment when the shadow of the first thread falls exactly upon the meridian given, and let another observer at the same time mark two distant points in the shadow of the second thread: a line drawn through these points is the meridian line required. Thus also a meridian line may be drawn upon a south wall by marking two points in the shadow of a thread hung at a little distance from it. If the meridians are near, he that observes the shadow of the first thread may let the other know the moment it falls upon the meridian line by saying, *Now*; if far distant, it should be done by the motion of the hand, because sound takes up some time in passing from one place to another. A quadrant or other astronomical instrument may now be fixed in the meridian line in such a manner as to be capable of different elevations, in order to observe the altitudes of the different celestial bodies; the plane of that side of the instrument on which the degrees arc marked being all the while kept in the meridian. The mural arc in the Royal Observatory at Greenwich is a wall of black marble; one side of which, standing exactly in the plane of the meridian, has a large and accurately divided brass quadrant fixed to it, moveable round its centre, and with telescope sights. See *ASTRONOMY*, n^o 497. At sea, where they cannot have a meridian line, the greatest height of a star or the sun is taken for the meridian height.

Having got a meridian line by either of the methods mentioned under the article *ASTRONOMY*, it may be prolonged to what length we please, and the distance of it measured. The meridian of the royal observatory at Paris being found, and an instrument with telescopic sights placed vertically therein, the north and south points of the visible horizon were observed through the sights, and a pillar erected upon the north point; then, by another instrument placed horizontally, several distant objects, as steeples, &c. were viewed, and the angles which the usual lines made with the meridian line were observed. From the places of these new objects, then, others were observed; and where natural objects were deficient, they set up large poles. Thus several triangles were formed along the meridian: and in order to measure those triangles, a paved way from *Villejuive* to *Juvisy* was made choice of for the fundamental base, as lying in a straight line from north to south. For the actual mensuration of this way, two poles were made use of, each of them four toises in length, and made of two pike-staves joined together at the great ends by a screw. One of the measuring poles was first laid upon the ground;

ground; the other was joined to it end to end along by a rope stretched from north to south: the first pole was then taken up and laid down at the end of the second, and so on successively; and for the greater ease in keeping the account, the measurer who laid down the second pole had ten little stakes given him, one of which he stuck into the ground at the end of his pole every time he laid it down; so that every stake marked eight toises; the whole, when stuck into the ground marking 80 toises. Thus the length of the road above-mentioned was twice measured, and found to be 5663 toises and 4 feet in going, and 5663 toises and 1 foot in returning; so that as a greater exactness could not be hoped for, 5663 toises were pitched upon as the true length of this fundamental base. This is represented fig. 5. by the line OP; and the calculations of the triangles upon it were made in the following manner. The angle COP was observed from O, one end of the base; from the other end the angle OPC; and from the station C, the angle OCP: and thus all the angles of the triangle CPO, and the length of one side OP, being known, the lengths of the remaining sides OC and PC were found by calculation. The next step was to observe all the angles of the triangle OBC, and from thence, and the known length of the side OC, to calculate the other side OB and BC. Then all the angles being observed, and the side BC being known of the triangle ABC, which may be called the first or principal triangle of the meridian of the observatory, the other sides AB and AC were found. Then, from one of the sides now known, and the angles observed, all the sides of the next adjoining triangle CBE were found. Thus they proceeded from one triangle to another to the place where the meridian ended in the south part of France; and there the last triangle was terminated by a base of the length of 7246 toises, which was actually measured in order to verify the preceding operations. The meridian line of Paris being prolonged in the manner just now described, the situation of several other places in France was determined by trigonometry, and an accurate map of the country drawn, especially of those parts which lie near the meridian of Paris.

48
To observe
the transits,
altitudes,
&c. of the
heavenly
bodies.

Having found a meridian line, the transits or passages of the heavenly bodies across it may be observed by hanging two threads with plummet exactly over it, at a little distance from one another, which consequently will be directly in the plane of the meridian: if you place your eye close to one of the threads in such a manner that you make it cover the other, and both appear as one thread, when a star is behind the threads, it is in the meridian. By the same method the sun may be viewed through a smoked glass: when the threads pass through his centre he is in the meridian. But the best way of observing either the sun, moon, stars, or planets, is through a telescope placed in the meridian, with two cross hairs, one of which is in a vertical, the other in an horizontal position. The sun is in the meridian when the vertical hair passes through his centre.

To find the elevation of the pole in any place, take the greatest and least height of some star which never sets, the middle height between these extremes is the elevation of the pole. Or the elevation of the pole may be found by one observation of the height of a

star in the meridian, if the declination of that star be known; for as the distance from the pole is the complement of its distance from the equator, this being subtracted from the greatest height of the star, leaves the elevation of the pole desired. The same thing may be done by observing the least height of a star, and adding to that the distance from the pole: but for observations of this kind we ought to choose the time when the stars are in the zenith, and not pitch upon any who happen to be near the horizon; because the refraction occasions such errors as are too considerable not to affect the observations materially.

The height of the equator is found by taking the height of the sun or a star when we know by an almanack they have no declination; or it may be otherwise known by taking the meridian height of the sun, and adding or subtracting the known declination. Having found the height of the equator, we know the elevation of the pole; or, having found the elevation of the pole, we know that of the equator, the one being the complement of the other.

A method much used by the ancients was that of taking the altitudes of the celestial bodies by means of a gnomon, or upright pillar erected for this purpose. Thus the height of the pole and the seasons of the year might be known by observing the length of the meridian shadow, which would be greater or less according to the altitude of the sun at that time. The most ancient observations of this kind were those made by Pytheas in the time of Alexander the Great, at Marseilles in France, by which he found the meridian length of the shadow at the summer solstice to be to the height of the gnomon as 213 $\frac{1}{2}$ to 600; the same which Gassendus afterwards found it in the year 1636.

49
Method of
taking alti-
tudes by a
gnomon.

The elevation of the pole may be found by means of the gnomon, by finding the meridian height of the sun; for this being given, we have the elevation of the equator, and consequently that of the pole. The meridian height of the sun may be found in the following manner. Let AC, fig. 1. be the gnomon, AB the shadow, and CB part of a ray drawn from the centre of the sun passing by the top of the gnomon and terminating the shadow at B. These three lines form a right-angled triangle BAC, whereof the two legs AB and AC are given, the number of feet and inches in them being found by actual mensuration. Hence the acute angles may be found in the following manner. Let one leg be radius, and the other will be tangent of the opposite angle. Thus, if we make AB radius, AC will be tangent of the opposite angle ABC. This tangent is found by the golden rule, as the number of feet, inches, &c. in AB, is to the number of feet, inches, &c. in AC; so is the radius to a fourth number, which is the tangent required. This fourth number looked for in the table of tangents gives the measure of the angle ABC, which is the meridian height of the sun required.

Plate
CCIX.

This method of observation, however, is by no means accurate; and Ricciolus takes notice of the following deficiencies in the ancient observations made in this manner: 1. They did not take into account the sun's parallax, which makes his apparent altitude ten seconds less than it would be if the gnomon were placed at the centre of the earth. 2. They neglected refraction,

50
Inaccu-
cies of this
method.

Principles
and
Practice.

tion, by which the apparent height of the sun is somewhat increased. 3. They made their calculations as if the shadow were terminated by a ray coming from the sun's centre; whereas it is bounded by one coming from the upper edge of his limb. In many cases, however, these errors are of no moment; but at any rate they may be corrected in the following manner: To the altitude of the sun found by the gnomon, add his parallax of 10'', and take from the sum the semidiameter of the sun at that time, which is about 16'; together with the refraction, which is different at different heights of the sun, and must be had from a table of refractions. Thus the altitude of the sun will be had free of any errors, excepting those unavoidable ones arising from the difficulty in finding the true length of the shadow by reason of the penumbra, which always accompanies it.

31
Gnomons
which do
not show
the altitude
by the sha-
dow.

Some gnomons show the altitude of the sun not by the shadow, but by an hole in the top made in a plate of metal inserted there, through which the rays fall upon a level pavement. In gnomons of this kind the centre of the instrument is always exactly under the hole in the metal-plate; and the method of finding the height of the sun is the same as that already described. A gnomon of this kind was made in the year 1576 by Egnatio Dante in the church of St Petronia at Bologna. Near the top of the south wall of the church he placed a brass plate about three-eighths of an inch thick, in which was cut a circular hole almost exactly an inch in diameter. The plate was set in the wall at an angle of about $45\frac{1}{2}$ deg. the height of the equator in that place. The height of the hole in the plate from the ground is near 66 feet, and the length of the line drawn upon the pavement is 169 feet. This line, however, is not exactly in the meridian, but as near it as the pillars of the church would admit: and on it the rays of the sun, passing through the hole, formed an ellipsis at different distances from the wall, according to the season of the year. Another gnomon of this kind was made in the same church by Dominico Cassini in 1645. He placed the brass-plate through which the rays of the sun were to pass in the roof of the church, and drew a meridian line 120 feet long upon the pavement; which performance was so much approved, that a medal was struck upon the occasion. In like manner Bianchini and Moraldi drew a meridian line upon the pavement of the great hall of the baths of Dioclesian, now the church of the Carthusians at Rome.

52
Construc-
tion of
these gno-
mons.

To construct gnomons of this kind, place the brass-plate with the hole in it in the south end of the roof of the building; by a thread with a plummet at the end of it let down through the centre of the hole, find the point in the pavement which is exactly under it; this point is the centre of the gnomon: from this centre draw several concentric circles: an hour or two before and after noon mark the points where the northern as also where the southern edge of the sun's picture touches these circles, and there will be several arches, through the middle of which a line drawn from the centre of the gnomon is a meridian line, as will be understood from what has been already said concerning the method of drawing these lines. The meridians just mentioned are usually marked upon long plates of brass, with which the marble pavement is in-

laid; there are also drawn upon it lines crossing the meridians at right angles, to show how far the centre of the sun's image reaches at different times of the year: when this at noon is farthest from the centre of the gnomon, the sun is then lowest, and it is the winter solstice: when the same picture is nearest to the centre of the gnomon, the sun is highest, and consequently he is then in his greatest north declination, and it is then the summer solstice.

Principles
and
Practice.

The time of the solstice is observed, by marking exactly the distance of the sun's picture from the centre of the gnomon the day before and the day after the solstitial day: if these distances be exactly equal, the meridian heights of the sun are for these two days exactly equal; and then the time of the sun's being in the solstitial point is exactly at noon: if the distance of the sun's picture from the centre of the gnomon be greater the day before the solstice than it is the day after, it shows that the time of the solstice is before noon; and if less, that it is after noon. It is, however, extremely difficult to determine the exact moment of the solstice by this method, or even to approach within some hours of it; for at those times the sun's declination, and consequently his meridian height, alters not above 15'' in a natural day; and therefore an error of more than 15'' in the observation of the sun's meridian height will occasion an error of a whole day in fixing the time of the solstice, an error of one half of 15'' will occasion an error of half a day; and so in proportion.

53
To find the
time of the
solstice.

The time of the equinox is found by a gnomon in the following manner: On the day of the equinox find the meridian height of the sun and the height of the equator. If these be equal, the equinox is exactly at noon; if the height of the sun be different from that of the equator, then as many minutes as the sun is higher than the equator, so many hours is the moment of the equinox before noon; as many minutes as the sun is lower than the equator, so many hours is the equinox after noon. The reason of this computation is, that at the equinox the declination of the sun alters at the rate of 34 minutes in a natural day, which is at the rate of a minute in an hour; whence it appears that the equinoxes are much more easily observed than the solstices. It is probable that many of the obelisks in Egypt were erected for the purpose of observing the altitude of the sun by the length of the shadow. It is likewise worth observing, that the Spaniards at the conquest of Peru found pillars of curious and costly workmanship, by the meridian shadows of which their *Amautas* or philosophers had by long experience and observation learned to determine the time of the equinoxes: these seasons of the year were celebrated by them with great festivity and rejoicing in honour of the sun, whom they imagined to sit at those times in all his glory upon the throne they had erected for him; and therefore on those days they presented him with rich offerings of gold, silver, jewels, and other valuable gifts; adorning his throne, as they did also the pillars, with fragrant herbs and flowers.

54
Of the
equinox.

The principal uses which geographers have for observing the altitudes of the celestial bodies with such accuracy, are to determine the length of the year, the seasons, but especially the distance of places on the earth, their situation with regard to one another, and

55
Geogra-
phical uses
of the ob-
servations
of the hea-
venly bo-
dies.

Principles and Practice.

the dimensions of the whole. An account of the most remarkable attempts for discovering the circumference of the globe has been given in the preceding section. The foundation of the whole is to obtain an exact measure of one degree of meridian; which being once got, we have only to multiply the number of miles, feet, or any other measure employed, by 360, the number of degrees in the circumference, and the product is that of the whole globe. This being obtained, we may easily determine its superficial and solid contents by the geometrical methods employed in other cases. According to the best calculations which have yet appeared, the dimensions of this globe are as follow.

	English miles.
One minute of a degree contains	$1\frac{2}{3}$
A degree	$69\frac{1}{2}$
The circumference	24,930
The diameter	$7935\frac{1}{2}$
The femidiameter	$3967\frac{1}{2}$
The superficial measure	200,000,000
The solid contents	two hundred and sixty-six thousand millions of cubic miles.

A second of a degree is no more than $101\frac{1}{2}$ English feet.

In making measurements of this kind, the principal difficulty arises from the want of an absolutely level surface, the length of which may be determined by actual mensuration as the foundation of our calculations. Snellius, as has already been mentioned, had a singular opportunity of this kind by means of a great extent of ice; and similar conveniences might be had on the frozen lakes in the north of Europe, though difficulties would there arise from the great refraction of the atmosphere. It must likewise be considered, that there is always some difference between the apparent level and the true, which in great distances is apt to affect our calculations materially. A truly level surface is the segment of any spherical surface concentric to the surface of the earth: thus the surface of the sea or any large piece of water when at rest forms itself into a true level. A true line of level then is an arch of a great circle, which we suppose to be described upon a truly level surface. The apparent level is a straight line drawn tangent to the true level; whence every point of the apparent level, excepting only that of contact, is somewhat higher than the true level. This difference is easily known after the femidiameter of the earth is known. Thus in fig. 6. let the observer standing at A look through a telescope placed horizontally at the object B; here BAC is a right-angled triangle, in which if AC be made radius, AB will be tangent, and CB secant of the angle ACB. Now, to find this tangent, say, as the number of feet in AC is to the number of feet in AB, the distance of the object; so is AC as radius to AB as tangent. Then having found the tangent AB in the table, we have the secant CB; from which if the radius CG be taken, the remainder GB is the excess of the secant above the radius, or the height of the apparent level above the true. The following table was constructed by Cassini.

A TABLE showing the Height of the Apparent Level above the True.

If the distance of the object from the place of the spectator be which measured in a great circle upon the earth amounts to

the height of the apparent level above the true will be

The Uses of this table are, 1. An arc of a great circle on the earth being given in seconds or minutes, to find the length of it in miles or feet. Thus an arc of 8 seconds is 812 feet six inches and four-tenths of an inch; and thus again an arc of 20' is 121880 English feet. 2. An arc of a great circle upon the earth being given in seconds or minutes, or in feet or inches, to find the height of the apparent level above the true. In very small arcs this is so little, that it may be disregarded, and is therefore marked only at 5", and afterwards at every 10" in the table of seconds, and at every single minute in the other. 3. The distance of any object which is viewed through sights placed horizontally being given, the height of it may be found; or conversely, the height of any object being given, the distance of it may be found. Thus, if the distance of an object whose top is in the horizon be 15' or 91410 feet, the height of that object is 199 feet 4 inches; and thus conversely, if the height of an object whose top is in the horizon be 199 feet 4 inches, the distance will be 91,410 feet. 4. If the distance of an object given be a number of feet which is not in the table, take that which is next to it, and say, as the square of the number thus taken is to the square of the number given; so is the height of the apparent level above the true, corresponding to the number taken, to the height of the apparent level which corresponds to the number given. Thus, if it be inquired what is the height of the apparent level above the true when the distance of the object is 200,000 feet, the nearest number to this in the table is 201,102, the height of the level corresponding thereto is 965 feet; say then, as the square of 201,102 is to the square of 200,000; so is 965 to a fourth number by which the apparent level exceeds the height of the true one, at the distance of 200,000 feet.

Hitherto we supposed the line of level to be a tangent to an arc of a great circle drawn upon the surface of the earth; whereas in levelling, the eye is usually at some distance above the surface, suppose 4 feet; but this makes no difference in levelling; for as the height of the eye must be added to the secant CB, fig. 6. because ML is supposed in levelling to be parallel to HD, there is indeed a difference between the length of AI and BL, but it is quite insensible. Another use of the table is for levelling, in order to convey water from one place to another. See LEVELLING. We shall now proceed to give a solution of some geographical problems relating to the horizon.

1. To find the extent of the visible horizon, the semidiameter of the earth and height of the eye being given. Let ADE, fig. 3. be an arc of a great circle upon the earth, C the centre of the earth, B the eye of the observer, BD the height of the eye, BA and BE lines drawn from the eye touching the surface of the earth at A and E, and terminating the visible horizon; the length of BA is required. In order to find it, add DB the height of the eye, which suppose to be 5 feet, to DC the semidiameter of the earth, which is 20,949,655 feet; and you have the length of CB 20,949,660 feet; draw CA, and you have a triangle BAC whose angle at A is a right one; make the hypotenuse CB radius, and CA will be the sine of the opposite angle ABC. Say then, as CB is to CA; so is the whole sine or radius to the sine of the angle ABC.

57
Of finding the extent of the horizon.

Principles and Practice.

Principles and Practice.

58
Depression of the horizon of the sea.

59
Extent of the horizon at any height of the eye.

ABC. This angle being found, its complement ACB is known, and consequently also the arc AD, which may be found in feet or miles by the table: Thus, in the foregoing example, as 20,949,660 is to 20,949,655; so is the radius 1000, &c. to a fourth number, viz. 9,999,993, which number is the sine of an angle of 89° 56'; the angle ABC then is 89° 56'; and therefore its complement ACD is 4', and the arc DA is 4'; that is, by the table, 24376 feet.

2. To find the depression of the visible horizon of the sea at a given height of the eye. In fig. 3. if the eye be at B, the sensible horizon is FG, the depression of the horizon of the sea is the angle FBA; which, being the complement of ABC, is equal to ACD, that is, 4'.

3. To find the extent of the visible horizon at any height of the eye by observation. The semidiameter of the horizon does not sensibly differ from an arch of a great circle upon the earth of the same number of minutes and seconds as the angle of depression is observed to be; and the number of feet contained in that arc may be found in the table: Thus, if the depression of the horizon be 30', its semidiameter is also 30'; that is, by the table 182,820 feet. Various accounts of the extent of the visible horizon are given by different authors: either because they differ in their accounts of the earth's semidiameter from whence that of the horizon is computed, or in the measures they make use of.

The following table, taken from Cassini, shows the different depressions of the horizon of the sea at different heights of the eye, both by observation and calculation; with the difference betwixt the two occasioned by refraction.

The height of the eye above the surface of the sea.		The depression of the horizon of the sea.

9	7, 3	{ 3 20	by observation
		{ 3 18	by calculation

Here the calculated depression is greater than that by observation in all the cases except the last, which is less by two seconds; but the instrument used by our author would not discover such a small difference. Refraction by raising the objects of vision makes the angle of depression less; but refraction itself is variable, and of consequence the depression and extent of the horizon also. Cassini informs us, that, even in the finest weather, refraction was different at the same hours of different days, and at different hours of the same day. The truth of this position is easily seen by fixing a telescope with cross hairs, so that the weather-cock of a distant steeple may be viewed through it: for at different times of the day the weather-cock will sometimes appear in the centre of the object-glass, sometimes above and sometimes below it: the same experiment may also be tried with plain sights. It has long been observed, that the top of a distant hill may at some times, when the refraction is greatest, be seen from a station from which at other times, when refraction is less, it cannot be seen, even when the weather is sufficiently clear.

Hitherto we have supposed the circumference of Earth not to be exactly circular, or the globe itself to be a perfect sphere; but, from some observations, this appears not to be the case. Some time ago, the French made an observation, showing that a pendulum vibrates slower in proportion as it is brought nearer to the equator: that is, the gravity or clerity of descent of the pendulum, and of all other bodies, is less in countries approaching to the equator than in places near either pole. This excited the curiosity of the celebrated philosophers Huygens and Newton, who thence conjectured that the earth must have some other figure than what was commonly supposed. Sir Isaac Newton afterwards demonstrated that this diminution of weight naturally arises from the earth's rotation round its axis; which, according to the laws of circular motion, repels all heavy bodies from the axis of motion: so that this motion, being swifter at the equator than in parts more remote, the weight of bodies must also be much less there than nearer the poles.—To determine this matter, several mathematicians were by the French king employed to measure a degree on the earth's surface in different parts of the world; and, according to their mensurations, the diameter of the earth from north to south is shorter than that from east to west by 36 miles.

With regard to the method of finding the longitudes and latitudes of particular places, rules have been already laid down under ASTRONOMY, n° 408, and 482, 483. The same thing, however, may be done by other methods. Thus the latitude may be found by observing exactly the meridian altitude of the sun, and knowing his declination for that day, the declination subtracted from the meridian altitude gives the complement of the latitude, and this last subtracted from 90° leaves the latitude required. As to the longitude Mr Harrison, by his invention of time-pieces which go much more exactly than either clocks or watches could be made to do formerly, hath in a great measure facilitated that. For supposing any person, possessed of one of these time-pieces, to set out on a journey, e. g. from London. If he adjusts his time-piece properly before he goes away, he will know the hour

60
Earth not an exact sphere.

61
Of finding the longitudes and latitudes.

Principles
and
Practice.

hour at London exactly, let him go where he pleases ; and when he hath proceeded so far either eastward or westward, that a difference is perceived betwixt the hours shown by his time-piece, and those on the clocks or watches at the place to which he goes, the distance of that place from London in degrees and minutes of longitude will be known ; and if the length of a degree of longitude is known, the real distance between the two places may also be easily found. It is not to be expected, however, that any instrument, with whatever care it may be constructed, can always be depended upon as an exact measurer of time ; and therefore, frequent corrections of longitudes taken in this manner will be necessary. The method of finding the longitude from the eclipses of Jupiter's satellites appears to be the best of any. Eclipses of the sun, and occultations of the stars by the moon, are also very proper, though they happen but seldom. Eclipses of the moon have also been made use of for this purpose ; but it is found impossible to observe either the beginning or end of a lunar eclipse with the accuracy necessary for determining the longitude of any place.—All these different methods agree in this, that they determine the longitude by the difference of time between the observation of the phenomenon in two different places ; and of this time, four minutes are to be allowed for every degree of longitude either east or west.

62
Of the dif-
ferent kinds
of maps.

After the geographer is thus become acquainted with the longitudes and latitudes of a great number of different places, he may delineate them upon paper, or make a *map*, either of the whole world, or of any particular country with which he is best acquainted. General maps of the world, or of very large tracts, answer the purpose of showing in what manner the different countries of the world lie with respect to each other. They cannot be made of such a size as to admit the delineation of many particular towns or cities, neither indeed is it at all required. Where the whole world is delineated at once, the mind can hardly take in more than the idea of the situations of different kingdoms from one another ; the situations of the different cities of each particular kingdom being almost wholly overlooked, and not attended to : and this happens likewise where a very large portion of the globe, as one of the four quarters, is represented on a single map. Besides these, therefore, it is necessary to have particular maps of all the different countries done upon a larger scale, that thus the mind may not be fatigued by endeavouring to comprehend too much at once. The qualifications which maps ought to have, in order to render them complete, are, 1. That they represent the countries exactly of the same shape, and in the same proportions to the eye, that they really have on the earth itself. 2. That the divisions of one country from another be distinctly marked, and readily perceptible, without a disagreeable and tedious search. 3. That the longitudes and latitudes of different places be found exactly on the map, and with little or no trouble.

The foundation of all maps is what is called *the projection of the sphere*, i. e. the delineation of those circles apparently traced out by the sun in the heavens, upon some substance, either plane or spherical, designed to represent the surface of the earth ; upon which also are delineated the parallels of latitude, and the meridians,

in as great number as the size of the map will admit of without confusion.

These delineations upon a spherical surface are very easy : and under the article *GLOBE*, full directions are given for the construction of the spherical substances upon which maps of the earth and the heavens are usually delineated ; and which, when furnished with the rest of their apparatus, are called *terrestrial* and *celestial globes*. The method of drawing the maps for these globes is never followed in any other case ; for which reason it is also referred to the article *GLOBE*. The ordinary kinds of maps are constructed by delineating the circles of the sphere upon a plane surface, according to the rules of perspective. This is properly the projection of the sphere ; and is designed to give a view of the terraqueous globe, as it would appear, at some distance, to an eye that could take in the whole extent of it at once.

§ I. Of Projections of the Spheres and Maps.

OF projections there are two kinds, the *orthographic* and *stereographic* ; both of which represent the surface of the earth projected upon the plane of one of its great circles.

I. The *orthographic* supposes the eye to be placed at an infinite distance in the axis of the circle of projection, while the *stereographic* supposes it to be only in the pole of that circle. The circles on which the projections are usually made, are, the equator, some of the meridians, or the rational horizon of some particular place. For maps of the world a meridian is generally chosen ; and most commonly that one which passes through Ferro, one of the Canary islands, because thus the continents of Europe, Asia and Africa are conveniently delineated in one circle, and America in the other.

1. To project the sphere orthographically on the plane of any meridian, we have only to consider, that as the eye is supposed to be at an infinite distance, all the rays which come from the disk of the earth are parallel ; and consequently all lines drawn from the eye to the disk must be perpendicular to the latter. Let therefore, A B C D, (fig. 1.) represent the plane of one of the meridians. The equator, which cuts all the meridians in the middle, must be represented by an infinite number of points let fall upon the plane of projection, and dividing it exactly in the middle ; that is, by the right line B D. The parallels of latitude being also perpendicular to the plane of the meridian, will be marked out by an infinite number of right lines let fall from their peripheries upon that plane, thus forming the right lines *ab, cd, &c.* The meridians will likewise be represented on the disk by an infinite number of right lines let fall perpendicularly from their peripheries upon the plane of projection, and thus will form the elliptic curves A 10 C A 20 C, &c. From an inspection of the figure, therefore, it appears, that in this projection both longitudes and latitudes are measured by a line of sines, and both of them decrease prodigiously as we approach the edges of the disk ; and hence the countries which lie at a distance from the equator are exceedingly distorted, and it is even impossible to draw them with any degree of accuracy. The orthographic projection on the plane of a meridian, therefore, is never used but for a map of the world.

Principles

meridian.

Plate
CCIX.

Principles
and
Practice.

65

On the e-
quator.
fig. 2.

2. On the plane of the equator, the orthographic projection represents the meridians as straight lines diverging from a centre, and the parallels of latitude as concentric circles. The latter, however, are by no means to be placed at equal distances from each other; for the meridians are to be divided by the line of lines, as in the last; and thus the equatorial parts of the globe are as much distorted and confused as the polar ones were in the foregoing. This projection, therefore, is seldom used for a map of the whole world, though it answers very well for a representation of the polar regions.

66

On any
particular
horizon,
fig. 3.

3. On the horizon of any particular place, except either of the poles, or any point lying directly under the equator, the orthographic projection represents both parallels and meridians by segments of ellipses. The figure shows a map done on the horizon of Ur of the Chaldees: it is obvious, however, that a considerable degree of distortion takes place here also; though less than in the former cases. Projections of this kind, therefore, are used only for the construction of solar eclipses. See ASTRONOMY, sect. x.

II. The *stereographic* projection of the sphere supposes the eye to be in the pole of the circle of projection. The laws of this projection are,

1. A right circle is projected into a line of half tangents.

2. The representation of a right circle, perpendicularly opposed to the eye, will be a circle in the plane of the projection.

3. The representation of a circle placed oblique to the eye, will be a circle in the plane of the projection.

4. If a great circle is to be projected upon the plane of another great circle, its centre will lie in the line of measures, distant from the centre of the primitive by the tangent of its elevation above the plane of the primitive.

5. If a lesser circle, whose poles lie in the plane of the projection, were to be projected; the centre of its representation would be in the line of measures, distant from the centre of the primitive, by the secant of the lesser circles distance from its pole, and its semi-diameter or radius be equal to the tangent of that distance.

6. If a lesser circle were to be projected, whose poles lie not in the plane of the projection, its diameter in the projection, if it falls on each side of the pole of the primitive, will be equal to the sum of the half tangents of its greatest and nearest distance from the pole of the primitive, set each way from the centre of the primitive in the line of measures.

7. If the lesser circle to be projected fall entirely on one side of the pole of the projection, and do not encompass it: then will its diameter be equal to the difference of the half tangents of its greatest and nearest distance from the pole of the primitive, set off from the centre of the primitive one; and the same way in the line of measures.

8. In the stereographic projection, the angles made by the circles of the surface of the sphere, are equal to the angles made by their representatives in the plane of their projection.

For a demonstration of these laws, see the articles PERSPECTIVE and PROJECTION. The method of deli-

neating general maps of the world will, however, be easily understood by the following directions.

1. To delineate a map of the earth upon the plane of a meridian. Draw a circle of any convenient magnitude, as ABCD, to represent one half of the earth's disc; draw two diameters AB, CD, intersecting each other at right angles; AB will then represent the equator, and CD that meridian which is directly perpendicular to the plane of projection, C will be the north pole, and D the south pole. Divide the circle into 360 equal parts, representing the degrees of latitude; or into smaller parts, if it can admit of such a division, to represent minutes. Then, by means of a sector, divide the equator AB into two lines of semi-tangents EA and EB, which will represent the degrees of longitude. Then with the secant of 80° , as a radius describe the arch of the circle CcD, which represents a meridian cutting the plane of projection, at an angle of 80° ; with the secant of 70° , describe the arch CdD, which represents a meridian cutting the plane of projection at 70° ; and thus proceed with the rest of the meridians, which are usually drawn at every 10 degrees longitude, as the parallels are at every 10 degrees latitude. These last are to be drawn with the tangents for radii as the meridians are with the secants; GH representing the parallel of 10 degrees, with the tangent of 80° , that of 20 with the tangent of 70, &c. The ecliptic AQB is drawn with the tangent of 66.31 for a radius, its greatest distance from the equator being 23.29. This is the most common projection for maps of the world, and is that on which the map Plate CCXIV. is delineated. It hath this disadvantage, however, that neither the degrees of longitude nor latitude continue of the same length, even under the same parallel; and consequently the shape of the countries is somewhat distorted: it is also exceedingly difficult to find the precise degree of longitude or latitude belonging to any place upon maps of this kind, as must be evident from an inspection of the figures.

2. On the plane of the horizon. Suppose, for instance, it is desired to have London the centre of the map: its latitude we will suppose to be 51 degrees 32 minutes. Take then the point E (fig. 5.) for London; and from this, as a centre, describe the circle ABCD to represent the horizon; which you are then to divide into four quadrants, and each of these into 90 degrees. Let the diameter BD be the meridian, B the northern quarter, D the southern; the line of equinoctial east and west shows the first vertical, A the west, C the east, or a place of 90 degrees from the zenith in the first vertical. All the verticals are represented by right lines drawn from the centre E to the several degrees of the horizon. Divide BD into 180 degrees, as in the former method; the point in EB representing 51 deg. 32 min. of the arch BC, will be the projection of the north pole, which note with the letter P. The point in ED representing 51 deg. 32 min. of the arch DC (reckoning from C towards D), will be the projection of the intersection of the equator and meridian of London; and from this, towards P, write the numbers of the degrees, 1, 2, 3, &c. As also towards D, and from B towards P, viz. 51, 52, 53, &c. Then taking the corresponding points of equal degrees, 88, 89, &c. about those, as diameters, describe circles, which will represent parallels or circles of latitude,

itude, with the equator, tropics, and polar circles. For the meridians, first describe a circle through the three points A, P, C. This will represent the meridian 90 degrees from London. Let its centre be M in BD (continued to the point N, which represents the south pole), PN being the diameter: through M draw a parallel to AC, viz. FH, continued each way to K and L. Divide the circle PHNF into 360 degrees, and from the point P draw right lines to the several degrees cutting KFHL: through the several points of intersection, and the poles P, N, as through three given points, describe circles representing all the meridians. The centres for describing the arches will be in the same KL, as being the same that are found by the former intersection; but are to be taken with this caution, that for the meridian next BDN towards A, the most remote centre towards L be taken for the first, the second from this, &c.—The circles of longitude and latitude thus drawn, insert the places from a table.

Maps of this kind may be useful for particular purposes: but the irregular length of the degrees, both of longitude and latitude, render them very unfit for representing the countries in their proper shape; and the difficulties in finding the particular degrees of longitude and latitude are even greater in this than any other projection, as is evident from the inspection of fig. 4.

III. Besides these, there may be a variety of other projections, though few of them are applicable to any particular purpose. The three following are those most generally useful, as having each some peculiar property which cannot be found in any other but themselves.

70
Projection
in which
the earth is
supposed to
be conica

I. If, instead of its globular figure, we suppose the earth to have a conical one, it is plain, that the meridians would be represented by straight lines diverging from the apex of the cone, while the parallels are shown by concentric circles placed at equal distances. This kind of projection is shown in Plate CCXIII. fig. 1, 2. It hath this great advantage, that the longitudes and latitudes may be found with the greatest ease by means of a moveable index placed on the centre. The whole earth may also be thus represented on a single circle: but thus the countries towards the south pole are prodigiously augmented in breadth in proportion to their length; for the degrees of longitude constantly increase the farther we are removed from the pole, while those of latitude still remain the same. This apparent error, however, doth not in the least affect the real proportion of the map, or render it more difficult to find the longitudes or latitudes upon it.

2. Mercator's projection supposes the earth, instead of a globular, to have a cylindrical figure; in consequence of which, the degrees of longitude become of an equal length throughout the whole surface, and are marked out on the map by parallel lines. The circles of latitude also are represented by lines crossing the former at right angles, but at unequal distances. The farther we remove from the equator, the longer the degrees of latitude become in proportion to those of longitude, and that in no less a degree than as the secant of an arch to the radius of the circle: that is, if we make one degree of longitude at the equator the radius of a circle; at one degree distant from the equator, a degree of latitude will be expressed by the secant of one degree; at ten degrees distance, by the secant of ten degrees; and so on.* A map of the world, therefore, cannot be delineated upon this projection, without distorting the shape of the countries in an extraordinary manner. The projection itself is, however, very useful in navigation, as it shows the different bearings with perfect accuracy, which cannot be done upon any other map. See CCXIII. fig. 3.

3. The globular projection is an invention of M. de la Hire, and is more useful than any of the former for exhibiting the true shape of the countries. It may be made in the following manner: Having drawn a circle representing one-half of the earth's disc, draw two diameters as before, which represent the equator and vertical meridian. Divide each of these into 180 equal parts for the measures of the degrees of longitude and latitude. Then through the two poles, and every tenth division on the equator, draw arches of circles for the meridians; and in like manner through every tenth degree on each semicircle draw an arch, which shall likewise pass through every tenth division on the meridian for the parallels of latitude.

IV. The construction of maps of particular parts of the earth requires a different operation. Large portions of its surface may indeed be drawn on the plane of the meridian, as before directed; but when a small part, as the island of Britain, for instance, is to be represented on a large scale, it would be found difficult to draw the arches of such large circles as are necessary, and therefore the following method may be adopted. In this case, the degrees of longitude and latitude may be both represented by straight lines. It is to be remembered, however, that though the degrees of latitude always continue of an equal length, it is not so with those of longitude. They must necessarily decrease as we approach the pole. The proportion in which they decrease may be found by the line of longitudes on the plane scale; or by the following

29	52	48	59	30	90	89	01	05
30	51	96	60	30	00	90	00	00

Suppose, then, it is required to draw the meridians and parallels for a map of Britain. That island is known to lie between 50 and 60 degrees of latitude, and two and seven of longitude. Having therefore chosen the length of your degrees of latitude, you must next proportion your degrees of longitude to it. By the table you find, that in the latitude of 50° the length of a degree of longitude is to one of latitude as 38,57 is to 60; that is, a degree of longitude in latitude 50 is somewhat more than half the length of a degree of latitude. The exact proportion may easily be taken by a diagonal scale; after which, you are to mark out seven or eight of those degrees upon a right line for the length of your intended map. On the extremities of this line raise two perpendiculars, upon which mark out ten degrees of latitude for the height of it. Then, having completed the parallelogram, consult the table for the length of a degree of longitude in lat. 60°, which is found to be very nearly one-half a degree of latitude. It will always be proper, however, to draw a vertical meridian exactly in the middle of the parallelogram, to which the meridian on each side may converge; and from this you are to set off the degrees

of longitude on each side. Then, having divided the lines bounding your map into as many parts as can conveniently be done, to serve for a scale, you may by their means set off the longitudes and latitudes with much less trouble than where curve lines are used. This method may always be followed where a particular kingdom is to be delineated, and will represent the true figure and situation of the places with tolerable exactness. The particular points of the compass on which the towns lie with respect to one another, or their bearings, cannot be exactly known, except by a globe or Mercator's projection. Their distances, however, may by this means be accurately expressed, and this is the only kind of maps to which a scale of miles can be truly adapted.

§ 2. Description and Use of the Globes and Armillary Sphere.

WHEN we have thus discovered, by means of maps; or any other way, the true situation of the different places of the earth with regard to one another, we may easily know every other particular relative to them; as, how far distant they are from us, what hour of the day it is, what season of the year, &c. at any particular place. As each of these problems, however, would require a particular and sometimes troublesome calculation, machines have been invented, by which all the calculations may be saved, and every problem in geography may be solved mechanically, and in the most easy and expeditious manner. These machines are the celestial and terrestrial globes, and the armillary sphere; of which, and the method of using them, we proceed to give a description.

If a map of the world be accurately delineated on a spherical ball, the surface thereof will represent the surface of the earth: for the highest hills are so inconsiderable with respect to the bulk of the earth, that they take off no more from its roundness than grains of sand do from the roundness of a common globe; for the diameter of the earth is 8000 miles in round numbers, and no known hill upon it is much above three miles in perpendicular height.

With regard to what we call *up* and *down*, see the article GRAVITY.

To an observer placed any where in the indefinite space, where there is nothing to limit his view, all remote objects appear equally distant from him; and seem to be placed in a vast concave sphere, of which his eye is the centre. The moon is much nearer to us than the sun; some of the planets are sometimes nearer and sometimes farther from us than the sun; others of them never come so near to us as the sun always is; the remotest planet in our system is beyond comparison nearer to us than any of the fixed stars are: and yet all these celestial objects appear equally distant from us. Therefore, if we imagine a large hollow sphere of glass to have as many bright studs fixed to its inside as there are stars visible in the heaven, and these studs to be of different magnitudes, and placed at the same angular distances from each other as the stars are; the sphere will be a true representation of the starry heaven, to an eye supposed to be in its centre, and viewing it all around. And if a small globe, with a map of the earth upon it, be placed on an axis in the centre of this starry sphere, and the sphere be made to turn round on this axis,

and
Practice.

74

The terrestrial globe.

75

The face of the heavens and of the earth represented in a machine.

Principles
and
Practice.

axis, it will represent the apparent motion of the heavens round the earth.

If a great circle be so drawn upon this sphere as to divide it into two equal parts or hemispheres, and the plane of the circle be perpendicular to the axis of the sphere, this circle will represent the *equinoctial*, which divides the heaven into two equal parts, called the *northern* and the *southern hemispheres*; and every point of that circle will be equally distant from the *poles*, or ends of the axis in the sphere. That pole which is in the middle of the northern hemisphere, will be called the *north pole of the sphere*; and that which is in the middle of the southern hemisphere, the *south pole*.

If another grand circle be drawn upon the sphere in such a manner as to cut the equinoctial at an angle of $23\frac{1}{2}$ degrees in two opposite points, it will represent the *ecliptic*, or circle of the sun's apparent annual motion; one half of which is on the north side of the equinoctial, and the other half on the south.

If a large stud be made to move eastward in this ecliptic in such a manner as to go quite round it in the time that the sphere is turned round westward 366 times upon its axis, this stud will represent the *sun* changing his place every day a $\frac{1}{365}$ th part of the ecliptic, and going round westward the same way as the stars do; but with a motion so much slower than the motion of the stars, that they will make 366 revolutions about the axis of the sphere in the time that the sun makes only 365. During one half of these revolutions, the sun will be on the north side of the equinoctial; during the other half, on the south; and at the end of each half, in the equinoctial.

If we suppose the terrestrial globe in this machine to be about one inch in diameter, and the diameter of the starry sphere to be about five or six feet, a small insect on the globe would see only a very little portion of its surface; but it would see one half of the starry sphere, the convexity of the globe hiding the other half from its view. If the sphere be turned westward round the globe, and the insect could judge of the appearances which arise from that motion, it would see some stars rising to its view in the eastern side of the sphere, whilst others were setting on the western: but as all the stars are fixed to the sphere, the same stars would always rise in the same points of view on the east side, and set in the same points of view on the west side. With the sun it would be otherwise; because the sun is not fixed to any point of the sphere, but moves slowly along an oblique circle in it. And if the insect should look towards the south, and call that point of the globe, where the equinoctial in the sphere seems to cut it on the left side, the east point; and where it cuts the globe on the right side, the west point; the little animal would see the sun rise north of the east, and set north of the west, for 182 $\frac{1}{2}$ revolutions; after which for as many more, the sun would rise south of the east, and set south of the west. And in the whole 365 revolutions, the sun would rise only twice in the east point, and set twice in the west. All these appearances would be the same, if the starry sphere stood still (the sun only moving in the ecliptic), and the earthly globe were turned round the axis of the sphere eastward. For, as the insect would be carried round with the globe, he would be quite insensible of its motion, and the sun and stars would appear to move westward..

I. Description of the Terrestrial Globe.

Principles
and
Practice.

76

The terrestrial globe,
described.
Pl. CCXI.
fig. 2.

THE equator, ecliptic, and tropics, polar circles, and meridians, are laid down upon the globe in the manner already described. The ecliptic is divided into 12 signs, and each sign into 30 degrees. Each tropic is $23\frac{1}{2}$ degrees from the equator, and each polar circle $23\frac{1}{2}$ degrees from its respective pole. Circles are drawn parallel to the equator, at every 10 degrees distance from it on each side to the poles: these circles are called *parallels of latitude*. On large globes there are circles drawn perpendicularly through every tenth degree of the equator, intersecting each other at the poles: but on globes of or under a foot diameter, they are only drawn through every fiftieth degree of the equator; these circles are generally called *meridians*, sometimes *circles of longitude*, and at other times *hour circles*.

The globe is hung in a brass ring (A), called the *brass meridian*, and turns upon a wire in each pole sunk half its thickness into one side of the meridian ring; by which means that side of the ring divides the globe into two equal parts, called the *eastern* and *western hemispheres*; as the equator divides it into two equal parts, called the *northern* and *southern hemispheres*. The ring is divided into 360 equal parts or degrees, on the side wherein the axis of the globe turns. One half of these degrees are numbered, and reckoned, from the equator to the poles, where they end at 90: their use is to show the latitudes of places. The degrees of the other half of the meridian are numbered from the poles to the equator, where they end at 90: their use is to show how to elevate either the north or south pole above the horizon, according to the latitude of any given place, as it is north or south of the equator.

The brass meridian is let into two notches made in a broad flat ring called the *wooden horizon*, B, C; the upper surface of which divides the globe into two equal parts, called the *upper* and *lower hemispheres*. One notch is in the north point of the horizon, and the other in the south. On this horizon are several concentric circles, which contain the months and days of the year, the signs and degrees answering to the sun's place for each month and day, and the 32 points of the compass and the circles of amplitude and azimuth.—The graduated side of the brass meridian lies towards the east side of the horizon, and should be generally kept towards the person who works problems by the globes.

There is a small horary circle D, so fixed to the north part of the brass meridian, that the wire in the north pole of the globe is in the centre of that circle; and on the wire is an index, which goes over all the 24 hours of the circle, as the globe is turned round its axis. Sometimes there are two horary circles, one between each pole of the globe and the brass meridian.

There is a thin slip of brass, called the *quadrant of altitude*, which is divided into 90 equal parts or degrees, answering exactly to so many degrees of the equator. It is occasionally fixed to the uppermost point of the brass meridian by a nut and screw. The divisions end at the nut E, and the quadrant is turned round upon it.

There is also applied occasionally to the globe a magnetic needle, freely moving over a circle divided into

into four times 90 degrees; reckoning from the north and south points towards the east and west, and also into the 32 points of the compass. As this needle makes nearly a certain constant angle with the meridian in every place, called the *variation*; therefore this compass being added to the frame, will rectify the position of the meridian of the globe when the variation of the needle is known. Thus at London, the variation of the needle is at this time about 23 degrees westward; therefore, by moving the frame of the globe about till the needle settles itself over the 23d degree, reckoning westward from the north point or *fleur de lis*, we shall have the brass meridian coinciding with the true meridian. The compass is sometimes fixed between the legs underneath the globe.

2. Description and Use of the Armillary Sphere.

77
Armillary
sphere de-
scribed.
Plate
CCX.
fig. 4.

THE exterior parts of this machine are, a compages of brass rings, which represent the principal circles of the heaven, viz. 1. The equinoctial AA, which is divided into 360 degrees (beginning at its intersection with the ecliptic in Aries), for showing the sun's right ascension in degrees; and also into 24 hours, for showing his right ascension in time. 2. The ecliptic BB, which is divided into 12 signs, and each sign into 30 degrees, and also into the months and days of the year; in such a manner, that the degree or point of the ecliptic in which the sun is, on any given day, stands over that day in the circle of months. 3. The tropic of Cancer CC, touching the ecliptic at the beginning of Cancer in *e*, and the tropic of Capricorn DD, touching the ecliptic at the beginning of Capricorn in *f*; each $23\frac{1}{2}$ degrees from the equinoctial circle. 4. The arctic circle E, and the antarctic circle F, each $23\frac{1}{2}$ degrees from its respective pole at N and S. 5. The equinoctial colure GG, passing through the north and south poles of the heaven at N and S, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The solstitial colure HH, passing through the poles of the heaven, and through the solstitial points Cancer and Capricorn in the ecliptic. Each quarter of the former of these colures is divided into 90 degrees, from the equinoctial to the poles of the world, for showing the declination of the sun, moon, and stars; and each quarter of the latter, from the ecliptic at *e* and *f*, to its poles *b* and *d*, for showing the latitude of the stars.

In the north pole of the ecliptic is a nut *b*, to which is fixed one end of a quadrantal wire, and to the other end a small sun Y, which is carried round the ecliptic BB, by turning the nut: and in the south pole of the ecliptic is a pin *d*, on which is another quadrantal wire, with a small moon Z upon it, which may be moved round by the hand: but there is a particular contrivance for causing the moon to move in an orbit which crosses the ecliptic at an angle of $5\frac{1}{2}$ degrees, in two opposite points called the *moon's nodes*; and also for shifting these points backward in the ecliptic, as the moon's nodes shift in the heaven.

Within these circular rings is a small terrestrial globe I, fixed on an axis KK, which extends from the north and south poles of the globe at *n* and *s*, to those of the celestial sphere at N and S. On this axis is fixed the flat celestial meridian LL, which may be set directly over the meridian of any place on the globe,

and then turned round with the globe, so as to keep over the same meridian upon it. This flat meridian is graduated the same way as the brass meridian of a common globe, and its use is much the same. To this globe is fitted the moveable horizon MM, so as to turn upon two strong wires proceeding from its east and west points to the globe, and entering the globe at the opposite points of its equator, which is a moveable brass ring let into the globe in a groove all around its equator. The globe may be turned by hand within this ring, so as to place any given meridian upon it, directly under the celestial meridian LL. The horizon is divided into 360 degrees all around its outermost edge, within which are the points of the compass for showing the amplitude of the sun and moon both in degrees and points. The celestial meridian LL, passes through two notches in the north and south points of the horizon, as in a common globe: but here, if the globe be turned round, the horizon and meridian turn with it. At the south pole of the sphere is a circle of 24 hours, fixed to the rings: and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is supported on a pedestal N, and may be elevated or depressed upon the joint O, to any number of degrees from 0 to 90, by means of the arc P, which is fixed in the strong brass arm Q, and slides in the upright piece R, in which is a screw at *r*, to fix it any proper elevation.

In the box T are two wheels (as in Dr Long's sphere), and two pinions, whose axes come out at V, and U; either of which may be turned by the small winch W. When the winch is put upon the axis V, and turned backward, the terrestrial globe, with its horizon and celestial meridian, keep at rest; and the whole sphere of circles turns round from east, by south, to west, carrying the sun Y, and moon Z, round the same way, and causing them to rise above and set below the horizon. But when the winch is put upon the axis U, and turned forward, the sphere with the sun and moon keep at rest; and the earth, with its horizon and meridian, turn round from west, by south, to east; and bring the same points of the horizon to the sun and moon, to which these bodies came when the earth kept at rest and they were carried round it; showing that they rise and set in the same points of the horizon, and at the same times in the hour-circle, whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour-index goes round its hour-circle; but if the sphere be turned, the hour-circle goes round below the index.

And so, by this construction, the machine is equally fitted to show either the real motion of the earth or the apparent motion of the heaven.

To rectify the sphere for use, first slacken the screw *r* in the upright stem R, and taking hold of the arm Q, move it up or down until the given degree of latitude for any place be at the side of the stem R; and then the axis of the sphere will be properly elevated so as to stand parallel to the axis of the world, if the machine be set north and south by a small compass: this done, count the latitude from the north pole, upon the celestial meridian LL, down towards the north notch of the horizon, and set the horizon to that latitude; then turn the nut *b* until the sun Y comes to

Principles
and
Practice.

Principles
and
Practice.

the given day of the year in the ecliptic, and the sun will be at its proper place for that day; find the place of the moon's ascending node, and also the place of the moon, by an ephemeris, and set them right accordingly: lastly, turn the winch W, until either the sun comes to the meridian LL, or until the meridian comes to the sun (according as you want the sphere or earth to move), and set the hour-index to the XII, marked noon, and the whole machine will be rectified. Then turn the winch, and observe when the sun or moon rise and set in the horizon, and the hour-index will shew the times thereof for the given-day.

As those who understand the use of the globes will be at no loss to work many other problems by this sphere, it is needless to enlarge any farther upon it.

3. Directions for using the Globes.

In using globes, keep the east side of the horizon towards you (unless the problem requires the turning of it), which side you may know by the word East upon the horizon; for then you have the graduated side of the meridian towards you, the quadrant of altitude before you, and the globe divided exactly into two equal parts, by the graduated side of the meridian.

78
Directions
for using
the terref-
trial globe.

In working some problems, it will be necessary to turn the whole globe and horizon about, that you may look on the west side thereof: which turning will be apt to jog the ball so, as to shift away the degree of the globe which was before set to the horizon or meridian: to avoid which inconvenience, you may thrust in the feather-end of a quill between the ball of the globe and the brazen meridian; which, without hurting the ball, will keep it from turning in the meridian, whilst you turn the west side of the horizon towards you.

PROB. I. *To find the latitude and longitude of any given place upon the globe*—Turn the globe on its axis, until the given place comes exactly under that graduated side of the brazen meridian on which the degrees are numbered from the equator; and observe what degree of the meridian the place then lies under; which is its latitude, north or south, as the place is north or south of the equator.

The globe remaining in this position, the degree of the equator, which is under the brazen meridian, is the longitude of the place, which is east or west, as the place lies on the east or west side of the first meridian of the globe.—All the Atlantic ocean, and America, is on the west side of the meridian of London; and the greatest part of Europe, and of Africa, together with all Asia, is on the east side of the meridian of London, which is reckoned the first meridian of the globe by the British geographers and astronomers.

PROB. II. *The longitude and latitude of a place being given, to find that place on the globe*.—Look for the given longitude in the equator (counting it eastward or westward from the first meridian, as it is mentioned to be east or west); and bringing the point of longitude in the equator to the brazen meridian, on that side which is above the south point of the horizon: then count from the equator, on the brazen meridian, to the degree of the given latitude, towards the north or south pole, according as the latitude is north or south;

and under that degree of latitude on the meridian you will have the place required.

Principles
and
Practice.

PROB. III. *To find the difference of longitude, or difference of latitude, between any two given places*.—Bring each of these places to the brazen meridian, and see what its latitude is: the lesser latitude subtracted from the greater, if both places are on the same side of the equator, or both latitudes added together if they are on different sides of it, is the difference of latitude required. And the number of degrees contained between these places, reckoned on the equator, when they are brought separately under the brazen meridian, is their difference of longitude, if it be less than 180; but if more, let it be subtracted from 360, and the remainder is the difference of longitude required. Or,

Having brought one of the places to the brazen meridian, and set the hour-index to XII, turn the globe until the other place comes to the brazen meridian; and the number of hours and parts of an hour, passed over by the index, will give the longitude in time; which may be easily reduced to degrees, by allowing 15 degrees for every hour, and one degree for every four minutes.

N. B. When we speak of bringing any place to the brazen meridian, it is the graduated side of the meridian that is meant.

PROB. IV. *Any place being given, to find all those places that have the same longitude or latitude with it*.—Bring the given place to the brazen meridian; then all those places which lie under that side of the meridian, from pole to pole, have the same longitude with the given place. Turn the globe round its axis; and all those places which pass under the same degree of the meridian that the given place does, have the same latitude with that place.

Since all latitudes are reckoned from the equator, and all longitudes are reckoned from the first meridian, it is evident, that the point of the equator which is cut by the first meridian, has neither latitude nor longitude.—The greatest latitude is 90 degrees, because no place is more than 90 degrees from the equator: And the greatest longitude is 180 degrees, because no place is more than 180 degrees from the first meridian.

PROB. V. *To find the antæci, periæci, and antipodes, of any given place*.—Bring the given place to the brazen meridian; and having found its latitude, keep the globe in that situation, and count the same number of degrees of latitude from the equator towards the contrary pole; and where the reckoning ends, you have the *antæci* of the given place upon the globe. Those who live at the equator have no *antæci*.

The globe remaining in the same position, set the hour-index to the upper XII on the horary circle, and turn the globe until the index comes to the lower XII; then the place which lies under the meridian, in the same latitude with the given place, is the *periæci* required. Those who live at the poles have no *periæci*.

As the globe now stands (with the index at the lower XII), the *antipodes* of the given place will be under the same point of the brazen meridian where its *antæci* stood before. Every place upon the globe has its *antipodes*.

PROB. VI. *To find the distance between any two places*

Principles
and
Practice.Principles
and
Practice.

places on the globe.—Lay the graduated edge of the quadrant of altitude over both the places, and count the number of degrees intercepted between them on the quadrant; then multiply these degrees by 60, and the product will give the distance in geographical miles: but to find the distance in miles, multiply the degrees by 69 $\frac{1}{2}$, and the product will be the number of miles required. Or, take the distance betwixt any two places with a pair of compasses, and apply that extent to the equator; the number of degrees, intercepted between the points of the compasses, is the distance in degrees of a great circle; which may be reduced either to geographical miles, or to English miles, as above.

PROB. VII. *A place on the globe being given, and its distance from any other place; to find all the other places upon the globe which are at the same distance from the given place.*—Bring the given place to the brazen meridian, and screw the quadrant of altitude to the meridian directly over that place; then keeping the globe in that position, turn the quadrant quite round upon it, and the degree of the quadrant that touches the second place will pass over all the other places which are equally distant with it from the given place.

This is the same as if one foot of a pair of compasses was set in the given place, and the other foot extended to the second place, whose distance is known; for if the compasses be then turned round the first place as a centre, the moving foot will go over all those places which are at the same distance with the second from it.

PROB. VIII. *The hour of the day at any place being given, to find all those places where it is noon at that time.*—Bring the given place to the brazen meridian, and set the index to the given hour; this done, turn the globe until the index points to the upper XII, and then all the places that lie under the brazen meridian have noon at that time.

N. B. The upper XII always stands for noon; and when the bringing of any place to the brazen meridian is mentioned, the side of that meridian on which the degrees are reckoned from the equator is meant, unless the contrary side be mentioned.

PROB. IX. *The hour of the day at any place being given, to find what o'clock it then is at any other place.*—Bring the given place to the brazen meridian, and set the index to the given hour; then turn the globe, until the place where the hour is required comes to the meridian, and the index will point out the hour at that place.

PROB. X. *To find the sun's place in the ecliptic, and his declination, for any given day of the year.*—Look on the horizon for the given day, and right against it you have the degree of the sign in which the sun is (or his place) on that day at noon. Find the same degree of that sign in the ecliptic line upon the globe, and having brought it to the brazen meridian, observe what degree of the meridian stands over it; for that is the sun's declination, reckoned from the equator.

PROB. XI. *The day of the month being given, to find all those places of the earth over which the sun will pass vertically on that day.*—Find the sun's place in the ecliptic for the given day, and having brought it to

the brazen meridian, observe what point of the meridian is over it; then, turning the globe round its axis, all those places which pass under that point of the meridian are the places required; for as their latitude is equal, in degrees and parts of a degree, to the sun's declination, the sun must be directly over-head to each of them at its respective noon.

PROB. XII. *A place being given in the torrid zone, to find those two days of the year on which the sun shall be vertical to that place.*—Bring the given place to the brazen meridian, and mark the degree of latitude that is exactly over it on the meridian; then turn the globe round its axis, and observe the two degrees of the ecliptic which pass exactly under that degree of latitude: lastly, find on the wooden horizon the two days of the year in which the sun is in those degrees of the ecliptic, and they are the days required: for on them, and none else, the sun's declination is equal to the latitude of the given place; and, consequently, he will then be vertical to it at noon.

PROB. XIII. *To find all those places of the north frigid zone, where the sun begins to shine constantly without setting, on any given day, from the 21st of March to the 23d of September.*—On these two days, the sun is in the equinoctial, and enlightens the globe exactly from pole to pole: therefore, as the earth turns round its axis, which terminates in the poles, every place upon it will go equally through the light and the dark, and so make the day and night equal to all places of the earth. But as the sun declines from the equator, towards either pole, he will shine just as many degrees round that pole as are equal to his declination from the equator: so that no place within that distance of the pole will then go through any part of the dark, and consequently the sun will not set to it. Now, as the sun's declination is northward from the 21st of March to the 23d of September, he must constantly shine round the north pole all that time; and on the day that he is in the northern tropic, he shines upon the whole north frigid zone; so that no place within the north polar circle goes through any part of the dark on that day. Therefore,

Having brought the sun's place for the given day to the brazen meridian, and found his declination (by Prob. IX) count as many degrees on the meridian, from the north pole, as are equal to the sun's declination from the equator, and mark that degree from the pole where the reckoning ends; then turning the globe round its axis, observe what places in the north frigid zone pass directly under that mark; for they are the places required.

The like may be done for the south frigid zone, from the 23d of September to the 21st of March, during which time the sun shines constantly on the south pole.

PROB. XIV. *To find the place over which the sun is vertical at any hour of a given day.*—Having found the sun's declination for the given day (by Prob. X.) mark it with a chalk on the brazen meridian: then bring the place where you are (suppose Philadelphia) to the brazen meridian, and set the index to the given hour; which done, turn the globe on its axis, until the index points to XII at noon; and the place on the globe, which is then directly under the point of the

Principles
and
Practice.

the sun's declination marked upon the meridian, has the sun that moment in the zenith, or directly over head.

PROB. XV. *The day and hour of a lunar eclipse being given; to find all those places of the earth to which it will be visible.*—The moon is never eclipsed but when she is full, and so directly opposite to the sun, that the earth's shadow falls upon her. Therefore, whatever place of the earth the sun is vertical to at that time, the moon must be vertical to the antipodes of that place: so that the sun will be then visible to one half of the earth, and the moon to the other.

Find the place to which the sun is vertical at the given hour (by Prob. XIV.) elevate the pole to the latitude of that place, and bring the place to the upper part of the brazen meridian, as in the former problem: then, as the sun will be visible to all those parts of the globe which are above the horizon, the moon will be visible to all those parts which are below it, at the time of her greatest obscuration.

PROB. XVI. *To rectify the globe for the latitude, the zenith, and the sun's place.*—Find the latitude of the place (by Prob. I.) and if the place be in the northern hemisphere, raise the north pole above the north point of the horizon, as many degrees (counted from the pole upon the brazen meridian) as are equal to the latitude of the place. If the place be in the southern hemisphere, raise the south pole above the south point of the horizon as many degrees as are equal to the latitude. Then, turn the globe till the place comes under its latitude on the brazen meridian, and fasten the quadrant of altitude so, that the chamfered edge of its nut (which is even with the graduated edge) may be joined to the zenith, or point of latitude. This done, bring the sun's place in the ecliptic for the given day (found by Prob. X.) to the graduated side of the brazen meridian, and set the hour-index to XII at noon, which is the uppermost XII on the hour-circle; and the globe will be rectified.

PROB. XVII. *The latitude of any place, not exceeding $66\frac{1}{2}$ degrees, and the day of the month, being given; to find the time of the sun's rising and setting, and consequently the length of the day and night.*—Having rectified the globe for the latitude, and for the sun's place on the given day (as directed in the preceding problem), bring the sun's place in the ecliptic to the eastern side of the horizon, and the hour-index will show the time of sun-rising; then turn the globe on its axis, until the sun's place comes to the western side of the horizon, and the index will show the time of sun-setting.

The hour of sun-setting doubled, gives the length of the day; and the hour of sun-rising doubled, gives the length of the night.

PROB. XVIII. *The latitude of any place, and the day of the month, being given; to find when the morning twilight begins, and the evening twilight ends, at that place.* This problem is often limited: for, when the sun does not go 18 degrees below the horizon, the twilight continues the whole night; and for several nights together in summer, between 49 and $66\frac{1}{2}$ degrees of latitude; and the nearer to $66\frac{1}{2}$, the greater is the number of these nights. But when it does begin and end, the following method will show the time for any given day.

Rectify the globe, and bring the sun's place in the

ecliptic to the eastern side of the horizon; then mark with a chalk that point of the ecliptic which is in the western side of the horizon, it being the point opposite to the sun's place: this done, lay the quadrant of altitude over the said point, and turn the globe eastward, keeping the quadrant at the chalk mark, until it is just 18 degrees high on the quadrant; and the index will point out the time when the morning twilight begins: for the sun's place will then be 18 degrees below the eastern side of the horizon. To find the time when the evening twilight ends, bring the sun's place to the western side of the horizon; and the point opposite to it, which was marked with the chalk, will be rising in the east: then, bring the quadrant over that point, and keeping it thereon, turn the globe westward, until the said point be 18 degrees above the horizon on the quadrant, and the index will show the time when the evening twilight ends; the sun's place being then 18 degrees below the western side of the horizon.

PROB. XIX. *To find on what day of the year the sun begins to shine constantly, without setting, on any given place in the north frigid zone; and how long he continues to do so.*—Rectify the globe to the latitude of the place, and turn it about until some point of the ecliptic, between Aries and Cancer, coincides with the north point of the horizon where the brazen meridian cuts it; then find, on the wooden horizon, what day of the year the sun is in that point of the ecliptic; for that is the day on which the sun begins to shine constantly on the given place without setting. This done, turn the globe, until some point of the ecliptic, between Cancer and Libra, coincides with the north point of the horizon, where the brazen meridian cuts it; and find, on the wooden horizon, on what day the sun is in that point of the ecliptic; which is the day that the sun leaves off constantly shining on the said place, and rises and sets to it as to other places on the globe. The number of natural days, or complete revolutions of the sun about the earth, between the two days above found, is the time that the sun keeps constantly above the horizon without setting: for all that portion of the ecliptic, which lies between the two points which intersect the horizon in the very north, never sets below it; and there is just as much of the opposite part of the ecliptic that never rises: therefore, the sun will keep as long constantly below the horizon in winter as above it in summer.

PROB. XX. *To find in what latitude the sun shines constantly without setting, for any length of time less than 182 $\frac{1}{2}$ of our days and nights.*—Find a point in the ecliptic half as many degrees from the beginning of Cancer (either toward Aries or Libra) as there are natural days in the time given; and bring that point to the north side of the brazen meridian; on which the degrees are numbered from the pole towards the equator: then keep the globe from turning on its axis, and slide the meridian up or down until the foresaid point of the ecliptic comes to the north point of the horizon, and then the elevation of the pole will be equal to the latitude required.

PROB. XXI. *The latitude of a place, not exceeding $66\frac{1}{2}$ degrees, and the day of the month, being given; to find the sun's amplitude or point of the compass on which he rises or sets.*—Rectify the globe, and bring the sun's place

Principles
and
Practice.

Principle and Practice. place to the eastern side of the horizon; then observe what point of the compass on the horizon stands right against the sun's place, for that is his amplitude at rising. This done, turn the globe westward, until the sun's place comes to the western side of the horizon, and it will cut the point of his amplitude at setting. Or you may count the rising amplitude in degrees, from the east point of the horizon, to that point where the sun's place cuts it; and the setting amplitude from the west point of the horizon, to the sun's place at setting.

Principles and Practice.

PROB. XXII. *The latitude, the sun's place, and his altitude, being given; to find the hour of the day, and the sun's azimuth, or number of degrees that he is distant from the meridian.*—Rectify the globe, and bring the sun's place to the given height upon the quadrant of altitude; on the eastern side of the horizon, if the time be in the forenoon; or the western side, if it be in the afternoon: then the index will show the hour; and the number of degrees in the horizon, intercepted between the quadrant of altitude and the south point, will be the sun's true azimuth at that time.

PROB. XXIII. *The latitude, hour of the day, and the sun's place, being given; to find the sun's altitude and azimuth.*—Rectify the globe, and turn it until the index points to the given hour; then lay the quadrant of altitude over the sun's place in the ecliptic, and the degree of the quadrant cut by the sun's place in his altitude at that time above the horizon; and the degree of the horizon cut by the quadrant is the sun's azimuth, reckoned from the south.

PROB. XXIV. *The latitude, the sun's altitude, and his azimuth, being given; to find his place in the ecliptic the day of the month, and hour of the day, though they had all been lost.*—Rectify the globe for the latitude and zenith, and set the quadrant of altitude to the given azimuth in the horizon; keeping it there, turn the globe on its axis until the ecliptic cuts the quadrant in the given altitude: that point of the ecliptic which cuts the quadrant there, will be the sun's place; and the day of the month answering thereto, will be found over the like place of the sun on the wooden horizon. Keep the quadrant of altitude in that position; and, having brought the sun's place to the brazen meridian, and the hour index to XII at noon, turn back the globe, until the sun's place cuts the quadrant of altitude again, and the index will show the hour.

Any two points of the ecliptic, which are equidistant from the beginning of Cancer or Capricorn, will have the same altitude and azimuth at the same hour though the months be different; and therefore it requires some care in this problem, not to mistake both the month and the day of the month; to avoid which, observe that from the 20th of March to the 21st of June, that part of the ecliptic which is between the beginning of Aries and beginning of Cancer is to be used; from the 21st of June to the 23d of September, between the beginning of Cancer and beginning of Libra; from the 23d of September to the 21st of December, between the beginning of Libra and the beginning of Capricorn; and from the 21st of December to the 20th of March, between the beginning of Capricorn and the beginning of Aries. And as one can never be at a loss to know in what quarter of the year he takes the sun's altitude and

azimuth, the above caution with regard to the quarters of the ecliptic will keep him right as to the month and day thereof.

PROB. XXV. *To find the length of the longest day at an given place.*—If the place be on the north side of the equator, find its latitude (by Prob. I.) and elevate the north pole to that latitude; then bring the beginning of Cancer to the brazen meridian, and set the hour-index to XII at noon. But if the given place be on the south side of the equator, elevate the south pole to its latitude, and bring the beginning of Capricorn to the brazen meridian, and the hour-index to XII. This done, turn the globe westward until the beginning of Cancer and Capricorn (as the latitude is north or south) comes to the horizon; and the index will then point out the time of sun-setting, for it will have gone over all the afternoon hours, between mid-day and sun-set; which length of time being doubled, will give the whole length of the day from sun-rising, to sun-setting. For, in all latitudes, the sun rises as long before mid-day, as he sets after it.

PROB. XXVI. *To find in what latitude the longest day is, of any given length, less than 24 hours.*—If the latitude be north, bring the beginning of Cancer to the brazen meridian, and elevate the north pole to about $66\frac{1}{2}$ degrees; but if the latitude be south, bring the beginning of Capricorn to the meridian, and elevate the south pole to about $66\frac{1}{2}$ degrees; because the longest day in north latitude is, when the sun is in the first point of Cancer; and in south latitude, when he is in the first point of Capricorn. Then set the hour-index to XII at noon, and turn the globe westward until the index points at half the number of hours given; which done keep the globe from turning on its axis, and slide the meridian down in the notches, until the aforesaid point of the ecliptic (viz. Cancer or Capricorn) comes to the horizon; then, the elevation of the pole will be equal to the latitude required.

PROB. XXVII. *The latitude of any place, not exceeding $66\frac{1}{2}$ degrees, being given; to find in what climate the place is.*—Find the length of the longest day at the given place, by Prob. XXV. and whatever be the number of hours whereby it exceedeth twelve, double the number, and the sum will give the climate in which the place is.

PROB. XXVIII. *The latitude, and the day of the month, being given; to find the hour of the day when the sun shines.* Set the wooden horizon truly level, and the brazen meridian due north and south by a mariner's compass; then, having rectified the globe, stick a small sewing needle into the sun's place in the ecliptic, perpendicular to that part of the surface of the globe; this done, turn the globe on its axis, until the needle comes to the brazen meridian, and set the hour index to XII at noon: then turn the globe on its axis, until the needle points exactly towards the sun (which it will do when it casts no shadow on the globe), and the index will show the hour of the day.

4. *The Use of the Celestial Globe.*

HAVING done for the present with the terrestrial globe, we shall proceed to the use of the celestial; first premising, that as the equator, ecliptic, tropics, polar

Principles
and
Practice.

polar circles, horizon, and brazen meridian, are exactly alike on both globes, all the former problems concerning the sun are solved the same way by both globes. The method also of rectifying the celestial globe is the same as rectifying the terrestrial. *N. B.* The sun's place for any day of the year stands directly over that day on the horizon of the celestial globe, as it does on that day of the terrestrial.

Latitude
and longi-
tude of the
stars.

The *latitude* and *longitude* of the stars, or of all other celestial phenomena, are reckoned in a very different manner from the latitude and longitude of places on the earth: for all terrestrial latitudes are reckoned from the equator; and longitudes from the meridian of some remarkable place, as of London by the British, and of Paris by the French. But the astronomers of all nations agree in reckoning the latitudes of the moon, stars, planets, and comets, from the ecliptic; and their longitudes from the equinoctial colure, in that semicircle of it which cuts the ecliptic at the beginning of Aries; and thence eastward, quite round, to the same semicircle again. Consequently those stars which lie between the equinoctial and the northern half of the ecliptic, have north declination and south latitude; those which lie between the equinoctial and the southern half of the ecliptic, have south declination and north latitude; and all those which lie between the tropics and poles, have their declination and latitudes of the same denomination.

There are six great circles on the celestial globe, which cut the ecliptic perpendicularly, and meet in two opposite points in the polar circles; which points are each ninety degrees from the ecliptic, and are called its poles. These polar points divide those circles into 12 semicircles; which cut the ecliptic at the beginnings of the twelve signs. They resemble so many meridians on the terrestrial globe: and as all places which lie under any particular meridian-semicircle on that globe have the same longitude; so all those points of the heaven, through which any of the above semicircles are drawn, have the same longitude.—And as the greatest latitudes on the earth are at the north and south poles of the earth, so the greatest latitudes in the heaven are at the north and south poles of the ecliptic.

For the division of the stars into constellations, &c. see ASTRONOMY, n^o 403, 406.

PROB. I. *To find the right ascension and declination of the sun, or any fixed star*—Bring the sun's place in the ecliptic to the brazen meridian: then that degree in the equinoctial which is cut by the meridian, is the sun's *right ascension*; and that degree of the meridian which is over the sun's place, is his *declination*. Bring any fixed star to the meridian, and its right ascension will be cut by the meridian in the equinoctial; and the degree of the meridian that stands over it is its declination.

So that right ascension and declination, on the celestial globe, are found in the same manner as longitude and latitude on the terrestrial.

PROB. II. *To find the latitude and longitude of any star*.—If the given star be on the north side of the ecliptic, place the 90th degree of the quadrant of altitude on the north pole of the ecliptic, where the 12 semicircles meet, which divide the ecliptic into the 12 signs; but if the star be on the south side of

the ecliptic, place the 90th degree of the quadrant on the south pole of the ecliptic: keeping the 90th degree of the quadrant on the proper pole, turn the quadrant about, until its graduated edge cuts the star: then the number of degrees in the quadrant, between the ecliptic and the star, is its latitude; and the degree of the ecliptic, cut by the quadrant, is the star's longitude, reckoned according to the sign in which the quadrant then is.

PROB. III. *To represent the face of the starry firmament, as seen from any given place of the earth, at any hour of the night*.—Rectify the celestial globe for the given latitude, the zenith and sun's place in every respect, as taught by the XVIIth problem for the terrestrial; and turn it about, until the index points to the given hour: then the upper hemisphere of the globe will represent the visible half of heaven for that time; all the stars upon the globe being then in such situations as entirely correspond to those in the heaven. And if the globe be placed duly north and south, by means of a small sea compass, every star in the globe will point towards the like star in the heaven: by which means, the constellations and remarkable stars may be easily known. All those stars which are in the eastern side of the horizon, are then rising in the eastern side of the heaven; all in the western, are setting in the western side; and all those under the upper part of the brazen meridian, between the south point of the horizon and the north pole, are at their greatest altitude, if the latitude of the place be north; but if the latitude be south, those stars which lie under the upper part of the meridian, between the north point of the horizon and the south pole, are at their greatest altitude.

PROB. IV. *The latitude of the place, and the day of the month, being given; to find the time when any known star will rise, or be upon the meridian, or set*.—Having rectified the globe, turn it about until the given star comes to the eastern side of the horizon, and the index will show the time of the star's rising; then turn the globe westward and when the star comes to the brazen meridian; the index will show the time of the star's coming to the meridian of your place; lastly, turn on, until the star comes to the western side of the horizon, and the index will show the time of the star's setting. *N. B.* In northern latitudes, those stars which are less distant from the north pole than the quantity of its elevation above the north point of the horizon never set; and those which are less distant from the south pole than the number of degrees by which it is depressed below the horizon never rise; and *vice versa* in southern latitudes.

PROB. V. *To find at what time of the year a given star will open upon the meridian, at a given hour of the night*.—Bring the given star to the upper semicircle of the brazen meridian, and set the index to the given hour; then turn the globe until the index points to XII at noon, and the upper semicircle of the meridian will then cut the sun's place; answering to the day of the year sought; which day may be easily found against the like place of the sun among the signs on the wooden horizon.

PROB. VI. *The latitude, day of the month, and azimuth of any known star being given; to find the hour of the night*.—Having rectified the globe for the latitude, zenith

Principles
and
Practice.Principles
and
Practice.

zenith, and sun's place, lay the quadrant of altitude to the given degree of azimuth in the horizon: then turn the globe on its axis, until the star comes to the graduated edge of the quadrant; and when it does, the index will point out the hour of the night.

PROB. VII. *The latitude of the place, the day of the month, and altitude of any known star, being given; to find the hour of night.*—Rectify the globe as in the former problem, guess at the hour of the night, and turn the globe until the index points at the supposed hour: then lay the graduated edge of the quadrant of altitude over the known star; and if the degree of the star's height in the quadrant upon the globe answers exactly to the degree of the star's observed altitude in the heaven, you have guessed exactly: but if the star on the globe is higher or lower than it was observed to be in the heaven, turn the globe backwards or forwards, keeping the edge of the quadrant upon the star, until its centre comes to the observed altitude in the quadrant; and then the index will show the true time of the night.

PROB. VIII. *An easy method for finding the hour of the night by any known stars, without knowing either their altitude or azimuth; and then of finding both their altitude and azimuth, and thereby the true meridian.*—Tie one end of a thread to a common musket bullet; and having rectified the globe as above, hold the other end of the thread in your hand, and carry it slowly round betwixt your eye and the starry heaven, until you find it cuts any two known stars at once. Then guessing at the hour of the night, turn the globe until the index points to that time in the hour circle; which done, lay the graduated edge of the quadrant over any one of these two stars on the globe which the thread cut in the heaven. If the said edge of the quadrant cuts the other star also, you have guessed the time exactly; but if it does not, turn the globe slowly backwards or forwards, until the quadrant (kept upon either star) cuts them both through their centres: and then the index will point out the exact time of the night; the degree of the horizon, cut by the quadrant, will be the true azimuth of both these stars from the south; and the stars themselves will cut their true altitudes in the quadrant. At which moment, if a common azimuth-compass be set upon a floor or level pavement, that these stars in the heaven may have the same bearing upon it (allowing for the variation of the needle) as the quadrant of altitude has in the wooden horizon of the globe, a thread extended over the north and south points of that compass will be directly in the plane of the meridian: and if a line be drawn upon the floor or pavement, along the course of the thread, and an upright wire be placed in the southmost end of the line, the shadow of the wire will fall upon that line, when the sun is on the meridian, and shines upon the pavement.

PROB. IX. *To find the place of the moon, or of any planet; and thereby to show the time of its rising, setting, and setting.*—See in Parker's or Weaver's ephemeris the geocentric place of the moon or planet in the ecliptic, for the given day of the month; and according to its longitude and latitude, as shown by the ephemeris, mark the same with a chalk upon the globe. Then, having rectified the globe, turn it round its

axis westward; and as the said mark comes to the eastern side of the horizon, to the brazen meridian, and to the western side of the horizon, the index will show at what time the planet rises, comes to the meridian, and sets, in the same manner as it would do for a fixed star.

For an explanation of the harvest-moons by a globe, see ASTRONOMY, n^o 370.

For the equation of time, see ASTRONOMY, n^o 383.

4. Description of the Modern Improvements applied to Globes.

GLOBES mounted in the common manner, and with their hour circles fixed on the meridian, although instructive instruments for explaining the first principles of geography and the spherical doctrine of astronomy, yet contain several defects; as they prevent any elevation of the north and south poles near to their axes, or the brazen meridian from being quite moveable round in the horizon. They do not show how all the phenomena illustrated by them arise from the motion of the earth; a matter of consequence to beginners: and they are only adapted to the present age; consequently do not serve accurately the purposes of chronology and history, which they might be made to do if the poles whereon they turn were contrived to move in a circle round those of the ecliptic, according to its present obliquity.

The late Mr. John Senex F. R. S. invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass at the distance of $23\frac{1}{2}$ deg. from the poles of the ecliptic. These shoulders are strongly fastened at the other end to an axis, which passes through the poles of the ecliptic, and is made to move round with a very stiff motion; so that when it is adjusted to any point of the ecliptic which the equator is made to intersect, the diurnal motion of the globe on its axis will not disturb it. When it is to be adjusted to any time, past or future, one of the brazen shoulders is brought under the meridian, and held fast to it with one hand, whilst the globe is turned about with the other; so that the point of the ecliptic which the equator is to intersect may pass under the 0 degree of the brazen meridian; then holding a pencil to that point, and turning the globe about, it will describe the equator according to its position at the time required; and transferring the pencil to $23\frac{1}{2}$ and $66\frac{1}{2}$ degrees on the brazen meridian, the tropics and polar circles will be so described for the same time. By this contrivance, the celestial globe may be so adjusted, as to exhibit not only the rising and setting of the stars in all ages and in all latitudes, but likewise the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Senex's celestial globes, especially the two greatest, of 17 and 28 inches in diameter, have been constructed upon this principle; so that by means of a nut and screw, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Transf. N^o 447. p. 201, 203. or Martyn's Abr. Vol. VIII. p. 217. and N^o 493, art. 18. in Phil. Transf. Vol. XLVI. p. 290.

To represent the above phenomena in the most natural and easy manner, the late Mr B. Martin applied to Mr Senex's contrivance a moveable, equinoctial, and

ment.

and solstitial colure; a moveable equinoctial circle, and a moveable ecliptic: all so connected together as to represent those imaginary circles in the heavens for any age of the world.

Mr. Joseph Harris, late essay-master of the mint, contrived to remedy the former of the defects above-mentioned, by placing two horary circles under the meridian, one at each pole; these circles are fixed tight between two brass rollers placed about the axis, so that when the globe is turned they are carried round with it, the meridian serving as an index to cut the horary divisions. The globe in this state serves universally and readily for solving problems in north and south latitudes, and also in places near the equator; whereas in the common construction, the axis and horary circle prevent the brass meridian from being moveable quite round in the horizon. This globe is also adapted for showing how the vicissitudes of day and night, and the alteration of their length, are really occasioned by the motion of the earth: for this purpose he divided the brass meridian at one of the poles into months and days, according to the sun's declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the globe according to the time of the day, the horizon will represent the circle separating light and darkness; and the upper half of the globe, the illuminated hemisphere, the sun being in the zenith. 85
Mr Adam's
additions.

Plate
CCXI.
fig. 1.

The late Mr. George Adam, mathematical instrument maker, has made some additional improvements in the construction of the globes. His globes, like others, are suspended at their poles in a strong brass circle MZÆS (see fig. 2. representing the celestial), and turn therein upon two iron pins, which form the axis. They have each a thin brass semicircle NHS moveable about these poles, with a small, thin, sliding circle H thereon; which semicircle is divided into two quadrants of 90 degrees each, from the equator to both the poles. On the terrestrial globe this semicircle is a moveable meridian, and its small sliding circle, which is divided into a few points of the compass, is the visible horizon of any particular place to which it is set. On the celestial globe this semicircle is a moveable circle of declination, and its small annexed circle an artificial sun or planet. Each globe has a brass wire TWY placed at the limits of the crepusculum or twilight; which, together with the globe, is mounted in a wooden frame, supported by a neat pillar and claw-feet, with a magnetic needle in a compass-box marked M in the figure. On the strong brass circle of the terrestrial globe, and about 23½ degrees on each side of the north pole, the days of each month are laid down according to the sun's declination; and this brass circle is so contrived, that the globe may be placed with the north and south poles in the plane of the horizon, and with the south pole elevated above it. The equator on the surface of either globe serves the purpose of the horary circle, by means of a semicircular wire placed in the plane of the equator (ÆF), carrying two indices (F); one on the east, the other on the west side of the strong brass circle; one of which is occasionally to be used to point out the time upon the

equator. In these globes, therefore, the indices being set to the particular time on the equator, the globes are turned round, and the indices point out the time by remaining fixed; whereas in the globes as generally mounted, the indices move over the horary circles while the globe is moving, and thus point out the change of time. For farther particulars of these globes, and the method of using them, Mr Adam's Treatise on their Construction and Use, &c. 1772, may be consulted.

The additions and alterations above-mentioned, made by Mr Adam, may save trouble to a practitioner in the performance of a few complex problems, and render the globes more elegant and costly; but to a young beginner, the more simple the construction of the globes, the better will they be adapted to initiate him into the rationale and practice of the problems in general; and as such, the globes, as improved by the late Mr B. Martin and Mr Wright, described below, appear to have considerably the advantage in simplicity, and to obviate several material defects that attend the construction of the other globes. The chief of the defects in the old globes is, that the horary circle being screwed on the meridian at the north pole, prevents the elevation of the south pole; which is necessary for the performance of the problems for all latitudes. In Mr Adam's, the semicircular wire ÆF preventing the equator being placed exactly in the horizon, or the poles in the zenith, the great distance of the strong brass circle NZÆS from the surface of the globe, on account of the brass semicircles, renders the solution of problems, which require the use of the strong circle, not very easy nor accurate.

An easy and expeditious method of elevating the south pole of the terrestrial globe; and by which means the new discoveries, tracks, &c. made of late years by Captain Cook and other eminent navigators in the south seas, may be clearly seen and traced by the eye over all the southern ocean, was made use of by Mr B. Martin in the construction of the following improvement.

There is a groove turned out on the back part of the brass meridian A (fig. 2.); and by unscrewing the nut of the hour circle D at the north pole, the circle is made to slide away to any other part of the meridian, as at G. The meridian is fixed or moveable at pleasure by a screw passing into the groove, though the piece or side of the notch in which it moves, on the bottom or nadir point: by properly loosening this screw, the meridian is free to move, and the globe with it, into any required position; but at the same time, it is confined within the notch of the brass-piece, and thereby the globe is prevented from falling out of the frame in any position thereof whatsoever. The hour-circle being removed, both the north and south poles of the globe may be placed in the horizon, and thereby form a right sphere, which the usual mounting of the globes does not admit of.

Also by this construction, the south pole may be elevated for all latitudes: for this purpose there is an hour-circle about the south pole between the meridian and the globe, which does not obstruct the sight of any land, none having been thereabouts discovered. Consequently the globe is thus equally useful for the

Principles
and
Practice.

86

Mr Mar-
tin's im-
provement.

Principles
and
Practice.

olution of all common geographical problems in the southern as in the northern hemisphere, and more extensively so than heretofore.

In this new method of mounting the globe, it may readily be converted into a *tellurian*; for as the globe cannot fall out of the frame, the horizon of the globe may be placed in a perpendicular position: then the sun's place in the ecliptic being brought to the meridian, and its declination found, the pole of the globe must be elevated to that declination; which may be done by means of the degrees cut on the outer edge of the meridian for that purpose. If a lighted candle be placed at a considerable distance, exactly the height of the centre of the globe, and in a line with the meridian, the globe will exhibit all the phenomena of our earth for that day; for in this case the horizon of the globe becomes the solar horizon, and divides the whole into the enlightened and dark hemispheres: therefore upon turning the globe about its axis from west to east, it will clearly appear that all places emerging out of the dark hemisphere into the luminous one, under the western part of the horizon, will see the sun then as rising; when they arrive at the meridian, it will be their noon; and when they descend into the dark hemisphere at the eastern part of the horizon, they will see the sun as setting.

When any place is under the meridian, set the hour-index to XII, and revolve the globe; then you will see the natural motion and position of that place at hours of the day; at what time the sun rises or sets to it; the length of the diurnal and nocturnal arches, or of day and night; at which place the sun does not rise and set at that time; and from whence the vicissitudes of the seasons throughout the year in all latitudes, &c. &c.

To give this experiment the best effect, the candle should be enclosed within a common dark lanthorn, and its light issue through a hole or lens made for that purpose.

On the outer part of the sliding hour-circle, at the north pole, are usually engraved the points of the compass; so that by bringing that circle centrally over any place on the globe, it will appear by inspection only upon what point of the compass any other place bears from it, and that all over the globe.

87
Mr
Wright's
more simple
improvement.

This method of the sliding hour-circle is equally applicable to the celestial globe. Mr G. Wright of London has yet farther simplified the construction of the hour-circles, and it is thereby rather less operose than Mr Martin's abovementioned. It consists of the following particulars: There are engraved on the globes two hour-circles, one at each of the poles; which are divided into a double set of 12 hours, as usual in the common brass ones, except that the hours are figured round both to the right and left (see fig. 3.). The hour-hand or index (A) is placed in such a manner under the brass meridian, as to be moveable at pleasure to any required part of the hour-circle, and yet remain there fixed during the revolution of the globe on its axis and is entirely independent of the poles of the globe. In this manner the motion of the globe round its axis, carrying the hour circle, the fixed index serves to point out the time, the same as in the reverse way by Mr Martin's or other globes.

There is a small advantage by having the hour-circle

figured both ways, as one hour serves as a complement to XII. for the other, and the time of sun rising and setting, and *vice versa*, may be both seen at the same time on the hour-circle. In the problems generally to be performed, the inner-circle is the circle of reckoning, and the outer one only the complement. Fig. 4. is a representation of the globe, with Mr Wright's improved hour-circle at C.

Mr William Jones, mathematical instrument maker, Holborn, who mounts globes according to the improvements abovementioned of Messrs Martin and Wright, applies a compass of a portable size to the east part of the wooden horizon circle of both globes (see F, fig. 2.), by a dove-tail slider on the lid of the compass-box; which method is found more convenient and ready in the performance of problems, than when fixed underneath the frame at the feet; and as it occasionally slides away from the globes, the compass becomes useful in other situations.

In order to the performance of the problems which relate to the altitudes and azimuths of celestial objects, Mr Smeaton, F. R. S. has made some improvements applicable to the celestial globe; and to give some idea, of the construction, they may be described as follows: Instead of a thin flexible slip of brass, which generally accompanies the globes, called the *quadrant of altitude*, Mr Smeaton substitutes an arch of a circle of the same radius, breadth, and substance, as the brass meridian, divided into degrees, &c. similar to the divisions of that circle, and which, on account of its strength, is not liable to be bent out of the plane of a vertical circle, as usual with the common quadrant put to globes. That end of this circular arch at which the divisions begin, rests on the horizon, being filed off square to fit and rest steadily on it throughout its whole breadth; and the upper end of the arch is firmly attached, by means of an arm, to a vertical socket, in such a manner that when the lower end of the arch rests on the horizon, the lower end of this socket shall rest on the upper edge of the brass meridian, directly over the zenith of the globe. This socket is fitted to and ground with a steel-spindle of the same length, so that it will turn freely on it without shaking; and the steel-spindle has an apparatus attached to its lower end, by which it can be fastened in a vertical position to the brass meridian, with its centre directly over the zenith point of the globe. The spindle being fixed firmly in this position, and the socket which is attached to the circular arch put on to it, and so adjusted that the lower end of the arch just rests on and fits close to the horizon; it is evident that the altitude of any object above the horizon will be shown by the degree which it intersects on this arch, and its azimuth by that end of the arch which rests on the horizon.

Besides this improvement, Mr Smeaton directs to place the index which is usually fixed on one end of the axis to point out the hour, in such a manner that its upper surface may move in the plane of the hour-circle rather than above it, as it usually does. He files off the end of this index to a circular arch, of the same radius with the inner edge of the hour-circle, to which it is to fit very exactly; and a fine line is drawn on its upper surface to determine the time by, instead of the tapering point which is generally

Principles
and
Practice.

88
Mr Smea-
ton's im-
prove-
ments.

Principles
and
Practice.

rally used. By these means half minutes may be distinguished, if the hour circle be four inches in diameter. Mr Smeaton also describes a contrivance for preventing the meridian from shifting after being rectified for the latitude of the place, and while the operator is engaged in adjusting other parts of the apparatus. But as the purpose which this is intended to answer appears to be much better performed by the turned groove on the meridian in Mr Martin's contrivance described above, we shall omit the particular description; and for farther explanations and figures of Mr Smeaton's improvements, refer the reader to the Phil. Transf. Vol. LXXIX, Part i.

For another improvement made to the celestial globe, by Mr Ferguson, see ASTRONOMY, n^o 493, and fig. 187 of plate LXXXI.

Most of the above problems may also be performed by means of accurate maps; but this requires a great deal of calculation, which is often very troublesome. The Analemma, or Orthographic Projection, delineated on Plate CCXII. will solve many of the most curious; and with the assistance of the maps will be almost equivalent to a terrestrial globe. The parallel lines drawn on this figure represent the degrees of the sun's declination from the equator, whether north or south; amounting to $23\frac{1}{2}$ nearly. On these lines are marked the months and days which correspond to such and such declinations. The size of the figure does not admit of having every day of the year inserted; but by making allowance for the intermediate days in proportion to the rest, the declination may be guessed at with tolerable exactness. The elliptical lines are designed to show the hours of sun-rising or sun-setting before or after six o'clock. As 60 minutes make an hour of time, a fourth part of the space between each of the hour-lines will represent 15 minutes; which the eye can readily guess at, and which is as great exactness as can be expected from any mechanical invention, or as is necessary to answer any common purpose. The circles drawn round the centre at the distance of $11\frac{1}{4}$ each, show the point of the compass on which the sun rises and sets, and on what point the twilight begins and ends.

In order to make use of this analemma, it is only necessary to consider, that, when the latitude of the place and the sun's declination are both north or both south, the sun rises before six o'clock, between the east and the elevated pole; that is, towards the north, if the latitude and declination are north; or towards the south, if the latitude and declination are south. Let us now suppose it is required to find the time of the sun's rising and setting, the length of the days and nights,

GEOMANCY, GEOMANTIA, a kind of divination, performed by means of a number of little points, or dots, made on paper at random: and considering the various lines and figures, which those points present; and thence forming a pretended judgment of futurity, and deciding any question proposed.

The word is formed of the Greek $\gamma\eta$, terra, "earth;" and $\muαντεια$, "divination;" it being the ancient cus-

tom to cast little pebbles on the ground, and thence to form their conjectures; instead of the points afterwards made use of.

the time when the twilight begins and ends, and what point of the horizon the sun rises and sets on, for the Lizard point in England, Franckfort in Germany, or Abbeville in France, on the 30th of April. The latitude of these places by the maps will be found nearly 50° north. Place the moveable index so that its point may touch 50° on the quadrant of north latitude in the figure; then observe where its edge cuts the parallel line on which April 30th is wrote. From this reckon the hour-lines towards the centre, and you will find that the parallel-line is cut by the index nearly at the distance of one hour and 15 minutes. So the sun rises at one hour 15 minutes before six, or 45 minutes after four in the morning, and sets 15 minutes after seven in the evening. The length of the day is 14 hours 30 minutes. Observe how far the intersection of the edge of the index with the parallel of April 30th is distant from any of the concentric circles; which you will find to be a little beyond that marked two points of the compass; and this shows, that on the 30th of April the sun rises two points and somewhat more from the east towards the north, or a little to the northward of E. N. E. and sets a little to the northward of W. N. W. To find the beginning and ending of twilight, take from the graduated arch of the circle $17\frac{1}{2}$ degrees with a pair of compasses; move one foot of the compasses extended to this distance along the parallel for the 30th of April, till the other just touches the edge of the index, which must still point at 50. The place where the other foot rests on the parallel of April 30th, then denotes the number of hours before six at which the twilight begins. This is somewhat more than three hours and an half; which shows, that the twilight then begins soon after two in the morning, and likewise that it begins to appear near five points from the east towards the north. The uses of this analemma may be varied in a great number of ways; but the example just now given will be sufficient for the ingenious reader.—The small circles on the same plate, marked *Island, Promontory, &c.* are added in order to render the maps more intelligible, by showing how the different subjects are commonly delineated on them.

HAVING thus explained the use of the globes, and general principles of geography, we must refer to the Maps for the situation of each particular country, with regard to longitude, latitude, &c. and to the names of the countries as they occur in the order of the alphabet, for the most remarkable particulars concerning them.

Polydore Virgil defines geomancy a kind of divination performed by means of clefts or chinks made in the ground; and takes the Persian Magi to have been the inventors thereof.

tom to cast little pebbles on the ground, and thence to form their conjectures; instead of the points afterwards made use of.

J. Smith & Co.

G E O M E T R Y

ORIGINALLY signified no more than the art of measuring the earth, or any distances or dimensions within it: but at present it denotes the science of magnitude in general; comprehending the doctrine and relations of whatever is susceptible of augmentation or diminution, considered in that light.

Hence to geometry may be referred the consideration not only of lines, surfaces, and solids; but also of time, velocity, number, weight, &c.

This science had its rise among the Egyptians, who were in a manner compelled to invent it, to remedy the confusion which generally happened in their lands, from the inundations of the river Nile, which carried away all boundaries, and effaced all the limits of their possessions. Thus this invention, which at first consisted only in measuring the lands, that every person might have what belonged to him, was called *geometry*, or the art of measuring land; and it is probable that the draughts and schemes, which they were annually compelled to make, helped them to discover many excellent properties of these figures; which speculations continued to be gradually improved, and are so to this day.

From Egypt geometry passed into Greece; where it continued to receive new improvements in the hands of Thales, Pythagoras, Archimedes, Euclid, &c. The Elements of Geometry, written by this last in 15 books, are a most convincing proof to what perfection this science was carried among the ancients. However, it must be acknowledged, that it fell short of modern geometry; the bounds of which, what by the invention of fluxions, and the discovery of the almost infinite orders of curves, are greatly enlarged.

We may distinguish the progress of geometry into three ages; the first of which was in its meridian glory at the time when Euclid's Elements appeared; the second, beginning with Archimedes, reaches to the time of Des Cartes, who, by applying algebra to the elements of geometry, gave a new turn to this science, which has been carried to its utmost perfection by Sir Isaac Newton and Mr Leibnitz.

In treating this useful subject, we shall divide it into two parts; the first containing the general principles; and the second, the application of these principles to the mensuration of surfaces, solids, &c.

PART I. GENERAL PRINCIPLES OF GEOMETRY.

Plate
CCXV.

Art. 1. A POINT is that which is not made up of parts, or which is of itself indivisible.

2. A line is a length without breadth, as A—B.

3. The extremities of a line are points; as the extremities of the line AB, are the points A and B, fig. 1.

4. If the line AB be the nearest distance between its extremes A and B, then it is called a *straight line*, as AB; but if it be not the nearest distance, then it is called a *curve line*, as *a b*, fig. 1.

5. A surface is that which is considered as having only length and breadth, but no thickness, as fig. 2.

6. The terms or boundaries of a surface are lines.

7. A plain surface is that which lies even between its extremes.

8. The inclination between two lines meeting one another (provided they do not make one continued line), or the opening between them, is called an *angle*; thus the inclination of the line AB to the line CB (fig. 3.) meeting one another at B, or the opening between the two lines AB and CB, is called an *angle*.

9. When the lines forming the angle are right lines, then it is called a *right-lined angle*, as fig. 4.; if one of them be right and the other curved, it is called a *mixed angle*, as fig. 5.; if both of them be curved, it is called a *curve-lined angle*, as fig. 6.

10. If a right line AB fall upon another DC, (fig. 7.) so as to incline neither to one side nor to the other, but make the angles ABD, ABC, on each side equal to one another; then the line AB is said to be *perpendicular* to the line DC, and the two angles are called *right-angles*.

11. An obtuse angle is that which is greater than a

right one, as fig. 8.; and an acute angle, that which is less than a right one, as fig. 9.

12. If a right line DC be fastened at one of its ends C, and the other end D be carried quite round, then the space comprehended is called a *circle*; the curve line described by the point D, is called the *periphery* or *circumference* of the circle; the fixed point C is called the *centre* of it; fig. 10.

13. The describing line CD is called the *radius*, viz. any line drawn from the centre to the circumference; whence all radii of the same or equal circles are equal.

14. Any line drawn through the centre, and terminated both ways by the circumference, is called a *diameter*, as BD is a diameter of the circle BADE. And the diameter divides the circle and circumference into two equal parts, and is double the radius.

15. The circumference of every circle is supposed to be divided into 360 equal parts, called *degrees*; and each degree is divided into 60 equal parts, called *minutes*; and each minute in 60 equal parts, called *seconds*; and these into *thirds*, *fourths*, &c. these parts being greater or less according as the radius is.

16. Any part of the circumference is called an *arch*, or *arc*; and is called an arc of as many degrees as it contains parts of the 360, into which the circumference was divided: thus if AD be the $\frac{1}{8}$ of the circumference, then the arc AD is an arc of 45 degrees.

17. A line drawn from one end of an arc to the other, is called a *chord*, and is the measure of the arc: thus the right line AB is the chord of the arch ADB, fig. 11.

18. Any

General Principles.

18. Any part of a circle cut off by a chord, is called a *segment*; thus the space comprehended between the chord AB and the circumference ADB (which is cut off by the chord AB) is called a *segment*. Whence it is plain,

1st, That all chords divide the circle into two segments.

2^{ndly}. The less the chord is, the more unequal are the segments, and *e contra*.

3^{dly}, When the chord is greatest, viz. when it is a diameter, then the segments are equal, viz. each a semicircle.

19. Any part of a circle (less than a semicircle) contained between two radii and an arc, is called a *sector*; thus the space contained between the two radii, AC, BC, and the arc AB, is called a *sector*, fig. 12.

20. The right sine of any arc, is a line drawn perpendicular from one end of the arc, to a diameter drawn through the other end of the same arc; thus (fig. 13.) AD is the right sine of the arc AB, it being a line drawn from A, the one end of the arc AB, perpendicular to CB, a diameter passing through B, the other end of the arc AB.

Now the sines standing on the same diameter, still increase till they come to the centre, and then becoming the radius, it is plain that the radius EC is the greatest possible sine, and for that reason it is called the *whole sine*.

Since the whole sine EC must be perpendicular to the diameter FB (by def. 20.), therefore producing the diameter EG, the two diameters FB, EG, must cross one another at right angles, and so the circumference of the circle must be divided by them into four parts, EB, BG, GF, and FE, and these four parts are equal to one another (by def. 10.) and so EB a quadrant, or fourth part of the circumference; therefore the radius EC is always the sine of the quadrant, or fourth part of the circle EB.

Sines are said to be of so many degrees, as the arc contains parts of the 360, into which the circumference is supposed to be divided: so the radius being the sine of a quadrant, or fourth part of the circumference, which contains 90 degrees (the fourth part of 360), therefore the radius must be the sine of 90 degrees.

21. The part of the radius comprehended between the extremity of the right sine and the lower end of the arc, viz. DB, is called the *versed sine* of the arc AB.

22. If to any point in the circumference, viz. B, there be drawn a diameter FCB, and from the point B, perpendicular to that diameter, there be drawn the line BH; that line is called a *tangent* to the circle in the point B; which tangent can touch the circle only in one point B, else if it touched it in more, it would go within it, and so not be a tangent but a chord, (by art. 17.)

23. The tangent of any arc AB, is a right line drawn perpendicular to a diameter through the one end of the arc B, and terminated by a line CAH, drawn from the centre through the other end A; thus BH is the tangent of the arc AB.

24. And the line which terminates the tangent, viz. CH, is called the *secant* of the arc AB.

General Principles.

25. What an arc wants of a quadrant is called the *complement* of that arc; thus AE, being what the arc AB wants of the quadrant EB, is called the complement of the arc AB.

26. And what an arc wants of a semicircle is called the *supplement* of that arc: thus since AF is what the arc AB wants of the semicircle BAF, it is the supplement of the arc AB.

27. The sine, tangent, &c. of the complement of any arc, is called the *co-sine*, *co-tangent*, &c. of that arc; thus the sine, tangent, &c. of the arc AE, is called the co-sine, co-tangent, &c. of the arc AB.

28. The sine of the supplement of an arc is the same with the sine of the arc itself; for drawing them according to the definition, there results the self-same line.

29. A right-lined angle is measured by an arc of a circle described upon the angular point as a centre, comprehended between the two legs that form the angle; thus (fig. 14.) the angle ABD is measured by the arc AD of the circle CADE that is described upon the point B as a centre; and the angle is said to be of as many degrees as the arc is; so if the arc AD be 45 degrees, then the angle ABD is said to be an angle of 45 degrees.

Hence the angles are greater or less, according as the arc described about the angular point, and terminated by the two legs, contain a greater or a less number of degrees.

30. When one line falls perpendicularly to another, as AB on CD, fig. 15. then the angles are right (by the 10 def.); and describing a circle on the centre B, since the angles ABC ABD are equal, their measures must be so too, *i. e.* the arcs AC AD must be equal; but the whole CAD is a semicircle, since CD, a line passing through the centre B, is a diameter; therefore each of the parts AC AD is a quadrant, *i. e.* 90 degrees; so the measure of a right angle is always 90 degrees.

31. If one line AB fall any way upon another, CD, then the sum of the two angles ABC ABD is always equal to the sum of two right angles; fig. 16. For on the point C, describing the circle CAD, it is plain; that CAD is a semicircle (by the 14th); but CAD is equal to CA and AD the measure of the two angles; therefore the sum of the two angles is equal to a semicircle, that is, to two right angles, (by the last).

Cor. 1. From whence it is plain, that all the angles which can be made from a point in any line, towards one side of the line, are equal to two right angles.

2. And that all the angles which can be made about a point, are equal to four right ones.

32. If one line AC cross another BD in the point E, then the opposite angles are equal, viz. BEA to CED, and BEC equal to AED; fig. 17. For upon the point E, as a centre, describing the circle ABCD, it is plain ABC is a semicircle, as also BCD (by the 14th); therefore the arc ABC is equal to the arc BCE; and from both taking the common arc BC, there will remain AB equal to CD, *i. e.* the angle BEA equal to the angle CED (by art. 29.) After the same manner we may prove, that the angle BEC is equal to the angle AED.

33. Lines which are equally distant from one another, are called *parallel lines*; as AB, CD, fig. 18.

General Principles.

General Principles.

34. If a line GH cross two parallels AB, CD, (fig. 19.) then the external opposite angles are equal, viz. GEB equal to CFH, and AEG equal to HFD. For since AB and CD are parallel to one another, they may be considered as one broad line, and GH crossing it; then the vertical or opposite angles GEB CFH are equal (by art. 32.), as also AEG and HFD by the same.

35. If a line GH cross two parallels AB, CD, then the alternate angles, viz. AEF and EFD, or CFE and FEB, are equal; that is, the angle AEF is equal to the angle EFD, and the angle CFE is equal to the angle FEB, for GEB is equal to AEF (by art. 32.), and CFH is equal to EFD (by the same); but GEB is equal to CFH (by the last); therefore AEF is equal to EFD. The same way we may prove FEB equal to EFC.

36. If a line GH cross two parallel lines AB, CD, then the external angle GEB is equal to the internal opposite one EFD, or GEA equal to CFE. For the angle AEF is equal to the angle EFD (by the last); but AEF is equal to GEB (by art. 32.), therefore GEB is equal to EFD. The same way we may prove AEG equal to CFE.

37. If a line GH cross two parallel lines AB, CD, then the sum of the two internal angles, viz. BEF and DFE, or AEF and CFE, are equal to two right angles; for since the angle GEB is equal to the angle EFD (by art. 36.), to both add the angle FEB, then GEB and BEF are equal to BEF and DFE; but GEB and BEF are equal to two right angles (by art. 31.), therefore BEF and DFE are also equal to two right angles. The same way we may prove that AEF and CFE are equal to two right angles.

38. A figure is any part of space bounded by lines or a line. If the bounding lines be straight, it is called a *rectilinear figure*, as fig. 20. if they be curved, it is called a *curvilinear figure*, as fig. 21. and fig. 22.; if they be partly curve lines and partly straight, it is called a *mixt figure*, as fig. 23.

39. The most simple rectilinear figure is that which is bounded by three rightlines, and is called a *triangle*, as fig. 24.

40. Triangles are divided into different kinds, both with respect to their sides and angles: with respect to their sides, they are commonly divided into three kinds, viz.

41. A triangle having all its three sides equal to one another, is called an *equilateral triangle*, as fig. 25.

42. A triangle having two of its sides equal to one another, and the third side not equal to either of them, is called an *Isosceles triangle*, as fig. 26.

43. A triangle having none of its sides equal to one another, is called a *scalene triangle*, as fig. 27.

44. Triangles, with respect to their angles, are divided into three different kinds, viz.

45. A triangle having one of its angles right, is called a *right-angled triangle*, as fig. 28.

46. A triangle having one of its angles obtuse, or greater than a right angle, is called an *obtuse-angled triangle*, as fig. 29.

47. Lastly, a triangle having all its angles acute, is called an *acute-angled triangle*, as fig. 30.

48. In all right-angled triangles, the sides compre-

hending the right angle are called the *legs*, and the side opposite to the right angle is called the *hypotenuse*. Thus in the right-angled triangle ABC, fig. 31. (the right angle being at B), the two sides AB and BC, which comprehend the right angle ABC, are the legs of the triangle; and the side AC, which is opposite to the right angle ABC, is the hypotenuse of the right-angled triangle ABC.

49. Both obtuse and acute angled triangles are in general called *oblique-angled triangles*; in all which any side is called the *base*, and the other two the *sides*.

50. The perpendicular height of any triangle is a line drawn from the vertex to the base perpendicularly; thus if the triangle ABC (fig. 32.) be proposed, and BC be made its base, then A will be the vertex, viz. the angle opposite to the base; and if from A you draw the line AD perpendicular to BC, then the line AD is the height of the triangle ABC standing on BC as its base.

Hence all triangles standing between the same parallels have the same height, since all the perpendiculars are equal by the nature of the parallels.

51. A figure bounded by four sides is called a *quadrilateral* or *quadrangular figure*, as ABCD, fig. 33.

52. Quadrilateral figures, whose opposite sides are parallel, are called *parallelograms*. Thus in the quadrilateral figure ABDC, if the side AC be parallel to the side BD which is opposite to it, and AB be parallel to CD, then the figure ABDC is called a *parallelogram*.

53. A parallelogram having all its sides equal and angles right, is called a *square*, as fig. 34.

54. That which hath only the opposite sides equal and its angles right, is called a *rectangle*, as fig. 35.

55. That which hath equal sides, but oblique angles, is called a *rhombus*, as fig. 36. and is just an inclined square.

56. That which hath only the opposite sides equal and the angles oblique, is called a *rhomboides*, as fig. 37. and may be conceived as an inclined rectangle.

57. When none of the sides are parallel to another, then the quadrilateral figure is called a *trapezium*.

58. Every other right-lined figure, that has more sides than four, is in general called a *polygon*. And figures are called by particular names according to the number of their sides, viz. one of five sides is called a *pentagon*, of six a *hexagon*, of seven a *heptagon*, and so on. When the sides forming the polygon are equal to one another, the figure is called a *regular figure* or *polygon*.

59. In any triangle ABC (fig. 38.) on of its sides, as BC, being produced towards D, the external angle ACD is equal to both the internal opposite ones taken together, viz. to ABC and BAC. In order to prove this, thro' C, draw CE parallel to AB; then since CE is parallel to AB, and the lines AC and BD cross them, the angle ECD is equal to ABC (by art. 36.) and the angle ACE equal to CAB (by art. 35.); therefore the angles ECD and ECA are equal to the angles ABC and CAB; but the angles ECD and ECA are together equal to the angle ACD; therefore the angle ACD is equal to both the angles ABC and CAB taken together.

Cor. Hence it may be proved, that if two lines AB and

General Principles.

and CD (fig. 39.) be crossed by a third line EF, and the alternate angles AEF and EFD be equal, the lines AB and CD will be parallel; for if they are not parallel, they must meet one another on one side of the line EF (suppose at G), and so form the triangle EFG, one of whose sides GE being produced at A, the exterior angle AEF must (by this article) be equal to the sum of the two angles EFG and EGF; but, by supposition, it is equal to the angles EFG alone; therefore the angle AEF must be equal to the sum of the two angles EFG and EGF, and at the same time equal to the angle EFG alone, which is absurd; so the lines AB and CD cannot meet, and therefore must be parallel.

60. In any triangle ABC, all the three angles taken together are equal to two right angles. To prove this, you must produce BC, one of its sides, to any distance, suppose to D; then by the last proposition, the external angle, ACD, is equal to the sum of the two internal opposite ones CAB and ABC; to both add the angle ACB, then the sum of the angles ACD and ACB will be equal to the sum of the angles CAB and CBA and ACB. But the sum of the angles ACD and ACB, is equal to two right ones (by art. 32.), therefore the sum of the three angles CAB and CBA and ACB, is equal to two right angles; that is, the sum of the three angles of any triangle ACB is equal to two right angles.

Cor. 1. Hence in any triangle given, if one of its angles be known, the sum of the other two is also known: for since (by the last) the sum of all the three is equal to two right angles, or a semicircle, it is plain, that taking any one of them from a semicircle or 180 degrees, the remainder will be the sum of the other two. Thus (in the former triangle ABC) if the angle ABC be 40 degrees, by taking 40 from 180 we have 140 degrees; which is the sum of the two angles BAC, ACB: the converse of this is also plain, viz. the sum of any two angles of a triangle being given, the other angle is also known by taking that sum from 180 degrees.

2. In any right-angled triangle, the two acute angles must just make up a right one between them; consequently, any one of the oblique angles being given, we may find the other by subtracting the given one from 90 degrees, which is the sum of both.

61. If in any two triangles, ABC (fig. 40.) DEF (fig. 41.) two sides of the one, viz. AB and AC, be equal to two sides of the other, viz. to DE and DF, each to each respectively, i. e. AB to DE and AC to DF; and if the angles included between the equal sides be equal, viz. the angle BAC equal to the angle EDF; then the remaining side of the one shall be equal to the remaining side of the other, viz. BC to EF; and the angles opposite to equal sides shall be equal, viz. ABC equal to DEF (being opposite to the equal sides AC and DF), also ACB equal to DFE (which are opposite to the equal sides AB and DE). For if the triangle ABC be supposed to be lifted up and put upon the triangle DEF, and the point A on the point D; it is plain, since BA and DE are of equal length, the point B will fall upon the point E; and since the angles BAC EDF are equal, the line AC will fall upon the line DF; and they being of equal length, the point C will fall upon the point F; and so the line

General Principles.

BC will exactly agree with the line EF, and the triangle ABC will in all respects be exactly equal to the triangle DEF; and the angle ABC will be equal to the angle DEF, also the angle ACB will be equal to the angle DFE.

Cor. 1. After the same manner it may be proved, that if in any two triangles ABC, DEF (see the preceding figure), two angles ABC and ACB of the one, be equal to two angles DEF and DFE of the other, each to each respectively, viz. the angle ABC to the angle DEF, and the angle ACB equal to the angle DFE, and the sides included between these angles be also equal, viz. BC equal to EF, then the remaining angles, and the sides opposite to the equal angles, will also be equal each to each respectively; viz. the angle BAC equal to the angle EDF, the side AB equal to DE, and AC equal to DF: for if the triangle ABC be supposed to be lifted up and laid upon the triangle DEF, the point B being put upon the point E, and the line BC upon the line EF, since BC and EF are of equal lengths, the point C will fall upon the point F, and since the angle ACB is equal to the angle DFE, the line CA will fall upon the line FD, and by the same way of reasoning the line BA will fall upon the line ED; and therefore the point of intersection of the two lines BA and CA, viz. A, will fall upon the point of intersection of the two lines ED and FD, viz. D, and consequently BA will be equal to ED, and AC equal to DF, and the angle BAC equal to the angle EDF.

Cor. 2. It follows likewise from this article, that if any triangle ABC (fig. 42.) has two of its sides AB and AC equal to one another, the angles opposite to these sides will also be equal, viz. the angles ABC equal to the angle ACB. For suppose the line AD bisecting the angle BAC, or dividing it into two equal angles BAD and CAD, and meeting BC in D, then the line AD will divide the whole triangle BAC into two triangles ABD and DAC; in which BA and AD two sides of the one, are equal to CA and AD two sides of the other, each to each respectively, and the included angles BAD and DAC are by supposition equal; therefore (by this article) the angle ABC must be equal to the angle ACB.

62. Any angle, as BAD (fig. 43.) at the circumference of a circle BADE, is but half the angle BCD at the centre standing on the same arch BED. To demonstrate this, draw through A and the centre C the right-line ACE, then the angle ECD is equal to both the angles DAC and ADC (by art. 59.); but since AC and CD are equal (being two radii of the same circle), the angles subtended by them must be equal also (by art. 62. cor. 2.), i. e. the angle CAD equal to the angle CDA; therefore the sum of them is double any one of them, i. e. DAC and ADC is double of CAD, and therefore ECD is also double of DAC: the same way it may be proved, that ECB is double of CAB; and therefore the angle BCD is double of the angle BAD, or BAD the half of BCD, which was to be proved.

Cor. 1. Hence an angle at the circumference is measured by half the arc it subtends; for the angle at the centre (standing on the same arc) is measured by the whole arc (by art. 29.); but since the angle at the centre is double that at the circumference, it is plain the angle

General Principles, angle at the circumference must be measured by only half the arc it stands upon.

Cor. 2. Hence all angles, ACB , ADB , AEB , &c. (fig. 44.) at the circumference of a circle, standing on the same chord AB , are equal to one another; for by the last corollary they are all measured by the same arc, *viz.* half the arc AB which each of them subtends.

Cor. 3. Hence an angle in a segment greater than a semicircle is less than a right angle: thus, if ADB be a segment greater than a semicircle (see the last figure), then the arc AB , on which it stands, must be less than a semicircle, and the half of it less than a quadrant or a right angle; but the angle ADB in the segment is measured by the half of AB , therefore it is less than a right angle.

Cor. 4. An angle in a semicircle is a right angle. For since ABD (fig. 46.) is a semicircle, the arc AED must also be a semicircle: but the angle ABD is measured by half the arc AED , that is, by half a semicircle or quadrant; therefore the angle ABD is a right one.

Cor. 5. Hence an angle in a segment less than a semicircle, as ABD (fig. 45.), is greater than a right angle: for since the arc ABD is less than a semicircle, the arc AED must be greater than a semicircle, and so its half greater than a quadrant, *i. e.* than the measure of a right angle; therefore the angle ABD , which is measured by half the arc AED , is greater than a right angle.

63. If from the centre C of the circle ABE (fig. 47.) there be let fall the perpendicular CD on the chord AB , then that perpendicular will bisect the chord AB in the point D . To demonstrate this, draw from the centre to the extremities of the chord the two lines CA , CB ; then, since the lines CA and CB are equal, the angles CAB , CBA , which they subtend, must be equal also (by art. 62. cor. 2.), but the perpendicular CD divides the triangle ACB into two right angled triangles ACD and CDB , in which the sum of the angles ACD and CAD in the one is equal to the sum of the angles DCB and CDB in the other, each being equal to a right angle (by cor. 2. of art. 61.) but CAD is equal to CBD , therefore ACD is equal to BCD . So in the two triangles ACD and BCD , the two sides AC and CD in the one, are equal to the two sides BC and CD in the other, each to each respectively, and the included angles ACD and BCD are equal; therefore the remaining sides AD and BD are equal (by art. 61.), and consequently AB is bisected in D .

64. If from the centre C of a circle ABE , there be drawn a perpendicular CD on the chord AB , and produced till it meet the circle in F , then the line CF bisects the arch AB in the point F ; for (see the foregoing figure) joining the points A and F , F and B by the straight lines AF , FB , then in the triangles ADF , BDF , AD is equal to DB (by art. 63.), and DF common to both; therefore AD and DF , two sides of the triangle ADF , are equal to BD and DF , two sides of the triangle BDF , and the included angles ADF BDF are equal, being both right; therefore (by art. 61.) the remaining sides AF and FB are equal; but in the same circle equal lines are chords of equal arches, therefore the arches AF and FB are equal. So the whole arch AFB is bisected in the point F by the line CF .

VOL VII.

General Principles, *Cor. 1.* From art. 63. it follows, that any line bisecting a chord at right angles is a diameter; for since (by art. 63.) a line drawn from the centre perpendicular to a chord, bisects that chord at right angles; therefore, conversely, a line bisecting a chord at right angles, must pass through the centre, and consequently be a diameter.

Cor. 2. From the two last articles it follows, that the sine of any arc is the half of the chord of twice the arc; for (see the foregoing scheme) AD is the sine of the arc AF , by the definition of a sine, and AF is half the arc AFB , and AD half the chord AB (by art. 63.); therefore the corollary is plain.

65. In any triangle, the half of each side is the sine of the opposite angle; for if a circle be supposed to be drawn through the three angular points A , B , and D of the triangle ABD , fig. 48. then the angle DAB is measured by half the arch BKD (by cor. 1. of art. 62.), but the half of BD , *viz.* BE , is the sine of half the arch BKD , *viz.* the sine of BK (by cor. 2. of the last), which is the measure of the angle BAD ; therefore the half of BD is the sine of the angle BAD : the same way, it may be proved, that the half of AD is the sine of the angle ABD , and the half of AB is the sine of the angle ADB .

66. The sine, tangent, &c. of any arch is called also the *sine, tangent, &c.* of the angle whose measure the arc is: thus, because the arc GD (fig. 49.) is the measure of the angle GCD ; and since GH is the sine, DE the tangent, HD the versed sine, CE the secant, also GK the co-sine, BF the co-tangent, and CF the co-secant, &c. of the arch GD ; then GH is called the *sine, DE the tangent, &c.* of the angle GCD , whose measure is the arch GD .

67. If two equal and parallel lines, AB and CD (fig. 50.) be joined by two others, AC and BD ; then these shall also be equal and parallel. To demonstrate this, join the two opposite angles A and D with the line AD ; then it is plain this line AD divides the quadrilateral, $ACDB$, into two triangles, *viz.* ABD , ACD , in which AB a side of the one, is equal to DC a side of the other, by supposition, and AD is common to both triangles; and since AB is parallel to CD , the angle BAD will be equal to the angle ADC (by art. 36.); therefore in the two triangles BA and AD , and the angle BAD is equal to CD and DA , and the angle ADC ; that is, two sides and the included angle in the one is equal to two sides and the included angle in the other; therefore (by art. 61.) BD is equal to AC , and since the angle DAC is equal to the angle ADB , therefore, the lines BD AC are parallel (by cor. art. 59.)

Cor. 1. Hence it is plain, that the quadrilateral $ABDC$ is a parallelogram, since the opposite sides are parallel.

Cor. 2. In any parallelogram the line joining the opposite angles (called the *diagonal*) as DA , divides the figure into two equal parts, since it has been proved that the triangles ABD ACD are equal to one another.

Cor. 3. It follows also, that a triangle ACD on the same base CD , and between the same parallels with a parallelogram $ABDC$, is the half of that parallelogram.

Cor. 4. Hence it is plain, that the opposite sides of a paral-

General Principles. parallelogram are equal; for it has been proved, that $ABDC$ being a parallelogram, AB will be equal to CD , and AC equal to BD .

68. All parallelograms on the same or equal bases, and between the same parallels, are equal to one another; that is, if BD and GH (fig. 51.) be equal, and the lines BH and AF be parallel, then the parallelograms $ABDC$, $BDFE$, and $EFHG$, are equal to one another. For AC is equal to EF , each being equal to BD (by *cor.* 4. of 67.) To both add CE , then AE will be equal to CF . So in the two triangles ABE CDF , AB a side of the one, is equal to CD a side in the other; and AE is equal to CF , and the angle BAE is equal to the angle DCF (by art. 36); therefore the two triangles ABE CDF are equal (by art. 61.); and taking the triangle CKE from both, the figure $ABKC$ will be equal to the figure $KDFE$; to both which add the little triangle KBD , then the parallelogram $ABDC$ will be equal to the parallelogram $BDFE$. The same way it may be proved, that the parallelogram $EFHG$ is equal to the parallelogram $EFDB$; so the three parallelograms $ABDC$, $BDFE$, and $EFHG$, will be equal to one another.

Cor. Hence it is plain, that triangles on the same base, and between the same parallels, are equal; since they are the half of the parallelograms on the same base and between the same parallels (by *cor.* 3. of last art.)

69. In any right-angled triangle, ABC , (fig. 52.) the square of the hypotenuse BC , viz. BCM^2 , is equal to the sum of the squares made on the two sides AB and AC , viz. to $ABDE$ and $ACGF$. To demonstrate this, through the point A draw AKL perpendicular to the hypotenuse BC , join AH , AM , DC , and BG ; then it is plain that DB is equal to BA (by art. 53.), also BH is equal to BC (by the same); so in the two triangles DBC ABH , the two sides DB and BC in the one are equal to the two sides AB and BH in the other; and the included angles DBC and ABH are also equal; (for DBA is equal to CBH , being both right; to each add ABC , then it is plain that DBC is equal to ABH) therefore the triangles DBC ABH are equal (by art. 61.), but the triangle DBC is half of the square $ADBE$ (by *cor.* 3. of 67.), and the triangle ABH is half the parallelogram $BKLH$ (by the same), therefore half the square $ADBE$ is equal to half the parallelogram $BKLH$. Consequently the square $ADBE$ is equal to the parallelogram $BKLH$. The same way it may be proved, that the square $ACGF$ is equal to the parallelogram $KCML$. So the sum of the squares $ADBE$ and $ACGF$ is equal to the sum of the parallelograms $BKLH$ and $KCML$, but the sum of these parallelograms is equal to the square BCM^2 ; therefore the sum of the squares on AB and AC is equal to the square on BC .

Cor. 1. Hence in a right-angled triangle, the hypotenuse and one of the sides being given, we may easily find the other, by taking the square of the given side from the square of the hypotenuse, and the square root of the remainder will be the side required.

Cor. 2. Hence the sides in a right-angled triangle being given, we may find the hypotenuse, by taking the sum of the squares of the given sides, and extracting the square root of that sum.

70. If upon the line AB (fig. 53.) there be drawn

a semicircle ADB , whose centre is C , and on the point C there be raised a perpendicular to the line AB , viz. CD ; then it is plain the arc DB is a quadrant, or contains 90 degrees; suppose the arc DB to be divided into 9 equal arcs, each of which will contain 10 degrees, then on the point B raising BE perpendicular to the line AB , it will be a tangent to the circle in quadrant, viz. $B 10$, $B 20$, $B 30$, $B 40$, &c. and if you draw the sine, tangent, &c. (as in the scheme) we shall have the sine, tangent, &c. to every 10 degrees in the quadrant: and the same way we may have the sine, tangent, &c. to every single degree in the quadrant, by dividing it into 90 equal parts beginning from B , and drawing the sine, tangent, &c. to all the arcs beginning at the same point B . By this method they draw the lines of sines, tangents, &c. of a certain circle on the scale; for after drawing them on the circle, they take the lengths of them, and set them off on the lines drawn for that purpose. The same way, by supposing the radius of any number of equal parts, (suppose 1000, or 10,000, &c.) it is plain the sine, tangent, &c. of every arc must consist of some number of these equal parts, and by computing them in parts of the radius, we have tables of sines, tangents, &c. to every arc in the quadrant, called *natural sines, tangents, &c.* and the logarithms of these give us tables of logarithmic sines, tangents, &c. See LOGARITHMS.

71. In any triangle, ABC , (fig. 1.) if one of its sides, as AC , be bisected in E (and consequently AC double of AE), and through E be drawn ED , parallel to BC , and meeting AB in D , then BC will be double of ED , and AB double of AD . Through D draw DF , parallel to AC , meeting BC in F : For since, by construction, DF is parallel to AC , and DE parallel to BC ; therefore (by art. 36.) the angle BFD will be equal to the angle BCA , and (by the same article) the angle BCA will be equal to the angle DEA , consequently the angle BFD will be equal to the angle DEA ; also (by art. 36.) the angle BDF will be equal to the angle DAE : and since DF is parallel to EC , and DE parallel to FC , the quadrilateral $DFCE$ will be a parallelogram; and therefore (by art. 59. *cor.* 4.) DF will be equal to EC , which, by construction, is equal to AE ; so in the two triangles BDF DAE , the two angles BFD and BDF in the one, are equal to the two angles DEA and DAE in the other, each to each respectively; and the included side DF is equal to the included side AE ; therefore (by art. 61. *cor.* 1.) AD will be equal to DB , and consequently AB double of AD ; also (by the same) DE will be equal to BF ; but DE is also (by art. 67. *cor.* 4.) equal to FC ; therefore BF and ED together, or BC , will be double of DE .

After the same manner it may be proved, that if in the triangle AKG , (fig. 2.) AE be taken equal to a third part of AK , and through E be drawn ED , parallel to KG , and meeting AG in D ; then ED will be equal to a third part of GK ; and AD equal to a third part of AG .

Likewise if in any triangle ABC , (fig. 3.) upon the side AB , be taken AE , equal to one-fourth, one-fifth, one-sixth, &c. of AB , and through E be drawn ED parallel to BC and meeting AC in D ; then D will be one-fourth, one-fifth, one-sixth, &c. of BC , and AD the like part of AC ; and, in general, if in any triangle

General Principles.

Plate CCXVI.

General Principles. angle ABC, there be assumed a point E on one of its sides AB, and through that point be drawn a line ED, parallel to one of its sides BC, and meeting the other side AC in D; then whatever part AE is of AB, the same part will ED be of BC, and AD of AC.

Cor. Hence it follows, that if in any triangle ABC, there be drawn ED, parallel to one of its sides BC, and meeting the other two in the points E and D, then $AE : AB :: ED : BC :: AD : AC$; that is, AE is to AB, as ED is to BC, and that as AD to AC.

72. If any two triangles ABC, fig. 4. a b c, fig. 5. are similar, or have all the angles of the one equal to all the angles of the other, each to each respectively; that is, the angle CAB equal to the angle c a b, and the angle ABC equal to the angle a b c, and the angle ACB equal to the angle a c b; then the sides opposite to the equal angles are proportioned, *viz.* $AB : a b :: AC : a c ::$ and $AB : a b :: BC : b c ::$ and $AC : a c :: BC : b c$. On the side AB of the largest triangle set off AE equal to a b, and through E draw ED parallel to BC, meeting AC in D; then since DE and BC are parallel, and AB crossing them, the angle AED will (by art. 36.) be equal to the angle ABC, which (by supposition) is equal to the angle a b c, also the angle DAE is by supposition equal to the angle c a b; so in the two triangles AED, a b c, the two angles DAE AED of the one, are equal to two angles c a b a b c of the other, each to each respectively, and the included side AE is (by construction) equal to the included side a b; therefore, (by art. 61. cor. 1) AD is equal to a c, and DE equal to b c; but since, in the triangle ABC, there is drawn DE parallel to BC one of its sides, and meeting the two other sides in the points D and E, therefore (by cor. art. 71.) $AB : AE :: AC : AD$, and $AB : AE :: BC : DE$, and $AC : AD :: BC : DE$; and in the three last proportions, instead of the lines AE, DE, and AD, putting in their equals a b, b c, and a c, we shall have $AB : a b :: AC : a c$, and $AB : a b :: BC : b c$, and lastly, $AC : a c :: BC : b c$.

73. The chord, sine, tangent, &c. of any arc in one circle, is to the chord, sine, tangent, &c. of the same arc in another, as the radius of the one is to the radius of the other, fig. 6. 6. Let ABD abd be two circles, BD bd two arcs of these circles, equal to one another, or consisting of the same number of degrees; FD fd the tangents, BD bd the chords, BE be the sines, &c. of these two arcs BD bd, and CD cd the radii of the circles; then I say $CD : cd :: FD : fd$, and $CD : cd :: BD : bd$, and $CD : cd :: BE : be$, &c. For since the arcs BD bd are equal, the angles BCD bcd will be equal; and FD fd, being tangents to the points D and d, the angles CDF cdf will be equal, being each a right angle (art. 22.) so in the two triangles CDF cdf, the two angles FCD CDF of the one, being equal to the two angles fcd cdf of the other, each to each, the remaining angle CFD will be equal to the remaining angle cfd (by art. 60.); therefore the triangles CFD cfd are similar, and consequently (by art. 73.) $CD : cd :: FD : fd$. In the same manner it may be demonstrated, that $CD : cd :: BD : bd$, and $CD : cd :: BE : be$, &c.

74. Let ABD (fig. 7.) be a quadrant of a circle described by the radius CD; BD any arc of it, and BA its complement; BG or CF the sine, CG or BF the co-

sine; DE the tangent, and CE the secant of that arc BD. Then since the triangles CDE CBG are similar or equiangular, it will be (by art. 72.) $DE : EC :: GB : BC$. *i. e.* the tangent of any arc, is to the secant of the same, as the sine of it is to the radius. Also since $DE : EC :: GB : BC$; therefore, by inverting that proportion, we have $EC : DE :: BC : GB$, *i. e.* the secant is to the tangent, as the radius is to the sine of any arc.

Again, since the triangles CDE CGB are similar, therefore (by art. 72.) it will be $CD : CE :: CG : CB$, *i. e.* as the radius is to the secant of any arc, so is the co-sine of that arc to the radius. And by inverting the proportion we have this, *viz.* as the secant of any arc is to the radius, so is the radius to the co-sine of that arc.

75. In all circles the chord of 60 degrees is always equal in length to the radius. Thus in the circle AEBD, (fig. 8.) if the arc AEB be an arc of 60 degrees, then drawing the chord AB, I say AB shall be equal to the radius CB or AC; for in the triangle ACB, the angle ACB is 60 degrees, being measured by the arc AEB; therefore the sum of the other two angles is 120 degrees, (by cor. 1. of 60.); but since AC and CB are equal, the two angles CAB, CBA will also be equal; consequently each of them half their sum 120, *viz.* 60 degrees; therefore all the three angles are equal to one another, consequently all the sides, therefore AB is equal to CB.

Cor. Hence the radius from which the lines on any scale are formed, is the chord of 60 on the line of chords.

Geometrical Problems.

PROB. 1. From a point C (fig. 9.) in a given line AB to raise a perpendicular to that line.

Rule. From the point C take the equal distances CB, CA on each side of it. Then stretch the compasses to any greater distance than CB or CA, and with one foot of them in B, sweep the arc EF with the other; again, with the same opening, and one foot in A, sweep the arc GH with the other, and these two arcs will intersect one another in the point D; then join the given points C and D with the line CD, and that shall be the perpendicular required.

2. To divide a given right line AB (fig. 10.) into two equal parts; that is, to bisect it.

Rule. Take any distance with your compasses that you are sure is greater than half the given line; then setting one foot of them in B, with the other sweep the arc DFC; and with the same distance, and one foot in A, with the other sweep the arc CED; these two arcs will intersect one another in the points CD, which joined by the right line CD will bisect AB in G.

3. From a given point D, (fig. 11.) to let fall a perpendicular on a given line AB.

Rule. Set one foot of the compasses in the point D, and extend the other to any greater distance than the least distance between the given point and the line, and with that extent sweep the arc AEB, cutting the line in the two points A and B, then (by the last prob.) bisect the line AB in the point C; lastly, join C and D, and that line CD is the perpendicular required.

General Principles.

4. (Fig. 12.) Upon the end B of a given right line BA, to raise a perpendicular.

Rule. Take any extent in your compasses, and with one foot in B fix the other in any point C without the given line; then with one point of the compasses in C, describe with the other the circle EBD, and through E and C draw the diameter ECD meeting the circle in D; join D and B, and the right line DB is that required; for EBD is a right angle (by *cor.* 4. of 63.)

5. (Fig. 13.) To draw one line parallel to another given line AB, that shall be distant from one another by any given distance D.

Rule. Extend your compasses to the given distance D; then setting one foot of them in any point of the given line (suppose A,) with the other sweep the arc FCG; again, at the same extent, and one foot in any other point of the given line B, sweep the arc HDK, and draw the line CD touching them, and that will be parallel to the given line AB, and distant from it by the line D as was required.

6. (Fig. 14.) To divide a given line AB into any number of equal parts, suppose 7.

Rule. From the point A draw any line AD, making an angle with the line AB, then through the point B, draw a line BC parallel to AD; and from A, with any small opening of the compasses, set off a number of equal parts (on the line AD) less by one than the proposed number (here 6.); then from B set off the same number of the same parts (on the line BC); lastly, join 1 and 6, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1, and these lines will cut the given line as required.

7. (Fig. 15.) To quarter a given circle, or to divide it into four equal parts.

Rule. Through the centre C of the given circle, draw a diameter AB, then upon the point C raise a perpendicular DCE to the line AB; and these two diameters AB and DE shall quarter the circle.

8. (Fig. 16.) Through three given points A, B, and D, to draw a circle. *Note,* the three points must not lie in the same straight line.

Rule. Join A and B, also B and D, with the straight lines AB BD; then (by prob. 2.) bisect AB with the line EC, also BD with the line FC, which two lines will cut one another in some point C; that is the centre of the circle required: then fixing one point of your compasses in C, and stretching the other to A, describe the circle ABDG, which will pass through the three points given. The reason of this is plain from *cor.* 1. of art. 64.

9. (Fig. 17.) From the point A of the given line AB, to draw another line (suppose AC) that shall make with AB an angle of any number of degrees, suppose 45.

Rule. Let the given line AB be produced, then take off your scale the length of the chord of 60 degrees, which is equal to the radius of the circle the scale was made for (by art. 75.); and setting one foot in A, with the other sweep the arc BC; then with your compasses take from your scale the chord of 45 degrees, and set off that distance from B to C. Lastly, join A and C, and the line AC is that required. For the angle CAB, which is measured by the arc BC, is an angle of 45 degrees, as was required.

10. An angle BAC (fig. 18.) being given, to find how many degrees it contains.

Rule. With your compasses take the length of your chord of 60 from your scale. Then, setting one foot of them in A, with the other sweep the arc BC, which is the arc comprehended between the two sides AB, AC produced if needful. Lastly, take with your compasses the distance BC, and applying it to your line of chords on the scale, you will find how many degrees the arc BC contains, and consequently the degrees of the angle BAC which was required.

11. Three lines $x, y,$ and z being given, (fig. 19.) to form a triangle of them; but any two of these lines taken together must always be greater than the third.

Rule. Make any one of them, as $x,$ the base; then with your compasses take another of them, as $z,$ and setting one foot in one end of the line $x,$ as B, with the other sweep the arc DE; and taking with your compasses the length of the other $y,$ set one foot of them in A, the other end of the line $x,$ and with the other sweep the arc FG, which will cut the other in C, lastly, join CA and CB, and the triangle CAB is that required.

12. To make a triangle, having one of its sides of any number of equal parts (suppose 160,) and one of the angles at that side 50 degrees, and the other 44 degrees.

Rule. Draw an indefinite line ED, (fig. 20.) then take off the line of equal parts with your compasses, 160 of them, and set them on the indefinite line, as BC; then (by prob. 9.) draw BA, making the angle ABC of 50 degrees, and (by the same) draw from C the line AC, making the angle ACB of 44 degrees; which two lines will meet one another in A, and the triangle ABC is that required. See TRIGONOMETRY.

13. Upon a given line AB (fig. 21.) to make a square.

Rule. Upon the extremity A of the given line AB, raise a perpendicular AC (by prob. 4); then take AC equal to AB, and with that extent, setting one foot of the compasses in C, sweep with the other foot the arc GH; then with the same extent, and one foot in B, with the other sweep the arc EF, which will meet the former in some point D; lastly, join C and D, D and B, and the figure ABDC will be the square required.

14. On a given line AB (fig. 22.) to draw a rhombus that shall have one of its angles equal to any number of degrees, suppose 60 degrees.

Rule. From the point A of the given line AB, draw the line AC, making the angle CAB of 60 degrees, (by prob. 9.) then take AC equal to AB, and with that extent, fixing one foot of the compasses in B, with the other describe the arc GH; and at the same extent fixing one foot of the compasses in C, with the other describe the arc EF cutting the former in D; lastly, join CD and DB, and the figure ACDB is that required.

16. Given two lines x and $z,$ of these two to make a rectangle.

Rule. Draw a line, as AB, (fig. 23. 23.) equal in length to one of the given lines $x;$ and on the extremity A of that line raise a perpendicular AC, on which

General Principles.

Lines and Angles. which take AC equal to the other line z ; then take with your compasses the length of the line AB, and at that extent, fixing one foot of them in C, with the other sweep the arc EF; and also taking with your compasses the extent of the line AC, fix one foot of them in B, and with the other sweep the arc GH, which will meet the former in D; lastly, join CD and BD, and the figure ABDC will be that required.

16. Two lines x and z being given, of these to form a rhomboides that shall have one of its angles any number of degrees, suppose 50.

Rule. Draw a line AB (fig. 24. 24.) equal in length to one of the lines, as x ; then draw the line AC, making with the former the angle BAC equal to that proposed, suppose 50 degrees, and on that line take AC equal to the given line z ; then with your compasses take the length of AB, and fixing one foot in C, sweep the arc EF; also taking the length of AC, and setting one foot in B, with the other sweep the arc GH, which will cut the former in D; then join CD and DB, so the figure ACDB will be that required.

Lines and Angles.

PART II. THE APPLICATION OF THE FOREGOING PRINCIPLES TO THE MENSURATION OF SURFACES, SOLIDS, &c.

CHAP. I. Of the Mensuration of Lines and Angles.

A Line or length to be measured, whether it be distance, height, or depth, is measured by a line less than it. In Scotland the least measure of length is an inch: not that we measure no line less than it, but because we do not use the name of any measure below that of an inch; expressing lesser measures by the fractions of an inch: and in this treatise we use decimal fractions as the easiest. Twelve inches make a foot; three feet and an inch make the Scots ell; six ells make a fall; forty falls make a furlong; eight furlongs make a mile: so that the Scots mile is 1184 paces, accounting every pace to be five feet. These things are according to the statutes of Scotland; notwithstanding which, the glaziers use a foot of only eight inches; and other artists for the most part use an English foot, on account of the several scales marked on the English foot-measure for their use. But the English foot is somewhat less than the Scots; so that 185 of these make 186 of those.

Lines, to the extremities and any intermediate point of which you have easy access, are measured by applying to them the common measure a number of times. But lines, to which you cannot have such access, are measured by methods taken from geometry; the chief whereof we shall here endeavour to explain. The first is by the help of the geometrical square.

“As for the English measures, the yard is 3 feet, or 36 inches. A pole is sixteen feet and a half, or five yards and a half. The chain, commonly called *Gunter's Chain*, is four poles, or 22 yards, that is, 66 feet. An English statute-mile is fourscore chains, or 1760 yards, that is, 5280 feet.

“The chain (which is now much in use, because it is very convenient for surveying) is divided into 100 links, each of which is $7\frac{2}{100}$ of an inch: whence it is easy to reduce any number of those links to feet, or any number of feet to links.

“A chain that may have the same advantages in surveying Scotland, as *Gunter's chain* has in England, ought to be in length 74 feet, or 24 Scots ells, if no regard is had to the difference of the Scots and English foot abovementioned. But if regard is had to that difference the Scots chain ought to consist of $74\frac{2}{3}$ English feet, or 74 feet 4 inches and $\frac{2}{3}$ ths of an inch. This chain being divided into 100 links, each of those links is 8 inches and $\frac{2}{100}$ of an inch. In the following table, the most noted measures are expressed in English inches and decimals of an inch.”

Lines and
Angles.Plate
CCXVII.

P R O P O S I T I O N I .

PROB. *To describe the structure of the geometrical square.*—The geometrical square is made of any solid matter, as brass or wood, or of any four plain rulers joined together at right angles (as in fig. 1.), where A is the centre, from which hangs a thread with a small weight at the end, so as to be directed always to the centre. Each of the sides BE and DE is divided into an hundred equal parts, or (if the sides be long enough to admit of it) into a thousand parts; C and F are two sights, fixed on the side AD. There is moreover an index GH, which, when there is occasion, is joined to the centre A, in such manner as that it can move round, and remain in any given situation. On this index are two sights perpendicular to the right line going from the centre of the instrument: these are K and L. The side DE of the instrument is called the upright side; BE the reclining side.

P R O P O S I T I O N II .

FIG. 2. *To measure an accessible height AB by the help of a geometrical square, its distance being known.*—Let BR be an horizontal plane, on which there stands perpendicularly any line AB: let BD, the given distance of the observator from the height, be 96 feet: let the height of the observator's eye be supposed 6 feet; and let the instrument, held by a steady hand, or rather leaning on a support, be directed towards the summit A, so that one eye (the other being shut) may see it clearly through the sights; the perpendicular or plumb-line meanwhile hanging free, and touching the surface of the instrument; let now the perpendicular be supposed to cut off on the right side KN 80 equal parts. It is clear that LKN, ACK, are similar triangles; for the angles LKN, ACK are right angles, and therefore equal; moreover, LN and AC are parallel, as being both perpendicular to the horizon; consequently (by art. 60. cor. 1. Part I.), the angles KLN, KAC, are equal; wherefore (by art. 60. cor. 2. of Part I.), the angles LNK and CAK are likewise equal: so that in the triangles NKL, KAC, (by art. 72. of Part I.) as NK : KL :: KC (i. e. BD) : CA; that is, as 80 to 100, so is 96 feet to CA. Therefore, by the rule of three, CA will be found to be 120 feet; and CB, which is 6 feet, being added, the whole height is 126 feet.

But if the distance of the observator from the height, as BE, be such, that when the instrument is directed as formerly toward the summit A, the perpendicular falls on the angle P, opposite to H, the centre of the instrument, and BE or CG be given of 120 feet; CA will also be 120 feet. For in the triangles HGP, ACG, equiangular, as in the preceding case, as PG : GH :: GC : CA. But PG is equal to GH; therefore GC is likewise equal to CA: that is, CA will be 120 feet, and the whole height 126 feet as before.

Let the distance BF be 300 feet, and the perpendicular or plumb-line cut off 40 equal parts from the reclining side: Now, in this case, the angles QAC, QZI, are equal, and the angles QZI, ZIS, are equal: therefore the angle ZIS is equal to the angle QAC. But the angles ZSI, QCA are equal, being right angles; therefore, in the equiangular triangles ACQ, SZI, it will be, as ZS : SI :: CQ : CA; that is, as 100 to 40, so is 300 to CA. Wherefore, by the rule of three, CA will be found to be of 120 feet. And, by adding

the height of the observator, the whole BA will be 126 feet. Note, that the height is greater than the distance, when the perpendicular cuts the upright side, and less if it cut the reclining side; and that the height and distance are equal, if the perpendicular fall on the opposite angle.

S C H O L I U M .

If the height of a tower to be measured as above, end in a point (as in fig. 3.), the distance of the observator opposite to it, is not CD, but is to be accounted from the perpendicular to the point A; that is, to CD must be added the half of the thickness of the tower, viz. BD: which must likewise be understood in the following propositions, when the case is similar.

P R O P O S I T I O N III .

FIG. 4. *From the height of a tower AB given, to find a distance on the horizontal plane BC, by the geometrical square.*—Let the instrument be so placed, as that the mark C in the opposite plane may be seen through the sights; and let it be observed how many parts are cut off by the perpendicular. Now, by what hath been already demonstrated, the triangles AEF, ABC, are similar; therefore, it will be as EF to AE, so AB (composed of the height of the tower BG) and of the height of the centre of the instrument A, above the tower BG) to the distance BC. Wherefore, if, by the rule of three, you say, as EF to AE, so is AB to BC, it will be the distance sought.

P R O P O S I T I O N IV .

FIG. 5. *To measure any distance at land or sea, by the geometrical square.*—In this operation, the index is to be applied to the instrument, as was shown in the description; and, by the help of a support, the instrument is to be placed horizontally at the point A; then let it be turned till the remote point F, whose distance is to be measured, be seen through the fixed sights; and bringing the index to be parallel with the other side of the instrument, observe by the sights upon it any accessible mark B, at a sensible distance: then carrying the instrument to the point B, let the immoveable sights be directed to the first station A, and the sights of the index to the point F. If the index cut the upright side of the square, as in K, in the two triangles BRK, and BAF, which are equiangular, it will be as BR to RK, so BA (the distance of the stations to be measured with a chain) to AF; and the distance AF sought will be found by the rule of three, But if the index cut the reclining side of the square in any point L, where the distance of a more remote point (G) is sought: in the triangles BLS, BAG, the side LS shall be to SB, as BA to AG, the distance sought; which accordingly will be found by the rule of three.

P R O P O S I T I O N V .

FIG. 6. *To measure an accessible height by means of a plain mirror.*—Let AB be the height to be measured: let the mirror be placed at C, in the horizontal plane BD, at a known distance BC; let the observer go back to D, till he see the image of the summit in the mirror, at a certain point of it, which he must diligently mark; and let DE be the height of the observator's eye. The triangles ABC and EDC are equiangular; for the angles at D and B are right angles; and ACB, ECD, are equal, being the angles of

Lines and Angles. of incidence and reflexion of the ray AC, as is demonstrated in optics; wherefore the remaining angles at A and E are also equal; therefore it will be as CD to DE, so CB to BA; that is, as the distance of the observator from the point of the mirror, in the right line betwixt the observator and the height, is to the height of the observator's eye, so is the distance of the tower from that point of the mirror, to the height of the tower sought; which therefore will be found by the rule of three.

Note 1. The observation will be more exact, if, at the point D, a staff be placed in the ground perpendicularly, over the top of which the observator may see a point of the glass exactly in a line betwixt him and the tower.

Note 2. In place of a mirror may be used the surface of water contained in a vessel, which naturally becomes parallel to the horizon.

PROPOSITION VI.

FIG. 7. To measure an accessible height AB by means of two staffs.—Let there be placed perpendicularly in the ground a longer staff DE, likewise a shorter one FG, so as the observator may see A, the top of the height to be measured, over the ends DF of the two staffs; let FH and DC, parallel to the horizon, meet DE and AB in H and C; then the triangles FHD, DCA, shall be equiangular; for the angles at C and H are right ones; likewise the angle A is equal to the angle FDH; wherefore the remaining angles DFH, and ADC, are also equal: wherefore, as FH, the distance of the staffs, to HD, the excess of the longer staff above the shorter; so is DC, the distance of the longer staff from the tower, to CA, the excess of the height of the tower above the longer staff. And thence CA will be found by the rule of three.

To which if the length DE be added, you will have the whole height of the tower BA.

SCHOLIUM

FIG. 8. Many other methods may be occasionally contrived for measuring an accessible height. For example, from the given length of the shadow BD, to find out the height AB, thus: Let there be erected a staff CE perpendicularly, producing the shadow EF: The triangles ABD, CEF, are equiangular; for the angles at B and E are right; and the angles ADB and CFE are equal, each being equal to the angle of the sun's elevation above the horizon: Therefore, as EF, the shadow of the staff, to EC, the staff itself; so BD the shadow of the tower, to BA, the height of the tower. Though the plane on which the shadow of the tower falls be not parallel to the horizon, if the staff be erected in the same plane, the rule will be the same.

PROPOSITION VII.

To measure an inaccessible height by means of two staffs.—Hitherto we have supposed the height to be accessible, or that we can come at the lower end of it; now if, because of some impediment, we cannot get to a tower, or if the point whose height is to be found out be the summit of a hill, so that the perpendicular be hid within the hill; if, for want of better instruments, such an inaccessible height is to be measured by means of two staffs, let the first observation be made with the staffs DE and FG, (as in prop. 6.); then the observator is to go off in a direct line from the height

and first station, till he come to the second station: where (fig. 11.) he is to place the longer staff perpendicularly at RN, and the shorter staff at OK, so that the summit A may be seen along their tops; that is, so that the point KNA may be in the same right line. Through the point N, let there be drawn the right line NP parallel to FA: Wherefore in the triangles KNP, KAF, the angles KNP, KAF are equal, also the angle AKF is common to both; consequently the remaining angle KPN is equal to the remaining angle KFA. And therefore, $PN : FA :: KP : KF$. But the triangles PNL, FAS are similar; therefore, $PN : FA :: NL : SA$. Therefore (by the 11. 5. Eucl.) $KP : KF :: NL : SA$. Thence, alternately, it will be, as KP (the excess of the greater distance of the short staff from the long one above its lesser distance from it) to NL: the excess of the longer staff above the shorter; so KF, the distance of the two stations of the shorter staff to SA, the excess of the height sought above the height of the shorter staff. Wherefore SA will be found by the rule of three. To which let the height of the shorter staff be added, and the sum will give the whole inaccessible height BA.

Note 1. In the same manner may an inaccessible height be found by a geometrical square, or by a plain speculum. But we shall leave the rules to be found out by the student, for his own exercise.

Note 2. That by the height of the staff we understand its height above the ground in which it is fixed.

Note 3. Hence depends the method of using other instruments invented by geometricians: for example, of the geometrical cross: and if all things be justly weighed a like rule will serve for it as here. But we incline to touch only upon what is most material.

PROPOSITION VIII.

FIG. 9. To measure the distance AB, to one of whose extremities we have access, by the help of four staffs.—Let there be a staff fixed at the point A; then going back at some sensible distance in the same right line, let another be fixed in C, so as that both the points A and B be covered and hid by the staff C; likewise going off in a perpendicular from the right line CB, at the point A (the method of doing which shall be shown in the following scholium), let there be placed another staff at H; and in the right line CGK (perpendicular to the same CB, at the point C), and at the point of it K, such that the points K, H, and B may be in the same right line, let there be fixed a fourth staff. Let there be drawn, or let there be supposed to be drawn, a right line GH parallel to CA. The triangles KGH, HAB, will be equiangular; for the angles HAB, KGH are right angles. Also the angles ABH, KHG are equal; wherefore, as KG (the excess of CK above AH) to GH, or to CA, the distance betwixt the first and second staff; so is AH, the distance betwixt the first and third staff, to AB the distance sought.

SCHOLIUM

Fig. 10. To draw on a plane a right line AE perpendicular to CH, from a given point A: take the right lines AB AD, on each side equal: and in the points B and D, let there be fixed stakes, to which let there be tied two equal ropes BE, DE, or one having a mark in the middle, and holding in your hand their extremities joined (or the mark in the middle, if it be but one), draw out the ropes on the ground; and then

Lines and
Angles.

then where the two ropes meet, or at the mark, when by it the rope is fully stretched, let there be placed a third stake at E; the right Line AE will be perpendicular to CH in the point A (prob. 1. of Part I.). In a manner not unlike to this, may any problems, that are resolved by the square and compasses, be done by ropes and a cord turned round as a radius.

P R O P O S I T I O N IX.

FIG. 12. *To measure the distance AB, one of whose extremities is accessible.*—From the point A, let the right line AC of a known length be made perpendicular to AB (by the preceding scholium): likewise draw the right line CD perpendicular to CB, meeting the right line AB in D: then as $DA : AC :: AC : AB$. Wherefore, when DA and AC are given, AB will be found by the rule of three.

S C H O L I U M.

All these preceding operations depend on the equality of some angles of triangles, and on the similarity of the triangles arising from that equality. And on the same principles depend innumerable other operations which a geometrician will find out of himself, as is very obvious. However, some of these operations require such exactness in the work, and without it are so liable to errors, that, *cæteris paribus*, the following operations, which are performed by a trigonometrical calculation, are to be preferred; yet could we not omit those above, being most easy in practice, and most clear and evident to those who have only the first elements of geometry. But if you are provided with instruments, the following operations are more to be relied upon. We do not insist on the easiest cases to those who are skilled in plain trigonometry, which is indeed necessary to any one who would apply himself to practice. See TRIGONOMETRY.

P R O P O S I T I O N X.

FIG. 13. *To describe the construction and use of the geometrical quadrant.*—The geometrical quadrant is the fourth part of a circle divided into 90 degrees, to which two sights are adapted, with a perpendicular or plumb-line hanging from the centre. The general use of it is for investigating angles in a vertical plane, comprehended under right lines going from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. This instrument is made of any solid matter, as wood, copper, &c.

P R O P O S I T I O N XI.

FIG. 14. *To describe and make use of the graphometer.*—The graphometer, is a semicircle made of any hard matter, of wood, for example, or brass, divided into 180 degrees; so fixed on a fulcrum, by means of a brass ball and socket, that it easily turns about, and retains any situation; two sights are fixed on its diameter. At the centre there is commonly a magnetic needle in a box. There is likewise a moveable ruler, which turns round the centre, and retains any situation given it. The use of it is to observe any angle, whose vertex is at the centre of the instrument in any plane (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains.

P R O P O S I T I O N XII.

FIG. 15. and 16. *To describe the manner in which angles are measured by a quadrant or graphometer.*—Let

I

there be an angle in a vertical plane, comprehended between a line parallel to the horizon HK, and the right line RA, coming from any remarkable point of a tower or hill, or from the sun, moon, or a star. Suppose that this angle RAH is to be measured by the quadrant: let the instrument be placed in the vertical plane, so that the centre A may be in the angular point; and let the sights be directed towards the object at R (by the help of the ray coming from it, if it be the sun or moon, or by the help of the visual ray, if it is any thing else), the degrees and minutes in the arc BC, cut off by the perpendicular, will measure the angle RAH required. For, from the make of the quadrant, BAD is a right angle; therefore BAR is likewise right, being equal to it. But, because HK is horizontal, and AC perpendicular, HAC will be a right angle: and therefore equal also to BAR. From those angles subtract the part HAB that is common to both; and there will remain the angle BAC equal to the angle RAH. But the arc BC is the measure of the angle BAC; consequently, it is likewise the measure of the angle RAH.

Note, That the remaining arc on the quadrant DC is the measure of the angle RAZ, comprehended between the aforesaid right line RA and AZ which points to the zenith.

Let it now be required to measure the angle ACB (fig. 16.) in any plane, comprehended between the right lines AC and BC, drawn from two points A and B, to the place of station C. Let the graphometer be placed at C, supported by its fulcrum (as was shown above); and let the immoveable sights on the side of the instrument DE be directed towards the point A; and likewise (while the instrument remains immoveable) let the sights of the ruler FG (which is moveable about the centre C) be directed to the point B. It is evident that the moveable ruler cuts off an arc DH, which is the measure of the angle ACB sought. Moreover, by the same method, the inclination of CE, or of FG, may be observed with the meridian line, which is pointed out by the magnetic needle inclosed in the box, and is moveable about the centre of the instrument, and the measure of this inclination or angle found in degrees.

P R O P O S I T I O N XIII.

FIG. 17. *To measure an accessible height by the geometrical quadrant.*—By the 12th prop. of this Part, let the angle C be found by means of the quadrant. Then in the triangle ABC, right-angled at B (BC being supposed the horizontal distance of the observer from the tower), having the angle at C, and the side BC, the required height BA will be found by the 3d case of plane trigonometry. See TRIGONOMETRY.

P R O P O S I T I O N XIV.

FIG. 18. *To measure an inaccessible height by the geometrical quadrant.*—Let the angle ACB be observed with the quadrant (by the 12th prop. of this Part); then let the observer go from C to the second station D, in the right line BCD (provided BCD be a horizontal plane); and after measuring this distance CD, take the angle ACD likewise with the quadrant. Then, in the triangle ACD, there is given the angle ADC, with the angle ACD; because ACB was given before: therefore (by art. 59. of Part I.) the remaining angle CAD is given likewise. But the side CD is likewise

Lines and
Angles.

13.

Lines and likewise given, being the distance of the stations C and D; therefore (by the first case of oblique-angled triangles in trigonometry) the side AC will be found. Wherefore, in the right-angled triangle ABC, all the angles and the hypotenuse AC are given; consequently, by the fourth case of trigonometry, the height sought AB will be found; as also (if you please) the distance of the station C, from AB the perpendicular within the hill or inaccessible height.

PROPOSITION XV.

FIG. 19. *From the top of a given height, to measure the distance BC.*—Let the angle BAC be observed by the 12th prop. of this; wherefore in the triangle ABC, right-angled at B, there is given by observation the angle at A; whence (by the 59th art. of Part I.) there will also be given the angle BCA: moreover the side AB (being the height of the tower) is supposed to be given. Wherefore, by the 3d case of trigonometry, BC, the distance sought, will be found.

PROPOSITION XVI.

FIG. 20. *To measure the distance of two places A and B, of which one is accessible, by the graphometer.*—Let there be erected at two points A and C, sufficiently distant, two visible signs; then (by the 12th prop. of this Part) let the two angles BAC, BCA, be taken by the graphometer. Let the distance of the stations A and C be measured with a chain. Then the third angle B being known, and the side AC being likewise known; therefore, by the first case of trigonometry, the distance required, AB, will be found.

PROPOSITION XVII.

FIG. 21. *To measure by the graphometer the distance of two places, neither of which is accessible.*—Let two stations C and D be chosen, from each of which the places may be seen whose distance is sought; let the angles ACD, ACB, BCD, and likewise the angles BDC, BDA, CDA, be measured by the graphometer; let the distance of the stations C and D be measured by a chain, or (if it be necessary) by the preceding practice. Now, in the triangle ACD, there are given two angles ACD and ADC; therefore, the third CAD is likewise given; moreover, the side CD is given; therefore, by the first case of trigonometry, the side AD will be found. After the same manner, in the triangle BCD, from all the angles and one side CD given, the side BD is found. Wherefore, in the triangle ADB, from the given sides DA and DB, and the angle ADB contained by them, the side AB (the distance sought) is found by the 4th case of trigonometry of oblique-angled triangles.

PROPOSITION XVIII.

FIG. 22 *It is required by the graphometer and quadrant to measure an inaccessible height AB, placed so on a steep, that one can neither go near it in an horizontal plane, nor recede from it, as we supposed in the solution of the 14th prop.*—Let there be chosen any situation, as C, and another D; where let some mark be erected: let the angles ACD and ADC be found by the graphometer; then the third angle DAC will be known. Let the side CD, the distance of the stations, be measured with a chain, and thence (by trigon.) the side AC will be found. Again, in the triangle ACB, right-angled at B, having found by the quadrant the angle ACB, the other angle CAB is known likewise: but the side AC in the triangle ADC is already known;

VOL. VII.

therefore the height required AB will be found by the 4th case of right-angled triangles. If the height of the tower is wanted, the angle BCF will be found by the quadrant: which being taken from the angle ACB already known, the angle ACF will remain: but the angle FAC was known before; therefore the remaining angle AFC will be known. But the side AC was also known before; therefore, in the triangle AFC, all the angles and one of the sides AC being known, AF, the height of the tower above the hill, will be found by trigonometry.

S C H O L I U M.

It were easy to add many other methods of measuring heights and distances; but if what is above be understood, it will be easy (especially for one that is versed in the elements) to contrive methods for this purpose, according to the occasion: so that there is no need of adding any more of this sort. We shall subjoin here a method by which the diameter of the earth may be found out.

PROPOSITION XIX.

FIG. 1. *To find the diameter of the earth from one observation.*—Let there be chosen a high hill AB, near the sea-shore, and let the observator on the top of it, with an exact quadrant divided into minutes and seconds by transverse divisions, and fitted with a telescope in place of the common sights, measure the angle ABE contained under the right line AB, which goes to the centre, and the right line BE drawn to the sea, a tangent to the globe at E; let there be drawn from A perpendicular to BD, the line AF meeting BE in F. Now in the right-angled triangle BAF all the angles are given, also the side AB, the height of the hill; which is to be found by some of the foregoing methods as exactly as possible; and (by trigonometry) the sides BF and AF are found. But by cor. 36th 3. Eucl. AF is equal to FE; therefore BE will be known. Moreover, by 36th 3. Eucl. the rectangle under BA and BD is equal to the square of BE. And thence by 17th 6. Eucl. as AB : BE :: BE : BD. Therefore, since AB and BE are already given, BD will be found by 11th 6. Eucl. or by the rule of three; and subtracting BA, there will remain AD the diameter of the earth sought.

S C H O L I U M.

Many other methods might be proposed for measuring the diameter of the earth. The most exact is that proposed by Mr Picart of the academy of sciences at Paris.

“ Accordidg to Mr Picart, a degree of the meridian at the latitude of $49^{\circ} 21'$ was 57,060 French toises, each of which contains six feet of the same measure: from which it follows, that if the earth be an exact sphere, the circumference of a great circle of it will be 123,249,600 Paris feet, and the semidiameter of the earth 19,615,800 feet: but the French mathematicians, who of late have examined Mr Picart's operations, assure us, that the degree in that latitude is 57,183 toises. They measured a degree in Lapland, in the latitude of $66^{\circ} 20'$, and found it of 57,438 toises. By comparing these degrees, as well as by the observations on pendulums, and the theory of gravity, it appears that the earth is an oblate spheroid; and (supposing those degrees to be accurately measured) the axis or diameter that passes through the poles will be the diameter

4 Q

Lines and Angles.

Plat. CCXVIII.

Lines and
Angles.

diameter of the equator as 177 to 178, or the earth will be 22 miles higher at the equator than at the poles. A degree has likewise been measured at the equator, and found to be considerably less than at the latitude of Paris; which confirms the oblate figure of the earth. But an account of this last mensuration has not been published as yet. If the earth was of an uniform density from the surface to the centre, then, according to the theory of gravity, the meridian would be an exact ellipsis, and the axis would be to the diameter of the equator as 230 to 231; and the difference of the semi-diameter of the equator and semi-axis about 17 miles."

In what follows, a figure is often to be laid down on paper, like to another figure given; and because this likeness consists in the equality of their angles, and in the sides having the same proportion to each other (by the definitions of the 6th of Eucl.) we are now to show what methods practical geometers use for making on paper an angle equal to a given angle, and how they constitute the sides in the same proportion. For this purpose they make use of a protractor (or, when it is wanting, a line of chords), and of a line of equal parts.

PROPOSITION XX.

FIG. 2. 3. 4. 5. and 6. *To describe the construction and use of the protractor, of the line of chords, and of the line of equal parts.*—The protractor is a small semicircle of brass, or such solid matter. The semicircumference is divided into 180 degrees. The use of it is, to draw angles on any plane, as on paper, or to examine the extent of angles already laid down. For this last purpose, let the small point in the centre of the protractor be placed above the angular point, and let the point AB coincide with one of the sides that contain the angle proposed; the number of degrees cut off by the other side, computing on the protractor from B, will show the quantity of the angle that is to be measured.

But if an angle is to be made of a given quantity on a given line, and at a given point of that line, let AB coincide with the given line, and let the centre A of the instrument be applied to that point. Then let there be a mark made at the given number of degrees; and a right line drawn from that mark to the given point, will constitute an angle with the given right line of the quantity required; as is manifest.

This is the most natural and easy method, either for examining the extent of an angle on paper, or for describing on paper an angle of a given quantity.

But when there is scarcity of instruments, or because a line of chords is more easily carried about (being described on a ruler on which there are many other lines besides), practical geometers frequently make use of it. It is made thus: let the quadrant of a circle be divided into 90 degrees (as in fig. 3.) The line CB is the chord of 90 degrees; the chord of every arc of the quadrant is transferred to this line CB, which is always marked with the number of degrees in the corresponding arc.

Note, That the chord of 60 degrees is equal to the radius, by corol. 15. 4th Eucl. If now a given angle EDF is to be measured by the line of chords from the centre D, with the distance DG (the chord of 60 degrees), describe the arc GF; and let the points G and F be marked where this arc intersects the sides

of the angle. Then if the distance GF, applied on the line of chords from C towards B, gives (for example) 25 degrees, this shall be the measure of the angle proposed.

When an obtuse angle is to be measured with this line, let its complement to a semicircle be measured, and thence it will be known. It were easy to transfer to the diameter of a circle the chords of all arches to the extent of a semicircle; but such are rarely found marked upon rules.

But now, if an angle of a given quantity, suppose of 50 degrees, is to be made at a given point M of the right line KL (fig. 5.) From the centre M, and the distance MN, equal to the chord of 60 degrees, describe the arc QN. Take off an arc NR, whose chord is equal to that of 50 degrees on the line of chords; join the points M and R; and it is plain that MR shall contain an angle of 50 degrees with the line KL proposed.

But sometimes we cannot produce the sides till they be of the length of a chord of 60 degrees on our scale; in which case it is fit to work by a circle of proportions (that is a sector), by which an arc may be made of a given number of degrees to any radius.

The quantities of angles are likewise determined by other lines usually marked upon rules, as the lines of sines, tangents, and secants; but as these methods are not so easy or so proper in this place, we omit them.

To delineate figures similar or like to others given, besides the equality of the angles, the same proportion is to be preserved among the sides of the figure that is to be delineated, as is among the sides of the figure given. For which purpose, on the rules used by artists, there is a line divided into equal parts, more or less in number, and greater or less in quantity according to the pleasure of the maker.

A foot is divided into inches; and an inch, by means of transverse lines, into 100 equal parts; so that with this scale, any number of inches below 12, with any part of an inch, can be taken by the compasses, providing such part be greater than the 100th part of an inch. And this exactness is very necessary in delineating the plans of houses, and in other cases.

PROPOSITION XXI.

FIG. 7. *To lay down on paper, by the protractor or line of chords, and line of equal parts, a right lined figure like to one given, providing the angles and sides of the figure given be known by observation or mensuration.* For example, suppose that it is known that in a quadrangular figure, one side is of 235 feet, that the angle contained by it and the second side is of 85°, the second side of 288 feet, the angle contained by it and the third side of 72°, and that the third side is 294 feet. These things being given, a figure is to be drawn on paper like to this quadrangular figure. On your paper at a proper point A, let a right line be drawn, upon which take 235 equal parts, as AB. The part representing a foot is taken greater or less, according as you would have your figure greater or less. In the adjoining figure, the 100th part of an inch is taken for a foot. And accordingly an inch divided into 100 parts, and annexed to the figure, is called a scale of 100 feet. Let there be made at the point B (by the preceding proposition) an angle ABC of 85°, and let BC be taken of 288 parts like to the former. Then let the angle BCD be made of 72°, and the side CD

Lines and
Angles.

of

Lines and Angles.

Surveying of Land.

of 294 equal parts. Then let the side AD be drawn; and it will complete the figure like to the given one. The measures of the angles A and D can be known by the protractor or line of chords, and the side AD by the line of equal parts; which will exactly answer to the corresponding angles and to the side of the primary figure.

After the very same manner, from the sides and angles given which bound any right-lined figure, a figure like to it may be drawn, and the rest of its sides and angles be known.

C O R O L L A R Y.

Hence any trigonometrical problem in right-lined triangles may be resolved by delineating the triangle from what is given concerning it, as in this proposition. The unknown sides are examined by a line of equal parts, and the angles by a protractor or line of chords.

P R O P O S I T I O N XXII.

The diameter of a circle being given, to find its circumference nearly.—The periphery of any polygon inscribed in the circle is less than the circumference, and the periphery of any polygon described about a circle is greater than the circumference. Whence Archimedes first discovered that the diameter was in proportion to the circumference, as 7 to 22 nearly; which serves for common use. But the moderns have computed the proportion of the diameter to the circumference to greater exactness. Supposing the diameter 100, the periphery will be more than 314, but less than 315. The diameter is more nearly to the circumference, as 113 to 355. But Ludolphus van Cuelen exceeded the labours of all; for by immense study he found, that supposing the diameter 100,000,000,000,000,000,000,000,000,000,000, the periphery will be less than

314,159,265,358,979,323,846,264,338,327,951; but greater than

314,159,265,358,979,323,846,264,338,327,950;

whence it will be easy, any part of the circumference being given in degrees and minutes, to assign it in parts of the diameter.

CHAP. II. Of Surveying and Measuring of LAND.

HITHERTO we have treated of the measuring of angles and sides, whence it is abundantly easy to lay down a field, a plane, or an entire country; for to this nothing is requisite but the protraction of triangles, and of other plain figures, after having measured their sides and angles. But as this is esteemed an important part of practical geometry, we shall subjoin here an account of it with all possible brevity; suggesting withal, that a surveyor will improve himself more by one day's practice than by a great deal of reading.

P R O P O S I T I O N XXIII.

To explain what surveying is, and what instruments Surveyors use.—First, it is necessary that the surveyor view the field that is to be measured, and investigate its sides and angles, by means of an iron chain (having a particular mark at each foot of length, or at any number of feet, as may be most convenient for reducing lines or surfaces, to the received measures), and the graphometer described above. Secondly, It is necessary to delineate the field in plano, or to form a map of it; that is, to lay down on paper a figure si-

milar to the field; which is done by the protractor (or line of chords) and the line of equal parts. Thirdly, It is necessary to find out the area of the field so surveyed and represented by a map. Of this last we are to treat below.

The sides and angles of small fields are surveyed by the help of a plain-table: which is generally of an oblong rectangular figure, and supported by a fulcrum, so as to turn every way by means of a ball and socket. It has a moveable frame, which surrounds the board, and serves to keep a clean paper put on the board close and right to it. The sides of the frame facing the paper are divided into equal parts every way. The board hath besides a box with a magnetic needle, and moreover a large index with two sights. On the edge of the frame of the board are marked degrees and minutes, so as to supply the room of a graphometer.

P R O P O S I T I O N XXIV.

FIG. 8. To delineate a field by the help of a plain-table, from one station whence all its angles may be seen and their distances measured by a chain.—Let the field that is to be laid down be ABCDE. At any convenient place F, let the plain-table be erected; cover it with clean paper, in which let some point near the middle represent the station. Then applying at this place the index with the sights, direct it so as that through the sights some mark may be seen at one of the angles, suppose A; and from the point F, representing the station, draw a feint right line along the side of the index: then, by the help of the chain, let FA the distance of the station from the foresaid angle be measured. Then taking what part you think convenient for a foot or pace from the line of equal parts, set off on the feint line the parts corresponding to the line FA that was measured; and let there be a mark made representing the angle of the field A. Keeping the table immoveable, the same is to be done with the rest of the angles; then right lines joining those marks shall include a figure like to the field, as is evident from 5, 6. Eucl.

C O R O L L A R Y.

The same thing is done in like manner by the graphometer: for having observed in each of the triangles, AFB, BFC, CFD, &c. the angle at the station F, and having measured the lines from the station to the angles of the field, let similar triangles be protracted on paper (by the 21. prop. of this), having their common vertex in the point of station. All the lines, excepting those which represent the sides of the field, are to be drawn faint or obscure.

Note 1. When a surveyor wants to lay down a field, let him place distinctly in a register all the observations of the angles, and the measures of the sides, until, at time and place convenient, he draw out the figure on paper.

Note 2. The observations made by the help of the graphometer are to be examined: for all the angles about the point F ought to be equal to four right ones. (by cor. 2. art. 30. of Part I.)

P R O P O S I T I O N XXV.

FIG. 9. To lay down a field by means of two stations, from each of which all the angles can be seen, by measuring only the distance of the stations.—Let the instrument be placed at the station F: and having chosen

Surveying
of Land.

a point representing it upon the paper which is laid upon the plain table, let the index be applied at this point, so as to be moveable about it. Then let it be directed successively to the several angles of the field: and when any angle is seen through the sights, draw an obscure line along the side of the index. Let the index, with the sights, be directed after the same manner to the station G: on the obscure line drawn along its side, pointing to A, set off from the scale of equal parts a line corresponding to the measured distance of the stations, and this will determine the point G. Then remove the instrument to the station G, and applying the index to the line representing the distance of the stations, place the instrument so that the first station may be seen through the sights. Then the instrument remaining immovable, let the index be applied to the point representing the second station G, and be successively directed by means of its sights to all the angles of the field, drawing (as before) obscure lines: and the intersection of the two obscure lines that were drawn to the same angle from the two stations will always represent that angle on the plan. Care must be taken that those lines be not mistaken for one another. Lines joining those intersections will form a figure on the paper like to the field.

S C H O L I U M.

It will not be difficult to do the same by the graphometer, if you keep a distinct account of your observations of the angles made by the line joining the stations, and the lines drawn from the stations to the respective angles of the field. And this is the most common manner of laying down whole countries. The tops of two mountains are taken for two stations, and their distance is either measured by some of the methods mentioned above, or is taken according to common repute. The sights are successively directed towards cities, churches, villages, forts, lakes, turnings of rivers, woods, &c.

Note, The distance of the stations ought to be great enough, with respect to the field that is to be measured; such ought to be chosen as are not in a line with any angle of the field. And care ought to be taken likewise that the angles, for example, FAG, FDG, &c. be neither very acute, nor very obtuse. Such angles are to be avoided as much as possible; and this admonition is found very useful in practice.

P R O P O S I T I O N XXVI.

FIG. 10. *To lay down any field, however irregular its figure may be, by the help of the graphometer.*—Let ABCEDHG be such a field. Let its angles (in going round it) be observed with a graphometer (by the 12. of this) and noted down; let its sides be measured with a chain; and (by what was said on the 21. of this) let a figure like to the given field be protracted on paper. If any mountain is in the circumference, the horizontal line hid under it is to be taken for a side, which may be found by two or three observations according to some of the methods described above; and its place on the map is to be distinguished by a shade, that it may be known a mountain is there.

If not only the circumference of the field is to be laid down on the plan, but also its contents, as villages, gardens, churches, public roads, we must proceed in this manner.

Let there be (for example) a church F, to be laid

down in the plan. Let the angles ABF BAF be observed and protracted on paper in their proper places, the intersection of the two sides BF and AF will give the place of the church on the paper: or, more exactly, the lines BF AF being measured, let circles be described from the centres B and A, with parts from the scale corresponding to the distances BF and AF, and the place of the church will be at their intersection.

Note 1: While the angles observed by the graphometer are taken down, you must be careful to distinguish the external angles, as E and G, that they may be rightly protracted afterwards on paper.

Note 2. Our observations of the angles may be examined by computing if all the internal angles make twice as many right angles, four excepted, as there are sides of the figure; (for this is demonstrated by 32, 1. Eucl.) But in place of any external angle DEC, its complement to a circle is to be taken.

P R O P O S I T I O N XXVII.

FIG. 11. *To lay down a plain field without instruments.*—If a small field is to be measured, and a map of it to be made, and you are not provided with instruments; let it be supposed to be divided into triangles, by right-lines, as in the figure; and after measuring the three sides of any of the triangles, for example of ABC, let its sides be laid down from a convenient scale on paper, (by the 22. of this.) Again, let the other two sides BD CD of the triangle CBD be measured and protracted on the paper by the same scale as before. In the same manner proceed with the rest of the triangles of which the field is composed, and the map of the field will be perfected; for the three sides of a triangle determine the triangle; whence each triangle on the paper is similar to its correspondent triangle in the field, and is similarly situated; consequently the whole figure is like to the whole field.

S C H O L I U M.

If the field be small, and all its angles may be seen from one station, it may be very well laid down by the plain-table, (by the 24. of this.) If the field be larger, and have the requisite conditions, and great exactness is not expected, it likewise may be plotted by means of the plain-table, or by the graphometer (according to the 25. of this); but in fields that are irregular and mountainous, when an exact map is required, we are to make use of the graphometer (as in the 26. of this), but rarely of the plain-table.

Having protracted the bounding lines, the particular parts contained within them may be laid down by the proper operations for this purpose (delivered in the 26th proposition; and the method described in the 27th proposition may be sometimes of service); for we may trust more to the measuring of sides than to the observing of angles. We are not to compute four-sided and many-sided figures till they are resolved into triangles: for the sides do not determine those figures.

In the laying down of cities, or the like, we may make use of any of the methods described above that may be most convenient.

The map being finished, it is transferred on clean paper, by putting the first sketch above it, and marking the angles by the point of a small needle. These points being joined by right lines, and the whole illuminated

Surveying

Scale of half an Inch divided into 100 parts.

H. Barker sculp.

PLATE 1

Surveying of Land. minated by colours proper to each part, and the figure of the mariner's compass being added to distinguish the north and south, with a scale on the margin, the map or plan will be finished and neat.

We have thus briefly and plainly treated of surveying, and shown by what instruments it is performed; having avoided those methods which depend on the magnetic needle, not only because its direction may vary in different places of a field (the contrary of this at least doth not appear,) but because the quantity of an angle observed by it cannot be exactly known; for an error of two or three degrees can scarcely be avoided in taking angles by it.

As for the remaining part of surveying, whereby the area of a field already laid down on paper is found in acres, roods, or any other superficial measures; this we leave to the following section, which treats of the mensuration of surfaces.

“ Besides the instruments described above, a surveyor ought to be provided with an off-set staff equal in length to 10 links of the chain, and divided into 10 equal parts. He ought likewise to have 10 arrows or small straight sticks near two feet long, shod with iron ferrils. When the chain is first opened, it ought to be examined by the off-set staff. In measuring any line, the leader of the chain is to have the 10 arrows at first setting out. When the chain is stretched in the line, and the near end touches the place from which you measure, the leader strikes one of the 10 arrows in the ground, at the far end of the chain. Then the leader leaving the arrow, proceeds with the chain another length: and the chain being stretched in the line, so that the near end touches the first arrow, the leader sticks down another arrow at his end of the chain. The line is preserved straight, if the arrows, be always set so as to be in a right line with the place you measure from, and that to which you are going. In this manner they proceed till the leader have no more arrows. At the eleventh chain, the arrows are to be carried to him again, and he is to stick one of them into the ground, at the end of the chain. And the same is to be done at the 21. 31. 41. &c. chains, if there are so many in a right line to be measured. In this manner you can hardly commit an error in numbering the chains, unless of 10 chains at once.

The off-set staff serves for measuring readily the distances of any things proper to be represented in your plan, from the station-line, while you go along. These distances ought to be entered into your field-book, with the corresponding distances from the last station, and proper remarks, that you may be enabled to plot them justly, and be in no danger of mistaking one for another when you extend your plan. The field-book may be conveniently divided into five columns. In the middle column the angles at the several stations taken by the theodolite are to be entered, with the distances from the stations. The distances taken by the off-set staff, on either side of the station-line, are to be entered into columns on either side of the middle column, according to their position with respect to that line. The names and characters of the objects, with proper remarks, may be entered in columns on either side of these last.

“ Because, in the place of the graphometer described by our author, surveyors now make use of the

Surveying of Land. theodolite, we shall subjoin a description of Mr Sifson's latest improved theodolite from Mr Gardner's practical surveying improved. See a figure of it in Plate CCXVIII.

“ In this instrument, the three staffs, by brass ferrils at top, screw into bell-metal joints, that are moveable between brass pillars, fixed in a strong brass plate; in which, round the centre, is fixed a socket with a ball moveable in it, and upon which the four screws press, that set the limb horizontal: Next above is another such plate, through which the said screws pass, and on which, round the centre, is fixed a frustum of a cone of bell-metal, whose axis (being connected with the centre of the bell) is always perpendicular to the limb, by mean of a conical brass ferril fitted to it, whereon is fixed the compass-box; and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes, in whose plate are fixed four brass pillars, that, joining at top, hold the centre pin of the bell-metal double sextant, whose double index is fixed on the centre of the same plate: Within the double sextant is fixed the spirit level, and over it the telescope.

“ The compass-box is graved with two diamonds for the north and south, and with 20 degrees on both sides of each, that the needle may be set to the variation, and its error also known.

“ The limb has two *fleurs de luce* against the diamonds in the box, instead of 180 each, and is curiously divided into whole degrees, and numbered to the left hand at every 10 to twice 180, having three indexes distant 120 (with Nonius's divisions on each for the decimals of a degree), that are moved by a pinion fixed below one of them, without moving the limb; and in another is a screw and spring under, to fix it to any part of the limb. It has also divisions numbered, for taking the quarter girt in inches of round timber at the middle height, when standing 10 feet horizontally distant from its centre; which at 20 must be doubled, and at 30 tripled; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off.

“ The double sextant is divided on one side from under its centre (when the spirit-tube and telescope are level) to above 60 degrees each way and numbered at 10, 20, &c. and the double index (through which it is moveable) shows on the same side the degree and decimal of any altitude or depression to that extent by Nonius's divisions: On the other side are divisions numbered, for taking the upright height of timber, &c. in feet, when distant 10 feet: which at 20 must be doubled, and at 30 tripled; and also the quantities for reducing hypotenusal lines to horizontal. It is moveable by a pinion fixed in the double index.

“ The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and show a distant object as perfect as most of triple its length. In its focus are very fine cross wires, whose intersection is in the plane of the double sextant; and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that, whenever the limb is set horizontal (which is readily done by making the spi-
rit

Surveying of Land.

rit-tube level over two screws, and the like over the other two), the double sextant and telescope are moveable in a vertical plane; and then every angle taken on the limb (though the telescope be never so much elevated or depressed) will be an angle in the plane of the horizon. And this is absolutely necessary in plotting a horizontal plane.

“If the lands to be plotted are hilly, and not in any one plane, the lines measured cannot be truly laid down on paper, without being reduced to one plane, which must be the horizontal, because angles are taken in that plane.—

“In viewing your objects, if they have much altitude or depression, either write down the degree and decimal shown on the double sextant, or the links shown on the back side; which last subtracted from every chain in the station-line, leaves the length in the horizontal plane. But if the degree is taken, the following table will show the quantity.

A Table of the links to be subtracted out of every chain in hypotenusal lines of several degrees altitude, or depression for reducing them to horizontal.

Degrees. Links.	Degrees. Links.	Degrees. Links.
4,05 — $\frac{1}{4}$	14,07 — 3	23,074 — 8
5,73 — $\frac{1}{2}$	16,26 — 4	24,495 — 9
7,02 — $\frac{3}{4}$	18,195 — 5	25,84 — 10
8,11 — 1	19,95 — 6	27,13 — 11
11,48 — 2	21,565 — 7	28,36 — 12

“Let the first station line really measure 1107 links, and the angle of altitude or depression be $19^{\circ}, 95'$; looking in the table you will find against $19^{\circ}, 95'$, is 6 links. Now 6 times 11 is 66, which subtracted from 1107, leaves 1041, the true length to be laid down in the plan.

It is useful in surveying, to take the angles, which the bounding lines form, with the magnetic needle, in order to check the angles of the figure, and to plot them conveniently afterwards.”

CHAP. III. *Of the Surfaces of Bodies.*

THE smallest superficial measure in Scotland is a square inch; 144 of which make a square foot. Wrights make use of these in the measuring of deals and planks; but the square foot which the glaziers use in measuring of glass, consists only of 64 square inches. The other measures are, first, the ell square; secondly, the fall containing 36 square ells; thirdly, the rood containing 40 falls; fourthly, the acre, containing 4 roods. Slaters, masons, and pavers, use the ell square and the fall; surveyors of land use the square ell, the fall, the rood and the acre.

The superficial measures of the English are, first, the square foot; secondly, the square yard, containing 9 square feet, for their yard contains only 3 feet; thirdly, the pole containing $30\frac{1}{4}$ square yards; fourthly, the rood containing 40 poles; fifthly, the acre, containing 4 roods. And hence it is easy to reduce Scotch superficial measures to the English.

“In order to find the content of a field, it is most convenient to measure the lines by the chains described above, p. 671. that of 22 yards for computing the English acres, and that of 24 Scots ells for the acres of Scotland. The chain is divided into 100 links, and

the square of the chain is 10,000 square links; 10 squares of the chain, or 100,000 square links, give an acre. Therefore if the area be expressed by square links, divide by 100,000, or cut off five decimal places and the quotient shall give the area in acres and decimals of an acre. Write the entire acres apart: but multiply the decimals of an acre by 4, and the product shall give the remainder of the area in roods and decimals of a rood. Let the entire roods be noted apart after the acres; then multiply the decimals of a rood by 40, and the product shall give the remainder of the area in falls or poles. Let the entire falls or poles be then writ after the roods, and multiply the decimals of a fall by 36, if the area is required in the measures of Scotland; but multiply the decimals of a pole by $30\frac{1}{4}$, if the area is required in the measures of England, and the product shall give the remainder of the area in square ells in the former case, but in square yards in the latter. If, in the former case, you would reduce the decimals of the square ell to square feet, multiply them by 9.50694; but, in the latter case, the decimals of the English square yard are reduced to square feet, by multiplying them by 9.

“Suppose, for example, that the area appears to contain 1265842 square links of the chain of 24 ells; and that this area is to be expressed in acres, roods, falls, &c. of the measures of Scotland. Divide the square links by 100,000, and the quotient 12.65842 shows the area to contain 12 acres $\frac{6}{10} \frac{5}{10} \frac{8}{10} \frac{4}{10} \frac{2}{10}$ of an acre. Multiply the decimal part by 4, and the product 2.63368 gives the remainder in roods and decimals of a rood. Those decimals of the rood being multiplied by 40, the product gives 25.3472 falls. Multiply the decimals of the fall by 36, and the product gives 12.4992 square ells. The decimals of the square ell multiplied by 9.50994 give 4.7458 square feet. Therefore the area proposed amounts to 12 acres, 2 roods, 25 falls, 12 square ells, and $4\frac{7}{10} \frac{4}{10} \frac{5}{10} \frac{8}{10}$ square feet.

“But if the area contains the same number of square links of Gunter’s chain, and is to be expressed by English measures, the acres and roods are computed in the same manner as in the former case. The poles are computed as the falls. But the decimals of the pole, viz. $\frac{3}{10} \frac{4}{10} \frac{7}{10} \frac{2}{10}$, are to be multiplied by $30\frac{1}{4}$ (or 30.25), and the product gives 10.5028 square yards. The decimals of the square yard, multiplied by 9, give 4.5252 square feet; therefore, in this case, the area is in English measure 12 acres, 2 roods, 25 poles, 10 square yards, and $4\frac{5}{10} \frac{2}{10} \frac{5}{10} \frac{2}{10}$ square feet.

“The Scots acre is to the English acre, by statute, as 100,000 to 78,694, if we have regard to the difference betwixt the Scots and English foot abovementioned. But it is customary in some parts of England to have 18.21, &c. feet to a pole, and 160 such poles to an acre; whereas, by the statute, 16 $\frac{1}{2}$ feet make a pole. In such cases the acre is greater in the duplicate ratio of the number of feet to a pole.

“They who measure land in Scotland by an ell of 37 English inches, make the acre less than the true Scots acre by $593\frac{6}{10}$ square English feet, or by about $\frac{1}{3}$ of the acre.

“An husband land contains 6 acres of sock and scythe-land, that is, of land that may be tilled with a plough, and mown with a scythe; 13 acres of arable land

Surface of Bodies.

Surfaces of
Bodies. Surfaces of
Bodies.

land make an oxgang or oxengate; four oxengate make a poand land of old extent (by a decree of the Exchequer, March 11. 1585), and is called *librata terræ*. A forty-shilling land of old extent contains 8 oxgang, or 104 acres.

“The arpent, about Paris, contains 32,400 square Paris feet, and is equal to $2\frac{1}{2}$ Scots roods, or $3\frac{3}{4}$ English roods.

“The *actus quadratus*, according to Varro, Collumella, &c. was a square of 120 Roman feet. The *jugerum* was the double of this. It is to the Scots acre as 10,000 to 20,456, and to the English acre as 10,000, to 16,097. It was divided (like the *as*) into 12 *uncia*, and the *uncia* into 24 *scrupula*.”—This, with the three preceding paragraphs, are taken from an ingenious manuscript, written by Sir Robert Stewart professor of natural philosophy. The greatest part of the table in p. 671. was taken from it likewise.

PROPOSITION XXVIII.

FIG. 12. To find out the area of a rectangular parallelogram ABCD.—Let the side AB, for example, be 5 feet long, and BC (which constitutes with BA a right angle at B) be 17 feet. Let 17 be multiplied by 5, and the product 85 will be the number of square feet in the area of the figure ABCD. But if the parallelogram proposed is not rectangular as BEFC, its base BC multiplied into its perpendicular height AB (not into its side BE) will give its area. This is evident from art. 68. of Part I.

PROPOSITION XXIX.

FIG. 13. To find the area of a given triangle.—Let the triangle BAC be given, whose base BC is supposed 9 feet long: let the perpendicular AD be drawn from the angle A opposite to the base, and let us suppose AD to be 4 feet. Let the half of the perpendicular be multiplied into the base, or the half of the base into the perpendicular, or take the half of the product of the whole base into the perpendicular, the product gives 18 square feet for the area of the given triangle.

But if only the sides are given, the perpendicular is found either by protracting the triangle, or by 12th and 13th 2. Eucl. or by trigonometry. But how the area of a triangle may be found from the given sides only, shall be shown in the 31st proposition.

PROPOSITION XXX.

FIG. 14. To find the area of any rectilinear figure.—If the figure be irregular, let it be resolved into triangles; and drawing perpendiculars to the bases in each of them, let the area of each triangle be found by the preceding proposition, and the sum of these areas will give the area of the figure.

SCHOLIUM 1.

In measuring boards, planks, and glass, their sides are to be measured by a foot-rule divided into 100 equal parts; and after multiplying the sides, the decimal fractions are easily reduced to lesser denominations. The mensuration of these is easy, when they are rectangular parallelograms.

SCHOLIUM 2.

If a field is to be measured, let it first be plotted on paper, by some of the methods above described, and let the figure so laid down be divided into triangles, as was shown in the preceding proposition.

The base of any triangle, or the perpendicular upon

the base, or the distance of any two points of the field, is measured by applying it to the scale according to which the map is drawn.

SCHOLIUM 3.

But if the field given be not in an horizontal plane, but uneven and mountainous, the scale gives the horizontal line between any two points, but not their distance measured on the uneven surface of the field. And indeed it would appear, that the horizontal plane is to be accounted the area of an uneven and hilly country. For if such ground is laid out for building on, or for planting with trees, or bearing corn, since these stand perpendicular to the horizon, it is plain, that a mountainous country cannot be considered as of greater extent for those uses than the horizontal plane; nay, perhaps, for nourishing of plants, the horizontal plane may be preferable.

If, however, the area of a figure, as it lies regularly on the surface of the earth, is to be measured, this may be easily done by resolving it into triangles as it lies. The sum of their areas will be the area sought; which exceeds the area of the horizontal figure more or less, according as the field is more or less uneven.

PROPOSITION XXXI.

FIG. 13. The sides of a triangle being given, to find the area, without finding the perpendicular.—Let all the sides of the triangle be collected into one sum; from the half of which let the sides be separately subtracted, that three differences may be found betwixt the foresaid half sum and each side; then let these three differences and the half sum be multiplied into one another, and the square root of the product will give the area of the triangle. For example, let the sides be 10, 17, 21; the half of their sum is 24; the three differences betwixt this half sum and the three sides, are 14, 7, and 3. The first being multiplied by the second, and their product by the third, we have 294 for the product of the differences; which multiplied by the foresaid half sum 24, gives 7056; the square root of which 84 is the area of the triangle. The demonstration of this, for the sake of brevity, we omit. It is to be found in several treatises, particularly in Clavius's Practice of Geometry.

PROPOSITION XXXII.

FIG. 15. The area of the ordinate figure ABFGH is equal to the product of the half circumference of the polygon, multiplied into the perpendicular drawn from the centre of the circumscribed circle to the side of the polygon.—For the ordinate figure can be resolved into as many equal triangles as there are sides of the figure; and since each triangle is equal to the product of half the base into the perpendicular, it is evident that the sum of all the triangles together, that is the polygon, is equal to the product of half the sum of the bases (that is the half of the circumference of the polygon) into the common perpendicular height of the triangles drawn from the centre C to one of the sides; for example, to AB.

PROPOSITION XXXIII.

FIG. 16. The area of a circle is found by multiplying the half of the periphery into the radius, or the half of the radius into the periphery.—For a circle is not different from an ordinate or regular polygon of an infinite number of sides, and the common height of the triangles in-

to

Surface of it becomes a parallelogram, whose base is the periphery of the circle of the base of the cylinder stretched into a right line, and whose height is the same with the height of the cylinder.

PROPOSITION XL.

FIG. 20. *To measure the surface of a right cone.*—The surface of a right cone is very little different from the surface of a right pyramid, having an ordinate polygon for its base of an infinite number of sides; the surface of which (excluding the base) is equal to the sum of the triangles. The sum of the bases of these triangles is equal to the periphery of the circle of the base, and the common height of the triangles is the sides of the cone AB; wherefore the sum of these triangles is equal to the product of the sum of the bases (i. e. the periphery of the base of the cone) multiplied into the half of the common height, or it is equal to half the product of the periphery of the base multiplied in the slant height.

If the area of the base is likewise wanted, it is to be found separately by the 33d prop. If the surface of a cone is supposed to be spread out on a plane, it will become a sector of a circle whose radius is the side of the cone, and the arc terminating the sector is made from the periphery of the base. Whence, by corol. 33d prop. of this, its dimension may be found.

COROLLARY.

Hence it will be easy to measure the surface of a *frustum* of a cone cut by a plane parallel to the base.

PROPOSITION XLI.

FIG. 21. *To measure the surface of a given sphere.*—Let there be a sphere whose center is A, and let the area of its convex surface be required. Archimedes demonstrates (37th prob. 1. book of the sphere and cylinder) that its surface is equal to the area of four great circles of the sphere; that is, let the area of the great circle be multiplied by 4, and the product will give the area of the sphere. or (by the 20th 6. and 2d 12. of Eucl.) the area of the sphere given is equal to the area of a circle whose radius is the right line BC, the diameter of the sphere. Therefore having measured (by 33 prop.) the circle described with the radius BC, this will give the surface of the sphere.

PROPOSITION XLII.

FIG. 22. *To measure the surface of a segment of a sphere.*—Let there be a segment cut off by the plane ED. Archimedes demonstrates (49. and 50. 1. *De sphaera*) that the surface of this segment, excluding the circular base, is equal to the area of a circle whose radius is the right line BE drawn from the vertex B of the segment to the periphery of the circle DE. Therefore (by the 33d prop.) it is easily measured.

COROLLARY 1.

Hence that part of the surface of a sphere that lies between two parallel planes is easily measured, by subtracting the surface of the lesser segment from the surface of the greater segment,

COROLLARY 2.

Hence likewise it follows, that the surface of a cylinder, described about a sphere (excluding the bases) is equal to the surface of the sphere, and the parts of the one to the parts of the other, intercepted between planes parallel to the bases of the cylinder.

CHAP. IV. *Of solid Figures and their Mesuration, Gauging, comprehending likewise the Principles of Gauging Vessels of all Figures.*

As in the former part of this treatise we took an inch for the smallest measure in length, and an inch square for the smallest superficial measure; so now, in treating of the mesuration of solids, we take a cubical inch for the smallest solid measure. Of these, 109 make a Scots pint; other liquid measures depend on this, as are generally known.

In dry measures, the Scots firloft, by statute, contains $19\frac{1}{2}$ pints; and on this depend the other dry measures: therefore, if the content of any solid be given in cubical inches, it will be easy to reduce the same to the common liquid or dry measures, and conversely to reduce these to solid inches. The liquid and dry measures, in use among other nations, are known from their writers.

“As to the English liquid measures, by act of parliament 1706, any round vessel commonly called a *cylinder*, having an even bottom, being seven inches in diameter throughout, and six inches deep from the top of the inside to the bottom (which vessel will be found by computation to contain $230\frac{1}{2}$ cubical inches), or any vessel containing 231 cubical inches, and no more, is deemed to be a lawful wine-gallon. An English pint therefore contains $28\frac{1}{2}$ cubical inches; 2 pints make a quart; 4 quarts a gallon; 18 gallons a roundlet; 3 roundlets and an half, or 63 gallons, make a hoghead; the half of a hoghead is a barrel: 1 hoghead and a third, or 84 gallons, make a puncheon; 1 puncheon and a half or 2 hogheads, or 126 gallons, makes a pipe or butt; the third part of a pipe or 42 gallons, make a tierce; 2 pipes, or 3 puncheons or 4 hogheads, make a ton of wine. Though the English wine gallon is now fixed at 231 cubical inches, the standard kept in Guildhall being measured, before many persons of distinction, May 25. 1688, it was found to contain only 224 such inches.

“In the English beer-measure, a gallon contains 282 cubical inches; consequently $35\frac{1}{2}$ cubical inches make a pint, 2 pints make a quart, 4 quarts make a gallon, 9 gallons a firkin, 4 firkins a barrel. In ale, 8 gallons make a firkin, and 32 gallons make a barrel. By an act of the first of William and Mary, 34 gallons is the barrel, both for beer and ale, in all places, except within the weekly bill of mortality.

“In Scotland it is known that 4 gills make a mutchkin, 2 mutchkins make a chopin; a pint is two chopins; a quart is two pints; and a gallon is four quarts or eight pints. The accounts of the cubical inches contained in the Scots pint vary considerably from each other. According to our Author, it contains 109 cubical inches. But the standard jugs kept by the dean of guild of Edinburgh (one of which has the year 1555, with the arms of Scotland, and the town of Edinburgh, marked upon it) having been carefully measured several times, and by different persons, the Scots pint, according to those standards, was found to contain about $103\frac{1}{2}$ cubic inches. The pewterers jugs (by which the vessels in common use are made) are said to contain sometimes betwixt 105 and 106 cubic inches. A cask that was measured by the brewers of Edinburgh, before the commissioners of excise

Gauging. cise in 1707, was found to contain $46\frac{7}{8}$ Scots pints; the same vessel contained $18\frac{1}{4}$ English ale-gallons. Supposing this mensuration to be just, the Scots pint will be to the English ale-gallon as 289 to 750; and if the English ale-gallon be supposed to contain 282 cubical inches, the Scots pint will contain 108.664 cubical inches. But it is suspected, on several grounds that the experiment was not made with sufficient care and exactness.

“The commissioners appointed by authority of parliament to settle the measures and weights, in their act of Feb. 19. 1618, relate, That having caused fill the Linlithgow firloot with water, they found that it contained $21\frac{1}{4}$ pints of the just Stirling jug and measure. They likewise ordain that this shall be the just and only firloot; and add, *That the wideness and broadness of the which firloot, under and above even over within the bisards, shall contain nineteen inches and the sixth part of an inch, and the deepness seven inches and a third part of an inch.* According to this act (supposing their experiment and computation to have been accurate) the pint contained only 99.56 cubical inches; for the content of such a vessel as is described in the act, is 2115.85, and this divided by $21\frac{1}{4}$ gives 99.56. But by the weight of water said to fill this firloot in the same act, the measure of the pint agrees nearly with the Edinburgh standard abovementioned.

“As for the English measures of corn, the Winchester gallon contains $272\frac{1}{4}$ cubical inches; 2 gallons make a peck; 4 pecks, or 8 gallons (that is, 2178 cubical inches), make a bushel; and a quarter is 8 bushels.

“Our author says, that $19\frac{1}{2}$ Scots pints make a firloot. But this does not appear to be agreeable to the statute abovementioned, nor to the standard-jugs. It may be conjectured, that the proportion assigned by him has been deduced from some experiment of how many pints, according to common use, were contained in the firloot. For if we suppose those pints to have been each of 108.664 cubical inches, according to the experiment made in the 1707 before the commissioners of excise described above; the $19\frac{1}{2}$ such pints will amount to 2118.94, cubical inches, which agrees nearly with 2115.85, the measure of the firloot by statute abovementioned. But it is probable, that in this he followed the act 1587, where it is ordained, That the wheat-firloot shall contain 19 pints and two joucattes. A wheat-firloot marked with the Linlithgow stamps being measured, was found to contain about 2211 cubical inches. By the statute of 1618, the barley-firloot was to contain 31 pints of the just Stirling-jug.

“A Paris pint is 48 cubical Paris inches, and is nearly equal to an English wine-quart. The *Boisseau* contains 664.68099 Paris cubical inches, or 780.36 English cubical inches.

“The Roman *amphora* was a cubical Roman foot, the *congius* was the eighth part of the *amphora*, the *sextarius* was one sixth of the *congius*. They divided the *sextarius* like the *as* or *libra*. Of dry measures, the *medimnus* was equal to two amphoras, that is, about $1\frac{1}{2}\frac{1}{3}$ English legal bushels; and the *modius* was the third part of the *amphora*.”

PROPOSITION XLIII.

Gauging. *To find the solid content of a given prism.*—By the 29th prop. let the area of the base of the prism be measured, and be multiplied by the height of the prism, the product will give the solid content of the prism.

PROPOSITION XLIV.

To find the solid content of a given pyramid.—The area of the base being found (by the 30th prop.), let it be multiplied by the third part of the height of the pyramid, or the third part of the base by the height, the product will give the solid content, by 17th 12. Eucl.

COROLLARY.

If the solid content of a *frustum* of a pyramid is required, first let the solid content of the entire pyramid be found; from which subtract the solid content of the part that is wanting, and the solid content of the broken pyramid will remain.

PROPOSITION XLV.

To find the content of a given cylinder.—The area of the base being found by prop. 33. if it be a circle, and by prop. 35. if it be an ellipse (for in both cases it is a cylinder), multiply it by the height of the cylinder, and the solid contents of the cylinder will be produced.

COROLLARY.

FIG. 23. And in this manner may be measured the solid content of vessels and casks not much different from a cylinder, as ABCD. If towards the middle EF it be somewhat grosser, the area of the circle of the base being found (by 33d prop.) and added to the area of the middle circle EF, and the half of their sum (that is, an arithmetical mean between the area of the base and the area of the middle circle) taken for the base of the vessel, and multiplied into its height, the solid content of the given vessel will be produced.

Note, That the length of the vessel, as well as the diameters of the base, and of the circle EF, ought to be taken within the staves; for it is the solid content within the staves that is sought.

PROPOSITION XLVI.

To find the solid content of a given cone.—Let the area of the base (found by prop. 33.) be multiplied into $\frac{1}{3}$ of the height, the product will give the solid content of the cone; for by the 10th 12. Eucl. a cone is the third part of a cylinder that has the same base and height.

PROPOSITION XLVII.

FIG. 24. 25. *To find the solid content of a frustum of a cone cut by a plane parallel to the plane of the base.*—First, let the height of the entire cone be found, and thence (by the preceding prop.) its solid content; from which subtract the solid content of the cone cut off at the top, there will remain the solid content of the *frustum* of the cone.

How the content of the entire cone may be found, appears thus: Let ABCD be the *frustum* of the cone (either right or scalenous, as in the figures 24. and 25.) let the cone ECD be supposed to be completed; let AG be drawn parallel to DE, and let AH and EF be perpendicular on CD; it will be (by 2d 6. Eucl.) as CG : CA :: CD : CE : but (by art. 72. of Part I.) as CA : AH :: CE : EF ; consequently (by 22d 5. Eucl.)

Gauging. as $CG : AH :: CD : EF$; that is, as the excess of the diameter of the lesser base is to the height of the frustum, so is the diameter of the greater base to the height of the entire cone.

C O R O L L A R Y.

FIG. 26. Some casks whose staves are remarkably bended about the middle, and strait towards the ends, may be taken for two portions of cones, without any considerable error. Thus $ABEF$ is a frustum of a right cone, to whose base EF , on the other side, there is another similar frustum of a cone joined, $EDCF$. The vertices of these cones, if they be supposed to be completed, will be found at G and H . Whence (by the preceding proposition) the solid content of such vessels may be found.

P R O P O S I T I O N XLVIII.

FIG. 27. A cylinder circumscribed about a sphere, that is, having its base equal to a great circle of the sphere, and its height equal to the diameter of the sphere, is to the sphere as 3 to 2.

Let $ABEC$ be the quadrant of a circle, and $ABDC$ the circumscribed square; and likewise the triangle ADC ; by the revolution of the figure about the right line AC , as axis, an hemisphere will be generated by the quadrant, a cylinder of the same base and height by the square, and a cone by the triangle. Let these three be cut any how by the plane HF , parallel to the base AB ; the section in the cylinder will be a circle whose radius is FH , in the hemisphere a circle of the radius EF , and in the cone a circle of the radius GF .

By art. 69. of Part I. EAq , or $HFq = EFq$ and FAq taken together (but $AFq = FGq$, because $AC = CD$); therefore the circle of the radius FH is equal to a circle of the radius EF , together with a circle of the radius GF ; and since this is true every where, all the circles together described by the respective radii HF (that is, the cylinder) are equal to all the circles described by the respective radii EF and FG (that is, to the hemisphere and the cone taken together); but (by the 10th 12. Eucl.) the cone generated by the triangle DAC is one-third part of the cylinder generated by the square BC . Whence it follows, that the hemisphere generated by the rotation of the quadrant $ABEC$ is equal to the remaining two-third parts of the cylinder, and that the whole sphere is $\frac{2}{3}$ of the double cylinder, circumscribed about it.

This is that celebrated 39th prop. 1. book of Archimedes of the sphere and cylinder; in which he determines the proportion of the cylinder to the sphere inscribed to be that of 3 to 2.

C O R O L L A R Y.

Hence it follows, that the sphere is equal to a cone whose height is equal to the semidiameter of the sphere, having for its base a circle equal to the superficies of the sphere, or to four great circles of the sphere, or to a circle whose radius is equal to the diameter of the sphere (by prop. 41. of this.) And indeed a sphere differs very little from the sum of an infinite number of cones that have their bases in the surface of the sphere, and their common vertex in the centre of the sphere; so that the superficies of the sphere (of whose dimension see prop. 41. of this) multiplied into the third part of the semidiameter, gives the solid content of the sphere.

P R O P O S I T I O N XLIX.

Gauging. FIG. 28. To find the solid content of a sector of the sphere.—A spherical sector ABC (as appears by the corollary of the preceding prop.) is very little different from an infinite number of cones, having their bases in the superficies of the sphere BEC , and their common vertex in the centre. Wherefore the spherical superficies BEC being found (by prop. 42. of this), and multiplied into the third part of AB the radius of the sphere, the product will give the solid content of the sector ABC .

C O R O L L A R Y.

It is evident how to find the solidity of a spherical segment less than a hemisphere, by subtracting the cone ABC from the sector already found. But if the spherical segment be greater than a hemisphere, the cone corresponding must be added to the sector, to make the segment.

P R O P O S I T I O N L.

FIG. 29. To find the solidity of the spheroid, and of its segments cut by planes perpendicular to the axis.—

In prop. 44. of this, it is shown, that every where $EH : EG :: CF : CD$; but circles are as the squares described upon their rays, that is, the circle of the radius EH is to the circle of the radius EG , as CFq to CDq . And since it is so every where, all the circles described with the respective rays EH (that is, the spheroid made by the rotation of the semi ellipse AFB around the axis AB) will be to all the circles described by the respective radii EG (that is, the sphere described by the rotation of the semicircle ADB on the axis AB) as FCq to CDq ; that is, as the spheroid to the sphere on the same axis, so is the square of the other axis of the generating ellipse to the square of the axis of the sphere.

And this holds, whether the spheroid be formed by a revolution around the greater or lesser axis.

C O R O L L A R Y 1.

Hence it appears, that the half of the spheroid, formed by the rotation of the space $AHFC$ around the axis AC , is double of the cone generated by the triangle AFC about the same axis; which is the 32d prop. of Archimedes of conoids and spheroids.

C O R O L L A R Y 2.

Hence, likewise, is evident the measure of segments of the spheroid cut by planes perpendicular to the axis. For the segment of the spheroid made by the rotation of the space $ANHE$, round the axis AE , is to the segment of the sphere having the same axis AC , and made by the rotation of the segment of the circle $AMGE$, as CFq to CDq .

But if the measure of this solid be wanted with less labour, by the 34th prop. of Archimedes of conoids and spheroids, it will be as BE to $AC + EB$; so is the cone generated by the rotation of the triangle AHE round the axis AE , to the segment of the sphere made by the rotation of the space $ANHE$ round the same axis AE ; which could easily be demonstrated by the method of indivisibles.

C O R O L L A R Y 3.

Hence it is easy to find the solid content of the segment of a sphere or spheroid intercepted between two parallel planes, perpendicular to the axis. This agrees as well to the oblate as to the oblong spheroid: as is obvious.

Gauging.

COROLLARY 4.

FIG. 30. If a cask is to be valued as the middle piece of an oblong spheroid, cut by the two planes DC and FG, at right angles to the axis: first, let the solid content of the half spheroid ABCED be measured by the preceding prop. from which let the solidity of the segment DEC be subtracted, and there will remain the segment ABCD; and this doubled will give the capacity of the cask required.

The following method is generally made use of for finding the solid content of such vessels. The double area of the greatest circle, that is, of that which is described by the diameter AB at the middle of the cask, is added to the area of the circle at the end, that is, of the circle DC or FG (for they are usually equal), and the third part of this sum is taken for a mean base of the cask; which therefore multiplied into the length of the cask OP, gives the content of the vessel required.

Sometimes vessels have other figures, different from those we have mentioned; the easy method of measuring which may be learned from those who practise this art. What hath already been delivered is sufficient for our purpose.

PROPOSITION LI.

FIG. 31. and 32. To find how much is contained in a vessel that is in part empty, whose axis is parallel to the horizon.—Let AGBH be the great circle in the middle of the cask, whose segment GBH is filled with liquor, the segment GAH being empty; the segment GBH is known, if the depth EB be known, and EH a mean proportional between the segments of the diameter AE and EB; which are found by a rod or ruler put into the vessel at the orifice. Let the basis of the cask at a medium be found, which suppose to be the circle CKDL; and let the segment KCL be similar to the segment GAH (which is either found by the rule of three, because as the circle AGBH is to the circle CKDL; so is the segment GAH to the segment KCL; or is found from the tables of segments made by authors); and the product of this segment multiplied by the length of the cask will give the liquid content remaining in the cask.

PROPOSITION LII.

To find the solid content of a regular and ordinate body, —A tetraedron being a pyramid, the solid content is found by the 44th prop. The hexaedron, or cube, being a kind of prism, it is measured by the 43d prop. An octaedron consists of two pyramids of the same square base, and of equal heights; consequently its measure is found by the 44th prop. A dodecaedron consists of 12 pyramids having equal equilateral and equiangular pentagonal bases; and so one of these being measured (by the 44th prop. of this), and multiplied by 12, the product will be equal to the solid content of the dodecaedron. The icosaedron consists of 20 equal pyramids having triangular bases; the solid content of one of which being found (by the 44th prop.), and multiplied by 20, gives the whole solid. The bases and heights of these pyramids, if you want to proceed more exactly, may be found by trigonometry. See TRIGONOMETRY.

PROPOSITION LIII.

To find the solid content of a body however irregular. —Let the given body be immersed into a vessel of

water, having the figure of a parallelepipedon or prism, and let it be noted how much the water is raised upon the immersion of the body. For it is plain, that the space which the water fills, after the immersion of the body, exceeds the space filled before its immersion, by a space equal to the solid content of the body, however irregular. But when this excess is of the figure of a parallelepipedon or prism, it is easily measured by the 43d prop. of this, viz. by multiplying the area of the base, or mouth of the vessel, into the difference of the elevations of the water before and after immersion: Whence is found the solid content of the body given.

In the same way the solid content of a part of a body may be found by immersing that part only in water.

There is no necessity to insist here on diminishing or enlarging solid bodies in a given proportion. It will be easy to deduce these things from the 11th and 12th books of Euclid.

“The following rules are subjoined for the ready computation of the contents of vessels, and of any solids in the measures in use in Great Britain.

“I. To find the content of a cylindric vessel in English wine gallons, the diameter of the base and altitude of the vessel being given in inches and decimals of an inch.

“Square the number of inches in the diameter of the vessel; multiply this square by the number of inches in the height: then multiply the product by the decimal fraction .0034; and this last product shall give the content in wine gallons and decimals of such a gallon. To express the rule arithmetically; let D represent the number of inches and decimals of an inch in the diameter of the vessel, and H the decimals of an inch in the height of the vessel; then the content in wine gallons shall be $DDH \times \frac{34}{10000}$, or $DDH \times .0034$. Ex. Let the diameter $D=51.2$ inches, the height $H=62.3$ inches, then the content shall be $51.2 \times 51.2 \times 62.3 \times .0034 = 555.27,342$ wine-gallons.—This rule follows from prop. 33. and 45. For by the former, the area of the base of the vessel is in square inches $DD \times .7854$; and by the latter, the content of the vessel in solid inches is $DDH \times 7854$; which divided by 231 (the number of cubical inches in a wine-gallon) gives $DDH \times .0034$, the content in wine-gallons. But though the charges in the excise are made (by statute) on the supposition that the wine-gallon contains 231 cubical inches, yet it is said, that in sale 224 cubical inches, the content of the standard measured at Guildhall (as was mentioned above), are allowed to be a wine-gallon.

“II. Supposing the English ale-gallon to contain 282-cubical inches, the content of a cylindric vessel is computed in such gallons, by multiplying the square of the diameter of a vessel by its height as formerly, and their product by the decimal fraction .0,027,851: that is, the solid content in ale gallons is $DDH \times .0,027,851$.

“III. Supposing the Scots pint to contain about 103.4 cubical inches (which is the measure given by the standards at Edinburgh, according to experiments mentioned above), the content of a cylindric vessel is computed in Scots pints, by multiplying the square of the diameter of the vessel by its height, and the product

Gauging.

Gauging. duct of these by the decimal fraction .0076. Or the content of such a vessel in Scots pints is $DDH \times .0076$.

“IV. Supposing the Winchester bushel to contain 2187 cubical inches, the content of a cylindric vessel is computed in those bushels by multiplying the square of the diameter of the vessel by the height, and the product by the decimal fraction .0,003,606. But the standard bushel having been measured by Mr Everard and others in 1696, it was found to contain only 2145.6 solid inches; and therefore it was enacted in the act for laying a duty upon malt, *That every round bushel, with a plain and even bottom, being 18 $\frac{1}{2}$ inches diameter throughout, and 8 inches deep, should be esteemed a legal Winchester bushel.* According to this act (ratified in the first year of queen Anne) the legal Winchester bushel contains only 2150.42 solid inches. And the content of a cylindric vessel is computed in such bushels, by multiplying the square of the diameter by the height, and their product by the decimal fraction .003,625. Or the content of the vessel in those bushels is $DDH \times .0,003,625$.

“V. Supposing the Scots wheat-firlot to contain $21\frac{1}{4}$ Scots pints (as is appointed by the statute 1618), and the pint to be conform to the Edinburgh standards abovementioned, the contents of a cylindric vessel in such firlots is computed by multiplying the square of the diameter by the height, and their product by the decimal fraction .00,358. This firlot, in 1426, is appointed to contain 17 pints; in 1457, it was appointed to contain 18 pints; in 1587, it is $19\frac{1}{4}$ pints; in 1628, it is $21\frac{1}{4}$ pints: and though this last statute appears to have been founded on wrong computations in several respects, yet this part of that act that relates to the number of pints in the firlot seems to be the least exceptionable; and therefore we suppose the firlot to contain $21\frac{1}{4}$ pints of the Edinburgh standard, or about 2197 cubical inches; which a little exceeds the Winchester bushel, from which it may have been originally copied.

“VI. Supposing the bear-firlot to contain 31 Scots pints (according to the statute 1518), and the pint conform to the Edinburgh standards, the content of a cylindric vessel in such firlots is found by multiplying the square of the diameter by the height, and this product by .000245.

“When the section of the vessel is not a circle, but an ellipsis, the product of the greatest diameter by the least is to be substituted in those rules for the square of the diameter.

“VII. To compute the content of a vessel that may be considered as a frustum of a cone in any of those measures.

“Let A represent the number of inches in the diameter of the greater base, B the number of inches in the diameter of the lesser base. Compute the square of A, the product of A multiplied by B, and the square of B, and collect these into a sum. Then find the third part of this sum, and substitute it in the preceding rules in the place of the square of the diameter; and proceed in all other respects as before. Thus, for example, the content in wine-gallons is $AA+AB+BB+\frac{1}{3} \times H \times .0034$.

“Or, to the square of half the sum of the diameters A and B, add one-third part of the square of

half their difference, and substitute this sum in the preceding rules for the square of the diameter of the vessel: for the square of $\frac{1}{2}A+\frac{1}{2}B$ added to $\frac{1}{3}$ of the square of $\frac{1}{2}A-\frac{1}{2}B$, gives $\frac{1}{3}AA+\frac{1}{3}AB+\frac{1}{3}BB$.

“VIII. When a vessel is a frustum of a parabolic conoid, measure the diameter of the section at the middle of the height of the frustum; and the content will be precisely the same as of a cylinder of the diameter of the same height with the vessel.

“IX. When a vessel is a frustum of a sphere, if you measure the diameter of the section at the middle of the height of the frustum, then compute the content of a cylinder of the diameter of the same height with the vessel, and from this subtract $\frac{1}{3}$ of the content of a cylinder of the same height of a base whose diameter is equal to its height; the remainder will give the content of the vessel. That is, if D represent the diameter of the middle section, and H the height of the frustum, you are to substitute $DD-\frac{1}{3}HH$ for the square of the diameter of the cylindric vessel in the first six rules.

“X. When the vessel is a frustum of a spheroid if the bases are equal, the content is readily found by the rule in p. 683. In other cases, let the axis of the solid be to the conjugate axis as n to 1; let D be the diameter of the middle section of the frustum, H the height or length of the frustum; and substitute in the first six rules $DD-\frac{HH}{3n^2}$ for the square of the diameter of the vessel.

“XI. When the vessel is an hyperbolic conoid, let the axis of the solid be to the conjugate axis as n to 1, D the diameter of the section at the middle of the frustum, H the height or length: compute $DD \times \frac{1}{3n^2} \times HH$, and substitute this sum for the square of the diameter of the cylindric vessel in the first six rules.

“XII. In general, it is usual to measure any round vessel, by distinguishing it into several frustums, and taking the diameter of the section at the middle of each frustum; thence to compute the content of each as if it was a cylinder of that mean diameter; and to give their sum as the content of the vessel. From the total content, computed in this manner, they subtract successively the numbers which express the circular areas that correspond to those mean diameters, each as often as there are inches in the altitude of the frustum to which it belongs, beginning with the uppermost; in this manner calculate a table for the vessel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry or wet inches: having regard to the inclination or drip of the vessel when it has any.

“This method of computing the content of a frustum from the diameter of the section at the middle of its height, is as exact in that case only when it is a portion of a parabolic conoid; but in such vessels as are in common use, the error is not considerable. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same in the different parts of the same or of similar vessels, when the altitude of the frustum is given. And when the altitudes are different, the error is in the triplicate ratio

Gauging. of the altitude. If exactness be required, the error in measuring the frustum of a conical vessel in this manner is $\frac{1}{2}$ of the content of a cone similar to the vessel, of an altitude equal to the height of the frustum. In a sphere, it is $\frac{1}{3}$ of a cylinder of a diameter and height equal to the frustum. In the spheroid and hyperbolic conoid, it is the same as in a cone generated by the right-angled triangle, contained by the two semiaxes of the figure, revolving about that side which is the semiaxis of the frustum.

“ In the usual method of computing a table for a vessel, by subtracting from the whole content the number that expresses the uppermost area as often as there are inches in the uppermost frustum and afterwards the numbers for the other are as successively; it is obvious, that the contents assigned by the table, when a few of the uppermost inches are dry, are stated a little too high if the vessel stands upon its lesser base; but too low when it stands on its greater base; because, when one inch is dry, for example, it is not the area at the middle of the uppermost frustum, but rather the area at the middle of the uppermost inch, that ought to be subtracted from the total content, in order to find the content in this case.

“ XIII. To measure round timber: Let the mean circumference be found in feet and decimals of a foot; square it; multiply this square by the decimal .079,577, and the product by the length. *Ex.* Let the mean circumference of a tree be 10.3 feet, and the length 24 feet. Then $10.3 \times 10.3 \times .079,577 \times 24 = 202.615$, is the number of cubical feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is .0,795,774,715, and that the areas of circles are as the squares of their circumferences.

“ But the common way used by artificers for measuring round timber, differs much from this rule. They call one fourth part of the circumference the *girt*, which is by them reckoned the side of a square, whose area is equal to the area of the section of the tree; therefore they square the *girt*, and then multiply by the length of the tree. According to their method the tree of the last example would be computed at 159.13 cubical feet only.

“ How square timber is measured, will be easily understood from the preceding propositions. Fifty solid feet of hewn timber, and forty of rough timber make a load.

Gauging. “ XIV. To find the burden of a ship, or the number of tons it will carry, the following rule is commonly given. Multiply the length of the keel taken within board, by the breadth of the ship within board, taken from the midship beam from plank to plank, and the product by the depth of the hold, taken from the plank below the keelson to the under part of the upper deck plank, and divide the product by 94, the quotient is the content of the tonnage required. This rule, however, cannot be accurate; nor can one rule be supposed to serve for the measuring exactly the burden of ships of all sorts. Of this the reader will find more in the Memoirs of the Royal Academy of Sciences at Paris for the year 1721.

“ Our author having said nothing of weights, it may be of use to add briefly, that the English Troy-pound contains 12 ounces, the ounce 20 penny-weight, and the penny weight 24 grains; that the Averdupois pound contains 16 ounces, the ounce 16 drams, and that 112 pounds is usually called the hundred weight. It is commonly supposed, that 14 pounds Averdupois are equal to 17 pounds Troy. According to Mr Everard's experiments, 1 pound Averdupois is equal to 14 ounces 12 penny-weight and 16 grains Troy, that is, to 7000 grains; and an Averdupois ounce is $437\frac{1}{2}$ grains. The Scots Troy-pound (which, by the statute 1718, was to be the same with the French) is commonly supposed equal to $15\frac{3}{4}$ ounces English Troy, or 7560 grains. By a mean of standards kept by the dean of guild at Edinburgh, it is $7599\frac{3}{4}$ or 7600 grains. They who have measured the weights which were sent from London after the union of the kingdoms to be the standards by which the weights in Scotland should be made, have found the English Averdupois pound (from a medium of the several weights) to weigh 7000 grains, the same as Mr Everard; according to which, the Scots, Paris, or Amsterdam pound, will be to the pound Averdupois as 38 to 35. The Scots Troy-stone contains 16 pounds, the pound 2 marks or 16 ounces, an ounce 16 drops, a drop 36 grains. Twenty Scots ounces make a Tron pound; but because it is usual to allow one to the score, the Tron-pound is commonly 21 ounces. Sir John Skene, however, makes the Tron-stone to contain only $19\frac{1}{4}$ pounds.”

G E O

George.

GEORGE I. II. and III. kings of Great Britain. —George I. the son of Ernest Augustus, duke of Brunswick Lunenburgh, and elector of Hanover: succeeded to the throne of Great Britain in 1714, in virtue of an act of parliament, passed in the latter part of the reign of king William III. limiting the succession of the crown, after the demise of this monarch, and queen Anne (without issue), to the princess Sophia of Hanover, and the heirs of her body, being Protestants.—George II. the only son of the former, succeeded him in 1727, and enjoyed a long reign of glory, dying amidst the most rapid and extensive conquests in the 77th year of his age. He was succeeded by

G E O

his grandson George III. For particulars, see BRITAIN, n^o 374—701.

George.

GEORGE, or *Knights of St GEORGE*, has been the denomination of several military orders, whereof that of the garter is one of the most illustrious. See GARTER, and *St GEORGE*, below.

King GEORGE'S ISLANDS, are two islands in the South Sea, lying in W. Long. 144. 56. S. Lat. 28. They were first discovered by commodore Byron in 1765, and have since been visited by Captain Cook in 1774. Commodore Byron's people had an encounter with the inhabitants, which proved fatal to some of the natives; but Captain Cook was more fortunate. A lieutenant and

George. and two boats well armed were sent on shore by Captain Cook; and landed without opposition. As soon as the gentlemen landed, the islanders embraced them by touching noses, a mode of civility used in New Zealand, which is 900 leagues distant, and the only place besides this where the custom has been observed to prevail. Notwithstanding this ceremony, however, very little real friendship seemed to take place on the part of the islanders. They crowded about the boats as the people were stepping into them, and seemed in doubt whether they should detain them or let them go; at last, however, not thinking themselves sufficiently strong, they seemed contented with their departure, and assisted them in pushing off their boats; but some of the most turbulent threw stones into the water which fell very near them, and all seemed to glory that they had as it were driven them off. The British, however, brought off five dogs of a white colour with fine long hair, with which the island seemed to be plentifully supplied. These they purchased with small nails, and some ripe bananas which had been brought from the Marquesas. On this island Mr Forester found a kind of scurvy grass, which the natives informed him they were wont to bruise and mix with shell-fish; after which, they threw it into the sea whenever they perceived a shoal of fish. This preparation intoxicates them for some time; and thus they are caught on the surface of the water without any other trouble than that of taking them out. The name of this plant among the natives is *enow*. The largest island, which they call *Tiookea*, is something of an oval shape, and about 10 leagues in circuit; the other island, which lies two leagues to the westward of *Tiookea*, is four leagues from the northeast to southwest, and from five to three miles broad. The soil of both is extremely scanty; the foundation consists of coral, very little elevated above the surface of the water.

GEORGE (St) or *GEORGE of Cappadocia*; a name whereby several orders, both military and religious, are denominated. It took its rise from a saint or hero famous throughout all the East, called by the Greeks *Μεγαλομάρτυρ*, q. d. *great martyr*.

On some medals of the emperors John and Manuel Comneni, we have the figure of St George armed, holding a sword or javelin in one hand, and in the other a buckler with this inscription; an O, and therein a little

P
A, and ΓΕ—ΠΙΟC, making Ο ΑΓΙΟΣ ΓΕΟΡΓΙΟΣ, *O Holy*

George. He is generally represented on horseback, as being supposed to have frequently engaged in combats in that manner. He is highly venerated throughout Armenia, Muscovy, and all the countries which adhere to the Greek rite; from the Greek, his worship has long ago been received into the Latin church; and England and Portugal have both chosen him for their patron saint.

Great difficulties have been raised about this saint or Hero. His very existence has been called in question. Dr Heylin who wrote first and most about him, concluded with giving him entirely up, and supposing him only a symbolical device; and Dr Pettingal has turned him into a mere Basilidian symbol of victory. Mr Pegg, in a paper in the *Archæologia* *, has attempted to restore him. And, finally, Mr Gibbon † has sunk him into an Arian bishop in the reigns of Constantius and Julian.—The bishop alluded to,

GEORGE the Cappadocian, was so surnamed, according to our author, from his parents or education; and was born at Epiphania in Cilicia, in a fuller's shop. "From this obscure and servile origin he raised himself by the talents of a parasite: and the patrons whom he assiduously flattered, procured for their worthless dependent a lucrative commission, or contract, to supply the army with bacon. His employment was mean: he rendered it infamous. He accumulated wealth by the basest arts of fraud and corruption; but his malversations were so notorious, that George was compelled to escape from the pursuits of justice. After this disgrace, in which he appears to have saved his fortune at the expence of his honour, he embraced with real or affected zeal, the profession of Arianism. From the love, or the ostentation, of learning, he collected a valuable library of history, rhetoric, philosophy, and theology; and the choice of the prevailing faction promoted George of Cappadocia to the throne of Athanasius." His conduct in this station is represented by our historian as polluted by cruelty and avarice, and his death considered as a just punishment for the enormities of his life, among which Mr Gibbon seems to rank his "enmity to the Gods."

The immediate occasion of his death, however, as narrated by ecclesiastical writers, will probably not appear calculated to add any stain to his memory. "There was in the city of Alexandria a place in which the heathen priests had been used to offer human sacrifices. This place, as being of no use, Constantius gave to the church of Alexandria, and George the bishop gave orders for it to be cleared, in order to build a Christian church on the spot. In doing this they discovered an immense subterraneous cavern, in which the heathen mysteries had been performed, and in it were many human skulls. These, and other things which they found in the place, the Christians brought out and exposed to public ridicule. The heathens provoked at this exhibition, suddenly took arms, and rushing upon the Christians, killed many of them with swords, clubs, and stones: some also they strangled, and several they crucified. On this the Christians proceeded no farther in clearing the temple; but the heathens, pursuing their advantage, seized the bishop as he was in the church, and put him in prison. The next day they dispatched him; and then fastening the body to a camel, he was dragged about the streets all day, and in the evening they burnt him and the camel together. This fate, Sozomen says, the bishop owed in part to his haughtiness while he was in favour with Constantius, and some say the friends of Athanasius were concerned in this massacre; but he ascribes it chiefly to the inveteracy of the heathens, whose superstitious he had been very active in abolishing.

"This George, the Arian bishop of Alexandria was a man of letters, and had a very valuable library, which Julian ordered to be seized for his own use; and in his orders concerning it, he says that many of the books were on philosophical and rhetorical subjects, though many of them related to the doctrine of the impious Galileans (as in his sneering contemptuous way he always affected to call the Christians).

'These books (says he) I could wish to have utterly destroyed; but lest books of value should be destroyed along with them, let these also be carefully sought for.'

George.

But Mr Gibbon gives a different turn to the affair of George's murder, as well as relates it with different circumstances. "The Pagans, (says he) excited his devout avarice; and the rich temples of Alexandria were either pillaged or insulted by the haughty prelate, who exclaimed in a loud and threatening tone, 'How long will these sepulchres be permitted to stand?' Under the reign of Constantius, he was expelled by the fury, or rather by the justice of the people; and it was not without a violent struggle, that the civil and military powers of the state could restore his authority and gratify his revenge. The messenger who proclaimed at Alexandria the accession of Julian, announced the downfall of the archbishop. George, with two of his obsequious ministers, count Diodorus and Dracontius master of the mint, was ignominiously dragged in chains to the public prison. At the end of 24 days, the prison was forced open by the rage of a superstitious multitude, impatient of the tedious forms of judicial proceedings. The enemies of gods and men expired under their cruel insults; the lifeless bodies of the archbishop and his associates were carried in triumph through the streets on the back of a camel; and the inactivity of the Athanasian party was esteemed a shining example of evangelical patience. The remains of these guilty wretches were thrown into the sea; and the popular leaders of the tumult declared their resolution to disappoint the devotion of the Christians, and to intercept the future honours of these martyrs, who had been punished like their predecessors, by the enemies of their religion. The fears of the Pagans were just, and their precautions ineffectual. The meritorious death of the archbishop obliterated the memory of his life. The rival of Athanasius was dear and sacred to the Arians, and the seeming conversion of those sectaries introduced his worship into the bosom of the Catholic church. The odious stranger, disguising every circumstance of time and place, assumed the mask of a martyr, a saint, and a Christian hero; and the infamous George of Cappadocia has been transformed into the renowned St George of England, the patron of arms, of chivalry, and of the garter."

Knights of St GEORGE. See GARTER. There have been various other orders under this denomination, most of which are now extinct; particularly one founded by the emperor Frederic III. in the year 1470, to guard the frontiers of Bohemia and Hungary against the Turks; another called *St George of Alfama*, founded by the kings of Arragon; another in Austria and Carinthia; and another in the republic of Genoa, still subsisting, &c.

Religious of St GEORGE. Of these there are divers orders and congregations; particularly canons regular of St George in Alga, at Venice, established by authority of pope Boniface IX. in the year 1404. The foundation of this order was laid by Bartholomew Colonna, who preached in 1396, at Padua, and some other villages in the state of Venice. Pope Pius V. in 1570, gave these canons precedence of all other religions. Another congregation of the same institute in Sicily, &c.

St GEORGE del Mina, the capital of the Dutch settlements on the gold-coasts of Guinea, situated seven or eight miles west of Cape-coast castle, the capi-

tal of the British settlements there. W. Long. 5'. and N. Lat. 5°.

St GEORGE, a fort and town of Asia, in the peninsula on this side the Ganges, and on the coast of Coromandel, belonging to the British; it is otherwise called *Madrafs*, and by the natives *Chilapatam*. It fronts the sea, and has a salt-water river on its back side, which hinders the fresh-water springs from coming near the town, so that they have no good water within a mile of them. In the rainy seasons it is incommoded by inundations; and from April to September, it is so scorching hot, that if the sea-breezes did not cool the there would be no living there. There are two towns, one of which is called the *White Town*, which is walled round, and has several bulwarks and bastions to defend it: it is 400 paces long and 150 broad, and is divided into regular streets. Here are two churches, one for the Protestants, and the other for the Papists; as also a good hospital, a town hall, and a prison for debtors. They are a corporation, and have a mayor and aldermen with other proper officers. The *Black Town* is inhabited by Gentoos, Mahometans, and Portuguese, and Armenian Christians, and each religion have their temples and churches. This, as well as the White Town is ruled by the English governor and his council. The diamond-mines are but a week's journey from this place, which renders them pretty plentiful, but there are no large ones since that great diamond was procured by governor Pitt. This colony produces very little of its own growth or manufacture for foreign markets, and the trade is in the hands of the Armenians and Gentoos. The chief things the British deal in, besides diamonds, are calicoes, chintz, muslins, and the like. This colony may consist of 80,000 inhabitants in the towns and villages, and there are generally 400 or 500 Europeans. Their rice is brought by sea to Gangam and Orixia, their wheat from Surat and Bengal, and their fire-wood from the islands of Diu, so that an enemy, with a superior force at sea, may easily distress them. The houses of the White Town are built with brick, and have lofty rooms and flat roofs; but the Black Town consists chiefly of thatched cottages. The military power is lodged in the governor and council, who are also the last resort in civil causes. The company have two chaplains, who officiate by turns, and have each rool. a-year, besides the advantages of trade. They never attempt to make proselytes, but leave that to the Popish missionaries. The salaries of the company's writers are very small: but if they have any fortune of their own, they may make it up by trade; which must generally be the case, for they commonly grow rich. It was taken by the French in 1746, who restored it at the peace of Aix-la-Chapelle.

St GEORGE'S, the largest of the Bermuda or Summer islands. W. Long. 65. 10. N. Lat. 32. 30.

Cross of St GEORGE, a red on a field argent, which makes part of the British standard.

GEORGIA, a country of Asia, bounded on the north by Circassia, on the east by Daghestan and Shirvan, on the south by Armenia, and on the west by the Euxine or Black Sea; comprehending the greatest part of the ancient Colchis, Iberia, and Albania. About the etymon of the name of this country, authors are not agreed. The most probable opinion is,

George, Georgia.

Georgia. is, that it is a corruption by softening of *Kurgia*, from the river Kur; whence also it is supposed that the inhabitants are called by the Persians indifferently *Gurgi* and *Kurgi*; and the country *Kurgistan* and *Gurgistan*: It is divided by a ridge of mountains into eastern and western; the former of which is again subdivided into the kingdoms of Caket, Carduel or Cartuel, and Gogueta; and the latter into the provinces of Abkhasia, Mireta, or Imeretia, and Guriel. Another division is into Georgia Proper, Abkhasia, and Mingrelia. A third division will be afterwards mentioned.

“Georgia (says Sir John Chardin) is as fertile a country as can be seen; the bread is as good here as in any part of the world; the fruit of an exquisite flavour, and of different sorts; no place in Europe yields better pears and apples, and no place in Asia better pomegranates. The country abounds with cattle, venison, and wild-fowl, of all sorts; the river Kur is well stocked with fish; and the wine is so rich, that the king of Persia has always some of it for his own table. The inhabitants are robust, valiant, and of a jovial temper; great lovers of wine, and esteemed very trusty and faithful; endowed with good natural parts, but, for want of education, very vicious. The women are generally so fair and comely, that the wives and concubines of the king of Persia and his court are for the most part Georgian women. Nature has adorned them with graces no where else to be met with: it is impossible to see them without loving them; they are of a good size, clean-limbed, and well-shaped.” Another traveller, however, of no mean character, thus expresses himself with respect to the women: “As to the Georgian women, they did not at all surprise us; for we expected to find them perfect beauties. They are, indeed, no way disagreeable; and may be counted beauties, if compared with the Curdes. They have an air of health that is pleasing enough; but, after all, they are neither so handsome nor so well shaped as is reported. Those who live in the towns have nothing extraordinary more than the others; so that I may, I think, venture to contradict the accounts that have been given of them by most travellers.”

This country formerly abounded with great cities, as appears not only from its history, but from the ruins of many of them still visible, which show that they must have been very large, opulent, and magnificently built. These were all destroyed by the inundations of northern barbarians from mount Caucasus, as the Alans, Huns, Suevi, and some others, so much noted in history for their strength, courage, and conquests.

The latest division of this country is into nine provinces; five of which are subject to the famous prince Heraclius, forming what is commonly called the kingdom of Georgia; and four are under the dominion of David, composing the kingdom or principality of Imeretia. See *IMERETIA*.

This whole country is so extremely beautiful, that some fanciful travellers have imagined they had here found the situation of the original garden of Eden. The hills are covered with forests of oak, ash, beech, chestnuts, walnuts, and elms, encircled with vines, growing perfectly wild, but producing vast quantities of grapes. From these is annually made as much wine as is necessary for the yearly consumption; the re-

mainder are left to rot on the vines. Cotton grows spontaneously, as well as the finest European fruit-trees. Rice, wheat, millet, hemp, and flax, are raised on the plains, almost without culture. The valleys afford the finest pasturage in the world; the rivers are full of fish; the mountains abound in minerals, and the climate is delicious; so that nature appears to have lavished on this favoured country every production that can contribute to the happiness of its inhabitants.

On the other hand, the rivers of Georgia, being fed by mountain torrents, are at all seasons either too rapid or too shallow for the purposes of navigation: the Black Sea, by which commerce and civilization might be introduced from Europe, has been till very lately in the exclusive possession of the Turks: the trade of Georgia by land is greatly obstructed by the high mountains of Caucasus: and this obstacle is still increased by the swarms of predatory nations, by which those mountains are inhabited.

It is said, that in the 15th century, a king of Georgia divided among his five sons the provinces of Carduel and Caket, Imeretia, Mingrelia, Guriel, and Abkhasia. These petty princes were too jealous to unite for their common defence, and too weak singly to resist a foreign enemy, or even to check the incroachments of their great vassals, who soon became independent. By forming a party among these nobles, the Turks gradually gained possession of all the western provinces, while the Persians occupied the governments of Carduel and Caket. Since that period the many unsuccessful attempts of the Georgians to recover their liberty, have repeatedly produced the devastation of their country. Abbas the Great is said to have carried off in one expedition from the provinces of Carduel and Caket no less than 80,000 families, a number which, probably, exceeds the whole actual population of those provinces. The most horrible cruelties were again exercised on the unhappy people, at the beginning of the present century, by the merciless Nadir; but these were trifling evils, compared with those arising from the internal dissensions of the great barons. This numerous body of men, idle, arrogant, and ferocious, possessed of an unlimited power over the lives and properties of their vassals, having no employment but that of arms, and no hopes of aggrandizing themselves but by the plunder of their rivals, were constantly in a state of warfare; and as their success was various, and the peasants of the vanquished were constantly carried off and sold to the Turks or Persians, every expedition increased the depopulation of the country. At length they invited the neighbouring mountaineers, by the hopes of plunder, to take part in their quarrels; and these dangerous allies, becoming acquainted with the country, and being spectators of the weakness of its inhabitants, soon completed its desolation. A few squalid wretches, half naked, half starved, and driven to despair by the merciless exactions of their landlords, are thinly dispersed over the most beautiful provinces of Georgia. The revolutions of Persia, and the weakness of the Turks, have indeed enabled the princes of the country to recover their independence; but the smallness of their revenue has hitherto disabled them from repressing effectually the tyranny of the nobles, and relieving the burdens of the peasants.

Georgia.

Georgia.

The capital of Georgia is Teflis, where prince Heraclius resides (See *TEFLIS*.) Of this prince, so celebrated for his exploits and success in shaking off the Ottoman yoke, we have the following account by the late professor Guldenstaedt when he travelled into these parts in 1770. "Heraclius, or, as he is called, the tzar Iracli, is above 60 years old, of a middle size, with a long countenance, a dark complexion, large eyes, and a small beard. He passed his youth at the court and in the army of the celebrated Nadir Shah, where he contracted a fondness for Persian customs and manners, which he has introduced into his kingdom. He has seven sons and six daughters. He is much revered and dreaded by the Persian khans his neighbours; and is usually chosen to mediate between them in their disputes with each other. When they are at war, he supports one of the parties with a few troops, who diffuse a spirit and courage among the rest, because the Georgian soldiers are esteemed the bravest of those parts; and prince Heraclius himself is renowned for his courage and military skill. When on horseback he has always a pair of loaded pistols at his girdle, and, if the enemy is near, a musket slung over his shoulder. In all engagements he is the foremost to give examples of personal bravery; and frequently charges the enemy at the head of his troops with the sabre in his hand. He loves pomp and expence; he has adopted the dress of Persia; and regulates his court after the manner of that country. From the example of the Russian troops, who were quartered in Georgia during the last Turkish war, he has learnt the use of plates, knives, and forks, dishes and household furniture, &c."

The subjects of Heraclius are estimated at about 60,000 families; but this, notwithstanding the present desolated state of the country, is probably an undervaluation. The peasants belonging to the queen, and those of the patriarch, pay no tax to the prince, and therefore do not appear on the books of the revenue officers. Many similar exceptions have likewise been granted by the prince to his sons-in-law, and his favourites. Besides, as the impost on the peasants is not a poll-tax, but a tax on hearths, the inhabitants of a village, on the approach of the collectors, frequently carry the furniture of several huts into one, and destroy the remainder, which are afterwards very easily replaced. It is probable, therefore, that the population of Georgia does not fall short of 350,000 souls. The revenues may be estimated at about 150,000 roubles, or 26,250*l*. They consist of, 1. The customs, farmed at 1750*l*.—2. Rent paid by the farmers of the mint at Teflis, 1750*l*.—3. The tribute paid by the Khans of Erivan and Gansha, 7000*l*.—and, 4. The hearth money levied on the peasants, amounting to 15,750*l*. The common coins here are the abasses, of about 15*d*. value, and a small copper coin, stamped at the mint at Teflis. Besides these, a large quantity of gold and silver money is brought into the country from Persia and Turkey, in exchange for honey, butter, cattle, and blue linens.

The government of Georgia is despotic; but, were it not for the assistance of the Russian troops, the prince would be frequently unable to carry his decrees into execution. The punishments in criminal cases are shockingly cruel; fortunately they are not frequent,

because it is seldom difficult to escape into some of the neighbouring countries, and because the prince is more enriched by confiscating the property of the criminal, than by putting him to torture. Judicial combats are considered as the privilege of nobility, and take place when the cause is extremely intricate, or when the power and interest of two claimants are so equal, that neither can force a decision of the court in his favour. This mode of trial is called an appeal to the judgment of God.

The dress of the Georgians nearly resembles that of the Cofaks; but men of rank frequently wear the habit of Persia. They usually dye their hair, beard, and nails with red. The Georgian women employ the same colour to stain the palms of their hands. On their heads they wear a cap or fillet, under which their black hair falls on their forehead: behind, it is braided into several tresses. Their eye-brows are painted with black, in such a manner as to form one entire line, and their faces are perfectly coated with white and red. Their robe is open to the girdle, so that they are reduced to conceal the breasts with their hands. Their air and manner are extremely voluptuous. Being generally educated in convents, they can all read and write; a qualification which is very unusual among the men, even of the highest rank. Girls are betrothed as soon as possible, often at three or four years of age. In the streets the women of rank are always veiled, and then it is indecent in any man to accost them. It is likewise uncivil in conversation to inquire after the wives of any of the company. These, however, are not ancient customs, but are a consequence of the violences committed by the Persians, under Shah Nadir.

Travellers accuse the Georgians of drunkenness, superstition, cruelty, sloth, avarice, and cowardice; vices which are every where common to slaves and tyrants, and are by no means peculiar to the natives of this country. The descendants of the colonists, carried off by Shah Abbas, and settled at Peria, near Ispahan, and in Masanderan, have changed their character with their government; and the Georgian troops, employed in Persia against the Affghans, were advantageously distinguished by their docility, their discipline, and their courage.

The other inhabitants of Georgia are Tartars, Offi, and Armenians, called in the Georgian language *Somakhi*. These last are found all over Georgia, sometimes mixed with the natives, and sometimes in villages of their own. They speak among themselves their own language, but all understand and can talk the Georgian. Their religion is partly the Armenian, and partly the Roman Catholic. They are the most oppressed of the inhabitants, but are still distinguished by that instinctive industry which every where characterizes the nation.

Besides these, there are in Georgia considerable numbers of Jews, called, in the language of the country, *Uria*. Some have villages of their own; and others are mixed with the Georgian, Armenian, and Tartar inhabitants, but never with the Offi. They pay a small tribute above that of the natives.

GEORGIA, one of the United States of America, lying between South Carolina and Florida. It extends 120 miles upon the sea-coast, and 300 miles from

Georgia.

Germany. from thence to the Apalachian mountains, and its boundaries to the north and south are the rivers Savannah and Alatamaha. The whole coast is bordered with islands; the principal of which are Skidaway, Wassaw, Oflabaw, St. Catherines, Sapelo, Frederica, Jekyl, Cumberland, and Amelia.

The settlement of a colony between the rivers Savannah and Alatamaha was meditated in England in 1732, for the accommodation of poor people in Great Britain and Ireland, and for the farther security of Carolina. Private compassion and public spirit conspired to promote the benevolent design. Humane and opulent men suggested a plan of transporting a number of indigent families to this part of America free of expence. For this purpose they applied to the king, George II. and obtained from him letters patent bearing date June 9, 1732, for legally carrying into execution what they had generously projected. They called the new province *Georgia*, in honour of the king, who encouraged the plan. A corporation consisting of 21 persons, was constituted by the name of, The Trustees for settling and establishing the colony of Georgia.

In November 1732, 116 settlers embarked for Georgia to be conveyed thither free of expence, furnished with every thing requisite for building and for cultivating the soil. Mr James Oglethorpe, one of the trustees, and an active promoter of the settlement, embarked as the head and director of these settlers. They arrived at Charlestown early in the next year. Mr Oglethorpe, accompanied by William Bull, shortly after his arrival, visited Georgia; and after surveying the country, marked the spot on which Savannah now stands, as the fittest to begin their settlement. Here they accordingly began and built a small fort; a number of small huts for their defence and accommodation. Such of the settlers as were able to bear arms were embodied, and well appointed with officers, arms, and ammunition. A treaty of friendship was concluded between the settlers and their neighbours the Creek Indians, and every thing wore the aspect of peace and future prosperity. But the fundamental regulations established by the trustees of Georgia were ill adapted to the circumstances and situation of the poor settlers, and of pernicious consequence to the prosperity of the province. Yet although the trustees were greatly mistaken with respect to their plan of settlement, it must be acknowledged their views were generous. Like other distant legislators, who framed their regulations upon principles of speculation, they were liable to many errors and mistakes; and however good their design, their rules were found improper and impracticable. These injudicious regulations and restrictions, the wars in which they were involved with the Spaniards and Indians, and the frequent insurrections among themselves, threw the colony into a state of confusion and wretchedness too great for human nature long to endure. Their oppressed situation was represented to the trustees by repeated complaints; till at length finding that the province languished under their care, and weary with the complaints of the people, they in the year 1752 surrendered their charter to the king, and it was made a royal government. — In the year 1740, the Rev. George Whitfield

12 miles from Savannah. Mr Whitefield died at Newbury Port, in New England, in October 1770, in the 56th year of his age, and was buried under the Presbyterian church in that place. From the time Georgia became a royal government in 1752, till the peace of Paris in 1763, she struggled under many difficulties arising from the want of credit, from friends, and the frequent molestations of enemies. The good effects of the peace were sensibly felt in the province of Georgia. From this time it began to flourish under the fatherly care of governor Wright. To form a judgement of the rapid growth of the colony, we need only attend to its exports. In the year 1763, they consisted of 7500 barrels of rice, 9633 pound of indigo, 1250 bushels of Indian corn, which, together with deer and beaver skins, naval stores, provisions, timber, &c. amounted to no more than L. 27,021 sterling. Ten years afterwards, in 1773, they amounted to L. 121,677 sterling. The chief articles of export from this state are rice, tobacco, indigo, sago, lumber of various kinds, naval stores, leather, deer-skins, snake-root, myrtle, bees-wax, corn, live stock, &c.

During the late war, Georgia was over-run by the British troops, and the inhabitants were obliged to flee into the neighbouring states for safety. Since the peace, the progress of the population of this state is said to have been astonishingly rapid: though it has been a good deal checked within these few years by the hostile irruptions of the Creek Indians, who frequently harass the frontiers of the state. Treaties have been held, and cessations of hostilities agreed to, and the late treaty with the United States will probably secure a lasting peace.

These Indians inhabit the middle parts of the state, and are the most numerous tribe of Indians of any within the limits of the United States. Their whole number is 17,280, of which 5860 are fighting men. Their principal towns lie in latitude 32° and longitude 110° 20' from Philadelphia. They are settled in a hilly but not mountainous country. The soil is fruitful in a high degree, and well watered, abounding in creeks and rivulets, whence they are called the *Creek Indians*. The Seminoles, a division of the Creek nation, inhabit a level flat country on the Apalachicola and Flint rivers, fertile and well watered. The Chactaws or flat-heads inhabit a very fine and extensive tract of hilly country, with large and fertile plains intervening, between the Alabama and Mississippi rivers, in the western part of this state. This nation have 43 towns and villages, in three divisions, containing 12,123 souls, of which 4041 are fighting men. The Chicasaws are settled on the head branches of the Tombecbe, Mobile, and Yazoo rivers, in the north-west corner of the state. Their country is an extensive plain, tolerably well watered from springs, and of a pretty good soil. They have 7 towns, the central one of which is in latitude 34° 23', and longitude 14° 30' west. The number of souls in this nation have been reckoned at 1725, of which 575 are fighting men.

That part of Georgia which has been laid out in counties is divided into the following, *viz.* Chatham, Effingham, Burke, Richmond, Wilkes, Liberty, Glynn, Camden, Washington, Greene, Franklin; and the chief towns are, Savannah, Ebenezer, Waynesborough and

Georgia. Louisville, Augusta, Washington, Sunbury, Brunswick, St Patrick's, Golphinton, Greensburg.—Savannah was formerly the capital, and is still the largest town (see SAVANNAH). But the present seat of government in this state is *Augusta*, situated on the southwest bank of Savannah river, about 134 miles from the sea, and 117 northwest of Savannah. The town, which contains about 200 houses, is on a fine large plain; and as it enjoys the best soil, and the advantage of a central situation between the upper and lower counties, is rising fast into importance. Louisville, however, is designed as the future seat of government in this state. It has lately been laid out on the bank of Ogeechee river, about 70 miles from its mouth, but is not yet built.

Savannah river forms a part of the divisional line which separates this state from South Carolina. It is formed principally of two branches, by the names of *Tugulo* and *Keowee*, which spring from the mountains. Ogeechee river, about 18 miles south of the Savannah, is a smaller river, and nearly parallel with it in its course. Alatomaha, about 60 miles south of Savannah river, is formed by the junction of the Okonee and Okemulgee branches. It is a noble river, but of difficult entrance. Like the Nile, it discharges itself by several mouths into the sea. Besides these, there is Turtle river, Little Sitilla, Great Sitilla, Crooked river, and St Mary's, which form a part of the southern boundary of the United States. The rivers in the middle and western parts of this state are Apalachicola, which is formed by the Chatahouchee and Flint rivers, Mobile, Pascagoula, and Pearl rivers. All these running southwardly, empty into the Gulf of Mexico.

In the grand convention at Philadelphia in 1787, the inhabitants of this state were reckoned at 90,000, including three-fifths of 20,000 negroes. But from the census returned June 25th 1791, the numbers stand thus: white inhabitants 53284, slaves 29264. Total 82548. No general character will apply to the inhabitants at large. Collected from different parts of the world, as interest, necessity, or inclination led them, their character and manners must of course partake of all the varieties which distinguish the several states and kingdoms from whence they came. There is so little uniformity, that it is difficult to trace any governing principles among them. An aversion to labour is too predominant, owing in part to the relaxing heat of the climate, and partly to the want of necessity to excite industry. An open and friendly hospitality, particularly to strangers, is an ornamental characteristic of a great part of this people.

In regard to religion, politics, and literature, this state is yet in its infancy. In Savannah is an episcopal church, a presbyterian church, a synagogue, and a German Lutheran church, supplied occasionally by a German minister from Ebenezer, where there is a large convenient stone church, and a settlement of sober industrious Germans of the Lutheran religion. In Augusta they have an episcopal church. In Midway is a society of Christians established on the congregational plan. Their ancestors emigrated in a colony from Dorchester, near Boston, about the year 1700,

and settled at a place named Dorchester, about 20 miles southwest of Charlestown, South Carolina. In 1752, for the sake of a better climate and more land, almost the whole society removed and settled at Midway. They, as a people, retain in a great measure that simplicity of manners, that unaffected piety and brotherly love which characterized their ancestors, the first settlers of New England. The upper counties are supplied pretty generally by baptist and methodist ministers; but the greater part of the state is without ministers of any denomination.

The numerous defects in the late constitution of this state, induced the citizens pretty universally to petition for a revision of it. It was accordingly revised, or rather a new one was formed, in the course of the year 1789, nearly upon the plan of the constitution of the United States, which has lately been adopted by the state.

The charter containing the present system of education in this state was passed in the year 1785. A college, with ample and liberal endowments, is instituted in Louisville, a high and healthy part of the country, near the centre of the state. There is also provision made for the institution of an academy in each county in the state, to be supported from the same funds, and considered as parts and members of the same institution, under the general superintendance and direction of a president and board of trustees, appointed for their literary accomplishments from the different parts of the state, and invested with the customary powers of corporations. The institution thus composed is denominated *the University of Georgia*. The funds for the support of the institution are principally in lands, amounting in the whole to about 50,000 acres, a great part of which is of the best quality, and at present very valuable. There are also nearly L.6000 sterling in bonds, houses, and town lots in the town of Augusta. Other public property to the amount of L.1000 in each county has been set apart for the purposes of building and furnishing their respective academies. The funds originally designed for the support of the orphan-house, are chiefly in rice plantations and negroes. For a farther account of this state, see APPENDIX.

GEORGIC, a poetical composition upon the subject of husbandry, containing rules therein, put into a pleasing dress, and set off with all the beauties and embellishments of poetry. The word is borrowed from the Latin *georgicus*, and that of the Greek *γεωργικός*, of *γη*, terra, "earth," and *εργαζομαι*, *opero*, "I work, or labour," of *εργον*, *opus*, "work." Hesiod and Virgil are the two greatest masters in this kind of Poetry. The moderns have produced nothing in this kind, except Rapin's book of Gardening; and the celebrated poem intitled *Cyder*, by Mr Philips, who, if he had enjoyed the advantage of Virgil's language, would have been second to Virgil in a much nearer degree.

GEORGIUM SIDUS. See ASTRONOMY, n° 328, &c.

GEPIDÆ, GEPIDES, or GEPIDI (anc. geog.), according to Procopius, were a Gothic people, or a canton or branch of them; some of whom, in the migration of the Goths, settled in an island at the mouth of the Vistula, which they called *Gepidos* after their own name, which denotes lazy or slothful; others in Dacia, calling their settlement there *Gepidia*.

GE-

Geranites,
Geranium.

GERANITES, in natural history, an appellation given to such of the semipellucid gems as are marked with a spot resembling a crane's eye.

GERANIUM, CRANE'S BILL, in botany: A genus of the decandria order, belonging to the monodelphia class of plants; and in the natural method ranking under the 14th order, *Gruinales*. Its characters are these: the flower hath a permanent empalement, composed of five small oval leaves, and five oval or heart-shaped petals, spreading open, which are in some species equal, and in others the upper two are much larger than the three lower. It has ten stamina, alternately longer than each other, but shorter than the petals, and terminated by oblong summits. In the bottom of the flower is situated a five-cornered germen, which is permanent. The flower is succeeded by five seeds, each being wrapped up in the husk of the beak, where they are twisted together at the point, so as to form the resemblance of a stork's beak. There are above 80 species.

The common wild sorts of this plant, and those also which are brought to the curious from the colder climates, are hardy enough, and require little care; but the African species, and the others from hot countries, which make so very beautiful a figure in our green-houses, require great care in their culture and propagation.

These may be propagated by seed, which should be sown toward the end of March in beds of light earth, and carefully shading them from the sun, and giving them frequent, but gentle waterings, till they are well rooted. The mats with which these beds are covered are to be taken off in gentle showers, and always in the hot weather at nights, that the plants may have the benefit of the dew. They should remain about two months in this bed, by which time they will have taken root. Some pots of about seven inches wide are then to be filled with light earth, and the plants are to be carefully taken up with as much as possible of their own earth about them, and planted severally in the middle of these pots; when they are to be set in a shady place and watered at times till they have taken root. When they are well rooted, they should be set in a more exposed place to harden them, and should stand out till the middle of October; but when the mornings begin to grow frosty, they must be removed into the green-house, and then placed as near the windows as possible, and the windows should be open upon them till the weather is very cold. During the winter they must be frequently watered a little at a time, and their dead leaves should be pulled off. They must not stand under the shade of other plants, nor need any artificial heat.

Those who are desirous that their plants should be large and flower soon, sow the seeds on a moderate hot-bed in the spring; when they are come up, they should not be drawn weak, and the pots into which they are transplanted should be plunged into another moderate hot-bed, shading them from the sun till they have taken root, and gradually inuring them to the open air, into which they should be removed in the beginning of June, and placed in a sheltered situation with other exotic plants.

The shrubby African geraniums are commonly propagated by cuttings, which, planted in a shady bor-

der, in June or July, will take good root in five or six weeks; and they may then be taken up and planted in separate pots, placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and treated as the seedling plants.

Geranium stands recommended as one of the greatest vulneraries and abstersgents of the vegetable world, and is highly extolled for its power of stopping profluvia of the menses, and hæmorrhages of all kinds. Experience confirms the truth of this, especially among the poor people in the country; and it were to be wished that the plant could be brought into more esteem in the shops, where at present it is disregarded.

GERAR, or **GERARA**, (anc. geog.), the south boundary of Canaan near Berséba; situated between Cades and Sur; two desarts well known, the former facing Egypt, the latter Arabia Petræa.

GERARD (John), a learned Lutheran divine, was professor of divinity, and rector of the Academy of Jena, the place of his birth. He wrote, 1. The harmony of the eastern languages; 2. A Treatise on the Coptic Church; and other works which are esteemed. He died in 1668.

GERARDE (John), a surgeon in London, and the greatest botanist of his time, was many years chief gardener to Lord Burleigh; who was himself a great lover of plants, and had the best collection of any nobleman in England, among which were a great number of exotics introduced by Gerarde. In 1597 he published his *Herbal*, which was printed at the expence of J. Norton, who procured the figures from Francfort. In 1663, Thomas Johnson, an apothecary, published an improved edition of Gerarde's book; which met with such approbation by the University of Oxford, that they conferred on him the degree of doctor of physick; and it is still much esteemed. The descriptions in the herbal are plain and familiar; and both these authors have laboured more to make their readers understand the characters of the plants, than to inform them that they themselves understood Greek or Latin.

GERARDIA, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personatæ*. The calyx is quinquefid, the corolla bilabiate; the under lip tripartite; the side lobes emarginated, and the middle one bipartite; the capsule bilocular and gaping.

GERBIER (Sir Balthazar), a painter of Antwerp, born in the year 1592, distinguished himself by painting small figures in distemper. King Charles I. was so pleased with his performances, that he invited him to his court, where he obtained the esteem of the duke of Buckingham, and grew into great favour. He was not only knighted, but sent to Brussels, where he long resided as agent for the king of Great Britain.

GERFALCON. See **FALCO**.

GERGESA, (anc. geog.) a Transjordan town, no otherwise known than by the *Gergeseni* of St Matthew, and *Gergesai* of Moses; supposed to have stood in the neighbourhood of Gadara and near the sea of Tiberias. The *Gergesai*, one of the seven ancient people of Canaan, less frequently mentioned than the rest, appear to have been less considerable and more obscure: their

Gerar
||
Gergesa.

name

Gerizim name is from *Girgasi*, one of Canaan's son's. See GIRGASHITES.

Germany. GERIZIM. See GARIZIM.

GERM, among gardeners. See GERMEN.

GERMAN, in matters of genealogy, signifies whole, entire, or own. *Germani, quasi eadem stirpe geniti*; (Fest.) Hence,

Brother-GERMAN, denotes a brother both by the father's and mother's side, in contradistinction to uterine brothers, &c. who are only so by the mother's side.

Cousins-GERMAN, are those in the first or nearest degree, being the children of brothers or sisters.

Among the Romans we have no instance of marriage between cousins-german before the time of the emperor Claudius, when they were very frequent.

Theodosius prohibited them under very severe penalties, even fine and proscription. See CONSANGUINITY.

GERMAN, or *Germanic*, also denotes any thing belonging to Germany; as the German empire, German flute, &c.

GERMANDER, in botany. See the article TEUCRIUM.

GERMANICUS CÆSAR, the son of Drusus, and paternal nephew to the emperor Tiberius, who adopted him; a renowned general, but still more illustrious for his virtues. He took the title of *Germanicus* from his conquests in that country; and though he had the moderation to refuse the empire offered to him by his army, Tiberius, jealous of his success, and of the universal esteem he acquired, caused him to be poisoned, A. D. 29, aged 34. He was a protector of learning; and composed some Greek comedies and Latin poems, some of which are still extant.

GERMANY, a very extensive empire of Europe, but which, in different ages of the world, has had very different limits. Its name, according to the most probable conjecture, is derived from the Celtic words *Ghar man*, signifying a warlike man, to which their other name, *Allman*, or *Aleman*, likewise alludes.

The ancient history of the Germans is altogether wrapped up in obscurity; nor do we, for many ages, know any thing more of them than what may be learned from the history of their wars with the Romans. The first time we hear them mentioned by the Roman historians, is about the year 211 B. C. at which time Marcellus subdued Insubria and Liguria, and defeated the Gætæ a German nation situated on the banks of the Rhine. From this time history is silent with regard to any of these northern nations, till the eruption of the Cimbri and Teutones, who inhabited the most northerly part of Germany. The event of their enterprise, is related under the articles AMBRONES, CIMBRI, and TEUTONES. We must not, however, imagine, because these people happened to invade Italy at the same time, that therefore their countries were contiguous to one another. The Cimbri and Teutones only, dwelt beyond the Rhine; while the Ambrones inhabited the country between Switzerland and Provence. It is indeed very difficult to fix the limits of the country called *Germany* by the Romans. The southern Germans were intermixed with the Gauls, and the northern ones with the Scythians; and thus the ancient history of the Germans includes that

I
Limits of
ancient
High Ger-
many.

of the Dacians, Huns, Goths, &c. till the destruction of the western Roman empire by them. Ancient Germany, therefore, we may reckon to have included the northern part of France, the Netherlands, Holland, *Germany* so called at present, Denmark, Prussia, Poland, Hungary, part of Turkey in Europe, and Muscovy.

The Romans divided Germany into two regions; Belgic or Lower Germany, which lay to the southward of the Rhine; and Germany Proper, or high Germany. The first lay between the rivers Seine and the Rhine; and in this we find a number of different nations, the most remarkable of which were the following.

1. The Ubii, whose territory lay between the Rhine and the Mosæ or Maese, and whose capital was the city of Cologne. 2. Next to them were the Tungri, supposed to be the same whom Cæsar calls *Eburones* and *Condrusi*; and whose metropolis, then called *Attuatica*, has since been named *Tongres*. 3. Higher up from them, and on the other side of the Moselle, were the Treviri, whose capital was Augusta Trevirorum, now *Triers*. 4. Next to them were the Tribocci, Nemetes, and Vangiones. The former dwelt in Alsace, and had Argentoratum, now *Strasbourg*, for their capital: the others inhabited the cities of Worms, Spire, and Mentz. 5. The Mediomatrici were situated along the Moselle, about the city of Metz in Lorraine; and above them were situated another German nation, named *Raurici*, *Rauraci*, or *Rauriaci*, and who inhabited that part of Helvetia, or Switzerland, about Basil. To the westward and southward of these were the Nervii, Sueffones, Silvanectes, Leuci, Rhemi, Lingones, &c. who inhabited Belgic Gaul.

Between the heads of the Rhine and Danube, was seated the ancient kingdom of Vindelicia, whose capital was called *Augusta Vindelicorum*, now *Augsburg*. Below it on the banks of the Danube were the kingdoms of Noricum and Pannonia. The first of these was divided into Noricum *Ripense* and *Mediterraneum*. It contained a great part of the provinces of Austria, Styria, Carinthia, Tyrol, Bavaria, and some others of less note. The latter contained the kingdom of Hungary, divided into Upper and Lower; and extending from Illyricum to the Danube, and the mountains Cætii in the neighbourhood of *Vindebona*, now *Vienna*.

Upper or High Germany lay beyond the Rhine and the Danube. Between the Rhine and the Elbe were the following nations. 1. The Chauci, Upper and Lower; who were divided from each other by the river *Visurges*, now the *Wefer*. Their country contained what is now called *Bremen*, *Lunenburg*, *Friezland* and *Groninghen*. The upper Chauci had the Cherusci, and the lower the Chamavi on the south-east, and the German Ocean on the north-west. 2. The Frisii, upper and lower, were divided from the lower Chauci by the river *Amisia*, now the *Ems*; and from one another by an arm of the Rhine. Their country still retains the name of *Friezland*, and is divided into east and west; but the latter is now dismembered from Germany, and become one of the Seven United Provinces. 3. Beyond the *Isela*, now the *Isel*, which bounded the country of the Frisii, were situated the *Bructeri*, who inhabited that tract now called *Broecmorland*; and the

Marfi,

Germany. Marfi, about the river Luppe. On the other side of that river were the *Ufipii Ufipites*; but these were famed for often changing their territories, and therefore found in other places. 4. Next to these were the Jaones, or inhabitants of Juliers, between the Maefe and the Rhine. 5. The Catti, another ancient and warlike nation, inhabited Hesse and Thuringia, from the Hartzian mountains to the Rhine and Wefer; among whom were comprehended the Mattiaci, whose capital is by some thought to be *Marpurg*, by others *Baden*. 6. Next to these were the Seducii bordering upon Suabia; Narifci, or the ancient inhabitants of Northgow, whose capital was Nuremberg; and the Marcomanni, whose country anciently reached from the Rhine to the head of the Danube, and to the Neckar. The Marcomanni afterwards went and settled in Bohemia and Moravia, under their general or king Maroboduus; and some of them in Gaul, whence they drove the Boii, who had seated themselves there. 6. On the other side of the Danube, and between the Rhine and it, were the Hermunduri, who possessed the country now called *Misnia* in Upper Saxony; though some make their territories to have extended much farther, and to have reached quite to, or even beyond, the kingdom of Bohemia, once the seat of the Boii, whence its name. 8. Beyond them, on the north of the Danube, was another seat of the Marcomanni along the river Albis, or Elbe, 9. Next to Bohemia were situated the Quadi, whose territories extended from the Danube, to Moravia, and the northern part of Austria. These are comprehended under the ancient name of *Suevi*; part of whom at length forced their way into Spain, and settled a kingdom there. 10. Eastward of the Quadi were situated the Bastarnæ, and parted from them by the Granna, now *Gran*, a river that falls into the Danube, and by the Carpathian mountains, from them called *Alpes Bastarnicæ*. The country of the Bastarnæ indeed made part of the European Sarmatia, and so without the limits of Germany properly so called; but we find these people so often in league with the German nations, and joining them for the destruction of the Romans, that we cannot but account them as one people.

Between those nations already taken notice of, seated along the other sides of the Danube and the Hercynian forest, were several others whose exact situation is uncertain, viz. the Martingi, Buri, Borades, Lygii, or Logiones, and some others, who are placed by our geographers along the forest abovementioned, between the Danube and the Vistula.

On this side the Hercynian forest, were the famed Rhætii, now *Grifons*, seated among the Alps. Their country, which was also called *Western Illyricum*, was divided into *Rhætia Prima* or *Propria*, and *Secunda*; and was then of much larger extent, spreading itself towards Suabia, Bavaria, and Austria.

On the other side of the Hercynian forest, were, 1. The Suevi, who spread themselves from the Vistula to the river Elbe. 2. The Longobardi, so called, according to some, on account of their wearing long beards; but, according to others, on account of their consisting of two nations, viz. the Bardi and Lingones. These dwelt along the river Elbe, and bordered southward on the Chauçi abovementioned. 3. The Burgundi, of whose original seat we are uncertain. 4. The

Semnonēs; who, about the time of Tiberius, were seated on the River Elbe. 5. The Angles, Saxons, and Goths; were probably the descendants of the Cimbri; and inhabited the countries of Denmark, along the Baltic sea, and the peninsula of Scandinavia, containing Norway, Sweden, Lapland, and Finnmark. 6. The Vandals were a Gothic nation, who proceeding from Scandinavia, settled in the countries now called *Mecklenburgh* and *Brandenburgh*. 7. Of the same race were the Dacians, who settled themselves in the neighbourhood of Palus Mæotis, and extended their territories along the banks of the Danube.

These were the names of the German nations who performed the most remarkable exploits in their wars with the Romans. Besides these, however, we find mention made of the Scordisci, a Thracian nation, who afterwards settled on the banks of the Danube. About the year 113 B. C. They ravaged Macedon, and cut off a whole Roman army sent against them; the general, M. Porcius Cato, grandson to Cato the censor, being the only person who had the good fortune to make his escape. After this they ravaged all Thessaly; and advanced to the coasts of the Adriatic, into which, because it stopped their further progress, they discharged a shower of darts. By another Roman general, however, they were driven back into their own country with great slaughter; and, soon after, Metellus so weakened them by repeated defeats, that they were incapable, for some time, of making any more attempts on the Roman provinces. At last, in the consulship of M. Livius Drusus and L. Calpurnius Piso, the former prevailed on them to pass the Danube, which thenceforth became the boundary between the Romans and them. Notwithstanding this, in the time of the Jugurthine war, the Scordisci repassed the Danube on the ice every winter, and being joined by the Triballi, a people of Lower Mæsia, and the Daci of Upper Mæsia, penetrated as far as Macedon, committing every where dreadful ravages. So early did these northern nations begin to be formidable to the Romans, even when they were most renowned for warlike exploits.

Till the time of Julius Cæsar, however, we hear nothing more concerning the Germans. About 58 years B. C. he undertook his expedition into Gaul; during which, his assistance was implored by the Ædui, against Ariovistus, a German prince who oppressed them. Cæsar, pleased with this opportunity of increasing his power, invited Ariovistus to an interview; but this being declined, he next sent deputies desiring him to restore the hostages he had taken from the Ædui and to bring no more troops over the Rhine into Gaul. To this a haughty answer was returned; and a battle soon after ensued, in which Ariovistus was entirely defeated, and with great difficulty made his escape.

In 55 B. C. Cæsar having subdued the Sueffones, Bellovaci, Ambiani, Nervii, and other nations of Belgic Gaul, hastened to oppose the Ufipetes and Tenceteri. These nations having been driven out of their own country by the Suevi, had crossed the Rhine with a design to settle in Gaul. As soon as he appeared, the Germans sent him a deputation, offering to join him provided he would assign them lands. Cæsar replied, that there was no room in Gaul for them; but

Expedition
of Julius
Cæsar into
Germany.

Germany. he would desire the Ubii to give them leave to settle among them. Upon this, they desired time to treat with the Ubii; but in the mean time fell upon some Roman squadrons: which so provoked Cæsar, that he immediately marched against them, and, coming unexpectedly upon them, defeated them with great slaughter. They fled in the utmost confusion; but the Romans pursued them to the conflux of the Rhine and the Maese, where the slaughter was renewed with such fury, that almost 400,000 of the Germans perished. After this, Cæsar being resolved to spread the terror of the Roman name through Germany, built a bridge over the Rhine, and entered that country. In this expedition, however, which was his last in Germany, he performed no remarkable exploit. A little before his death, indeed, he had projected the conquest of that as well as of a great many other countries; but his assassination prevented the execution of his designs. Nor is there any thing recorded of the Germans till about 17 B. C. when the Tencteri made an irruption into Gaul, and defeated M. Lollius, proconsul of that province. At last, however, they were repulsed, and forced to retire with great loss beyond the Rhine.

6
Rhæti invade Italy.

Soon after this the Rhæti invaded Italy, where they committed the greatest devastations, putting all they met to the sword, without distinction of sex or age: nay, we are told, that when they happened to take women with child, they consulted their augurs to know whether the child was a male or female; and if they pronounced it a male, the mother was immediately massacred. Against these barbarians was sent Drusus, the second son of Livia, a youth of extraordinary valour and great accomplishments. He found means to bring them to a battle; in which the Romans proved victorious, and cut in pieces great numbers of their enemies, with very little loss on their own side. Those who escaped the general slaughter, being joined by the Vindelici took their rout towards Gaul, with a design to invade that province. But Augustus, upon the first notice of their march, dispatched against them Tiberius with several chosen legions. He was no less successful than Drusus had been; for, having transported his troops over the lake Brigantium, now Constance, he fell unexpectedly on the enemy, gave them a total overthrow, took most of their strong holds, and obliged the whole nation to submit to such terms as he chose to impose upon them.

7
They are subdued, with the Vindelici and Norici.

Thus were the Vindelici, the Rhæti, and Norici, three of the most barbarous nations in Germany, subdued. Tiberius, to keep the conquered countries in awe, planted two colonies in Vindelicia, and opened from thence a road into Rhætia and Noricum. One of the cities which he built for the defence of his colonies, he called, from his father Drusus, *Drusomagus*; the other by the name of Augustus, *Augusta Vindelicorum*; which cities are now known by the names of *Mimminghen* and *Augsburgh*. He next encountered the Pannonians, who had been subdued by Agrippa, but revolted on hearing the news of that great commander's death, which happened 11 years B. C. Tiberius, however, with the assistance of their neighbours the Scordisci, soon forced them to submit. They delivered up their arms, gave hostages, and put the Romans in possession of all their towns and strong holds. Tiberius spared

8
And the Pannonians.

their lives; but laid waste their fields, plundered their cities, and sent the best part of their youth into other countries. Germany.

In the mean time, Drusus having prevented the Gauls from revolting, which they were ready to do, prepared to oppose the Germans who dwelt beyond the Rhine. They had collected the most numerous and formidable army that had ever been seen in those parts; with which they were advancing towards the Rhine, in order to invade Gaul. Drusus defeated them as they attempted to cross that river; and pursuing the advantage he had gained, entered the country of the Usipetes, now *Relinchusen*, and from thence advanced against the Sicambri, in the neighbourhood of the Lype and Issel. There he overthrew in a great battle, laid waste their country, burnt most of their cities, and following the course of the Rhine, approached the German ocean, reducing the Frisii and the Chauci between the Ems and the Elbe. In these marches the troops suffered extremely for want of provisions; and Drusus himself was often in great danger of being drowned, as the Romans who attended him were at that time quite unacquainted with the flux and reflux of the ocean.

9
Exploits of Drusus in Germany.

The Roman forces went into east Friesland for their winter-quarters; and next year (10 B. C.) Drusus marched against the Tencteri, whom he easily subdued. Afterwards, passing the Lupias, now the Lype, he reduced the Catti and Cherusci, extending his conquests to the banks of the Visurgis or Weser: which he would have passed, had he not been in want of provisions, the enemy having laid waste the country to a considerable distance. As he was retiring, the Germans unexpectedly fell upon him in a narrow passage; and having surrounded the Roman army, cut a great many of them in pieces. But Drusus having animated his men by his example, after a bloody conflict, which lasted the whole day, the Germans were defeated with such slaughter, that the ground was strewed for several miles with dead bodies. Drusus found in their camp a great quantity of iron-chains which they had brought for the Romans; and so great was their confidence, that they had agreed before hand about the division of the booty. The Tencteri were to have the horse, the Cherusci and Sicambri the baggage, and the Usipetes and Catti the captives. After this victory, Drusus built two forts to keep the conquered countries in awe; the one at the confluence of the Lype and the Alme, and the other in the country of the Catti on the Rhine. On this occasion he also made a famous canal, long after called in honour of him *Fossa Drusiana*, to convey the waters of the Rhine into the Sala or Sale. It extended eight miles; and was very convenient for conveying the Roman troops by water to the countries of the Frisii and Chauci, which was the design of the undertaking.

The following year (9 B. C.) Augustus, bent on subduing the whole of Germany, advanced to the banks of the Rhine, attended by his two sons-in-law Tiberius and Drusus. The former he sent against the Daci, who lived up to the south of the Danube; and the latter to complete the conquests he had so successfully begun in the western parts of Germany. The former easily overcame the Daci, and transplanted 40,000 of them into Gaul. The latter having passed

Plate CCXIX.

Hours East from London.

Germany. the Rhine, subdued all the nations from that river to the Elbe; but having attempted in vain to cross this last, he set out for Rome: an end, however, was put to his conquests and his life by a violent fever, with which he was seized on his return.

10
Arminius
heads the
Germans
against the
Romans.

After the death of Drusus, Tiberius again over-ran all those countries in which Drusus had spent the preceding summer: and struck some of the northern nations with such terror, that they sent deputies to sue for peace. This, however, they could not obtain upon any terms; the emperor declaring that he would not conclude a peace with one, unless they all desired it. But the Catti, or according to some the Sicambri, could not by any means be prevailed upon to submit; so that the war was still carried on, though in a languid manner, for about 18 years. During this period, some of the German nations had quitted their forests, and begun to live in a civilized manner under the protection of the Romans; but one Quintilius Varus being sent to command the Roman forces in that country, so provoked the inhabitants by his extortions, that not only those who still held out refused to submit, but even the nations that had submitted were seized with an eager desire of throwing off the yoke. Among them was a young nobleman of extraordinary parts and valour, called *Arminius*. He was the son of Sigmimer, one of the most powerful lords among the Catti, had served with great reputation in the Roman armies, and been honoured by Augustus with the privileges of a Roman citizen and the title of knight. But the love of his country prevailing over his gratitude, he resolved to improve the general discontent which reigned among his countrymen, to deliver them from the bondage of a foreign dominion. With this view he engaged, underhand, the leading men of all the nations between the Rhine and the Elbe, in a conspiracy against the Romans. In order to put Varus off his guard, he at the same time advised him to show himself to the inhabitants of the more distant provinces, administer justice among them, and accustom them, by his example, to live after the Roman manner, which he said would more effectually subdue them than the Roman sword. As Varus was a man of a peaceable temper, and averse from military toils, he readily consented to this insidious proposal; and, leaving the neighbourhood of the Rhine, marched into the country of the Cherusci. Having there spent some time in hearing causes and deciding civil controversies, Arminius persuaded him to weaken his army, by sending out detachments to clear the country of robbers. When this was done, some distant nations of Germany rose up in arms by Arminius's directions; while those through which Varus was to pass in marching against them, pretended to be in a state of profound tranquillity, and ready to join the Romans against their enemies.

11
Cuts off
Varrus
with his
army.

On the first news of the revolt, Varus marched against the enemy with three legions and six cohorts; but being attacked by the Germans as he passed thro' a wood, his army was almost totally cut off, while he himself and most of his officers fell by their own hands. Such a terrible overthrow, though it raised a general consternation in Rome, did not, however, dishearten Augustus, or cause him to abandon his enterprize. About two years after (A. D. 12.), Tiberius and Ger-

VOL. VII.

manicus were appointed to command in Germany. The death of Augustus, however, which happened soon after, prevented Tiberius from going on his expedition; and Germanicus was for some time hindered from proceeding in his, by a revolt of the legions, first in Pannonia, and then in Germany. About the year 15, Germanicus having brought over the soldiers to their duty, laid a bridge across the Rhine, over which he marched 12,000 legionaries, 26 cohorts of the allies, and eight alæ (squadrons of 300 each) of horse. With this he first traversed the Cælian forest (part of the Hercynian, and thought to lie partly in the duchy of Cleves, and partly in Westphalia), and some other woods. On his march he was informed that the Marfi were celebrating a festival with great mirth and jollity. Upon this he advanced with such expedition, that he surprized them in the midst of their debauch; and giving his army full liberty to make what havoc they pleased, a terrible massacre ensued, and the country was destroyed with fire and sword for 50 miles round, without the loss of a single man on the part of the Romans.—This general massacre roused the Bructeri, the Tubantes, and the Esipetes; who, besetting the passes through which the Roman army was to return, fell upon their rear, and put them in to some disorder; but the Romans soon recovered themselves, and defeated the Germans with considerable loss.

12
Exploits of
Germani-
cus.

The following year (A. D. 16.), Germanicus taking advantage of some intestine broils which happened among the Catti, entered their country, where he put great numbers to the sword. Most of their youth, however, escaped by swimming over the Adrana, now the Eder, and attempted to prevent the Romans from laying a bridge over that river: but being disappointed in this, some of them submitted to Germanicus, while the greater part abandoning their villages, took refuge in the woods; so that the Romans, without opposition, set fire to all their villages, towns, &c. and having laid their capital in ashes, began their march back to the Rhine.

Germanicus had scarce reached his camp, when he received a message from Segestes, a German prince, in the interest of the Romans, acquainting him that he was besieged in his camp by Arminius. On this advice, he instantly marched against the besiegers; entirely defeated them; and took a great number of prisoners, among whom was Thufeldis, the wife of Arminius, and daughter of Segestes, whom the former had carried off and married against her father's will. Arminius then, more enraged than ever, for the loss of his wife whom he tenderly loved, stirred up all the neighbouring nations against the Romans. Germanicus, however, without being dismayed by such a formidable confederacy, prepared himself to oppose the enemy with vigour: but, that he might not be obliged to engage such numerous forces at once, he detached his lieutenant Cæcina, at the head of 40 cohorts, into the territories of the Bructeri; while his cavalry, under the command of Pedro, entered the country of the Frisii. As for Germanicus himself, he embarked the remainder of his army, consisting of four legions, on a neighbouring lake; and transported them by rivers and canals to the place appointed on the river Ems, where the three bodies met. In their

4 T

march

Germany. march they found the sad remains of the legions conducted by Varus, which they buried with all the ceremony their circumstances could admit. After this they advanced against Arminius, who retired and posted himself advantageously close to a wood. The Roman general followed him; and coming up with him, ordered his cavalry to advance and attack the enemy. Arminius, at their first approach, pretended to fly; but suddenly wheeled about, and giving the signal to a body of troops, whom he had concealed in the wood, to rush out, obliged the cavalry to give ground. The cohorts then advanced to their relief; but they too were put into disorder, and would have been pushed into a morass, had not Germanicus himself advanced with the rest of the cavalry to their relief. Arminius did not think it prudent to engage these fresh troops, but retired in good order; upon which Germanicus also retired towards the Ems. Here he embarked with four legions, ordered Cæcina to reconduct the other four by land, and sent the cavalry to the sea-side, with orders to march along the shore to the Rhine. Tho' Cæcina was to return by roads well known, yet Germanicus advised him to pass with all possible speed, a causeway, called the *long bridges*; which led across vast marshes, surrounded on all sides with woods and hills that gently rose from the plain.

Arminius, however, having got notice of Cæcina's march, arrived at the long bridges before Cæcina, and filled the woods with his men, who, on the approach of the Romans, rushed out, and attacked them with great fury. The legions, not able to manage their arms in the deep waters and slippery ground, were obliged to yield; and would in all probability have been entirely defeated, had not night put an end to the combat. The Germans, encouraged by their success, instead of refreshing themselves with sleep, spent the whole night in diverting the courses of the springs which rose in the neighbouring mountains; so that, before day, the camp which the Romans had begun was laid under water, and their works were overturned. Cæcina was for some time at a loss what to do; but at last resolved to attack the enemy by day-break, and, having driven them to their woods, to keep them there in a manner besieged, till the baggage and wounded men should pass the causeway, and get out of the enemy's reach. But when his army was drawn up, the legions posted on the wings, seized with a sudden panic, deserted their stations, and occupied a field beyond the marshes. Cæcina thought it advisable to follow them; but the baggage stuck in the mire, as he attempted to cross the marshes, which greatly embarrassed the soldiers. Arminius perceiving this, laid hold of the opportunity to begin the attack; and crying out, "This is a second Varus, the same fate attends him and his legions," fell on the Romans with inexpressible fury. As he had ordered his men to aim chiefly at the horses, great numbers of them were killed; and the ground becoming slippery with their blood and the slime of the marsh, the rest either fell or threw their riders, and, galloping through the ranks, put them in disorder. Cæcina distinguished himself in a very eminent manner; but his horse being killed, he would have been taken prisoner, had not the first legion rescued him. The greediness of the enemy, however, saved the Romans from utter destruction;

for just as the legions were quite spent, and on the point of yielding, the barbarians on a sudden abandoned them in order to seize their baggage. During this respite, the Romans struggled out of the marsh, and having gained the dry fields, formed a camp with all possible speed, and fortified it in the best manner they could.

The Germans having lost the opportunity of destroying the Romans, contrary to the advice of Arminius, attacked their camp next morning, but were repulsed with great slaughter; after which they gave Cæcina no more molestation till he reached the banks of the Rhine. Germanicus, in the mean time, having conveyed the legions he had with him down the river Ems into the ocean, in order to return by sea to the river Rhine, and finding that his vessels were overloaded, delivered the second and 14th legions to Publius Vitellius, desiring him to conduct them by land. But this march proved fatal to great numbers of them; who were either buried in the quicksands, or swallowed up by the overflowing of the tide, to which they were as yet utter strangers. Those who escaped, lost their arms, utensils, and provisions; and passed a melancholy night upon an eminence which they had gained by wading up to the chin. The next morning the land returned with the tide of ebb; when Vitellius, by an hasty march, reached the river Usingis, by some thought to be the Hoerenster, on which the city of Groningen stands. There Germanicus, who had reached that river with his fleet, took the legions again on board, and conveyed them to the mouth of the Rhine, whence they all returned to Cologne, at a time when it was reported they were totally lost.

This expedition, however, cost the Romans very dear, and procured very few advantages. Great numbers of men had perished; and by far the greatest part of those who had escaped so many dangers returned without arms, utensils, horses, &c. half naked, lamed, and unfit for service. The next year, however, Germanicus, bent on the entire reduction of Germany, made vast preparations for another expedition. Having considered the various accidents that had befallen him during the war, he found that the Germans were chiefly indebted for their safety to their woods and marshes, their short summers and long winters; and that his troops suffered more from their long and tedious marches than from the enemy. For this reason he resolved to enter the country by sea, hoping by that means to begin the campaign earlier, and surprise the enemy. Having therefore quitted with great dispatch, during the winter, 1000 vessels of different sorts, he ordered them early in the spring (A. D. 16) to fall down the Rhine, and appointed the island of the Batavians for the general rendezvous of his forces. When the fleet was sailing, he detached Silius one of his lieutenants, with orders to make a sudden irruption into the country of the Catti; and, in the mean time, he himself, upon receiving intelligence that a Roman fort on the Luppias was besieged, hastened with six legions to its relief. Silius was prevented, by sudden rains, from doing more than taking some small booty, with the wife and daughter of Arpen king of the Catti; neither did those who besieged the fort wait the arrival of Germanicus. In the mean time, the fleet arriving at the island of the Batavians, the

Germany. provisions and warlike engines were put on board and sent forward; ships were assigned to the legions and allies; and the whole army being embarked, the fleet entered the canal formerly cut by Drusus, and from his name called *Fossa Drusiana*. Hence he sailed prosperously to the mouth of the Ems; where, having landed his troops, he marched directly to the Weser, where he found Arminius encamped on the opposite bank, and determined to dispute his passage. The next day Arminius drew out his troops in order of battle: but Germanicus, not thinking it advisable to attack them, ordered the horse to ford over under the command of his lieutenants Stertinius and Emilius; who, to divide the enemy's forces, crossed the river in two different places. At the same time Cariovalda, the leader of the Batavian auxiliaries, crossed the river where it was most rapid: but, being drawn into an ambuscade, he was killed, together with most of the Batavian nobility; and the rest would have been totally cut off, had not Stertinius and Emilius hastened to their assistance. Germanicus in the mean time passed the river without molestation. A battle soon after ensued; in which the Germans were defeated with so great a slaughter that the ground was covered with arms and dead bodies for more than 10 miles round: and among the spoils taken on this occasion, were found, as formerly, the chains with which the Germans had hoped to bind their captives.

In memory of this signal victory Germanicus raised a mount, upon which he placed as trophies the arms of the enemy, and inscribed underneath the names of the conquered nations. This so provoked the Germans, though already vanquished and determined to abandon their country, that they attacked the Roman army unexpectedly on its march, and put them into some disorder. Being repulsed, they encamped between a river and a large forest surrounded by a marsh except on one side, where it was inclosed by a broad rampart formerly raised by the Angrivarii as a barrier between them and the Cherusci. Here another battle ensued; in which the Germans behaved with great bravery, but in the end were defeated with great slaughter.

After this second defeat, the Angrivarii submitted, and were taken under the protection of the Romans, and Germanicus put an end to the campaign. Some of the legions he sent to their winter-quarters by land, while he himself embarked with the rest on the river Ems, in order to return by sea. The ocean proved at first very calm, and the wind favourable: but all of a sudden a storm arising, the fleet, consisting of 1000 vessels, was dispersed: some of them were swallowed up by the waves; others were dashed in pieces against the rocks, or driven upon remote and inhospitable islands, where the men either perished by famine, or lived upon the flesh of the dead horses with which the shores soon appeared strewed; for, in order to lighten their vessels, and disengage them from the shoals, they had been obliged to throw overboard their horses and beasts of burden, nay, even their arms and baggage. Most of the men, however, were saved, and even great part of the fleet recovered. Some of them were driven upon the coast of Britain; but the petty kings who reigned there generously sent them back.

On the news of this misfortune, the Catti, taking new courage, ran to arms; but Caius Silius being de-

tached against them with 30,000 foot and 3000 horse, kept them in awe. Germanicus himself, at the head of a numerous body, made a sudden irruption into the territories of the Marfi, where he recovered one of Varus's eagles, and having laid waste the country, he returned to the frontiers of Germany, and put his troops into winter-quarters; whence he was soon recalled by Tiberius, and never suffered to return into Germany again.

After the departure of Germanicus, the more northern nations of Germany were no more molested by the Romans. Arminius carried on a long and successful war with Maroboduus king of the Marcomanni, whom he at last expelled, and forced to apply to the Romans for assistance; but, excepting Germanicus, it seems they had at this time no other general capable of opposing Arminius, so that Maroboduus was never restored. After the final departure of the Romans, however, Arminius having attempted to enslave his country, fell by the treachery of his own kindred. The Germans held his memory in great veneration; and Tacitus informs us, that in his time they still celebrated him in their songs.

Nothing remarkable occurs in the history of Germany from this time till the reign of the emperor Claudius. A war indeed is said to have been carried on by Lucius Domitius, father to the emperor Nero. But of his exploits we know nothing more than that he penetrated beyond the river Elbe, and led his army farther into the country than any of the Romans had ever done. In the reign of Claudius, however, the German territories were invaded by Cn. Domitius Corbula, one of the greatest generals of his age. But when he was on the point of forcing them to submit to the Roman yoke, he was recalled by Claudius, who was jealous of the reputation he had acquired.

In the reign of Vespasian, a terrible revolt happened among the Batavians and those German nations who had submitted to the Romans; a particular account of which is given under the article ROME. The revolters were with difficulty subdued: but, in the reign of Domitian, the Dacians invaded the empire, and proved a more terrible enemy than any of the other German nations had been. After several defeats, the emperor was at last obliged to consent to pay an annual tribute to Decebalus king of the Dacians; which continued to the time of Trajan. But this warlike prince refused to pay tribute; alleging, when it was demanded of him, that "he had never been conquered by Decebalus." Upon this the Dacians passed the Danube, and began to commit hostilities in the Roman territories. Trajan, glad of this opportunity to humble an enemy whom he began to fear, drew together a mighty army, and marched with the utmost expedition to the banks of the Danube. As Decebalus was not apprised of his arrival, the emperor passed the river without opposition, and entering Dacia, laid waste the country with fire and sword. At last he was met by Decebalus with a numerous army. A bloody engagement ensued, in which the Dacians were defeated; though the victory cost the Romans dear: the wounded were so numerous, that they wanted linen to bind up their wounds; and to supply the defect, the emperor generously devoted his own wardrobe. After the victory, he pursued Decebalus from

Germany.

Germany. place to place, and at last obliged him to consent to a peace on the following terms: 1. That he should surrender the territories which he had unjustly taken from the neighbouring nations. 2. That he should deliver up his arms, his warlike engines, with the artificers who made them, and all the Roman deserters. 3. That for the future he should entertain no deserters, nor take into his service the natives of any country subject to Rome. 4. That he should dismantle all his fortresses, castles, and strong-holds. And, lastly, that he should have the same friends and foes with the people of Rome.

With these hard terms Decebalus was obliged to comply, though fore against his will; and being introduced to Trajan, threw himself on the ground before him, acknowledging himself his vassal: after which the latter, having commanded him to send deputies to the senate for the ratification of the peace, returned to Rome.

This peace was of no long duration. Four years after (A. D. 105), Decebalus, unable to live in servitude as he called it, began, contrary to the late treaty, to raise men, provide arms, entertain deserters, fortify his castles, and invite the neighbouring nations to join him against the Romans as a common enemy. The Scythians hearkened to his solicitations; but the Jazges, a neighbouring nation, refusing to bear arms against Rome, Decebalus invaded their country. Hereupon Trajan marched against him; but the Dacian, finding himself unable to withstand him by open force, had recourse to treachery, and attempted to get the emperor murdered. His design, however, proved abortive, and Trajan pursued his march into Dacia. That his troops might the more readily pass and re-pass the Danube, he built a bridge over that river; which by the ancients is styled the most magnificent and wonderful of all his works*. To guard the bridge, he ordered two castles to be built; one on this side the Danube, and the other on the opposite side; and all this was accomplished in the space of one summer. Trajan, however, as the season was now far advanced, did not think it advisable to enter Dacia this year, but contented himself with making the necessary preparations.

* See *Architecture*, n^o 139.

19
They are subdued by Trajan.

In the year 106, early in the spring, Trajan set out for Dacia; and having passed the Danube on the bridge he had built, reduced the whole country, and would have taken Decebalus himself had he not put an end to his own life, in order to avoid falling into the hands of his enemies. After his death the kingdom of Dacia was reduced to a Roman province; and several castles were built in it, and garrisons placed in them, to keep the country in awe.

After the death of Trajan, the Roman empire began to decline, and the northern nations to be daily more and more formidable. The province of Dacia indeed was held by the Romans till the reign of Gallienus; but Adrian, who succeeded Trajan, caused the arches of the bridge over the Danube to be broken down, lest the barbarians should make themselves masters of it, and invade the Roman territories. In the time of Marcus Aurelius, the Marcomanni and Quadi invaded the empire, and gave the emperor a terrible overthrow. He continued the war, however, with better success afterwards, and invaded their country in

18
Marco-
manni and
Quadi for-
midable to
the empire.

his turn. It was during the course of this war that the Roman army is said to have been saved from destruction by that miraculous event related under the article CHRISTIANS, p. 717. col. 2.

In the end, the Marcomanni and Quadi were, by repeated defeats, brought to the verge of destruction; inasmuch that their country would probably have been reduced to a Roman province, had not Marcus Aurelius been diverted from pursuing his conquests by the revolt of one of his generals. After the death of Marcus Aurelius, the Germanic nations became every day more and more formidable to the Romans. Far from being able to invade and attempt the conquest of these northern countries, the Romans had the greatest difficulty to repress the incursions of their inhabitants. But for a particular account of their various invasions of the Roman empire, and its total destruction by them at last, see the article ROME.

The immediate destroyers of the Roman empire were the Heruli; who, under their leader Odoacer, dethroned Augustus the last Roman emperor, and proclaimed Odoacer king of Italy. The Heruli were soon expelled by the Ostrogoths; and these in their turn were subdued by Justinian, who re-annexed Italy to the eastern empire. But the popes found means to obtain the temporal as well as spiritual jurisdiction over a considerable part of the country, while the Lombards subdued the rest. The last proved very troublesome to the popes, and at length besieged Adrian I. in his capital. In this distress he applied to Charles the Great king of France; who conquered both Italy and Germany, and was crowned emperor of the west in 800.

The posterity of Charlemagne inherited the empire of Germany until the year 880; at which time the different princes assumed their original independence, rejected the Carolinian line, and placed Arnulph king of Bohemia on the throne. Since this time, Germany has ever been considered as an elective monarchy. Princes of different families, according to the prevalence of their interest and arms, have mounted the throne. Of these the most considerable, until the Austrian line acquired the imperial power, were the houses of Saxony, Franconia, and Swabia. The reigns of these emperors contain nothing more remarkable than the contests between them and the popes; for an account of which, see the article ITALY. From hence, in the beginning of the 13th century, arose the factions of the Guelphs and Ghiblins, of which the former was attached to the popes, and the latter to the emperor; and both, by their virulence and inveteracy, tended to disquiet the empire for several ages. The emperors too were often at war with the infidels; and sometimes, as happens in all elective kingdoms, with one another, about the succession.

But what more deserves our attention is the progress of government in Germany, which was in some measure opposite to that of the other kingdoms of Europe. When the empire raised by Charlemagne fell asunder, all the different independent princes assumed the right of election; and those now distinguished by the name of *electors* had no peculiar or legal influence in appointing a successor to the imperial throne; they were only the officers of the king's household, his secretary, his steward, chaplain, marshal, or master of his horse,

History of
Germany
since the
time of
Charle-
magne,

Germany. horse, &c. By degrees, however, as they lived near the king's person, and held like all other princes, independent territories belonging to them, they increased their influence and authority; and in the reign of Otho III. 984, acquired the sole right of electing the emperor. Thus while in the other kingdoms of Europe, the dignity of the great lords, who were all originally allodial or independent barons, was diminished by the power of the king, as in France, and by the influence of the people, as in Great Britain; in Germany, on the other hand, the power of the electors was raised upon the ruins of the emperor's supremacy, and of the people's jurisdiction. In 1440, Frederic III. duke of Austria was elected emperor, and the imperial dignity continued in the male line of that family for 300 years. His successor Maximilian married the heiress of Charles duke of Burgundy; whereby Burgundy and the 17 provinces of the Netherlands were annexed to the house of Austria. Charles V. grandson of Maximilian, and heir to the kingdom of Spain, was elected emperor in the year 1519. Under him MEXICO and PERU were conquered by the Spaniards; and in his reign happened the REFORMATION in several parts of Germany; which, however, was not confirmed by public authority till the year 1648, by the treaty of Westphalia, and in the reign of Ferdinand III. The reign of Charles V. was continually disturbed by his wars with the German princes and the French king Francis I. Though successful in the beginning of his reign, his good fortune towards the conclusion of it began to forsake him; which with other reasons, occasioned his abdication of the crown. See CHARLES V.

His brother Ferdinand I. who in 1558 succeeded to the throne, proved a moderate prince with regard to religion. He had the address to get his son Maximilian declared king of the Romans in his own lifetime, and died in 1564. By his last will he ordered, that if either his own male issue, or that of his brother Charles, should fail, his Austrian estates should revert to his second daughter Anne, wife to the elector of Bavaria, and her issue. We mention this destination, as it gave rise to the late opposition made by the house of Bavaria to the pragmatic sanction, in favour of the empress queen of Hungary, on the death of her father Charles VI. The reign of Maximilian II. was disturbed with internal commotions, and an invasion from the Turks; but he died in peace in 1576. He was succeeded by his son Rodolph; who was involved in wars with the Hungarians, and in differences with his brother Matthias, to whom he ceded Hungary and Austria in his lifetime. He was succeeded in the empire by Matthias; under whom the reformers, who went under the names of *Lutherans* and *Calvinists*, were so much divided among themselves, as to threaten the empire with a civil war. The ambition of Matthias at last tended to reconcile them; but the Bohemians revolted, and threw the imperial commissaries out of a window at Prague. This gave rise to a ruinous war, which lasted 30 years. Matthias thought to have exterminated both parties; but they formed a confederacy, called the *Evangelic League*, which was counterbalanced by a Catholic league.

Matthias dying in 1618, was succeeded by his cousin Ferdinand II.; but the Bohemians offered their

Germany. crown to Frederic the elector Palatine, the most powerful Protestant prince in Germany, and son-in-law to his Britannic majesty James I. That prince was incautious enough to accept of the crown: but he lost it, by being entirely defeated by the duke of Bavaria and the imperial generals at the battle of Prague; and he was even deprived of his electorate, the best part of which was given to the duke of Bavaria. The Protestant princes of Germany, however, had among them at this time many able commanders, who were at the head of armies, and continued the war with wonderful obstinacy: among them were the margrave of Baden Durlach, Christian duke of Brunswic, and count Mansfield; the last was one of the best generals of the age. Christian IV. king of Denmark declared for them; and Richlieu, the French minister, was not fond of seeing the house of Austria aggrandized. The emperor, on the other hand, had excellent generals; and Christian, having put himself at the head of the evangelic league, was defeated by Tilly, an Imperialist of great reputation in war. Ferdinand made so moderate a use of his advantages obtained over the Protestants, that they formed a fresh confederacy at Leipzig, of which the celebrated Gustavus Adolphus king of Sweden was the head. An account of his glorious victories is given under the article SWEDEN. At last he was killed at the battle of Lutzen in 1632. But the Protestant cause did not die with him. He had brought up a set of heroes, such as the duke of Saxe Weimer, Torstenson, Banier, and others, who shook the Austrian power; till, under the mediation of Sweden, a general peace was concluded among all the belligerent powers, at Munster, in the year 1648; which forms the basis of the present political system of Europe.

Ferdinand II. was succeeded by his son Ferdinand III. This prince died in 1657; and was succeeded by the emperor Leopold, a severe, unamiable, and not very fortunate prince. He had two great powers to contend with, France on the one side, and the Turks on the other; and was a loser in his war with both. Louis XIV. at that time king of France, was happy in having the two celebrated generals Condé and Turenne in his service. The latter had already distinguished himself by great exploits against the Spaniards; and, on the accession of Leopold, the court of France had taken the opportunity of confirming the treaty of Munster, and attaching to her interest several of the independent princes of Germany. The tranquillity which now took place, however, was not established upon any permanent basis. War with Spain was resumed in the year 1668: and the great success of Turenne in the Netherlands stimulated the ambition of the prince of Condé to attempt the conquest of Franche Compté at that time under the protection of the house of Austria. This was accomplished in three weeks: but the rapid success of Louis had awakened the jealousy of his neighbours to such a degree, that a league was formed against him by England, Holland, and Sweden; and the French monarch, dreading to enter the lists with such formidable enemies, consented to the treaty of Aix-la-Chapelle, by which, among other articles, Franche Compté was restored. The flames of war, however, were renewed by the insatiable ambition of the French monarch; who, having enter-

Germany. ed into an alliance with Charles II. of England, aimed at nothing less than the total overthrow of the Dutch republic. The events of that war are related under the article UNITED PROVINCES: here it is sufficient to observe, that the misfortunes of the Dutch excited the compassion of the emperor and court of Spain, who now openly declared themselves their allies. Turenne was opposed by the prince of Orange in conjunction with the celebrated imperial general Montecuculi, whose artful conduct eluded even the penetration of Turenne, and he sat down suddenly before the city of Bonne. Here he was joined by the prince of Orange, who had likewise found means to elude the vigilance of the French generals. Bonne surrendered in a short time, and several other places of Cologne fell into the hands of the allies; who likewise cut off the communication betwixt France and the United Provinces; so that Louis was soon obliged to recall his armies, and abandon all his conquests with greater rapidity than they had been made. In 1674 he was abandoned by his ally Charles II. of England, and the bishop of Munster and elector of Cologne were compelled to renounce their allegiance to him; but notwithstanding these misfortunes, he continued every where to make head against his enemies, and even meditated new conquests. With a powerful army he again invaded Franche Comte in person, and in six weeks reduced the whole province to his obedience. In Alsace, Turenne defeated the imperial general at Sintzheim, and ravaged the palatinate. Seventy thousand Germans were surprised: a considerable detachment was cut in pieces at Mulhausen; the elector of Brandenburg, who had been intrusted with the chief command, was routed by Turenne near Colmar; a third body met with a similar fate at Turkheim; and the whole German forces were obliged at last to evacuate the province and repass the Rhine.

In consequence of these disasters the Imperial general Montecuculi was recalled to act against Turenne. The military skill of the two commanders seemed to be nearly equal; but before the superiority could be adjudged to either, Turenne was killed by a cannon ball as he was reconnoitring a situation for erecting a battery. By his death the Imperialists obtained a decided superiority. Montecuculi penetrated into Alsace; and the French, under de Lorges nephew to the deceased general, were happy in being able to escape a defeat.

Part of the German army now sat down before Treves, where they were opposed by Mareschal Crequi; but the negligence of that general exposed him to such a dreadful defeat, that he was obliged to fly into the city with only four attendants. Here he endeavoured in vain to animate the people to a vigorous defence. The garrison mutinied against his authority; and, when he refused to sign the capitulation they made, delivered him up prisoner to the enemy. Louis in the mean time had taken the field in person against the prince of Orange; but the disastrous state of affairs in Germany induced him to recall the prince of Condé to make head against Montecuculi. In this campaign the prince seemed to have the advantage. He compelled the Germans to raise the sieges of Hagenau and Saverne; and at last to repass the Rhine without having been able to force him to a battle.

This was the last campaign made by these celebrated commanders; both of them now, contented with the fame they had acquired, retiring from the field to spend the remainder of their days in peace. The excellent discipline, however, which the two great French generals had introduced into their armies, still continued to make them very formidable, though it did not always insure them a victory. In Germany, the duke of Lorrain, who had recovered Philippsburgh, was repeatedly defeated by Mareschal Crequi, who had been ransomed from his captivity, and become more prudent by his defeat. In Flanders, the prince of Orange was overmatched by the duke of Orleans and Marshal Luxemburg. A peace was at length concluded at Nimeguen in 1679, by which the king of France secured himself Franche Comte with a great many cities in the Netherlands; while the king of Sweden was reinstated in those places of which he had been stripped by the Danes and Germans. This tranquillity, however, was of no long duration. Louis employed every moment in preparations for new conquests; possessed himself of the imperial city of Strasburgh by treachery; and dispossessed the elector Palatine and the elector of Treves of the lordships of Falkenburg, Germansheim, and Valdentz. On the most frivolous pretences he had demanded Alost from the Spaniards; and on their refusal, seized upon Luxemburg. His conduct, in short, was so intolerable that the prince of Orange, his inveterate enemy, found means to unite the whole empire in a league against him. Spain and Holland became parties in the same cause; and Sweden and Denmark seemed also inclined to accede to the general confederacy. Notwithstanding this formidable combination, however, Louis seemed still to have the advantage. He made himself master of the cities of Philippsburgh, Manheim, Frankendal, Spires, Worms, and Oppenheim; the fruitful country of the palatinate was ravaged in a dreadful manner; the towns were reduced to ashes; and the people, driven from their habitations, were every where left to perish through the inclemency of the weather and want of provisions. By this cruelty his enemies were rather exasperated than vanquished: the Imperialists, under the conduct of the duke of Lorrain, resumed their courage, and put a stop the French conquests. At length all parties, weary of a destructive war, consented to the treaty of Ryswick in 1697. By this treaty Louis gave up to the empire, Fribourg, Brisac, Kheil, and Philippsburgh: he consented also to destroy the fortifications of Strasburg. Fort Louis and Traerbach, the works of which had exhausted the skill of the great Vauban, with Lorrain, Treves, and the Palatinate, were resigned to their respective princes; inasmuch that the terms to which the French monarch now consented, after so many victories, were such as could scarce have been expected under the pressure of the greatest misfortunes. The views of Louis, however, in consenting to this apparently humiliating treaty, were beyond the views of ordinary politicians. The health of the king of Spain was in such a declining way, that his death appeared to be at hand; and Louis now resolved to renew his pretensions to that kingdom, which he had formerly by treaty solemnly renounced. His designs in this respect could not be concealed from the vigilance of

Germany.

Germany. William III. of Britain; of which Louis being sensible, and knowing that the emperor had claims of the same nature on Spain, he thought proper to enter into a very extraordinary treaty with William. This was no less than the partition of the whole Spanish dominions, which were now to be distributed in the following manner. To the young prince of Bavaria were to be assigned Spain and the East Indies; the dauphin, son to Louis, was to have Naples, Sicily, and the province of Guipuscoa; while the Archduke Charles, son to the Emperor Leopold, was to have only the duchy of Milan. By this scandalous treaty the indignation of Charles was roused, so that he bequeathed the whole of his dominions to the prince of Bavaria. This scheme, however, was disconcerted by the sudden death of the prince; upon which a new treaty of partition was concluded between Louis and William. By this the kingdom of Spain, together with the East India territories, were to be bestowed on the Archduke Charles, and the duchy of Milan upon the duke of Lorraine. The last moments of the Spanish monarch were disturbed by the intrigues of the rival houses of Austria and Bourbon; but the haughtiness of the Austrian ministers so disgusted those of Spain, that they prevailed upon their dying monarch to make a new will. By this the whole of his dominions were bequeathed to Philip duke of Anjou, grandson to the king of France; and Louis, prompted by his natural ambition, accepted the kingdom bequeathed to his grandson, excusing himself to his allies in the best manner he could for departing from his engagements with them. For this, however, he was made to pay dear. His insatiable ambition and his former successes had alarmed all Europe. The Emperor, the Dutch, and the king of England, entered into a new confederacy against him; and a bloody war ensued, which threatened to overthrow the French monarchy entirely. While this war (of which an account is given under the article BRITAIN) was carried on with such success, the Emperor Leopold died in the year 1705.

He was succeeded by his son Joseph, who put the electors of Cologne and Bavaria to the ban of the empire; but being ill served by Prince Louis of Baden general of the empire, the French partly recovered their affairs, notwithstanding their repeated defeats. The duke of Marlborough had not all the success he expected or deserved. Joseph himself was suspected of a design to subvert the Germanic liberties; and it was plain by his conduct, that he expected England should take the labouring oar in the war, which was to be entirely carried on for his benefit. The English were disgusted at his slowness and selfishness: but he died in 1711, before he had reduced the Hungarians; and leaving no male issue, he was succeeded in the empire by his brother Charles VI. whom the allies were endeavouring to place on the throne of Spain, in opposition to Philip duke of Anjou, grandson to Louis XIV.

When the peace of Utrecht took place in 1713, Charles at first made a show as if he would continue the war; but he found himself unable, now that he was forsaken by the English. He therefore was obliged to conclude a peace with France at Baden in 1714, that he might attend the progress of the Turks in Hungary; where they received a total defeat from Prince

Eugene at the battle of Peterwaradin. They received another of equal importance from the same general in 1717, before Belgrade, which fell into the hands of the Imperialists; and next year the peace of Passarowitz, between them and the Turks, was concluded. Charles employed every minute of his leisure in making arrangements for increasing and preserving his hereditary dominions in Italy and the Mediterranean. Happily for him, the crown of Britain devolved to the house of Hanover; an event which gave him a very decisive weight in Europe, by the connections between George I. and II. and the empire. Charles was sensible of this; and carried matters with so high a hand, that, about the years 1724 and 1725, a breach ensued between him and George I. and so unsteady was the system of affairs all over Europe at that time, that the capital powers often changed their old alliances, and concluded new ones contradictory to their interest. Without entering into particulars, it is sufficient to observe, that the safety of Hanover, and its aggrandizement, was the main object of the British court; as that of the emperor was the establishment of the pragmatic sanction in favour of his daughter the (late empress-queen), he having no male issue. Mutual concessions upon those great points restored a good understanding between George II. and the emperor Charles; and the elector of Saxony, flattered with the view of gaining the throne of Poland, relinquished the great claims he had upon the Austrian succession.

The emperor, after this, had very bad success in a war he entered into with the Turks, which he had undertaken chiefly to indemnify himself for the great sacrifices he had made in Italy to the princes of the house of Bourbon. Prince Eugene was then dead, and he had no general to supply his place. The system of France, however, under cardinal Fleury, happened at that time to be pacific; and she obtained for him, from the Turks, a better peace than he had reason to expect. Charles, to keep the German and other powers easy, had, before his death, given his eldest daughter, the late empress-queen, in marriage to the duke of Lorraine, a prince who could bring no accession of power to the Austrian family.

Charles died in 1740; and was no sooner in the grave, than all he had so long laboured for must have been overthrown, had it not been for the firmness of George II. The young king of Prussia entered and conquered Silesia, which he said had been wrongfully dismembered from his family. The king of Spain and the elector of Bavaria set up claims directly incompatible with the pragmatic sanction, and in this they were joined by France; though all those powers had solemnly guaranteed it. The imperial throne, after a considerable vacancy, was filled up by the elector of Bavaria, who took the title of *Charles VII.* in January 1742. The French poured their armies into Bohemia, where they took Prague; and the queen of Hungary, to take off the weight of Prussia, was forced to cede to that prince the most valuable part of the duchy of Silesia by a formal treaty.

Her youth, her beauty, and sufferings, and the noble fortitude with which she bore them, touched the hearts of the Hungarians; into whose arms she threw herself and her little son; and though they had been always remarkable for their disaffection to the
house

Germany.

Germany. house of Austria, they declared unanimously in her favour. Her generals drove the French out of Bohemia; and George II. at the head of an English and Hanoverian army, gained the battle of Dettingen, in 1743. Charles VII. was at this time miserable on the imperial throne, and would have given the queen of Hungary almost her own terms; but she haughtily and impolitically rejected all accommodation, though advised to it by his Britannic majesty, her best and indeed only friend. This obstinacy gave a colour for the king of Prussia to invade Bohemia, under pretence of supporting the imperial dignity; but though he took Prague, and subdued the greatest part of the kingdom, he was not supported by the French; upon which he abandoned all his conquests, and retired into Silesia. This event confirmed the obstinacy of the queen of Hungary; who came to an accommodation with the emperor, that she might recover Silesia. Soon after, his Imperial majesty, in the beginning of the year 1745, died; and the duke of Lorraine, then grand duke of Tuscany, consort to the queen of Hungary, after surmounting some difficulties, was chosen emperor.

The bad success of the allies against the French and Bavarians in the Low Countries, and the loss of the battle of Fontenoy, retarded the operations of the empress-queen against his Prussian majesty. The latter beat the emperor's brother, Prince Charles of Lorraine, who had before driven the Prussians out of Bohemia; and the conduct of the empress-queen was such, that his Britannic majesty thought proper to guarantee to him the possession of Silesia, as ceded by treaty. Soon after, his Prussian Majesty pretended that he had discovered a secret convention which had been entered into between the empress-queen, the empress of Russia, and the king of Poland as elector of Saxony, to strip him of his dominions, and to divide them among themselves. Upon this his Prussian majesty, very suddenly, drove the king of Poland out of Saxony, defeated his troops, and took possession of Dresden; which he held till a treaty was made under the mediation of his Britannic majesty, by which the king of Prussia acknowledged the duke of Lorraine, great duke of Tuscany, for emperor. The war, however, continued in the Low Countries, not only to the disadvantage, but to the discredit, of the Austrians and Dutch, till it was finished by the treaty of Aix-la-Chapelle, in April 1758. By that treaty Silesia was once more guaranteed to the king of Prussia. It was not long before that monarch's jealousies were renewed and verified; and the empress of Russia's views falling in with those of the empress-queen and the king of Poland, who were unnaturally supported by France in their new schemes, a fresh war was kindled in the empire. The king of Prussia declared against the admission of the Russians into Germany, and his Britannic majesty against that of the French. Upon those two principles all former differences between these monarchs were forgotten, and the British parliament agreed to pay an annual subsidy of 670,000*l.* to his Prussian majesty during the continuance of the war.

The flames of war now broke out in Germany with greater fury and more destructive violence than ever. The armies of his Prussian majesty, like an irresistible

torrent, burst in Saxony; totally defeated the imperial general Brown at the battle of Lowositz; forced the Saxons to lay down their arms, though almost impregnably fortified at Pirna; and the elector of Saxony fled to his regal dominions in Poland. After this, his Prussian majesty was put to the ban of the empire; and the French poured, by one quarter, their armies, as the Russians did by another, into the empire. The conduct of his Prussian majesty on this occasion is the most amazing that is to be met with in history; for a particular account of which, see the article PRUSSIA.

At last, however, the taking of Colberg by the Russians, and of Schweidnitz by the Austrians, was on the point of completing his ruin, when his most formidable enemy, the empress of Russia, died, January 5th 1762; George II. his only ally, had died on the 25th of October 1760.

The deaths of those illustrious personages were followed by great consequences. The British ministry of George III. sought to finish the war with honour, and the new emperor of Russia recalled his armies. His Prussian majesty was, notwithstanding, so very much reduced by his losses, that the empress-queen, probably, would have completed his destruction, had it not been for the wise backwardness of other German princes, not to annihilate the house of Brandenburg. At first the empress-queen rejected all terms proposed to her, and ordered 30,000 men to be added to her armies. The visible backwardness of her generals to execute her orders, and new successes obtained by his Prussian majesty, at least prevailed on her to agree to an armistice, which was soon followed by the treaty of Hubertsburgh, which secured to his Prussian Majesty the possession of Silesia. Upon the death of the emperor her husband, in 1765, her son Joseph, who had been crowned king of the Romans in 1764, succeeded him in the empire.

This prince showed an active and restless disposition, much inclined to extend his territories by conquest, and to make reformations in the internal policy of his dominions, yet without taking any proper methods for accomplishing his purposes. Hence he was almost always disappointed; insomuch that he wrote for himself the following epitaph: "Here lies Joseph, unfortunate in all his undertakings." In the year 1788, a war commenced betwixt him and the king of Prussia; in which, notwithstanding the impetuous valour of that monarch, Joseph acted with such caution that his adversary could gain no advantage over him; and an accommodation took place without any remarkable exploit on either side. In 1781 he took the opportunity of the quarrel betwixt Britain and the United Provinces, to deprive the latter of the barrier towns which had been secured to them by the treaty of Utrecht. These indeed had frequently been of great use to the House of Austria in its state of weakness; but Joseph, conscious of his own strength, looked upon it as derogatory to his honour to allow so many of his cities to remain in the hands of foreigners, and to be garrisoned at his expence. As at that time the Dutch were unable to resist, the Imperial orders for evacuating the barrier towns were instantly complied with; nor did the court of France, though then in friendship with Holland, make any offer to interpose. Encouraged by this success, Joseph next demanded the free

navi-

Germany. navigation of the Scheldt; but as this would evidently have been very detrimental to the commercial interests of Holland, a flat refusal was given to his requisitions. In this the emperor was much disappointed; having flattered himself that the Hollanders, intimidated by his power, would yield the navigation of the river as easily as they had done the barrier. Great preparations were made by the emperor, which the Dutch, on their part, seemed determined to resist. But while the emperor appeared so much set upon this acquisition, he suddenly abandoned the project entirely, and entered into a new scheme of exchanging the Netherlands for the duchy of Bavaria. This was opposed by the king of Prussia; and by the interference of the court of France, the emperor found himself at last obliged also to abandon his other scheme of obtaining the navigation of the Scheldt. A treaty of peace was concluded, under the guarantee of his most Christian majesty. The principal articles were, that the States acknowledged the emperor's sovereignty over the Scheldt from Antwerp to the limits of Scf-tingen; they agreed to demolish certain forts, and to pay a considerable sum of money in lieu of some claims which the emperor had on Maestricht, and by way of indemnification for laying part of his territories under water.

The treaty with the Dutch was no sooner concluded than a quarrel with the Turks took place, which terminated in an open war. It does not appear that the emperor had at this time any real provocation, but seems to have acted merely in consequence of his engagements with Russia to reduce the dominions of the Grand Signior. All these foreign engagements, however, did not in the least retard the progress of reformation which the emperor carried on throughout his dominions with a rapidity scarcely to be matched, and which at last produced the revolt of the Austrian Netherlands. In the course of his labours in this way a complete code of laws was compiled. These were at first greatly commended for their humanity, as excluding almost entirely every species of capital punishment; yet, when narrowly considered, the commutations were found to be so exceedingly severe, that the most cruel death would, comparatively speaking, have been an act of mercy. Even for smaller crimes the punishments were severe beyond measure; but the greatest fault of all was, that the modes of trial were very defective, and the punishments so arbitrary, that the most perfect and innocent character lay at the mercy of a tyrannical judge. The innovations in ecclesiastical matters were, however, most offensive to his subjects in the Netherlands. Among the many changes introduced into this department, the following were some of the most remarkable. 1. An abridgement of divine service. 2. A total suppression of vocal performers in choirs. 3. The introduction of the vernacular language instead of the Latin in administering the sacraments. 4. The prohibition of chanting hymns in private houses. 5. The suppression of a great number of religious houses, and the reduction of the number of the clergy. 6. The total abolition of the papal supremacy throughout the Imperial dominions. The same spirit of innovation displayed itself even in the most minute matters. Many favours were bestowed upon the Jews; and in 1786 the emperor wrote with his own hand to the different handicraft

VOL. VII.

and trading corporations in Vienna, requesting that their youth might be received as apprentices in that city. Severe laws against gaming were enacted and put in execution with equal rigour. Heavy restrictions were also laid on all the societies of free-masons in Germany, while those in the Netherlands were totally suppressed.

The great number of innovations in religious matters were highly resented by the inhabitants of the Netherlands, who have always been remarkable for their attachment to the Romish religion in its most superstitious form. Indeed the alterations in the civil constitution were so great, that even those who were least bigotted in this respect began to fear that their liberties were in danger, and an universal dissatisfaction was excited. The emperor behaved at first in a very haughty manner, refused to yield the smallest point to the solicitations of his subjects. Finding, however, that a general revolt was about to take place, and being unable at that time, on account of the Turkish war, to spare such a force as would be necessary to reduce the provinces to obedience, he thought proper, in the autumn of 1787, to promise a restoration of their ancient constitution and privileges. His promises, however, were found to be so delusive, and his conduct was so arbitrary and capricious, that in the end of the year 1789, the States of all the provinces in the Austrian Netherlands came to a resolution of entirely throwing off the yoke. Articles of a federal union were drawn up, and a new republic was formed under the title of the *Belgic Provinces*. The situation of the emperor's affairs at that time did not allow him to take the measures necessary for preventing this revolt; to which perhaps his ill state of health also contributed. About the beginning of February 1790 his distemper increased to such a degree as to be thought dangerous; and continuing daily to grow worse, he sunk under it on the 20th of the same month, in the 40th year of his age, and 26th of his reign.

The leaders of the Austrian revolution, however, soon became so disagreeable to their countrymen, that they were obliged to fly; and the congress, which had been established as the supreme legislative body, behaved with such tyranny, that they became generally detested. Mean time the late emperor was succeeded by his brother Peter Leopold Joseph grand duke of Tuscany, under whose administration matters have taken a more favourable turn. By his wisdom, moderation, and humanity, he has already in a great measure retrieved the bad consequences of his predecessor's conduct, having made peace with the Ottomans, and regained the allegiance of the Netherlands; and upon the whole seems to be actuated not more by a sense of his own rights, than by a regard to the rights and happiness of his subjects.

At present, Germany is bounded, on the north, by the Baltic Sea, Denmark, and the German Ocean; on the east, by Prussia, Hungary, and Poland; and on the west by the Low Countries, Lorraine, and Franche Comte: so that it now comprehends the Palatinate, of Cologne, Triers, and Liege, which formerly belonged to the Gauls; and is dismembered of Friesland, Groningen, and Over yssel, which are now incorporated with the Low Countries.

Since the time of Charles the Great, this country

4 U

has

Germany.

²¹ *Germany.* has been divided into High and Low Germany. The first comprehends the Palatinate of the Rhine, Franconia, Suabia, Bavaria, Bohemia, Moravia, Austria, Carinthia, Carniola, Stiria, the Swifs, and the Grifons. The provinces of Lower Germany are, the Low Country of the Rhine, Triers, Cologne, Mentz, Westphalia, Hesse, Brunswic, Misnia, Lufatia, High Saxony upon the Elbe, Low Saxony upon the Elbe, Mecklenburgh, Lunenburg, Brandenburg, and Pomerania.

²² *Situation, extent, &c. of Germany.*
Constitution of the empire.

Monarchy was first established in Germany by Clodovick: after him Charlemagne extended his power and his dominions; and so great had the empire become, that during his reign, and that of his son, government was administered in the provinces by persons vested with power for that purpose under the title of *Dukes*. In the districts of these provinces, justice was distributed by a comes or count, which officer was in German called *Graf*. But from their courts lay an appeal to that of the emperor, before a president styled *Comes Palatinus*, that is, "count Palatine, or of the palace," in German denominated *Pfalzgraf*. The frontiers or marches were governed by a marquis, styled by the Germans *Markgraf*, similar to the lord warden in England. Generally the centre of the empire was ruled by an officer, who possessed a similar power, but a greater extent of dominion, than the Grave, under the title of *Landgrave*. Towns and castles, which were occasionally honoured with the residence of the emperor, were governed by a *Burggraf*. It may be remarked, however, that the signification of the above mentioned titles, and the extent of power which they conferred upon the persons honoured with them, differ according to the successive ages and the gradual development of the German constitution.

By reason of family broils in the Imperial house, and civil wars in the dominions, the dignity of the sovereign was depressed, and a new form in the government raised up. The dukes exalted themselves above the power of the emperor, and secured for their sons a succession to their greatness; while the interest of the sovereign, in order to strengthen the bond of personal attachment, ratified to others and their descendants that sway which had been formerly delegated and dependent on his will. Hence arose the modern constitution of distinct principalities, acknowledging one head in the person of the emperor. But shortly after the election of Conrade duke of Franconia to the throne, this new-gained authority of the princes became doubtful. However, after most violent disturbances and confusions, the regulations yielded to by Albert II. and his successors, particularly by Frederick III. laid the foundation of the German constitution: but the power and form of which were afterwards improved by Maximilian. Before Charles V. mounted the throne on the death of Maximilian, the electors formed a bulwark against the Imperial power, by an instrument called the *capitulation*; to which articles of government he and all emperors elected since have sworn previous to their investiture with Imperial dignity.

²³ *Of the electors.*

When the German monarchy received an elective form, the right of election was not limited to the great officers of state, for other princes participated of this privilege. But the empire being governed by four dukes, the princes under their authority, in order to

court their favour, gave to them the disposal of their votes, and of those of their vassals. The three archbishops also, who were necessarily present at the coronation, obtained the electoral dignity. However, beside this origin of the modern electors, the high stations about court procured their possessors an influence over other members, and their general residence there gave them a solid advantage in their constant and early presence at the diet of election. For in times of turbulence several emperors were elected, when princes had not an opportunity to attend. And hence sprung up a sanction to that right, which the high officers of the household had assumed, of electing without any consultation of the other members of the empire. Pope Gregory X. too, either conceiving that they did possess, or willing that they should acquire, this right, exhorted them in a bull to terminate the troubles of Germany by electing an emperor. And since that period they have been held as the sole electors. But the possession of this high power was strengthened by a league amongst themselves called the *electoral union*, which received additional confirmation from the emperor Louis of Bavaria, and was formally and fully ratified by that famous constitution of Charles IV. termed the *golden bull*; according to which, the territories and the high offices by which the electoral dignity is conveyed, must descend according to the right of primogeniture, and are indivisible.

The golden bull declares the following number and titles of the electors: The archbishop of Mentz as great chancellor of the German empire; the elector of Cologne as great chancellor of the empire in Italy; the elector of Triers as great chancellor of the empire in Gaul and Arles; the king of Bohemia as cup-bearer; the count Palatine as high steward, the duke of Saxony as grand marshal; the margrave of Brandenburg as grand chamberlain. The number originally was seven, but the emperor Leopold created the duke of Lunenburg, ancestor to the present British sovereign, an elector; to whom the post of arch-treasurer was afterwards given; and thus Hanover forms the eighth electorate. But this number cannot be increased by the emperor without a previous election by the electors themselves; who, thus capable of electing, and of being elected, may style themselves *Coimperantes*; and they exercise part of the imperial authority, if a vacancy of the throne happen. But when or before this occurs, the election of the emperor is proceeded to after the following manner: The elector of Mentz, before the lapse of a month after the death of the emperor, summons, as great chancellor of the empire, the rest of the electors to attend on some fixed day within the space of three months from the date of the summons. The electors generally send their ambassadors to the place of election, which is held at Frankfort on the Mayne; but saving the right of the city of Frankfort, it may be held elsewhere.

²⁴ *Election of the emperor.*

When the diet of electors is assembled, they proceed to compose the capitulation, to which the emperor when elected is to swear. The capitulation being adjusted, the elector of Mentz appoints a day for the election. When this day arrives, the gates of the city are shut, and the keys delivered to the elector of Mentz. The electors or their ambassadors, protestants excepted, repair in great pomp to mass; and after its celebration

Germany. bration they took a solemn oath to choose, unbiassed and uninfluenced, the person that appears most proper for the imperial dignity. After this they repair to the sacristy, where the elector of Mentz first asks, if there be any impediment known against their proceeding at present to an election? and next he obtains a promise that the person elected by the majority shall be received as emperor. The declarations of the electoral ambassadors, in respect to these two points, are recorded by two notaries of the empire. Then all witnesses withdraw; and the elector of Mentz collecting the suffrages, which are *viva voce*, and giving his own last, the witnesses are recalled, and he declares the person whom the electors had chosen. But the election is not complete, nor is the new emperor proclaimed, until the capitulation be sworn to either by himself or by his ambassadors if he be absent. From this time he is styled king of the Romans until the coronation takes place; which ceremony confers the title of emperor. According to the golden bull, it should be celebrated at Aix-la-Chapelle, out of respect to Charlemagne, who resided there; but saving the right to Aix la-Chapelle, it may take place elsewhere. The coronation is performed by the archbishop of Mentz or elector of Cologne. And when he is seated on his throne, the duke of Saxony delivers into his hand the sword of Charles the Great, with which he makes some knights of the holy Roman empire, and is also obliged to confer that honour upon such others as are nominated by the respective electors. When he proceeds to dinner in the great hall, he is seated at a table elevated two steps higher than that of the electors, and is served by counts of the empire. The electors, each of whom has also his table, are attended by the gentlemen of their respective courts. These electors, who assist personally at the ceremony, sit and eat at their own tables; but those who are represented by ambassadors have only their tables covered out of form with plates, at which the ambassadors do not sit.

For the benefit of the empire during the reign of an emperor, his presumptive successor may be elected king of the Romans. But this election confers at first a mere title; for by an express article in his capitulation, the king of the Romans swears not to interfere with the government during the life of the emperor; but on his decease, the coronation confirms him emperor without a second election.

Should there not be a king of the Romans, and the throne become vacant, the government is administered by vicars of the empire, who are the electors Palatine and of Saxony, as count palatine and arch-marshal of the empire. Each has his district and tribunal of the vicariate; and by the golden bull it is established, that all acts of the vicars are valid; but they are all fully confirmed by the emperor; which confirmation, by an article of his capitulation, he is bound to give.

There are also vicars of the emperor. These offices are constituted by a delegation of the imperial power from the emperor to any prince of the empire, when he is unable to execute his authority himself. But these vicars stand accountable to the emperor; their acts may be annulled and their offices revoked, all dependent on the will of the emperor, and determinable at his pleasure.

When the race of Charlemagne ceased to govern in Germany. Germany, the princes and states associated to continue the empire; and that its majesty might be visible, and its laws enforced, they agreed to choose an emperor. From this emperor all electors and princes except those before 1582 receive investiture of their dominions; counts and free cities from the Aulic council. But this investiture is no more than a sign of submission to the majesty of the empire, which is deposited in the emperor. For as the constituted members of the empire are dependent on that collective union from which they derive protection, they therefore show this dependence on the emperor, because he represents the majesty of the union, or of the empire; but in all other respects they are independent and free.

These princes or sovereigns may even wage war with the prince wearing the imperial crown, as possessed of other titles and dominions unconnected with his imperial station. Nor can the sovereignty of any member be affected so long as he remains loyal to the empire; which loyalty constitutes his duty, and secures him its protection. But should he be guilty of any violation against the emperor, as head of the empire, such a crime would commit him to the punishment of its laws, and he would be put under the ban. For this crime would be against that collective body of sovereigns whose union constitutes the empire; and therefore any violation of that union is justly punished with deprivation of these territories which render such sovereigns members of the empire. Nor can this punishment of the ban derogate from the dignity of those princes who derive their sovereignty from this constitution, and whose subjection is an act of their own consent. However, no member of the empire can at present be put under the ban without being first heard, and without the concurrence of the electors, princes, and states, being previously obtained.

The emperor is endowed with many privileges, and his power partly appears in the exercise of his reserved rights, or the peculiar prerogatives annexed to the imperial dignity. He grants to princes the investiture of their dominions; but to this he is bound as the laws direct. He confers titles, but promises that they shall be bestowed only on such persons as will maintain their dignity, and can support their rank. Beside, he can give merely the title: for the power or privilege of prince or count can be obtained only from their respective bodies. But in some instances, even titles are of high importance. For the descendants of a prince are incapable of succession, if their mother be of inferior rank to their father; but the conferring of a title ennobles her and removes the bar, if the collateral line consents.

The emperor can also make cities, found universities, grant the privilege of fairs, &c. He can also dispense with the tedious terms of minority, and empower princes to assume at an earlier age the government of their own dominions. He decides all rank and precedency, and has a power of *primæ preces*, that is, of granting for once in every chapter of the empire a vacant seat. But he is not above the law; for electors have not only chosen but deposed emperors. However, the influence of the capitulation is to prevent such rigorous proceedings: but should the capitulation be violated, the college of electors might proceed to remonstrance; and if these remonstrances should

25

Powers of
the emperor.

Germany. be without effect, in conjunction with the diet, they might resort to more forcible remedies.

²⁶
Diet of the empire.

The diet is that assembly of the states in which the legislative power of the empire resides; and is composed of the electors, princes, prelates, counts, and free cities of the empire. It has sat since 1663, and is held usually at Ratisbon. The emperor, when present, presides in person; when absent, by his commissary, whose communication of proposals from the emperor to the assembly is called the *commissorial decree*. The elector of Mentz, as chancellor of the empire, is director of the diet; and to his chancery are all things addressed that are to be submitted to the empire; the reading of which by his secretary to the secretaries of the other ministers at the diet is denominated *per dictaturam*, and constitutes the form of transmitting papers or memorials to the dictature of the empire — The diet is composed of three distinct colleges, each of which has its particular director. The first college is that of electors; of which the archbishop of Mentz is director as first elector. The second college is that of princes. It consists of princes, archbishops and bishops; and of prelates, abbots, and counts, who are not considered as princes. Each prince spiritual and temporal has a vote, but prelates and counts vote by benches. The prelates are divided into two benches, the counts into four: and each bench has only one vote. The archduke of Austria and the archbishop of Saltzburg are alternately directors of the college of princes. The third college is that of the free cities of the empire; the director of which is the minister of the city in which the diet happens to sit.

In all these colleges, the sentiments of the majority is conclusive, except in respect of fundamental laws, which affect the whole empire, or such matters as relate to religion. In these they must be unanimous.

Where religion is interested, the proceedings are also different. The colleges are then considered as consisting of two bodies, the *evangelic* and the *catholic*; and if any religious points be proposed, it must meet not only the unanimous concurrence of the proposing body, but must have the majority of the other to establish it. This distinction arose from a conjunction called the *evangelic body*; which was formed by the Protestant states and princes to guard the Protestant interest in Germany, by watching over the laws for the security of their religion, and, in case of violation, by obtaining redress from the imperial throne. For in any part of the empire, as in the palatinate, where the count is a Papist and the subjects are Protestants, should oppressions arise, application would be made to the evangelic body through the director. The elector of Saxony is director of the evangelic body, though he is a Papist: but therefore his representations in favour of the Protestants have more force; and beside, should he abuse an office which invests him with considerable weight and influence, he could be instantly deprived of it.

The first two colleges are styled superior, and in effect constitute the diet: for all points that come before the diet, are generally first deliberated in the college of electors, and pass from that to the college of princes; in which, if any objections arise, a free conference takes place between the directors of each college. And should they, in consequence of this free

conference, concur, they invite the third college to accede to their joint opinion; which invitation is generally complied with: but should this college return a refusal, the opinion of the other two colleges is in some few cases engrossed in the chancery, and delivered to the emperor's commissary as the opinion of the empire. The opinion of the third college is merely mentioned at the close. However, though the superior colleges do in effect constitute the diet: yet the received maxim is, that no two colleges constitute a majority, that is, the majority of voices at the diet; nor can the emperor confirm the opinion of two colleges as an opinion of the diet. By the peace of Westphalia, a decisive vote was recognized as a right of the imperial cities, which the two superior colleges should not infringe upon; their vote being, by the fundamental law, of equal weight with that of the electors and princes.

After a measure is approved of by the colleges, it is submitted to his imperial majesty to receive his negative or confirmation. Should he approve the point, it is published in his name as the resolution of the empire, which states are exhorted to obey, and tribunals desired to consider as such.

The diet not only makes and explains laws, but decides ambiguous cases. It must also be consulted before war is made; appoints the field-marshal who is to command the army, and assigns him his council of war. The diet also enters into and makes alliances, but usually empowers the emperor to negotiate them; and foreign states have their ambassadors at the diet, but the diet sends no ministers to foreign courts.

In the origin of the empire, justice was administered in the districts of the provinces by counts, and appeals lay from their courts to that of the emperor before the count palatine. But as civil broils shook the power of the emperor, they interrupted also the course of justice. The consequent inconveniences caused several solicitations to be preferred from the states to different emperors for the establishment of a court of justice, which should take cognizance of great as well as small causes. And at length such a court was erected by Maximilian I. under the title of the *Imperial Chamber at Worms*, in the year 1495; but was removed to Spires in 1533, and to Weizlar in 1696, where it is now held. The members of this court are a judge of the chamber and 25 assessors, partly Protestants partly Papists. The president is appointed by the emperor, the assessors by the states. The court receives appeals from inferior jurisdictions, and decides dubious titles; and all causes before it between prince and prince, or princes and private persons, are adjudged according to the laws of the respective parties, or according to the Imperial law. This tribunal is under the inspection of visitors appointed by the states; and, during their visitation, the sentences of the court are subject to revision. Appeals lie afterwards also from the judgment of the visitors to that of the diet.

The emperors, finding themselves deprived of many of their powers, wished to raise their prerogatives by forming a tribunal, of which they would name the judges, and before whom causes in the last resort should come. But Maximilian foresaw, in respect to the new tribunal, that though a consciousness of its importance made the states struggle for its erection, the expences of its establishment would make them neglect

Germany.

²⁷

stration of
justice, &c.

²⁸
Aulic
council.

Germany. its support ; and the event bore witness to his sagacity. But when, through the omissions and negligence of the states, there happened to be a cessation in the distribution of justice by the Imperial chamber, he revived his court of the count Palatinate or Aulic council. And in order to gain the quiet acquiescence of the states, under the mask of a partition of power, and of generous moderation, he desired them to add eight to the number of assessors, and the salaries of all should be discharged by him. The states swallowed the bait, but soon perceived that they had lost part of their liberty.

The emperor, by keeping the tribunal always open, by filling its seats with men of first-rate talents, and by having its sentences duly and speedily executed, drew all causes before it. The states remonstrated, declaring, that the Imperial chamber ought to be not only the supreme, but sole tribunal of that kind. The emperor answered, that he had erected the Imperial chamber in consequence of their solicitations ; but as they had not supplied the tribunal with judges, he provided for that deficiency by a constant administration of justice in the establishment of another.

The Aulic counsel now subsists with equal authority, each receiving appeals from inferior jurisdictions ; but neither appealing to the other, as the *dernier resort* from both must be had to the diet. However to the Aulic council belong the reserved right of the emperor ; and to the Imperial chamber also are annexed peculiar powers. The Imperial chamber subsists during a vacancy of the throne under the authority of the vicars of the empire ; whereas the Aulic council does not exist until appointed by the succeeding emperor.

The Aulic council consists of a president, vice-president, and seventeen assessors, of whom six are Protestants. The vice-chancellor of the empire is also intitled to a seat ; and all decrees issuing from the council pass through his hands to those who are to execute them. This tribunal obtains for the emperor, through the appeals from the courts of other princes, a new authority beside that which he possesses from his reserved rights ; but electors and some princes, as those of Hanover, Austria, Brunswick, Swedish Pomerania, Hesse, are free from this dependence on the emperor, to whose Aulic council their subjects cannot appeal : nor can it take cognizance of ecclesiastical or criminal causes, both of which appertain to territorial justice ; which we shall presently consider when we have surveyed the executive instrument of Imperial justice.

The division of the empire, into circles is a regulation coeval with the establishment of the Imperial chamber by Maximilian, in order to strengthen the arm of justice with vigour to enforce its decrees. The original division was into six circles, which are called the *ancient circles* ; and are Bavaria, Franconia, Suabia, Lower Saxony, the Upper Rhine, and Westphalia. But the powerful princes, who at first declined bringing their dominions under the form of circles, were led by a political finesse of the emperors to adopt the regulation, and increase the number to ten, by forming the four new circles of Austria, Burgundy, the electorate circle, and Upper Saxony.

Over these circles preside directors, to whom the tribunals of justice commit the execution of their decrees. The six old circles have two directors each,

the four new have one each. The office of director is permanent and hereditary, as it belongs always to the first prince in the circle, upon whom it confers high authority : for all the decrees of the Imperial chamber and Aulic counsel are of no avail unless the director will execute them.

The directors of the circles are not only instruments of war but of peace : for in case of an Imperial war, they are to collect the troops of the circle ; and if any state or prince of their respective circles suffer violation from others, they are to yield protection and enforce the peace ; or should there be any tumultuous uprisings of the people, the suppression of such belongs to them.

The emperor is the executive instrument of the whole empire ; the directors are such of the constitutive parts called circles. The prosperity and security of which being at stake, the directors, as presidents, must hold frequent diets in their respective circles, in order to consult on and adopt salutary measures for their safety and welfare : but as the interests of those near to us are generally so intimately blended with our own, that the good of either cannot be pursued without the mutual concurrence of both, there arise negotiations on particular points between the diets of different circles, which are therefore styled *confederate circles* : and these negotiations being more frequent amongst the circles of the Upper and Lower Rhine, or Westphalia, they are denominated the *corresponding circles*.

Every prince is sovereign in his own country ; and may enter into alliances, and pursue by all political measures his own private interest, as other sovereigns do ; for if even an Imperial war be declared, he may remain neuter if the safety of the empire, be not at stake.

Each state or sovereign appoints in general three colleges for its government. The first is the *geheimerath*, or privy council ; the second is the *regierung*, or regency ; the third the *rentkammer*, or chamber of finances. Each of these has a president ; and a member of the first college is always president of the second.—The *geheimerath* represents the prince, and superintends the other two. The *regierung* regulates limits of territories, holds conferences with other princes, and is in most countries a court of justice ; however in some states there is also a court of justice called *justitz department*. And besides the right of conferences assigned to the *regierung* by the sovereign when there are disputes between princes, there are also an *austrage*, or arbitration, appointed in order to decide them. Attention must be paid to this privilege of princes, who must be called on to appoint an *austrage* before resort be had to the Imperial tribunal, but to which there still lies an appeal from the judgment of the *austrage*. The *rentkammer* attends to the regulation of domains and estates, to the territorial revenues, and management of the taxes.

Every sovereign or prince is arbitrary in laws of policy, but not of revenue ; for no new tax or impost can be laid on his country without the consent of the nobles and subjects. For this purpose, on the *land tag*, or day on which his subjects are to be convened, which is once in the period of four or five years, and at no other time can he assemble them, he calls together,

Germany.

29

Powers of the German princes.

Germany. ther the nobles and commissaries or deputies of the towns of his dominions. The nobles usually attend in person, but may send representatives. To this assembly the prince proposes the taxes, &c. and a majority of voices disposes of the measures.

Villages, though considerable, send no deputies to this assembly; because they are either already represented by their respective lords, or because they rank too low, being in a state of vassalage when compared to towns; for their inhabitants must mend highways, and can be impressed as soldiers; from both of which inhabitants of towns are exempt.

On the land tag, the respective quotas also of each place are fixed, in order to discharge the princes contingent in case of an Imperial war.

30
Military force and annual revenue.

There is no fixed standing army of the empire; but the various states furnish their quotas pursuant to the agreement of 1681, when called upon by the diet in case of war, viz.

	Foot.	Horse.
Upper Saxony	2707	1321
Lower Saxony	2707	1321
Westphalia	2707	1321
Upper Rhine	2853	491
Lower Rhine	2707	600
Burgundy	2707	1321
Franconia	1902	980
Austria	5507	2521
Bavaria	1494	800
Swabia	2707	1321

Total - 27,998 11,997

The whole number of forces in the service of the several German princes have been stated at half a million; others calculate that the ecclesiastical princes can furnish 74,500 men, the temporal princes 379,000 and the emperor 90,000, as head of the house of Austria. Total 543,500.

The revenue accruing to the emperor as such in time of peace, is very trifling, only about 20,000 crowns, being the contribution of a few imperial towns; but in case of war, extraordinary aids, called *Roman months*, laid on by the diet, are contributed by the different circles at the following rate for raising 1½ million of florins, viz.

	Florins.	Xtr.
Upper Saxony	156,360	15
Lower Saxony	156,360	15
Westphalia	156,360	15
Upper Rhine	101,411	30
Lower Rhine	105,654	5
Burgundy	156,360	15
Franconia	113,481	25
Austria	306,390	20
Bavaria	91,261	5
Swabia	156,360	15

Total - 1,499,999 40

The actual revenue of all Germany has been calculated at nearly L. 18,000,000 sterling, or 100 million of dollars.

31
Productions and commerce.

From the great extent of the empire, every variety of soil is to be met with; but it is upon the whole more fertile than otherwise. The middle parts are most productive in corn and cattle; the southern abound with excellent wines and fruits. The northern part from their coldness, are rather unfavourable to vege-

tation; however, agriculture throughout improves exceedingly. Their mines, though early explored, still continue great sources of wealth. They produce, excepting tin, almost every mineral. Of quicksilver, one mine alone is computed to yield 5000 pounds weight a-year. They furnish the finest sort of clay for porcelain, and have excellent and extensive salt-works.

From the central situation of Germany, its commerce with the rest of Europe is very extensive. Its minerals are decidedly the first native articles for trade; after which its medicinal waters, salt, hemp, flax, linen, silk, wines, fruits, corn, cattle, stuffs, cloths, timber, porcelain, wrought iron and steel, drugs, oil, and colours, are the principal. The artizans furnished by the revocation of the edict of Nantz, enable Germany no longer to stand in need of the wrought silks of other countries. Great commercial fairs still exist in Germany, and it is considered upon the whole that the balance of trade is in its favour.

With regard to the character of the ancient Germans, they are described to us by the Greek and Roman writers as resembling the Gauls; and differing from other nations by the largeness of their stature, ruddy complexion, blue eyes, and yellow bushy hair, haughty and threatening looks, strong constitutions, and being proof against hunger, cold, and all kinds of hardship.

32
Character of the ancient Germans.

Their native disposition displayed itself chiefly in their martial genius, and in their singular fidelity. The former of these they did indeed carry to such an excess as came little short of downright ferocity; but, as to the latter, they not only valued themselves highly upon it, but were greatly esteemed by other nations for it; insomuch that Augustus, and several of his successors, committed the guard of their persons to them, and almost all other nations either courted their friendship and alliance, or hired them as auxiliaries: though it must be owned, at the same time, that their extreme love of liberty, and their hatred of tyranny and oppression, have often hurried them to treachery and murder, especially when they have thought themselves ill used by those who hired them: for in all such cases they were easily stirred up, and extremely vindictive. In other cases, Tacitus tells us, they were noble, magnanimous, and beneficent, without ambition to aggrandize their dominions, or invading those from whom they received no injury; rather choosing to employ their strength and valour defensively than offensively; to preserve their own, than to ravage their neighbours.

Their friendship and intercourse was rather a compound of honest bluntness and hospitality, than of wit and humour, or gallantry. All strangers were sure to meet with a kind reception from them to the utmost of their ability; even those who were not in a capacity to entertain them, made it a piece of duty to introduce them to those who could; and nothing was looked upon as more scandalous and detestable, than to refuse them either the one or the other. They do not seem, indeed, to have had a taste for grand and elegant entertainments: they affected in every thing, in their houses, furniture, diet, &c. rather plainness and simplicity, than sumptuousness and luxury. If they learned of the Romans and Gauls the use of money, it was rather because they found it more convenient than

Germany. than their ancient way of bartering one commodity for another; and then they preferred those ancient coins which had been stamped during the times of the Roman liberty, especially such as were either milled or cut in the rims, because they could not be so easily cheated in them as in some others, which were frequently nothing but copper or iron plated over with silver. This last metal they likewise preferred before gold, not because it made a greater show, but because it was more convenient for buying and selling: And as they became in time more feared by, or more useful to, the Romans; so they learned how to draw enough of it from them to supply their whole country, besides what flowed to them from other nations.

As they despised superfluities in other cases, so they did also in the connubial way: every man was contented with one wife, except some few of their nobles, who allowed themselves a plurality, more for show than pleasure; and both were so faithful to each other, and chaste, true, and disinterested, in their conjugal affections, that Tacitus prefers their manners in this respect to those of the Romans. The men sought not dowries from their wives, but bestowed them upon them. Their youth, in those cold climes, did not begin so soon to feel the warmth of love as they do in hotter ones: it was a common rule with them not to marry young; and those were most esteemed who continued longest in celibacy, because they looked upon it as an effectual means to make them grow tall and strong; and to marry, or be concerned with a woman, before they were full 20 years old, was accounted shameful wantonness. The women shared with their husbands not only the care of their family, and the education of their children, but even the hardships of war. They attended them in the field, cooked their victuals for them, dressed their wounds, stirred them up to fight manfully against their enemies, and sometimes have by their courage and bravery recovered a victory when it was upon the point of being snatched from them. In a word, they looked upon such constant attendance on them, not as a servitude, like the Roman dames, but as a duty and an honour. But what appears to have been still a harder fate upon the ancient German dames was, that their great Odin excluded all those from his *valhalla*, or paradise, who did not, by some violent death, follow their deceased husbands thither. Yet notwithstanding their having been anciently in such high repute for their wisdom and supposed spirit of prophecy, and their continuing such faithful and tender helpmates to their husbands, they sunk in time so low in their esteem, that, according to the old Saxon law, he that hurt or killed a woman was to pay but half the fine that he should have done if he had hurt or killed a man.

³³
Their funerals...

There is scarcely any one thing in which the Germans, though so nearly allied in most of their other customs to the Gauls, were yet more opposite to them than in their funerals. Those of the latter were performed with great pomp and profusion; those of the former were done with the same plainness and simplicity which they observed in all other things: the only grandeur they affected in them was, to burn the bodies of their great men with some peculiar kinds of wood; but then the funeral pile was neither adorned with the clothes

and other fine furniture of the deceased, nor perfumed with fragrant herbs and gums: each man's armour, that is, his sword, shield, and spear, were flung into it, and sometimes his riding-horse. The Danes, indeed, flung into the funeral-pile of a prince, gold, silver, and other precious things, which the chief mourners, who walked in a gloomy guise round the fire, exhorted the bystanders to fling liberally into it in honour of the deceased. They afterwards deposited their ashes in urns, like the Gauls, Romans, and other nations; as it plainly appears, from the vast numbers which have been dug all over the country, as well as from the sundry dissertations which have been written upon them by several learned moderns of that nation. One thing we may observe, in general, that, whatever sacrifices they offered for their dead, whatever presents they made to them at their funerals, and whatever other superstitious rites they might perform at them, all was done in consequence of those excellent notions which their ancient religion had taught them, the immortality of the soul, and the bliss or misery of a future life.

It is impossible, indeed, as they did not commit any thing to writing till very lately, and as none of the ancient writers have given us any account of it, to guess how soon the belief of their great Odin, and his paradise, was received among them. It may, for aught we know, have been older than the times of Tacitus, and he have known nothing of it, by reason of their scrupulous care in concealing their religion from strangers: but as they conveyed their doctrines to posterity by songs and poems, and most of the northern poets tell us that they have drawn their intelligence from those very poems which were still preserved among them; we may rightly enough suppose that whatever doctrines are contained in them, were formerly professed by the generality of the nation, especially since we find their ancient practice so exactly conformable to it. Thus, since the surest road to this paradise was, to excel in martial deeds, and to die intrepidly in the field of battle: and since none were excluded from it but base cowards, and betrayers of their country; it is natural to think, that the signal and excessive bravery of the Germans flowed from this ancient belief of theirs: and, if their females were so brave and faithful, as not only to share with their husbands all the dangers and fatigues of war, but at length to follow them by a voluntary death, into the other world; it can hardly be attributed to any thing else but a strong persuasion of their being admitted to live with them in that place of bliss. This, belief, therefore, whether received originally from the old Celtes, or afterwards taught them by the since deified Odin, seems, from their general practice, to have been universally received by all the Germans, though they might differ one from another in their notions of that future life.

³⁴
Their belief of a future state.

The notion of a future happiness obtained by martial exploits, especially by dying sword in hand, made them bewail the fate of those who live to an old age, as dishonourable here, and hopeless hereafter: upon them account, they had a barbarous way of sending them into the other world, willing or not willing. And this custom lasted several ages after their receiving Christianity, especially among the Prussians and Veni-di; the former of whom, it seems, dispatched by a quick

Germany. quick death, not only their children, the sick, servants &c. but even their parents, and sometimes themselves: and among the latter we have instances of this horrid parricide being practised even in the beginning of the 14th century. All that need be added is, that, if those persons, thus supposed to have lived long enough, either desired to be put to death, or at least seemed cheerfully to submit to what they knew they could not avoid, their exit was commonly preceded with a fast, and their funeral with a feast; but if they endeavoured to shun it, as it sometimes happened, both ceremonies were performed with the deepest mourning. In the former, they rejoiced at their deliverance, and being admitted into bliss; in the latter, they bewailed their cowardly excluding themselves from it. Much the same thing was done towards those wives who betrayed a backwardness to follow their dead husbands.

35
Remark-
able for
drinking to
excess.

We must likewise observe, that, in these funerals, as well as in all their other feasts, they were famed for drinking to excess; and one may say of them, above all the other descendants of the ancient Celtes, that their hospitality, banquets, &c. consisted much more in the quantity of strong liquors, than in the elegance of eating. Beer and strong mead, which were their natural drink, were looked upon as the chief promoters of health, strength, fertility, and bravery; upon which account, they made no scruple to indulge themselves to the utmost in them, not only in their feasts, and especially before an engagement, but even in their common meals.

36
Character
of the mo-
dern Ger-
mans.

The modern Germans in their persons are tall and strong built. The ladies have generally fine complexions; and some of them, especially in Saxony, have all the delicacy of features and shape that are so bewitching in a certain island of Europe.

Both men and women affect rich dresses, which in fashion are the same as in France and England; but the better sort of men are excessively fond of gold and silver lace, especially if they are in the army. The ladies at the principal courts differ not much in their dress from the French and English, only they are not so excessively fond of paint as the former. At some courts they appear in rich furs; and all of them are loaded with jewels, if they can obtain them. The female part of the burghers families, in many German towns, dress in a very different manner, and some of them inconceivably fantastic, as may be seen in many prints published in books of Travels; but in this respect they are gradually reforming, and many of them make quite a different appearance in their dress from what they did 30 or 40 years ago. As to the peasantry and labourers, they dress as in other parts of Europe, according to their employments, conveniency, and opulence. In Westphalia, and most other parts of Germany, they sleep between two feather-beds, or rather the upper one of down, with sheets stitched to them, which by use becomes a very comfortable practice. The most unhappy part of the Germans are the tenants of little needy princes, who squeeze them to keep up their own grandeur; but, in general, the circumstances of the common people are far preferable to those of the French.

The Germans are naturally a frank, honest, hospitable people, free from artifice and disguise. The higher orders are ridiculously proud of titles, ancestry,

and show. The Germans, in general, are thought to want animation, as their persons promise more vigour and activity than they commonly exert even in the field of battle. But when commanded by able generals, especially the Italians, such as Montecuculi and prince Eugene, they have done great things, both against the Turks and the French. The Imperial arms have seldom made any remarkable figure against either of those two nations, or against the Swedes or Spaniards, when commanded by German generals. This possibly might be owing to the arbitrary obstinacy of the court of Vienna; for in the two last wars the Austrians exhibited prodigies of military valour and genius.

Industry, application, and perseverance, are the great characteristics of the German nation, especially the mechanical part of it. Their works of art would be incredible were they not visible, especially in watch and clock making, jewellery, turnery, sculpture, drawing, painting, and certain kinds of architecture. The Germans have been charged with intemperance in eating and drinking; and perhaps not unjustly, owing to the vast plenty of their country in wine and provisions of every kind. But those practices seem now to be wearing out. At the greatest tables, though the guests drink pretty freely during dinner, yet the repast is commonly finished by coffee after three or four public toasts have been drank. But no people have more feasting at marriages, funerals, and birth-days.

The German nobility are generally men of so much honour, that a sharper in other countries, especially in England, meets with more credit if he pretends to be a German, than of any other nation.

The merchants and tradesmen are very civil and obliging. All the sons of noblemen inherit their fathers titles, which greatly perplexes the heralds and genealogists of that country. This perhaps is one of the reasons why the German husbands are not quite so complaisant as they ought otherwise to be to their ladies, who are not intitled to any pre-eminence at the table; nor indeed do they seem to effect it, being far from either ambition or loquacity, though they are said to be somewhat too fond of gaming. From what has been premised, it may easily be conceived, that many of the German nobility having no other hereditary estate than a high-sounding title, easily enter into their armies, and those of other sovereigns. Their fondness for title is attended with many other inconveniences. Their princes think that the cultivation of their lands, though it may treble their revenue, is below their attention; and that, as they are a species of beings superior to labourers of every kind, they would demean themselves in being concerned in the improvement of their grounds.

The domestic diversions of the Germans are the same as in England; billiards, cards, dice, fencing, dancing, and the like. In summer, people of fashion repair to places of public resort, and drink the waters. As to their field-diversions, besides their favourite one of hunting, they have bull and bear beating, and the like. The inhabitants of Vienna live luxuriously, a great part of their time being spent in feasting and carousing; and in winter, when the several branches of the Danube are frozen over, and the ground covered

37

Germination.

with snow, the ladies take their recreations in sledges of different shapes, such as griffins, tygers, swans, scollop-shells, &c. Here the lady sits, dressed in velvet lined with rich furs, and adorned with laces and jewels, having on her head a velvet cap; and the sledge is drawn by one horse, stag, or other creature, set off with plumes of feathers, ribbons, and bells. As this diversion is taken chiefly in the night-time, servants ride before the sledge with torches, and a gentleman sitting on the sledge behind guides the horse.

38
Religion
and learn-
ing.

The Reformation first spread in Germany to most advantage: and since the religious peace of 1555, there have been established the Roman Catholic, prevailing mostly in the south; the Lutheran in the north; and the Calvinist, called also the *Reformed*, near the Rhine. Civil wars considerably deranged this settlement: it was, however, established by the celebrated peace of Westphalia, that the religion of the Seven States should remain as in 1624. The Romish superior clergy consist of eight archbishops, 40 bishops, and many abbots. The Protestant clergy are governed by consistories under the sovereign of each state. The *Corpus Catholicorum* is under the direction of the archbishop, elector of Mentz; and the *Corpus Evangelicorum*, or Protestants, under the elector of Saxony; who have the care of the public concerns of their respective bodies.

Literature is at present in a very advanced state throughout almost all Germany, but particularly in the Protestant states. It is but about half a century since the German language has been purified and cultivated; since which various works of taste and elegance, as well as superior productions in the different walks of science, have appeared in it.—There are 38 universities in Germany; 19 Protestant, 17 Catholic, and 2 which partake of both; besides a number of literary societies and academic institutions: and education in general is particularly attended to even in the very lowest ranks.

GERMEN, the seed-bud; defined by Linnæus to be the base of the pistillum, which contains the rudiments of the seed; and, in progress of vegetation, swells and becomes the seed-vessel.

In assimilating the vegetable and animal kingdoms, Linnæus denominates the seed-bud the *ovarium* or *uterus* of plants; and affirms its existence to be chiefly at the time of the dispersion of the male-dust by the antheræ; as, after its impregnation, it becomes a seed-vessel. See BOTANY.

GERMEN, by Pliny and the ancient botanists, is used to signify a bud containing the rudiments of the leaves. See GEMMA.

GERMINATION, among botanists, comprehends the precise time which the seeds take to rise after they have been committed to the soil.—The different species of seeds are longer or shorter in rising according to the degree of heat which is proper to each. Millet, wheat, and several of the grasses, rise in one day; blite, spinach, beans, mustard, kidney-beans, turnips, and rocket, in three days; lettuce and dill, in four; cucumber, gourd, melon, and cress, in five; raddish and beet, in six; barley, in seven; orach, in eight; purslane, in nine; cabbage, in ten; hyssop, in thirty; parsley, in forty or fifty days; peach, almond, walnut, chefnut,

VOL. VII.

pæony, horned-poppy, hyecoum, and ranunculus fal-catus, in one year; rose-bush, cornel-tree, hawthorn, medlar, and hazel-nut, in two. The seeds of some species of orchis, and of some liliaceous plants, never rise at all. Of seeds, some require to be sowed almost as soon as they are ripe, otherwise they will not sprout or germinate. Of this kind are the seeds of coffee and fraxinella. Others, particularly those of the pea-bloom flowers, preserve their germinating faculty for a series of years.—Mr. Adanson asserts, that the sensitive plant retains that virtue for 30 or 40 years.

Air and water are the agents of germination. The humidity of the air alone makes several seeds to rise that are exposed to it. Seeds too are observed to rise in water, without the intervention of earth; but water without air is insufficient.—Mr. Homberg's experiments on this head are decisive. He put several seeds under the exhausted receiver of an air-pump, with a view to establish something certain on the causes of germination. Some of them did not rise at all; and the greatest part of those which did, made very weak and feeble productions. Thus it is for want of air that seeds which are buried at a very great depth in the earth, either thrive but indifferently, or do not rise at all. They frequently preserve, however, their germinating virtue for many years within the bowels of the earth, and it is not unusual, upon a piece of ground being newly dug to a considerable depth, to observe it soon after covered with several plants, which had not been seen there in the memory of man. Were this precaution frequently repeated, it would doubtless be the means of recovering certain species of plants which are regarded as lost; or which perhaps, never coming to the knowledge of botanists, might hence appear the result of a new creation. Some seeds require a greater quantity of air than others. Thus purslane, which does not rise till after lettuce in the free air, rises before it *in vacuo*; and both prosper but little, or perish altogether, while cresses vegetate as freely as in the open air.

GERONTES, in antiquity, a kind of judges, or magistrates, in ancient Sparta, answering to what the Aréopagites were at Athens. See ARÉOPAGUS.

The word is formed of the Greek γερων, which signifies "old man." Whence also the word *gerontic*, something belonging to an old man; and *Geronicon*, a famous book among the modern Greeks, containing the lives of the ancient monks. The senate of gerontes was called *gerusia*, that is, assembly or council of old men.

The gerontes were originally instituted by Lycurgus: their number, according to some, was 28; and according to others, 32. They governed in conjunction with the king, whose authority they were intended to balance, and to watch over the interests of the people. Polybius defines their office in few words, when he says, *per ipsos, & cum ipsis omnia administrari*. None were to be admitted into this office under 60 years of age, they held it for life. They were succeeded by the ephori.

GEROPOGON, in botany: A genus of the polygamia æqualis order, belonging to the syngeneta class of plants; and in the natural method ranking under the 49th order, *Compositæ*. The receptacle is paleaceous, with the points of the paleæ sharp or bristly; the calyx is simple; the seeds of the disc have a feathered pappus; those of the radius have a pappus of five awns.

GERRETZ. See REMBRANDT.

GERVAISE, (or GERVASE), of Tilbury, a famous English writer of the 13th century; thus named from his being born at Tilbury on the Thames. He was nephew to Henry II. king of England; and was in great credit with Otho IV. emperor of Germany, to whom he dedicated a description of the world, and a Chronicle. He also composed a History of England, that of the Holy Land, and other works.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative; as nom. *amandum*, gen. *amandi*, dat. *amando*, accus. *amandum*, abl. *amando*. The word is formed of the Latin *gerundivus*, and that from the verb *gerere*, "to bear."

The *gerund*, expresses not only the *time*, but also the *manner*, of an action; as "he fell in running post." It differs from the participle, in that it expresses the *time*, which the participle does not; and from the tense properly so called, in that it expresses the *manner*, which the tense does not. See GRAMMAR.

GERUNDA, (anc. geog.), a town of the Aufetani, in the Hither Spain, on the south or right side of the river Sambroca. *Gerundenses*, the people. Now *Gironne* in Catalonia, on the Ter. E. Long. 2. 35. Lat. 42.

GESNER (Conrad), a celebrated physician and naturalist, was born at Zurich in 1516. Having finished his studies in France, he travelled into Italy, and taught medicine and philosophy in his own country with extraordinary reputation. He was acquainted with the languages; and excelled so much in natural history, that he was surnamed the *Pliny of Germany*. He died in 1564, leaving many works behind him; the principal of which are, 1. A history of animals, plants, and fossils; *Bibliotheca Universalis*. A Greek and Latin lexicon. This author is by Boerhaave emphatically styled *Monstrum Eruditionis*, a prodigy of learning. Those indeed (as Mr Coxe observes in his Letters on Switzerland) "who are conversant with the works of this great scholar and naturalist, cannot repress their wonder and admiration at the amplitude of his knowledge in every species of erudition, and the variety of his discoveries in natural history, which was his peculiar delight. Their wonder and admiration is still further augmented, when they consider the gross ignorance of the age which he helped to enlighten, and the scanty succours he possessed to aid him in thus extending the bounds of knowledge; that he composed his works, and made those discoveries which would have done honour to the most enlightened period, under the complicated evils of poverty, sickness, and domestic uneasiness.

GESNER (Solomon), the celebrated author of the Death of Abel, and many other admired works in the German language, was born at Zurich in the year 1730. In his early years he showed very few signs of superior abilities; and his progress in the rudiments of education was so slow, that his master gave him up as incapable of any greater attainments than writing and the four first rules of arithmetic. Upon this he was placed under a clergyman in the neighbourhood, a relation of his father's, and who showed himself better acquainted with the art of discovering the

natural inclinations of his pupils. This gentleman often carried young Gefner with him into the fields, where he made him observe the beauties of nature; and finding that he took great pleasure in such lessons, and seemed to listen to them with peculiar attention, he occasionally repeated some of the most striking passages of the ancient authors, who have written on these subjects in the most agreeable and pleasing manner. By this ingenious artifice, the mind of young Gefner began to open, and its powers to expand; and it is, perhaps, owing to this circumstance, that he became so fond of the language of Virgil and Theocritus. When he arrived at a proper age to think of pursuing some line of business, Mr Gefner made choice of that of a bookseller, which was the profession of his father, and in some measure of his family. Of five houses at Zurich in the printing and bookselling business, two were occupied by Gefners: one belonged to two brothers of that name; and the other, that in which our poet had a share, was known by the firm of *Orel, Gefner, and Company*. It was known also by the extent of its correspondence, and by the choice and elegance of the works which it gave the public.

Though Mr Gefner was a bookseller, he did not, however, damp his genius by submitting to the drudgery of business. He indulged himself freely in pursuing his favourite object, and his partners never envied him that time which he devoted to meditation and to study. In 1752, he made a tour through Germany, not so much for the purpose of extending his commerce, as to see and be acquainted with those authors who have done honour to their country. The following circumstance, which occurred during this tour, deserves to be mentioned, as it is strikingly characteristic of that timidity which often accompanies true genius. When Mr Gefner was at Berlin, he was admitted into a literary society, of which Gleim and Lessing were members. Each of the authors who composed it used to read in turn some piece of their own composition, and Mr. Gefner was very desirous of submitting to these able critics a small work, which was his first attempt; but it was far from resembling those poets, whom Horace, and other satyrists have ridiculed, and who stun every one they meet by reciting their verses before them. As each of the members had done reading, Gefner was observed to move his hand with a kind of tremor towards his pocket, and to draw it back again without the manuscript which he ought to have produced. Having not as yet published any thing, none of the company could guess the cause of a motion which his modesty prevented him from explaining. The work which he had not the courage to show, was his small poem, intitled *Night*, which he published on his return to Zurich in 1753. It was considered as an original, of which no model is to be found among the moderns; but in the opinion of the author, it was only a piece of imaginary painting, or, to use an expression of his own, in one of his letters to Mr Huber who has translated his works, "A caricature composed in the moments of folly or intoxication." In this little poem he has introduced a short episode on the origin of the glow-worm, containing a poetical explanation of this natural phosphorus, which has all the beauty of Ovid's *Metamorphoses* without their prolixity.

Gefner.

Gefner. lidity. The success of this essay emboldened the too timid muse of our young bookseller, and he published a pastoral romance, called *Daphnis*, in three cantos. The applause that was deservedly bestowed upon this performance induced the author to publish, some time after, his Idylls and some other rural poems in imitation of those of Theocritus. Pastoral poetry, which at this time was little known in Germany but by translations from foreign poets, began to find many partisans, and to be preferred to every other kind. Desirous, therefore, of tracing out a new path for himself, our poet thought that he could not do a more acceptable service to his countrymen, than to paint the felicity of innocence and rural life, and the tender emotions of love and gratitude. The only author worthy of notice who had preceded Mr Gefner in this career, was Mr Rost of Leipfick, whose pastoral poems appeared for the first time in 1744. This writer polished the language of the German shepherds; he had address enough to unite spirit and simplicity in a kind of writing which appears insipid without the former, and which becomes unnatural and disgusting if it is too abundant. He sometimes throws a delicate veil over those images which are deficient in decency, but it is to be regretted that it is often too slight. Such was the antagonist against whom Gefner had to contend. Our poet, however, pursued a different course. Instead of placing, like Rost, his scenes in modern times, he goes back with Theocritus to the golden age, that happy age which we are fond of reviewing when our passions are calm, and when freed from those anxious cares which hurry us beyond ourselves, we contemplate amidst tranquillity the beauties and fertility of the country. The characters of Gefner's Idylls, therefore, are taken from those societies which exist no longer but in the remembrance or rather the imagination. His shepherds are fathers, children, and husbands, who blush not at these titles so dear to nature, and to whom generosity, beneficence, and respect for the Deity, are sometimes no less familiar than love. These Idylls were the principal and favourite object of his pursuit, and that part of his work which acquired him the greatest reputation, especially among his countrymen. His death of Abel, which is well known, was published for the first time in 1758. It is written, like the rest of his pieces, in poetical prose; and was so much sought after, that it went through no less than three editions in the space of a year, without speaking of the spurious ones which appeared in Holland, at Berlin, and in France. The French edition was followed by several others. One came out in Italian; another in the Dutch language; a fourth in the Danish; and, lastly, two in English, one of them in prose and the other in verse. Among the pieces which Mr Gefner published after the Death of Abel, was his First Navigator, a poem in three cantos, which many people in Germany consider as his master-piece. He made an attempt also in the pastoral drama, but not with the same success as in other kinds of rural poetry. He produced likewise, in the same style, *Evander* and *Alcimne*, in three acts; and *Erastus*, a small piece of one act, which was represented with some applause in several societies, both at Leipfick and Vienna.

But though poetry was Gefner's darling pursuit, and though he enriched the literature of his country

with works which will render his name immortal, he did not confine himself to one manner of imitating nature; he in turns took up the pencil and the pen, and his active genius equally directed them both. In his infancy he had received a few lessons in drawing, and he had afterwards pursued his study, but without any intention of becoming an artist. At the age of thirty, he felt that violent desire, which may be considered as the voice of genius; and this was in some measure excited by the sight of a beautiful collection formed by Mr Heidegger, whose daughter he had married. To please his father-in-law, he studied this treasure, composed principally of the best pieces of the Flemish school; and to this new taste he had almost sacrificed every other. Mr Gefner at first ventured only to delineate some decorations for the frontispieces of curious books printed in his office; but by little and little, he had the courage to make other attempts. In 1765, he published 10 landscapes etched and engraved by himself, and dedicated them to his friend Mr Watelet. Mr Gefner owed him this mark of respect for the care which he took to ornament with beautiful vignettes Mr Huber's translation of his Idylls. Twelve other pieces appeared in 1769; and after these attempts, Mr Gefner executed ornaments for many works which came from his presses, among which were his own works, a German translation of Swift, and several others.

Were we to judge from Mr Gefner's enthusiasm for his favourite pursuits, and from the time and attention which he bestowed upon them, we should be apt to conclude, that he found little leisure for discharging his duty as a citizen. The contrary, however, was the case, for he passed almost the half of his life in the first employments of the state. In 1765 he was called to the grand council, in 1767 to the lesser. In 1768 he was appointed bailiff of Eilibach, that of the four guards in 1776, and in 1781 superintendant of waters, which office in 1787 was continued to him for six years. In all these stations Mr Gefner discharged his duty with the most scrupulous fidelity; and died of a paralytical disorder, lamented by his countrymen and by those who had the pleasure of his acquaintance, on the 2d of March 1788, at the age of 56.

As a pastoral poet, Gefner undoubtedly is intitled to a very distinguished rank; and we may justly say, that if he has been equalled by any, he has been excelled by none. It is commonly believed, that pastoral poetry is very limited and confined; but those who read the works of Gefner will be convinced, that it is susceptible of much variety when treated of by the hand of a master. His pastoral romance of *Daphnis* is not inferior in natural simplicity to the celebrated work of Longus; but it surpasses it far in variety of images and incident. *Erastus* and *Evander* are instructive and interesting poems, on account of the contrast between the world and nature which reigns throughout them; and his *First Navigator* unites the mildest philosophy to all the splendor and imagery of fairy-land. If we analyse his dramatic poems, we shall find in them interesting fictions, characters well delineated, and situations replete with novelty. His language is that of the Graces, and the chastest ears might listen to the love which he has created. If he has sometimes the humour of Sterne and Fontaine, it is without their

Gesner
||
Gesture.

licentiousness. The severest taste can find in his writings no lacuna to supply, no phrase deserving reprehension, nor could a more ingenious choice of expressions be substituted in the room of those which he has adopted.—Gesner's character, as a man, appears to be no less amiable. In whatever point of view we consider him, whether as a husband, a father, a friend, a magistrate, or a citizen, his virtues are equally conspicuous. He was naturally of a melancholy turn, but he was no enemy to rational and well-timed mirth; while the mildness and affability of his temper rendered his company always engaging, and endeared him to those who had the pleasure of his acquaintance. Possessed of that nobleness of sentiment, united with great modesty, which is the usual attendant of true genius, he was simple in his external appearance, as well as in his conversation. His language was lively and animated; but his reserve before strangers resembled timidity, and it was only in the presence of those with whom he was acquainted, that his real character appeared in its full lustre.

Mr Gesner's reputation and virtues were known even to the remotest parts of Europe. The Empress of Russia Catharine II. presented him with a gold medal as a mark of her esteem. Strangers of all nations gave him no less flattering testimonies of their admiration; and travellers thought they had seen only the half of Switzerland, if they had not been in the company of Gesner, or procured some of his landscapes or drawings. In this last way he had acquired so much reputation, that he was ranked among the best artists of Germany; and Mr Fueslin, his countryman, who was himself a painter, in the preface to the third volume of the new edition which he published of his 'Historical essay on the painters, engravers, architects and sculptors, who have done honour to Switzerland,' gives a distinguished place to Mr Gesner, though then living.

GESNERIA, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personatae*. The calyx is quinquefid, and placed on the germen; the corolla incurvated and then recurvated; the capsule inferior and bilocular.

GESSORIANUM (anc. geog.), a port and station for ships of the Morini in Belgica. In Cæsar's time, according to Dio, there was no town; but Florus speaks of it as one: and the Gessoriacenses Muri are mentioned by Eumenius in his Panegyric. The author of Tabula Theodosiana, commonly called *Peutingger's map*, says expressly, that Gessoriacum was in his time called *Bononia*. Now *Boulogne* in Picardy. E. Long. 1. 30. N. Lat. 50. 40.

GESTATION, among physicians. See PREC-NANCY.

GESTRICIA, a province of Sweden, bounded by Helsingia on the north, by the Bothnic gulph on the east, by Upland on the south, and by Dalecarlia on the west.

GESTURE, a motion of the body, intended to signify some idea or passion of the mind. It consists principally in the actions of the hands and face; and may be defined, a suitable conformity of the motions of the countenance, and of several parts of the body, in speaking to the subject matter of the discourse. See DECLAMATION, and ORATORY, no 130, 131.

GETA (SEPTIMIUS), a son of the emperor Severus, brother to Caracalla. In the eighth year of his age, he was moved with compassion at the fate of some of the partizans of Niger and Albinus who were to be executed, and his father struck with his humanity retracted the sentence. After Severus's death, he reigned at Rome conjointly with his brother; but Caracalla, who envied his virtues and was jealous of his popularity, ordered him to be poisoned; and when this could not be effected, he murdered him in the arms of his mother Julia, who in the attempt of defending the fatal blows from his body received a wound in her arm, from the hand of her son, A. D. 212. Geta had not yet reached the 23d year of his age, and the Romans had reason to lament the death of so virtuous a prince, while they groaned under the cruelties and oppression of Caracalla.

GETHIN (Lady Grace), an English lady of uncommon parts, was the daughter of Sir George Norton of Abbots-Leigh in Somersetshire, and born in the year 1676. She had all the advantages of a liberal education; and became the wife of Sir Richard Gethin, of Gethin-Grott in Ireland. She was mistress of great accomplishments, natural and acquired, but did not live long enough to display them to the world; for she died in the 21st year of her age. She was buried in Westminster-abbey, where a beautiful monument with an inscription is erected over her; and for perpetuating her memory, provision was made for a sermon to be preached in Westminster-abbey, yearly, on Ash-Wednesday for ever. She wrote, and left behind her, in loose papers, a work, which, soon after her death, was methodized, and published under the title of '*Reliquiæ Gethinianæ*; or, Some remains of the most ingenious and excellent lady, Grace lady Gethin, lately deceased. Being a collection of choice discourses, pleasant apophthegms, and witty sentences. Written by her, for the most part, by way of essay, and at spare hours.' Lond. 1700, 4to; with her picture before it.

GETHSEMANE (anc. geog.), a village in the mount of Olives, whither Jesus Christ sometimes retreated in the night time. It was in a garden belonging to this village that he suffered the agony in which he sweated drops of blood; and here he was arrested by Judas and the rest who were conducted by this traitor. The place is by Maundrel described as an even plot of ground, not above 57 yards square, lying between the foot of Mount Olivet and the brook Cedron.

GETHYLLIS, in botany: A genus of the monogynia order, belonging to the dodecandria class of plants; and in the natural method ranking under the ninth order, *Spathaceæ*. The corolla is six-cleft, and the stamina are in six different directions; the capsule is trilocular.

GEUM, AVENS, or *Herb-Bennet*: A genus of the polygamia order, belonging to the icofandria class of plants; and in the natural method ranking under the 35th order, *Senticosæ*. The calyx is cleft into ten parts; there are five petals, and each of the seeds has a jointed awn. There are five species; of which the most remarkable are, 1. The urbanam, with thick fibrous roots of an aromatic taste, rough, serrated leaves, and upright, round, hairy stalks terminated by large yellow

Geta
||
Geum.

Ghent,
Ghost.

yellow flowers, succeeded by globular fruit. 2. The rivale, with a very thick, fleshy, and fibrous root, hairy leaves, and upright stalks, 10 or 12 inches high, terminated by purple flowers nodding on one side. Of this there are varieties with red and with yellow flowers.—Both these are natives of Britain, and are easily propagated either by the root or seed. The roots of the first, gathered in the spring before the stem comes up, and infused in ale, give it a pleasant flavour, and prevent its growing sour. Infused in wine, they have a stomachic virtue. The taste is mildly austere and aromatic, especially when the plant grows in warm dry situations; but in moist shady places, it hath little virtue. Cows, goats, sheep, and swine, eat the plant; horses are not fond of it.—The powdered root of the second species will cure tertian agues, and is daily used for that purpose by the Canadians. Sheep and goats eat the plant; cows, horses, and swine, are not fond of it.

GHENT, a city of the Austrian Netherlands, capital of the province of Flanders. It is seated on four navigable rivers, the Scheld, the Lys, the Lieve, and the Moere, which run through it, and divide it into canals. These form 26 little isles, over which there are 300 bridges: among which there is one remarkable for a statue of brass of a young man who was obliged to cut off his father's head; but as he was going to strike, the blade flew into the air, and the hilt remained in his hand, upon which they were both pardoned. There is a picture of the whole transaction in the town-house. Ghent is surrounded with walls and other fortifications, and is tolerably strong for a place of its circumference. But all the ground within the walls is not built upon. The streets are large and well paved, the market-places spacious, and the houses built with brick. But the Friday's market-place is the largest, and is remarkable for the statue of Charles V. which stands upon a pedestal in the imperial habit, That of Cortere is remarkable for a fine walk under several rows of trees. In 1737 a fine opera-house was built here, and a guard-house for the garrison. Near the town is a very high tower, with a handsome clock and chimes. The great bell weighs 11,000 pounds.

This town is famous for the pacification signed here, in 1526, for settling the tranquillity of the Seventeen Provinces, which was afterwards confirmed by the king of Spain. It was taken by Louis XIV. in 1678, who afterwards restored it. The French took possession of it again after the death of Charles II. of Spain. In 1706, it was taken by the duke of Marlborough; and by the French in 1708; but it was retaken the same year. Last of all, the French took it by surprise after the battle of Fontenoy; but at the peace of Aix-la-Chapelle it was rendered back. This is the birth-place of John of Gaunt. It is very well seated for trade, on account of its rivers and canals. It carries on a great commerce in corn; and has linen, woollen, and silk manufactures. The number of inhabitants is about 70,000. E. Long. 4. o. N. Lat. 51. 44.

GHOST, an apparition, or spirit of a person deceased.

The ancients supposed every man to be possessed of three different ghosts, which after the dissolution of the human body were differently disposed of. These three ghosts are distinguished by the names of *Manes*,

Spiritus, *Umbra*. The *manes*, they fancied, went down into the infernal regions; the *spiritus* ascended to the skies; and the *umbra* hovered about the tomb, as being unwilling to quit its old connections. Thus Dido (Virg. *Æn.* iv. 384.) threatens Æneas after death that she will haunt him with her *umbra*, whilst her *manes* rejoice in his torments below. This idea of a threefold soul is very clearly expressed in these lines, which have been attributed to Ovid.

Bis duo sunt homini: MANES, CARO, SPIRITUS, UMBRA:
Quatuor ista loci bis duo suscipiunt
Terra tegit CARNEM, tumulum circumvolat UMBRA,
Orcus habet MANES, SPIRITUS astra petit.

The most striking outlines of the popular superstitions respecting ghosts among us, are thus humorously collected by Captain Grose in his Provincial Glossary: "A ghost is supposed to be the spirit of a person deceased, who is either commissioned to return for some especial errand, such as the discovery of a murder, to procure restitution of lands or money unjustly withheld from an orphan or widow—or, having committed some injustice whilst living cannot rest till that is redressed. Sometimes the occasion of spirits revisiting this world, is to inform their heir in what secret place, or private drawer in an old trunk, they had hidden the title-deeds of the estate; or where, in troublesome times, they buried their money or plate. Some ghosts of murdered persons, whose bodies have been secretly buried, cannot be at ease till their bones have been taken up, and deposited in consecrated ground with all the rites of Christian burial.

"Sometimes ghosts appear in consequence of an agreement made, whilst living, with some particular friend, that he who first died should appear to the survivor.

"Glanvil tells us of the ghost of a person who had lived but a disorderly kind of life, for which it was condemned to wander up and down the earth, in the company of evil spirits, till the day of judgment.

"In most of the relations of ghosts, they are supposed to be mere aerial beings, without substance, and that they can pass through walls, and other solid bodies at pleasure. A particular instance of this is given, in relation the 27th, in Glanvil's collection, where one David Hunter, neat-herd to the bishop of Down and Connor, was for a long time haunted by the apparition of an old woman, whom he was by a secret impulse obliged to follow whenever she appeared, which he says he did for a considerable time, even if in bed with his wife: and because his wife could not hold him in his bed, she would go too, and walk after him till day, though she saw nothing; but his little dog was so well acquainted with the apparition, that he would follow it as well as his master. If a tree stood in her walk, he observed her always to go through it. Notwithstanding this seeming immateriality, this very ghost was not without some substance; for, having performed her errand, she desired Hunter to lift her from the ground; in the doing of which, he says, she felt just like a bag of feathers. We sometimes also read of ghosts striking violent blows; and that, if not made way for, they overturn all impediments, like a furious whirlwind. Glanvil mentions an instance of this, in relation 17th, of a Dutch lieutenant who had the faculty of seeing ghosts; and who, being prevented making:

Ghost.

Ghost. king way for one which he mentioned to some friends as coming towards them, was, with his companions, violently thrown down, and sorely bruised. We further learn, by relation 16th, that the hand of a ghost is 'as cold as a clod.'

"The usual time at which ghosts make their appearance is midnight, and seldom before it is dark; though some audacious spirits have been said to appear even by day-light: but of this there are few instances, and those mostly ghosts who have been laid perhaps in the Red Sea (of which more hereafter), and whose times of confinement were expired: these, like felons confined to the lighters, are said to return more troublesome and daring than before. No ghosts can appear on Christmas eve; this Shakespeare has put into the mouth of one of his characters in Hamlet.

"Ghosts commonly appear in the same dress they usually wore whilst living, though they are sometimes clothed all in white; but that is chiefly the churchyard ghosts, who have no particular business, but seem to appear *pro bono publico*, or to scare drunken rustics from tumbling over their graves.

"I cannot learn that ghosts carry tapers in their hands, as they are sometimes depicted, though the room in which they appear, if without fire or candle, is frequently said to be as light as day. Dragging chains is not the fashion of English ghosts; chains and black vestments being chiefly the accoutrements of foreign spectres seen in arbitrary governments: dead or alive, English spirits are free. One instance, however, of an English ghost dressed in black, is found in the celebrated ballad of William and Margaret, in the following lines:

And clay-cold was her lily hand,
That held her *sable* brow.

This, however, may be considered as a poetical licence, used in all likelihood for the sake of the opposition of *lily* to *sable*.

"If, during the time of an apparition, there is a lighted candle in the room, it will burn extremely blue: this is so universally acknowledged, that many eminent philosophers have busied themselves in accounting for it, without once doubting the truth of the fact. Dogs too have the faculty of seeing spirits, as is instanced in David Hunter's relation above quoted; but in that case they usually show signs of terror, by whining and creeping to their master for protection: and it is generally supposed that they often see things of this nature when their owner cannot; there being some persons, particularly those born on a Christmas eve, who cannot see spirits.

"The coming of a spirit is announced some time before its appearance, by a variety of loud and dreadful noises; sometimes rattling in the old hall like a coach and six, and rumbling up and down the staircase like the trundling of bowls or cannon balls. At length the door flies open, and the spectre stalks slowly up to the bed's foot, and opening the curtains, looks steadfastly at the person in bed by whom it is seen; a ghost being very rarely visible to more than one person, although there are several in company. It is here necessary to observe, that it has been universally found by experience, as well as affirmed by diverse apparitions themselves, that a ghost has not the power to speak till it has been first spoken to; so that, notwith-

standing the urgency of the business on which it may come, every thing must stand still till the person visited can find sufficient courage to speak to it: an event that sometimes does not take place for many years. It has not been found that female ghosts are more loquacious than those of the male sex, both being equally restrained by this law.

"The mode of addressing a ghost is by commanding it, in the name of the Three Persons of the Trinity, to tell you who it is, and what is its business: this it may be necessary to repeat three times; after which it will, in a low and hollow voice, declare its satisfaction at being spoken to, and desire the party addressing it not to be afraid, for it will do him no harm. This being premised, it commonly enters into its narrative; which being completed, and its request or commands given, with injunctions that they be immediately executed, it vanishes away, frequently in a flash of light; in which case, some ghosts have been so considerate as to desire the party to whom they appeared to shut their eyes: sometimes its departure is attended with delightful music. During the narration of its business, a ghost must by no means be interrupted by questions of any kind; so doing is extremely dangerous: if any doubts arise, they must be stated after the spirit has done its tale. Questions respecting its state, or the state of any of their former acquaintance, are offensive, and not often answered; spirits perhaps being restrained from divulging the secrets of their prison house. Occasionally spirits will even condescend to talk on common occurrences, as is instanced by Glanvil in the apparition of Major George Sydenham to Captain William Dyke, relation 10th, wherein the major reproved the captain for suffering a sword he had given him to grow rusty: saying, "Captain, captain, this sword did not use to be kept after this manner when it was mine." This attention to the state of arms, was a remnant of the major's professional duty when living.

"It is somewhat remarkable that ghosts do not go about their business like the persons of this world. In cases of murder, a ghost, instead of going to the next justice of the peace, and laying its information, or to the nearest relation of the person murdered, appears to some poor labourer who knows none of the parties, draws the curtain of some decrepit nurse or alms-woman, or hovers about the place where his body is deposited. The same circuitous mode is pursued with respect to redressing injured orphans or widows; when it seems as if the shortest and most certain way would be, to go to the person guilty of the injustice, and haunt him continually till he be terrified into a restitution. Nor are the pointing out lost writings generally managed in a more summary way; the ghost commonly applying to a third person, ignorant of the whole affair, and a stranger to all concerned. But it is presumptuous to scrutinize too far into these matters: ghosts have undoubtedly forms and customs peculiar to themselves.

"If, after the first appearance, the persons employed neglect, or are prevented from, performing the message or business committed to their management, the ghost appears continually to them, at first with a discontented, next an angry, and at length with a furious countenance, threatening to tear them in pieces if the matter

Ghost.

Ghost,
Giagh.

matter is not forthwith executed; sometimes terrifying them, as in Glanvil's relation 26th, by appearing in many formidable shapes, and sometimes even striking them a violent blow. Of blows given by ghosts there are many instances, and some wherein they have been followed with an incurable lameness.

"It should have been observed, that ghosts, in delivering their commissions, in order to ensure belief, communicate to the persons employed some secret, known only to the parties concerned and themselves, the relation of which always produces the effect intended. The business being completed, ghosts appear with a cheerful countenance, saying they shall now be at rest, and will never more disturb any one; and, thanking their agents, by way of reward communicate to them something relative to themselves, which they will never reveal.

"Sometimes ghosts appear, and disturb a house, without deigning to give any reason for so doing: with these, the shortest and only way is to exorcise, and eject them; or, as the vulgar term is, lay them. For this purpose there must be two or three clergymen, and the ceremony must be performed in Latin; a language that strikes the most audacious ghost with terror. A ghost may be laid for any term less than an 100 years, and in any place or body, full or empty; as, a solid oak—the pommel of a sword—a barrel of beer, if a yeoman or simple gentleman—or a pipe of wine, if an esquire or a justice. But of all places the most common, and what a ghost least likes, is the Red Sea; it being related, in many instances, that ghosts have most earnestly besought the exorcists not to confine them in that place. It is nevertheless considered as an indisputable fact, that there are an infinite number laid there, perhaps from its being a safer prison than any other nearer at hand; though neither history nor tradition gives us any instance of ghosts escaping or returning from this kind of transportation before their time.

"Another species of human apparition may be here noticed, though it does not come under the strict description of a ghost. These are the exact figures and resemblance of persons then living, often seen not only by their friends at a distance, but many times by themselves; of which there are several instances in Aubrey's Miscellanies: one of Sir Richard Napier, a physician of London, who being on the road from Bedfordshire to visit a friend in Berkshire, saw at an inn his own apparition lying on his bed as a dead corpse; he nevertheless went forward, and died in a short time: another of Lady Diana Rich, daughter of the Earl of Holland, who met her own apparition walking in a garden at Kensington, and died a month after of the small-pox. These apparitions are called *fetches*; in Cumberland, *swarths*; and in Scotland, *wraiths*: they most commonly appear to distant friends and relations, at the very instant preceding the death of the person whose figure they put on. Sometimes, as in the instances above mentioned, there is a great interval between the appearance and death." For a philosophical inquiry into the subject of apparitions in general, see the article SPECTRE.

GIACH, in chronology, a cycle of 12 years; in use among the Turks and Cathayans.

Each year of the giagh bears a name of some animal: the first that of a mouse; the second that of a

bullock; the third of a lynx or leopard; the fourth of a hare; the fifth of a crocodile; the sixth of a serpent; the seventh of a horse; the eighth of a sheep; the ninth of a monkey; the tenth of a hen; the eleventh of a dog; and the twelfth of a hog.

They also divide the day into 12 parts, which they call *giaghs*, and distinguish them by the names of some animals. Each giagh contains two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

GIALLOLINO, in natural history, a fine yellow pigment much used under the name of NAPLES YELLOW.

GIANT, a person of extraordinary bulk and stature.

The Romances of all ages have furnished us with so many extravagant accounts of giants of incredible bulk and strength, that the existence of such people is now generally disbelieved. It is commonly thought, that the stature of man hath been the same in all ages; and some have even pretended to *demonstrate* the impossibility of the existence of giants mathematically. Of these Mr M'Laurin hath been the most explicit. "In general (says he) it will easily appear, that the efforts tending to destroy the cohesion of beams arising from their own gravity only, increase in the quadruplicate ratio of their lengths; but that the opposite efforts tending to preserve their cohesion, increase only in the triplicate proportion of the same lengths. From which it follows, that the greater beams must be in greater danger of breaking than the lesser similar ones; and that though a lesser beam may be firm and secure, yet a great similar one may be made so long, that it will necessarily break by its own weight. Hence Galileo justly concludes, that what appears very firm, and succeeds very well in models, may be very weak and infirm, or even fall to pieces by its own weight, when it comes to be executed in large dimensions according to the model. From the same principle he argues, that there are necessary limits in the operations of nature and art, which they cannot surpass in magnitude. Were trees of a very enormous size, their branches would fall by their own weight. Large animals have not strength in proportion to their size; and if there were any land-animals much larger than those we know, they could hardly move, and would be perpetually subject to the most dangerous accidents. As to the animals of the sea, indeed, the case is different; for the gravity of the water in a great measure sustains those animals; and in fact these are known sometimes to be vastly larger than the greatest land-animals. Nor does it avail against this doctrine to tell us, that bones have sometimes been found which were supposed to have belonged to giants of immense size; such as the skeletons mentioned by Strabo and Pliny, the former of which was 60 cubits high, and the latter 46: for naturalists have concluded on just grounds, that in some cases these bones had belonged to elephants; and that the larger ones were bones of whales, which had been brought to the places where they were found by the revolutions of nature that have happened in past times. Though it must be owned, that there appears no reason why there may not have been men who have exceeded by some feet in height the tallest we have seen."

It will easily be seen, that arguments of this kind

Gialloline,
Giant.

Giant.

can never be conclusive; because, along with an increase of stature in any animal, we must always suppose a proportional increase in the cohesion of the parts of its body. Large works sometimes fail when constructed on the plan of models, because the cohesion of the materials whereof the model is made, and of the large work, are the same; but a difference in this respect will produce a very remarkable difference in the ultimate result. Thus, suppose a model is made of fir-wood, the model may be firm and strong enough; but a large work made also of fir, when executed according to the plan of the model, may be so weak that it will fall to pieces with its own weight. If, however, we make use of iron for the large work instead of fir, the whole will be sufficiently strong, even though made exactly according to the plan of the model. The like may be said with regard to large and small animals. If we could find an animal whose bones exceeded in hardness and strength the bones of other animals as much as iron exceeds fir, such an animal might be of a monstrous size, and yet be exceedingly strong. In like manner, if we suppose the flesh and bones of a giant to be greatly superior in hardness and strength to the bones of other men, the great size of his body will be no objection at all to his strength. The whole of the matter therefore concerning the existence of giants must rest on the credibility of the accounts we have from those who pretend to have seen them, and not on any arguments drawn *à priori*.

In the scripture we are told of *giants*, who were produced from the marriages of the *sons of God* with the *daughters of men*.* This passage indeed has been differently interpreted, so as to render it doubtful whether the word translated *giants* does there imply any extraordinary stature. In other parts of scripture, however, giants, with their dimensions, are mentioned in such a manner that we cannot possibly doubt; as in the case of Og king of Bashan, and Goliath. In a memoir read before the Academy of Sciences at Rouen, M. Le Cat gives the following account of giants that are said to have existed in different ages.

“Profane historians have given seven feet of height to Hercules their first hero; and in our days we have seen men eight feet high. The giant who was shown in Rouen in 1735, measured eight feet some inches. The emperor Maximin was of that size; Shenkius and Platerus, physicians of the last century, saw several of that stature; and Gæropius saw a girl who was ten feet high.—The body of Orestes, according to the Greeks, was eleven feet and a half; the giant Galbarrâ, brought from Arabia to Rome under Claudius Cæsar, was near ten feet; and the bones of Secundilla and Pusio, keepers of the gardens of Sallust, were but six inches shorter. Funnam, a Scotsman, who lived in the time of Eugene II. king of Scotland, measured eleven feet and a half: and Jacob le Maire, in his voyage to the straits of Magellan, reports, that on the 17th of December 1615, they found at Port Desire several graves covered with stones; and having the curiosity to remove the stones, they discovered human skeletons of ten and eleven feet long. The chevalier Scory, in his voyage to the peak of Teneriff, says, that they found in one of the sepulchre caverns of that mountain the head of a Guanche which had 80 teeth, and that the body was not less than 15 feet long. The

* See *Ante-diluvians*, p. 66. col. 1.

giant Ferragus, slain by Orlando nephew of Charlemagne, was 18 feet high. Rioland, a celebrated anatomist, who wrote in 1614, says, that some years before there was to be seen in the suburbs of St Germain the tomb of the giant Iforet, who was 20 feet high. In Rouen, in 1509, in digging in the ditches near the Dominicans, they found a stone tomb containing a skeleton whose skull held a bushel of corn, and whose shin-bone reached up to the girdle of the tallest man there, being about four feet long, and consequently the body must have been 17 or 18 feet high. Upon the tomb was a plate of copper, whereon was engraved, “In this tomb lies the noble and puissant lord, the chevalier Ricon de Vallemont, and his bones.” Platerus, a famous physician, declares, that he saw at Lucerne the true human bones of a subject which must have been at least 19 feet high. Valence in Dauphiné boasts of possessing the bones of the giant Bucart, tyrant of the Vivarais, who was slain by an arrow by the count De Cabillon his vassal. The Dominicans had a part of the shin-bone, with the articulation of the knee, and his figure painted in fresco, with an inscription, showing that this giant was 22 feet and a half high, and that his bones were found in 1705, near the banks of the Morderi, a little river at the foot of the mountain of Crussol, upon which (tradition says) the giant dwelt.

“January 11. 1613, some masons digging near the ruins of a castle in Dauphiné in a field which (by tradition) had long been called *the giant’s field*, at the depth of 18 feet discovered a brick-tomb 30 feet long, 12 feet wide, and 8 feet high; on which was a grey stone, with the words *Theutobochus Rex* cut thereon. When the tomb was opened, they found a human skeleton entire, 25 feet and a half long, 10 feet wide across the shoulders, and five feet deep from the breast-bone to the back. His teeth were about the size each of an ox’s foot, and his shin-bone measured four feet.—Near Mazarino, in Sicily, in 1516, was found a giant 30 feet high; his head was the size of an hog’s head, and each of his teeth weighed five ounces. Near Palermo, in the valley of Mazara, in Sicily, a skeleton of a giant 30 feet long was found, in the year 1548; and another of 33 feet high, in 1550; and many curious persons have preserved several of these gigantic bones.

“The Athenians found near their city two famous skeletons, one of 34 and the other of 36 feet high.

“At Totu, in Bohemia, in 758, was found a skeleton, the head of which could scarce be encompassed by the arms of two men together, and whose legs, which they still keep in the castle of that city, were 26 feet long. The skull of the giant found in Macedonia, September 1691, held 210 pounds of corn.

“The celebrated Sir Hans Sloane, who treated this matter very learnedly, does not doubt these facts; but thinks the bones were those of elephants, whales, or other enormous animals.

“Elephants bones may be shown for those of giants; but they can never impose on connoisseurs. Whales, which, by their immense bulk, are more proper to be substituted for the largest giants, have neither arms nor legs; and the head of that animal hath not the least resemblance to that of a man. If it be true, therefore, that a great number of the gigantic bones which we have mentioned have been seen by anatomists, and

Giant.

Giant. by them have been reputed real human bones, the existence of giants is proved."

With regard to the credibility of all or any of these accounts, it is difficult to determine any thing. If, in any castle of Bohemia, the bones of a man's leg 26 feet in length are preserved, we have indeed a decisive proof of the existence of a giant, in comparison of whom most others would be but pigmies. Nor indeed could these bones be supposed to belong to an elephant; for an elephant itself would be but a dwarf in comparison of such an enormous monster. But if these bones were really kept in any part of Bohemia, it seems strange that they have not been frequently visited, and particular descriptions of them given by the learned who have travelled into that country. It is certain, however, that there have been nations of men considerably exceeding the common stature. Thus, all the Roman historians inform us, that the Gauls and Germans exceeded the Italians in size; and it appears that the Italians in those days were of much the same stature with the people of the present age. Among these northern nations, it is also probable, that there would be as great differences in stature as there are among the present race of men. If that can be allowed, we may easily believe that some of these barbarians might be called *giants*, without any great impropriety. Of this superiority of size, indeed, the historian Florus gives a notable instance in Teutobochus, abovementioned, king of the Teutones: who being defeated and taken prisoner by Marius, was carried in triumph before him at Rome, when his head reached above the trophies that were carried in the same procession.

But whether these accounts are credited or not, we are very certain, that the stature of the human body is by no means absolutely fixed. We are ourselves a kind of giants in comparison of the Laplander; nor are these the most diminutive people to be found upon the earth. The abbe la Chappe, in his journey into Siberia, in order to observe the last transit of Venus, passed through a village inhabited by people called *Wotiacks*, neither men nor women of whom were above four feet high. The accounts of the Patagonians also, which cannot be entirely discredited, render it very probable, that somewhere in South America there is a race of people very considerably exceeding the common size of mankind, and consequently that we cannot altogether discredit the relations of giants handed down to us by ancient authors; though what degree of credit we ought to give them, is not easy to be determined. See *PATAGONIA*.

Rebel GIANTS, in ancient mythology, were the sons of Cœlus and Terra. According to Hesiod, they sprang from the blood of the wound which Cœlus received from his son Saturn, and Hyginus calls them sons of Tartarus and Terra. They are represented as men of uncommon stature, with strength proportioned to their gigantic size. Some of them, as Cottus, Briareus, and Gyges, had each 50 heads and 100 arms, and serpents instead of legs. They were of a terrible aspect, their hair hung loose about their shoulders, and their beard was suffered to grow unmolested. Pallene and its neighbourhood was the place of their residence. The defeat of the Titans, to whom they were nearly related, incensed them against Jupiter, and they all

VOL. VII.

conspired to dethrone him. Accordingly they reared Mount Ossa upon Pelion, and Olympus upon Ossa; and from thence attacked the gods with huge rocks. Some of which fell into the sea and became islands, and others fell on the earth and formed mountains. Jupiter summoned a council of the gods; when being informed that it was necessary to obtain the assistance of some mortal, he by the advice of Pallas called up his son Hercules; and with the aid of this hero he exterminated the giants Enceladus, Polybotes, Alcyon, Porphyryon, the two sons of Alcœus, Ephialtus, Othus, Eurytus, Clytius, Tythys, Pallas, Hypolitus, Agrius, Thoon, and Typhon, the last of whom it was more difficult to vanquish than all the others. Jupiter having thus gained a complete victory, cast the rebels down to Tartarus, where they were to receive the full punishment of their enormous crimes: according to the accounts of some of the poets, he buried them alive under Mount Etna, and different islands.

GIANTS-Causeway, a vast collection of Basaltic pillars in the county of Antrim in Ireland. See the article *BASALTES*.

The principal or grand causeway (for there are several less considerable and scattered fragments of similar workmanship) consists of a most irregular arrangement of many hundred thousands of columns of a black kind of rock, hard as marble: almost all of them are of a pentagonal figure, but so closely and compactly situated on their sides, though perfectly distinct from top to bottom, that scarce any thing can be introduced between them. The columns are of an unequal height and breadth; some of the highest, visible above the surface of the strand, and at the foot of the impending angular precipice, may be about 20 feet; they do not exceed this height, at least none of the principal arrangement. How deep they are fixed in the strand, was never yet discovered. This grand arrangement extends nearly 200 yards, visible at low water; how far beyond is uncertain: from its declining appearance, however, at low water, it is probable it does not extend under water to a distance any thing equal to what is seen above. The breadth of the principal causeway, which runs out in one continued range of columns, is, in general, from 20 to 30 feet; at one place or two it may be nearly 40 for a few yards. In this account are excluded the broken and scattered pieces of the same kind of construction, that are detached from the sides of the grand causeway, as they do not appear to have ever been contiguous to the principal arrangement, though they have frequently been taken into the width; which has been the cause of such wild and dissimilar representations of this causeway, which different accounts have exhibited. The highest part of this causeway is the narrowest, at the very foot of the impending cliff from whence the whole projects, where, for four or five yards, it is not above ten or fifteen feet wide. The columns of this narrow part incline from a perpendicular a little to the westward, and form a slope on their tops, by the very unequal height of the columns on the two sides, by which an ascent is made at the foot of the cliff, from the head of one column to the next above, *gradatim*, to the top of the great causeway, which, at the distance of half a dozen yards from the cliff, obtains a perpendicular position, and lowering in its general height,

Giants Causeway.

Giant
Causeway.

height, widens to about 20 or between 20 and 30 feet, and for 100 yards nearly is always above water. The tops of the columns for this length being nearly of an equal height, they form a grand and singular parade, that may be easily walked on, rather inclining to the water's edge. But from high-water mark, as it is perpetually washed by the beating surges on every return of the tide, the platform lowers considerably, and becomes more and more uneven, so as not to be walked on but with the greatest care. At the distance of 150 yards from the cliff, it turns a little to the east for 20 or 30 yards, and then sinks into the sea. The figure of these columns is almost unexceptionably pentagonal, or composed of five sides; there are are but very few of any other figure introduced: some few there are of three, four, and six sides, but the generality of them are five-sided, and the spectator must look very nicely to find any of a different construction: yet what is very extraordinary, and particularly curious, there are not two columns in ten thousand to be found, that either have their sides equal among themselves, or whose figures are alike. Nor is the composition of these columns or pillars less deserving the attention of the curious spectator. They are not of one solid stone in an upright position; but composed of several short lengths, curiously joined, not with flat surfaces, but articulated into each other like ball and socket, or like the joints in the vertebræ of some of the larger kind of fish, the one end at the joint having a cavity, into which the convex end of the opposite is exactly fitted. This is not visible, but by disjoining the two stones. The depth of the concavity or convexity is generally about three or four inches. And what is still farther remarkable of the joint, the convexity, and the correspondent concavity, is not conformed to the external angular figure of the column, but exactly round, and as large as the size or diameter of the column will admit; and consequently as the angles of these columns are in general extremely unequal, the circular edges of the joint are seldom coincident with more than two or three sides of the pentagonal, and from the edge of the circular part of the joint to the exterior sides and angles they are quite plain. It is still farther very remarkable, likewise, that the articulations of these joints are frequently inverted, in some the concavity is upwards, in others the reverse. This occasions that variety and mixture of concavities and convexities on the tops of the columns, which is observable throughout the platform of this causeway, yet without any discoverable design or regularity with respect to the number of either. The length also of these particular stones, from joint to joint, is various: in general, they are from 18 to 24 inches long; and, for the most part, longer toward the bottom of the columns than nearer the top, and the articulation of the joints something deeper. The size or diameter likewise of the columns is as different as their length and figure; in general, they are from 15 to 20 inches in diameter. There are really no traces of uniformity or design discovered throughout the whole combination, except in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finishing in any part, either in height, length, or breadth, of this curious causeway. If there

is here and there a smooth top to any of the columns above water, there are others just by, of equal height, that are more or less convex or concave, which show them to have been joined to pieces that have been washed or by other means taken off. And undoubtedly those parts that are always above water have, from time to time, been made as even as might be; and the remaining surfaces of the joints must naturally have been worn smoother by the constant friction of weather and walking, than where the sea, at every tide, is beating upon it and continually removing some of the upper stones and exposing fresh joints. And farther, as these columns preserve their diameters from top to bottom, in all the exterior ones, which have two or three sides exposed to view, the same may with reason be inferred of the interior columns whose tops only are visible. Yet what is very extraordinary, and equally curious, in this phenomenon, is, that notwithstanding the universal dissimilitude of the columns, both as to their figure and diameter, and though perfectly distinct from top to bottom, yet is the whole arrangement so closely combined at all points, that hardly a knife can be introduced between them either on the sides or angles. And it is really a most curious piece of entertainment to examine the close contexture and nice insertion of such an infinite variety of angular figures as are exhibited on the surface of this grand parade. From the infinite dissimilarity of the figure of these columns, this will appear a most surprising circumstance to the curious spectator; and would incline him to believe it a work of human art, were it not, on the other hand, inconceivable that the wit or invention of man should construct and combine such an infinite number of columns, which should have a general apparent likeness, and yet be so universally dissimilar in their figure, as that, from the minutest examination, not two in ten or twenty thousand should be found, whose angles and sides are equal among themselves, or of the one column to those of the other. That it is the work of nature, there can be no doubt to an attentive spectator, who carefully surveys the general form and situation, with the infinitely various figuration of the several parts of this causeway. There are no traces of regularity or design in the outlines of this curious phenomenon; which, including the broken and detached pieces of the same kind of workmanship, are extremely scattered and confused, and, whatever they might originally, do not at present appear to have any connection with the grand or principal causeway, as to any supposable design or use in its first construction, and as little design can be inferred from the figure or situation of the several constituent parts. The whole exhibition is, indeed, extremely confused, disuniform, and destitute of every appearance of use or design in its original construction. But what, beyond dispute, determines its original to have been from nature, is, that the very cliffs, at a great distance from the causeway, especially in the bay to the eastward, exhibit at many places the same kind of columns, figured and jointed in all respects like those of the grand causeway: some of them are seen near to the top of the cliff, which in general, in these bays to the east and west of the causeway, is near 300 feet in height; others again are seen about midway, and at different elevations from the strand. A very con-

Giants
Causeway.

siderable

Giants
Causeway
||
Gibbous.

considerable exposure of them is seen in the very bottom of the bay to the eastward, near a hundred rods from the causeway, where the earth has evidently fallen away from them upon the strand, and exhibits a most curious arrangement of many of these pentagonal columns, in a perpendicular position, supporting in appearance, a cliff of different strata of earth, clay, rock, &c. to the height of 150 feet or more, above. Some of these columns are between 30 and 40 feet high, from the top of the sloping bank below them; and, being longest in the middle of the arrangement, shortening on either hand in view, they had obtained the appellation of *organs*, from a rude likeness in this particular to the exterior or frontal tubes of that instrument; and as there are few broken pieces on the strand near it, it is probable that the outside range of columns that now appears is really the original exterior line, to the seaward, of this collection. But how far they extend internally into the bowels of the incumbent cliff, is unknown. The very substance, indeed, of that part of the cliff which projects to a point, between the two bays on the east and west of the causeway, seems composed of this kind of materials; for besides the many pieces that are seen on the sides of the cliff, that circulate to the bottom of the bays, particularly the eastern side, there is, at the very point of the cliff, and just above the narrow and highest part of the causeway, a long collection of them seen, whose heads or tops just appearing without the sloping bank, plainly show them to be in an oblique position, and about half-way between the perpendicular and horizontal. The heads of these, likewise, are of mixed surfaces, convex and concave, and the columns evidently appear to have been removed from their original upright, to their present inclining or oblique position, by the sinking or falling of the cliff.

GIBBET, or GIBET, a machine in manner of a gallows, whereon notorious criminals, after execution, are hung in irons or chains, as spectacles *in terrorem*. See GALLOWS.—The word in French, *gibet*, properly denotes what we call gallows: it is supposed to come originally from the Arabic *gibel*, “mount or elevation of ground;” by reason *gibets* are usually placed on hills or eminences.

GIBBOUS, a term in medicine, denoting any protuberance or convexity of the body, as a person hunched or humpbacked.

Infants are much more subject to gibbosity than adults, and it oftener proceeds from external than internal causes. A fall, blow, or the like, frequently thus distorts the tender bones of infants. When it proceeds from an internal cause, it is generally from a relaxation of the ligaments that sustain the spine, or a caries of its vertebræ; though the spine may be inflected forward, and the vertebræ thrown out by a too strong and repeated action of the abdominal muscles. This, if not timely redressed, grows up and fixes as the bones harden, till in adults it is totally irretrievable: but when the disorder is recent, and the person young, there are hopes of a cure. The common method is by a machine of pasteboard, wood, or steel, which is made to press principally on the gibbous part; and this by long wearing may set all right. The surgeons, however, have a different instrument, which they call a *cross*, much more efficacious, though not quite so

convenient in the wearing. By the use of this, the parts are always prevented from growing any worse, and are often cured. During the application of these assistances, the parts should be at times rubbed with hungary-water, spirit of lavender, or the like, and defended with a strengthening plaster.

GIBBOUS, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned or falcated; and the light one hunched out, convex, or gibbous.

GIBEAH, a city in the tribe of Benjamin, lying north of Jerusalem about 20 or 30 furlongs, and built upon a hill as its name imports.—This city gave birth to Saul, the first king of Israel, for which reason it is frequently called Gibeah of Saul, or Gibeah the native country of Saul.

GIBELINS, or GIBELLINS, a famous faction in Italy, opposite to another called the GUELPHS.

Those two factions ravaged and laid waste Italy for a long series of years; so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violences and slaughters. The Gibelins stood for the emperor against the pope: but concerning their origin and the reason of their names we have but a very obscure account. According to the generality of authors, they rose about the year 1240, upon the emperor Frederick II.'s being excommunicated by the pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor. But the most probable opinion is that of Maimbourg, who says, that the two factions of Guelphs and Gibelins arose from a quarrel between two ancient and illustrious houses on the confines of Germany, that of the Henries of Gibeling, and that of the Guelphs of Adorf.

GIBEON, a city seated on an eminence about 40 furlongs from Jerusalem northward, and not far from the city of Gibeah. See GEBÄ.

This was the capital city of the Gibeonites, who took the advantage of Joshua's oath, and of that which the elders of Israel likewise swore to them, upon an artificial representation which they made of their belonging to a very remote country, and their desire of making an alliance with the Hebrews. Joshua (ix. 3. 4, & seq.) and the elders inconsiderately entered into a league with these people; but soon discovered their mistake. Upon this, sending for the Gibeonites, they reproached them with their fraud; and without revoking the promise which they had made to them, of giving them their lives, they condemned them to carry wood and water to the tabernacle of the Lord, as slaves and captives taken in war; in which state of servitude they remained till the ruin and entire dispersion of the Jewish nation.

The Gibeonites were descended from the Hivites, the old inhabitants of that country; and possessed four cities, whereof Gibeon was the capital. The cities were Cephira, Beeroth, Kirjathjearim, and Gibeon, Josh. ix. 17. These cities were afterwards given to the tribe of Benjamin, except Kirjathjearim, which fell to the tribe of Judah. The Gibeonites continued ever after subject to those burdens which Joshua had imposed on them, and were very faithful to the Israelites.

Gibbous
||
Gibeon.

Giblets,
Gibraltar

GIBLETS, the offals or entrails of a goose; including the heart and liver, with the feet, gizzard, &c. The word is supposed to be formed of *goblets*; from the French *gobeau*, "mouthful."—Giblets make a considerable article in cookery: they boil giblets, stew giblets, make ragous of giblets, giblet-pies, &c.

GIBRALTAR, a famous promontory, or rather peninsula, of Spain, lying in N. Lat. 35. 50. W. Long. 5. 35. To the ancients it was known by the name of *Galpe*, and was also called one of the *Pillars of Hercules*; by the Arabians it is called *Gabel Tarek*, that is "the mount of Tarek, from *Tarek*, the name of the Saracen general who conquered Spain in the beginning of the eighth century. The whole is an immense rock, rising perpendicularly about 440 yards, measuring from north to south about two English miles, but not above one in breadth from east to west.—The town lies along the bay on the west side of the mountain on a declivity; by which, generally speaking, the rains pass through it, and keep it clean. The old town was considerably larger than the new, which at present consists of between 400 and 500 houses. Many of the streets are narrow and irregular; the buildings are of different materials; some of natural stone out of the quarries, some of a facitious or artificial stone, and a few of brick. The people are supplied with fresh provisions chiefly from the coast of Barbary, with fruit, roots, and vegetables of all sorts from thence, or from their own gardens. Besides what is properly called the town, there are several spacious and commodious public edifices erected; such as barracks for the soldiers, with apartments for their officers, magazines of different kinds, storehouses for provisions, &c. The inhabitants, exclusive of the British subjects dependent on the garrison, or who reside there from other motives, consist of some Spaniards, a few Portuguese, a considerable number of Genoese, and about as many Jews; making in the whole, according to Dr Campbell, between two and three thousand, without reckoning the garrison; though some make them much fewer. The town may be said to have two ports; the first lying to the north, and is proper only for small vessels; the other is very commodious only for large vessels, and has a fine stone quay. The bay is very beautiful and capacious, being in breadth about five miles, and in length eight or nine, with several small rivers running into it. It is very advantageous to the place. There is no ground to be found in the middle of it at 100 fathoms depth, so that a squadron may lie there in great safety; the breezes from it are very refreshing; and it contributes likewise to the subsistence of the inhabitants, by supplying them with plenty of fish.

The strait of Gibraltar, through which the ocean passes into the Mediterranean, thereby dividing Europe from Africa, runs from west to east about 13 leagues. In this strait there are three remarkable promontories or capes on the Spanish side, and as many opposite to them on the Barbary side. The first of these, on the side of Spain, is cape Trefalgar, opposite to which is cape Spartel; and in the neighbourhood of this stood the fortress of Tangier, once in the possession of the British. The next on the Spanish side is Tarifa; and over against it lies Malabata, near the town of Alcafar, where the straits are about five leagues broad. Lastly, Gibraltar, facing the mountain of Abyla, near the

fortress and town of Ceuta, which make the eastern Gibraltar. entry of the straits.

This important fortress seems to have been first particularly noticed as a place of consequence in the year 712. At that time the general of the caliph Al Walid landed with an army of 12,000 men on the isthmus between Mons Calpe and the continent; and that he might secure an intercourse with Africa, ordered a castle to be built on the face of that hill. Part of the building still remains; and, from an inscription discovered above the principal gate, appears to have been finished in 725. It continued in the possession of the Saracens till the beginning of the 14th century, when it was recovered by Ferdinand king of Castile. In 1333, however, it was obliged to surrender to the son of the emperor of Fez, who came to the assistance of the Moorish king of Granada. An attempt was made upon it in 1349 by Alonzo king of Castile; but when the fortress had been reduced to the last extremity, a pestilential fever broke out in the Spanish camp, which carried off the king himself, with great part of his army; after which the enterprise was abandoned.

The fortress continued in the possession of the Saracen descendants of the prince of Fez until the year 1410, when it was taken possession of by Joseph III. king of Granada. A design of attacking it was formed by Henry de Gusman in 1435; but the enterprise having miscarried through his imprudence, he was defeated and slain. However, it was at length taken after a gallant defence by his son John de Gusman in 1462; since which time it has remained in the hands of the Christians. In 1540, it was surprised and pillaged by Piali Hamet, one of Barbarossa's corsairs; but the pirates having fallen in with some Sicilian galleys, were by them defeated, and all either killed or taken.

In the reign of Charles V. the fortifications of Gibraltar were modernised, and such additions made as to render them almost impregnable. It was taken by the English, however, in the reign of queen Anne, and since that time has remained in their possession; and probably will always do so, unless ceded by treaty, as it appears altogether impossible to reduce it by any force of artillery let it be ever so great. In the year 1704, in consequence of the resolution adopted by the court of Britain to assist the archduke Charles in his pretensions to the Spanish crown, Sir George Rooke was sent with a powerful fleet into the Mediterranean. His orders being limited, nothing of consequence was done for some time, until at last an attempt on Gibraltar was resolved upon; not so much on account of the importance of the conquest, as to prevent any reflections against the admiral for inactivity. On the 21st of July that year, 1800 troops were landed upon the isthmus under the command of the prince of Hesse Darmstadt; and on the refusal of the governor to surrender, preparations were made for attacking the place. Early in the morning of the 23d, a cannonade, was begun from the fleet, and kept up so briskly, that in five or six hours the Spaniards were driven from many of their guns, especially at the new mole-head. The admiral perceiving, that by gaining this part of the fortification, the reduction of the rest would be facilitated, ordered out some armed boats to take possession of it. On their approach the Spaniards sprung a mine,

Gibraltar. mine, which demolished part of the works, killed two lieutenants and 40 private soldiers, wounding about 60 more. Notwithstanding this disaster, the assailants kept possession of the work, and took a small bastion, now the eight-gun battery, half way between the mole and the town. On this the governor thought proper to capitulate, and the prince of Hesse took possession of the gates on the 24th. The garrison, consisting at most of 150 men marched out with the honours of war; and the Spaniards who chose to remain were allowed the same privileges they had enjoyed under the reign of Charles II. The works were found very strong, and the place well provided with ammunition and military stores.

This conquest was achieved with the loss of about 60 killed and 216 wounded on the part of the English. The prince of Hesse remained governor; and 18 men of war were left at Lisbon under the command of Sir John Leake, to succour the garrison if there should be occasion. The loss of such an important fortress, however, having alarmed both the courts of Madrid and Paris, orders were sent to the marquis de Villadarias, a Spanish grandee, to lay siege to it, in which he was to be assisted by a naval force from Toulon. The prince immediately applied to Sir John Leake for assistance: but before the latter had time to comply with his request, a French fleet arrived, and debarked six battalions to the assistance of the Spaniards; after which they proceeded to the westward, leaving only six frigates in the bay. The trenches were opened on the 11th of October, about which time Sir John arrived with 20 sail of English and Dutch ships; but hearing that the French were about to attack him with a superior force, he judged it proper to return and refit. Having very prudently left orders at Lisbon to make preparations for this purpose in his absence, he was enabled to accomplish the work with such expedition, that on the 29th of the same month, he returned, and surprised in the bay three frigates, a fire-ship, two English prizes, a tartan, and a store-ship. After this exploit he landed some reinforcements, supplied the garrison with six months provision and ammunition; at the same time detaching on shore a body of 500 sailors to assist in repairing the breaches which had been made by the enemy's fire.

Thus the Spaniards were disappointed in their hopes of success from an attack which had been projected that very night, and for which purpose 200 boats had been collected. Still, however they did not despair; and supposing that the garrison would be off their guard and secure on account of the vicinity of their fleet, they formed the rash design of attempting to surprise the place though the British admiral was still before it. In this mad attempt 500 volunteers associated, taking the sacrament never to return unless they accomplished their purpose. They were conducted by a goat-herd to the south side of the rock near the cave-guard, at that time called *the pass of locust-trees*. This they mounted, and lodged themselves the first night in the Cave of St Michael; the next they scaled Charles V.'s Wall; surprised and massacred the guard at Middle-hill: where afterwards, by ropes and ladders, several hundreds of the party designed to support them were hauled up; but being discovered, they

were attacked by a small party of grenadiers, and all of them at last either killed or taken. These brave adventurers were to have been supported by a body of French troops, and some feints were proposed to draw off the attention of the garrison; but, through the disagreement of the commanding officers, these proposals were not put in execution, and thus the volunteers were left to their fate.

Notwithstanding these misfortunes the Spaniards still continued the siege, and fitted out a strong squadron from Cadiz, with a design to intercept the convoys of provisions which might be sent to the garrison: flattering themselves at the same time, that on the arrival of their fleet, Sir John would be obliged to retire, and the garrison of consequence to surrender to their united attacks. They continued their fire therefore with additional fury, dismounted many of the cannon, and did essential injury to the works in several different places. The prince of Hesse, however, was by no means deficient in his endeavours to disappoint their expectations. As it was probable that an attempt might be made to storm the curtain, a cuvette was dug in the ditch which was filled by the tide, and a double row of palisades placed parallel to the works. The chambers of the mine under the glacis were loaded, and all means taken to defeat such an attempt; but on a sudden the Spaniards seemed to have altered their design, and threatened an attack on the lines which the garrison had on the declivity of the hill to flank the glacis, and overlook their advanced works. While affairs remained in this situation, part of the succours they had long expected arrived in the bay, December 7. 1704, and in two days after, the remainder came in with near 2000 men, along with a proportionable quantity of ammunition and provisions. These had sailed from Cape Spartel under convoy of four frigates; but were in imminent danger of falling into the hands of the enemy, whose fleet they mistook for their own; however they escaped by the fortunate circumstance of being becalmed, so that they could not get up to them.

Sir John Leake having thus powerfully reinforced the garrison, thought his presence in the bay no longer necessary, and therefore set sail for Lisbon, where he arrived about the end of the year. In the beginning of January 1705 the Spaniards were reinforced by a considerable body of infantry, and on the 11th of the month made an attack on the extremity of the King's Lines, but were repulsed. The attack was renewed next day with 600 grenadiers, French and Wailoons, supported by 1000 Spaniards under lieutenant-general Fuy. They disposed themselves in such a manner as showed an intention to storm a breach which had been made in the Round Tower at the extremity of the King's Lines, and another in the entrenchment on the hill. The retrenchment which covered the latter breach, with part of the entrenchment joining the precipice of the rock, was defended at night by a captain, three subalterns, and 90 men: but it was customary for the captain to withdraw, with two subalterns and 60 men at day-break. The Round Tower was defended by 180 men, commanded by a lieutenant colonel. The marquis, by deserters from the garrison, had obtained intelligence of the strength of these posts, and planned his attack accordingly. The

de-

Gibraltar detachments for the upper breach mounted the rock at midnight, and concealed themselves in the cliffs until the captain had withdrawn; after which, advancing to the point of the entrenchment, they threw grenades on the subaltern and his party, so that they were obliged to leave the place. At the same time 300 men stormed the Round Tower, where lieutenant-colonel Bar made a vigorous defence, though the enemy, having passed the breach above, annoyed them on the flanks with great stones and grenades. Observing, however, the Spaniards marching down to cut off his retreat from the town, he retired; and, by getting over the parapet of the King's Lines, descended into the covered way, where the English guards were posted. Thus the garrison were alarmed; all the regiments were assembled at their proper posts; and captain Fisher endeavoured to stop the progress of the enemy with 17 men, but they were repulsed, and himself taken prisoner. At last, however, the Tower was retaken by lieutenant-colonel Moncal at the head of 400 or 500 men, after it had been in the possession of the enemy upwards of an hour.

12
They are repulsed.

13
The siege carried on with fresh ardour.

14
The French fleet dispersed by a storm.

15
The siege turned into a blockade, and at last raised.

The garrison were now farther reinforced by six companies of Dutch troops and 200 English soldiers, together with some provisions and stores. The assailants, however, were still determined to go on. The marquis de Villadarias was superseded by the Mariscal Tesse a Frenchman, with whom Admiral Pointis was desired to co-operate in blocking up the place. The Mariscal therefore joined the army with four fresh battalions, besides eight companies which had been sent before: the ordnance, which had been greatly injured by constant use, was exchanged for others, and the works as they then stood, put into the best repair. On the part of the English a reinforcement was ordered under the command of Sir Thomas Dilkes and Sir John Hardy, to join Admiral Leake at Lisbon; which junction being effected, the whole fleet, consisting of 28 English, 4 Dutch, and 8 Portuguese men of war, having on board two battalions of land-forces, set sail from Lisbon. Happily for the besieged, however, the incessant rains and storms about this time had retarded the operations of the land-forces, and greatly distressed the fleet of the enemy. Eight ships of the latter were forced from their anchors by the strong westerly wind, and obliged to drive aloft. At this critical period Sir John Leake, with the allied fleet, entered the straits. On his approach the few remaining French ships put out to sea; and the British admiral discovering five sail making out of the bay, and a gun fired at them from the garrison, immediately gave chase. Three French men of war were taken, and the admiral's ship and another driven on shore, where they were burnt. The rest, on hearing the report of the guns, had made the best of their way to Toulon.

The garrison was now so well supplied, that Marshal Tesse withdrew his troops from the trenches, and formed a blockade, drawing an intrenchment across the isthmus to prevent the garrison from ravaging the country. The prince of Hesse remained for some time in the place where he repaired the batteries, and made some additions to the fortifications; after which he

joined the arch-duke Charles at Lisbon. As the latter, however, was resolved to try his fortune with the Earl of Peterborough in Valencia and Catalonia, the prince was sent back to Gibraltar to prepare part of the garrison for embarkation, and soon after was followed by the whole fleet. Major General Ramos was now appointed governor of Gibraltar, in which only two new battalions were left, as nothing was to be feared from the enemy. The new governor, however, brought with him 400 men for the greater security of the place; but soon resigned his government to Colonel Roger Elliot, during whose time Gibraltar was made a free port by a special order from the queen.

Colonel Elliot was succeeded by colonel Congreve before the year 1714, and he by Colonel Cotton a short time after. In 1720 the Spaniards seem to have threatened another attack. Ceuta, a Spanish fortress in Barbary, had been for many years besieged by the Moors; and a powerful armament, commanded by the marquis de Lada, was now assembled in Gibraltar-bay, under pretence of relieving the African fortresses, but with a secret design of first surprising Gibraltar; for which purpose they had provided scaling ladders, &c. The armament, however, had not been fitted out with such secrecy, but that the British ministry had intelligence of it. On this they sent orders to colonel Kane, governor of Minorca, to embark with part of his garrison for Gibraltar under convoy of the fleet in the Mediterranean. On his arrival he found the place in a critical situation. The garrison consisted only of three weak battalions under major Hetherington, besides whom there was only one other field officer, major Baiteroux, in the place, and no more than 14 days provisions remaining. The posture of affairs, however, was altered by the arrival of colonel Kane with 500 men with provisions and ammunition; which reinforcement, together with the spirited behaviour of the British commodore, induced the Spanish commander to abandon his design, though he remained of opinion that the fortresses might then have been carried by a general assault.

Notwithstanding this disappointment, the Spaniards continued to keep a watchful eye over Gibraltar; and, in the latter end of the year 1726, assembled an army in the neighbourhood of Algeiras, encamping, on the 20th of January following, on the plain below St Roch, and erecting a battery on the beach to protect their camp. Though admiral Hopson was then at anchor in the bay of Gibraltar, yet as he had received no intelligence of the actual commencement of hostilities between Britain and Spain, he was obliged to allow the boats of the latter to pass with provisions, arms, and ammunition, between Algeiras and the camp, at the same time that colonel now brigadier Kane, who had been a second time sent from Minorca, lay under similar embarrassments. The operations of the Spaniards however seemed so evidently to tend towards an attack, that the governor thought proper to order such of that nation as were in the town to leave it, and to forbid their galleys to anchor under his guns (A).

The brigadier then desired him to keep out of his reach, otherwise he should do his utmost to force him; but to this the Spanish commander replied, that, as the garrison could command no more than they had power to maintain, he should obey his catholic majesty's orders, and encroach as far as possible. Hostilities, however, were not commenced until the 10th of February 1727, when the Spaniards, having brought materials for batteries to the old wind-mill on the neutral ground, it was determined in a council of war, that the Spanish general had commenced hostilities by encroaching so far on the liberties of the garrison. Still, however, the governor sent to the count to know the reason of breaking ground before the garrison; but received for answer, that "he was in his master's territories, and was not answerable to any other person for his conduct." On this the governor opened the batteries of the Old Mole and those of Willis upon the Spanish workmen; however, they persisted in carrying on their operations, and at night marched a party down to the Devil's Tower, where they immediately broke ground, and began a communication with their other works. The governor was now informed by some deserters, that the enemy were forming a mine in a cave under Willis's battery, with a design to blow it up: but the plot being thus happily discovered, a party was immediately stationed to cut off the communication. On the 22d of February the Spaniards opened on the garrison with 17 pieces of cannon besides mortars; and the day following brigadier Kane left Gibraltar to send a reinforcement from Minorca. On the 3d of March the enemy opened a new battery of 22 guns on the Old Mole, and on the 8th another of 15 guns, bearing also upon the same Mole, the guns of which had annoyed the western flank of their approaches.

All this time the garrison had kept up a constant and well directed fire from the batteries which bore upon the works of the enemy; but the ordnance in general being old, were frequently bursting; by which they suffered more than from the fire of the besiegers. The latter were also greatly distressed by the fleet under admiral Hopson and Sir Charles Wager, who, since the beginning of the siege, had intercepted their home-bound ships, and at the same time greatly benefited the garrison by bringing the prizes into the bay. Finding the Spaniards, however, obstinately bent on their enterprise, they formed a design on the second of April, to bombard Algeiras, from whence the besieged were supplied with various articles of ammunition; but the fleet happening to be becalmed, the design was afterwards unaccountably abandoned; and on the arrival of a reinforcement from Minorca, they failed to the westward, leaving the garrison to defend themselves the best way they could.

The enemy continued to augment their batteries, and erect new ones, until they amounted at last to 60 cannon besides mortars; and, on the 3d of May, the governor received intelligence that a general assault was

intended; to repel which he took every proper precaution. The enemy, however, still added to their approaches, and considerable reinforcements were received by both parties. Hostilities, however, ceased on the 12th, when news arrived that the preliminaries of a general peace were signed; since which time to the year 1779 no farther attempts were made on Gibraltar. In the course of these two sieges the loss of the Spaniards was very considerable; that of 1705 costing them not less than 10,000 men, including those who died of sickness; and in that of 1727 their loss was computed at near 3000, besides casualties, which could not be ascertained. That of the garrison amounted in 1705 to 400; and in of 1727 to 300; a very small number, considering that during the siege 70 cannon and 30 mortars burst on the batteries.

The hostile manifesto presented by the Spanish ambassador to the court of London at the commencement of the late war, was soon followed by an interruption of communication betwixt Spain and the fortrefs of Gibraltar. No direct intention of attacking or distressing it, however, was manifested till the 16th of July, when the port was completely blocked up by a squadron of two 74 gun ships, several frigates, galleys, &c. Ten days after they began to form a camp on the plain below St Roch, three miles from the fortrefs. The garrison at this time consisted of 5382 men, including officers, with a company engineers and artificers; but the greatest expectations were formed from the abilities and valour of general Elliot the governor. As soon as the breaking off the communication with Spain indicated approaching hostilities, the governor took every precaution that could be suggested by military wisdom; but though informed of the rupture betwixt the two courts having actually taken place, and though he beheld the hostile operations of the enemy, no means were used to interrupt them till the 12th of September, when the batteries of Green's Lodge, Willis, and Queen Charlotte, were opened for a few hours, with a view to disturb the workmen.

From this time to the beginning of the year 1780 the enemy continued the blockade both by sea and land, but without doing any damage to the works or garrison; and it was not until the 12th of January that a single person was wounded. This happened to be a woman, who, passing near one of the houses, was slightly hurt by a shot from the enemy. In the mean time, however, the usual supplies of provisions being cut off, the garrison began to feel all the horrors of famine. All the necessaries of life were very scarce, and to be procured only at exorbitant prices. Veal, mutton, and beef, sold from half a crown to four shillings per pound; fresh pork from two to three shillings; salted beef and pork fifteen pence; fowls eighteen shillings per couple; ducks a guinea; fire-wood, five shillings per hundred weight; a pint of milk and water fifteen pence; a small cabbage cost five shillings, and a small bunch of outer leaves five pence; Irish butter half a crown per pound; candles as much; and eggs sixpence each. As the rock, however, is almost surrounded

Gibraltar. rounded by the sea, it was natural to suppose, that in such a scarcity of other provisions great benefit would have been derived from the ocean; but the fishermen, being all foreigners, and under no regulation, took advantage of the present scarcity of provisions in the garrison to exact a most exorbitant price for the fish they supplied.

²⁵
The Spanish fleet defeated and their admiral taken by Rodney.

Had matters remained long in this state, it is plain that the fortress, however strong, must have fallen into the hands of the enemy. They were, however, effectually relieved in consequence of the victory gained by admiral Rodney over the Spanish fleet commanded by Don Juan de Langara. The former had been furnished with a strong squadron, in order to relieve this important fortress: with which having set sail, he in a few days fell in with a Spanish fleet of 16 transports bound from Bilboa to Cadiz, and laden with provisions and naval stores, convoyed by a man of war of 64 guns, four frigates, and two armed vessels. Of these only a single transport escaped, the rest being all captured on the 8th of January 1780; and the loss of them, at the same time that it promised to be very serviceable to the garrison, was equally detrimental to the enemy, who were now in great want both of provisions and materials for their shipping.

This advantage was soon after followed by a much greater. On the 16th of the same month, a Spanish squadron of 11 sail of the line was discovered off Cape St Vincent; and the British admiral having taken the proper methods to come up with them as quickly as possible, an engagement took place about four in the afternoon. At this time the headmost ships of the British line closed in with the nearest of the enemy, and in half an hour one of the Spaniards, mounting 70 guns, and having on board 600 men, blew up, and all on board perished. In two hours more another Spanish ship of the line was taken; notwithstanding which the fight continued with great vigour till two in the morning, when the headmost ship of the enemy struck to the Sandwich; after which the firing ceased. The weather throughout the night was so tempestuous that it was with the utmost difficulty the British could take possession of those ships which surrendered. These were six in number, but two of them drove ashore and were lost, only four being brought safe into Gibraltar. These were the admiral's ship of 80 guns and 700 men, with three others of 70 guns and 600 men. The engagement, however, happened so near the shore, and the British were so eager in securing the lee-gage to prevent the enemy's escape, that Admiral Rodney's ship, together with some of the largest in the fleet, were in great danger of running on the shoals of St Lucar; nor could they be got into deep water again without much labour and the exertion of great naval skill. It was the opinion of all who were present in the action, that had this engagement happened in the day-time, or had the weather been less boisterous, not one of the Spanish ships could have escaped; and even as it was, those which got off were so essentially damaged as to be unfit for service.

²⁶
The garrison relieved and reinforced.

The news of this important victory arrived at Gibraltar on the evening of the day after it was fought; and in two days more the garrison was completely relieved by the arrival of the fleet and convoy, at the same time that they were farther reinforced by a regiment

of highlanders, consisting of 1051 men, officers included. An opportunity was also taken of sending away with the fleet all the invalids and women in the garrison; with whom they set sail on the 10th of February, leaving in the bay only the Edgar and Panther ships of the line, with two frigates.

On the departure of the British fleet the blockade was immediately resumed; and notwithstanding the ample supplies lately received, the garrison soon began again to experience the inconveniency of wanting fresh provisions. It had hitherto received these in abundance from the coast of Barbary; but an unaccountable alteration had now taken place, so that the friendship of the emperor of Morocco was transferred from Great Britain to Spain in a manner totally unprecedented. His partiality towards the latter was the more surprising, as Britain had given no provocation, and the enmity between Spain and Morocco seemed to be in a manner constitutional, and founded upon such causes as could never cease to operate. Thus, however, the garrison became daily more and more distressed, from being obliged to make constant use of their salt provisions, and even this with the strictest economy. The industry and resolution of the British seamen and officers, indeed, sometimes overcame all obstacles, so that they found means to procure the necessary refreshments; though in so doing they were certainly exposed to the utmost danger from the enemy. At the same time the defence of the garrison was so vigorous, that while it continued to be supplied even in this scanty manner, the Spaniards began to lose all hope of reducing it; for which reason they formed a project of burning all the British shipping in the bay. The night appointed for putting this scheme in execution was the 6th of June 1780, when ten fire-ships favoured by an uncommon darkness, stood over from the Spanish to the British side of the bay. Their design was to set fire to the storehouses nearest to the water side, as well as to the shipping there; but having been too precipitate in firing their ships, and being received also by a very heavy cannonade, the attempt was frustrated. On this occasion the skill and intrepidity of the British seamen was eminently displayed. Having manned their boats, they grappled the fireships already in flames; and, notwithstanding their dreadful appearance and the danger of their exploding, towed them clear of the vessels under the walls, and extinguished them.

Gibraltar,

²³
The garrison again reduced to straits.

²⁸
Unsuccessful attempt to burn the British shipping.

The failure of this project was a grievous disappointment to Don Barcelo, the Spanish admiral, who lay ready with his squadron to intercept the British vessels that might attempt to escape; at the same time that the batteries on their lines were in readiness to bombard the town, if the fire-ships had succeeded in causing any conflagration on shore. The failure of the present attempt, however, was soon followed by other disasters. As soon as they had, with great labour, pushed forward their new works, and constructed new batteries, they were certainly destroyed by the besieged; and their mortification on these occasions was the greater, as it was usual for the governor to allow them to complete their works before he commenced his destructive operations. Thus the labour of many days were often lost in a few hours, and afterwards was to be resumed with as little prospect of success as before.

²⁹
Spanish works destroyed.

Gibraltar. fore. The garrison were now considerably annoyed by the Spanish gun-boats, to which indeed the shipping were equally exposed with themselves. These vessels from 30 to 40 tons burden, constructed so that they lay low in the water, which rendered them difficult to be aimed at. They had 13 oars on a side, carried 40 or 50 men, with a 26 pounder on the prow; and, from the facility of managing them, two were deemed, in calm weather, to be a match for a frigate of moderate size. All their efforts, however, could still do no more than to reduce the garrison to great straits for want of provisions; and to this dreadful inconvenience the British submitted with the greatest cheerfulness. From the time of Admiral Rodney's departure in the month of February 1780 to the month of October, almost the only provisions in the garrison were such as tended to produce the scurvy; which accordingly raged in such a manner as to threaten the most fatal consequences. An antidote, however, was happily procured by the capture of a Danish dogger from Malaga laden with lemons and oranges, which the governor immediately purchased for the use of the garrison, and distributed among them. "At this time (says Captain Drinkwater) the scurvy had made dreadful ravages in our hospitals, and more were daily confined; many, however, unwilling to yield to its first attacks, persevered in their duty to the more advanced stages. It was therefore not uncommon, at this period, to see men, who, some months before, were hale, and capable of enduring any fatigue, supporting themselves to their posts upon crutches, and even with that assistance scarcely able to move along. The most fatal consequences in short were to be apprehended to the garrison from this terrible disorder, when this Dane was happily directed to our relief." According to Mr Cairncross, an eminent surgeon, who was present during this siege, "the scurvy, which now raged in Gibraltar, differed in no respect from that disease usually contracted by sailors in long sea-voyages; and of which the immediate cause seemed to be the subsisting for a length of time upon salted provisions only, without a sufficient quantity of vegetables or other acescent foods. The circumstances related in the voyage of that celebrated circumnavigator Lord Anson, of consolidated fractures disuniting, and the callosity of the bone being perfectly dissolved, occurred frequently in our hospitals, and old sores and wounds opened anew from the nature of the disorder. Various antiscorbutics were used without success, such as acid of vitriol, sour crout, extract of malt, essence of spruce, &c.; but the only specifics were fresh lemons and oranges given liberally; or, when they could not be procured, the preserved juice in such quantities, from one to four ounces per day, as the patient could bear. Whilst the lemons were found, from one to three were administered each day as circumstances directed. The juice given to those in the most malignant state was sometimes diluted with sugar, wine, or spirits; but the convalescents took it without dilution. Women and children were equally affected, nor were the officers exempted from this dreadful disorder. It became almost general at the commencement of the winter season, owing to the cold and moisture; and in the beginning of spring when vegetables were scarce. The juice was preserved by adding to 60 gallons of

expressed liquor about five or ten gallons of brandy, which kept it in so wholesome a state, that several casks were opened in good condition at the close of the siege. The old juice, however, was not so speedily efficacious as the fruit, though by persevering longer in its use it seldom failed."

Till this month the allowance of salt provisions had continued undiminished; but now it was judged necessary to reduce the allowance of bread and meat, and to make some other regulations in order to enforce the strictest economy with regard to food. Every thing of this kind that could be practised, however, seemed insufficient to preserve the garrison from absolute want. In the beginning of the year 1781 provisions became exceedingly scarce, by reason of the almost total expenditure of what was contained in the public stores, and the vigilance of the enemy's cruizers. About the middle of February the town bakers left off work for want of flour; and many of the poorer sort wanted bread. The price of fresh provisions again rose to a most enormous height. Small pigs sold at two guineas: turnkeys at three; geese at 30 shillings; fowls and ducks at 10 shillings; damaged biscuit a shilling the pound; pease 18d.; and all other necessaries in proportion; at the same time the scarcity of fuel was such, that it was sometimes scarcely procurable in quantity sufficient to dress the victuals.

The garrison had hitherto derived assistance occasionally from the gardens on the neutral ground, though vast quantities of vegetables had been removed thence by the enemy. Towards the end of the month of October 1780, however, the Spaniards determined to expel the British from the gardens entirely; and this they accomplished in spite of all that could be done to prevent them. From this time the resources with regard to vegetables depended entirely upon the attention paid to cultivation; which, happily for the garrison, was attended with such success, especially during the winter months, that the produce came at last to be nearly equal to the demands. At last, on the 12th of April 1781, supplies were brought by the British fleet under admirals Darby, Digby, and Ross, though they could not be got in without great difficulty. The gun-boats already mentioned were now much increased in number and strength of construction; infesting the bay in such a manner as greatly to interrupt the debarkation of the stores. As no vessels of the same kind had been prepared to oppose them, they could scarce be prevented from effecting their purpose of burning the store-ships. With this view they had approached them every morning in hazy weather to the number of between 20 and 30, several of them carrying mortar-pieces; and as they used both sails and oars, they eluded all pursuit, by withdrawing on the rise of any breeze. To keep off these troublesome guests several stout frigates were obliged to station themselves along the bay for the protection of the shipping; but even this did not prevent them from continuing their molestation; and notwithstanding the vigilance and activity of the British sailors, it was seldom that they could come near enough to do them any damage. In spite of all their endeavours, however, the garrison was effectually relieved; an exploit which so exceedingly irritated the court of Spain, that they determined to exert the utmost force of the kingdom rather than fail

Gibraltar. in the execution of their favourite project. The works before the town were therefore carried on with more vigour than ever, and the most tremendous preparations made to cause the obstinate garrison feel the resentment of an exasperated enemy. Their batteries were now mounted with guns of the heaviest metal, and with mortar-pieces of the largest size; the number of the former augmented to near 200, and of the latter to upwards of 80. For three weeks this prodigious artillery continued to pour fourth an almost incessant shower of shot and shells, inasmuch, that, in the time just mentioned, they had consumed 100,000 lb. of gunpowder, and thrown into the town four or five thousand shot or shells every 24 hours.

³⁸
The town
entirely de-
stroyed.

By such an immense bombardment the town was almost totally laid in ruins. The inhabitants, computed at more than 3000 in number, experienced every difficulty that could arise from the destruction of their habitations: several of them were killed, and all forced to leave the town, and take shelter under tents with what accommodation could be provided for them in such scenes of horror and confusion. Numbers took the opportunity of retiring with the fleet; while many that remained were now reduced from a state of opulence to the greatest distress. The conduct of Governor Elliot was very humane and compassionate to such

as were obliged to stay; allowing them a free passage to England, and supplying them with provisions for the voyage. Gibraltar.

⁵⁹
Disorderly
behaviour
of the sol-
diers.

During this bombardment, not only the greatest part of the effects belonging to the inhabitants were destroyed, but the fortifications were in many places greatly injured; and the worst was, that the remainder were destroyed by the soldiers, who had arrived at such a pitch of licentiousness, that they neither regarded nor would obey their officers. They were incited to this destructive scheme by the avarice of some of the inhabitants who had hoarded up and concealed a quantity of necessary articles, in order to procure an advanced price. They now, therefore, kept no bounds in dissipation, waste, and extravagance; a remarkable instance of which is given by Captain Drinkwater, in their roasting a pig by a fire made of cinnamon. To put a stop to these atrocious proceedings, rigorous measures were of necessity adopted; and it was intimated, that any soldier convicted of being drunk or asleep upon his post, or found marauding, should be immediately executed. The loss of human lives during this dreadful bombardment was less than could have been expected; but many remarkable circumstances are taken notice of by Captain Drinkwater, some of which are related in the note (B)

(B) Two boys belonging to the artificer company were endowed with such wonderful strength of vision, that they could see the shot of the enemy in the air almost as soon as it came from the mouth of the gun; and were therefore constantly placed upon some part of the works to give notice to the soldiers of the approaching danger. During the time of the hottest fire, however, the men were so habituated to the fall of shells and shot around them, that they contracted an insensibility of danger, and almost required to be cautioned by their officers to avoid the explosion of a shell when lying with the fusee burning at their feet. In consequence of this inattention, they frequently neglected the advice of the boys abovementioned, and their neglect could not but be productive of fatal effects. An instance of this happened on the Princess Amelia's battery, where a shot thus disregarded came through one of the capped embrasures, carried off one of the legs from three soldiers, and wounded a fourth in both. In other cases, in which the persons themselves have observed the shot or shells coming towards them, they have been fascinated by its appearance, and unable to move from the spot, as small birds are said to be by the rattle-snake. "This sudden arrest of the faculties (says our author) was nothing uncommon: several instances occurred to my own observation, where men, totally free, have had their senses so engaged by a shell in its descent, that though sensible of their danger, even so far as to cry for assistance, they have been immoveably fixed to the place. But what is more remarkable, these men have so instantaneously recovered themselves on its fall to the ground, as to remove to a place of safety before the shell burst." In this manner Lieutenant Lowe of the 12th regiment was fascinated by a shot which he saw coming, but had not power to remove from the place before it fell upon him and took off his leg.

Where these shells burst they produced instant and certain destruction, mangling in the most dreadful manner. The following are some instances. A matross had the misfortune of breaking his thigh by some accident; and being a man of great spirit, could scarce bear the confinement necessary for its reunion. In consequence of this he went abroad too soon, and thus unfortunately broke the bone a second time. Being now confined to bed, a shell happened to fall into the room where he was, and, rebounding, lodged itself directly upon him. The convalescents and sick instantly summoned all their strength, and crawled out of the room, while the poor matross lay below the shell, kept down by its weight, and utterly unable to stir. In a few seconds it burst, and took off both his legs, and scorched him in a dreadful manner. He survived the explosion, was sensible to the last moment, and died regretting that he had not been killed on the batteries. The case of a soldier of the 73d regiment shows that even in the most dangerous cases we should never despair of recovery while life remains. This unfortunate man had been knocked down by the wind of a shell, which, instantly bursting, killed his companion, and mangled himself in a shocking manner. His skull was dreadfully fractured, his left arm broken in two pieces, one of his legs shattered, the skin and muscles torn off from part of his right hand, the middle finger broken to pieces, and his whole body most severely bruised and marked with gunpowder. He presented so horrid an object to the surgeons, that they had not the least hopes of saving his life, and were at a loss what part to attend to first. He was that evening trampled; a few days afterwards his leg was amputated, and other wounds and fractures were dressed. Being possessed of a most excellent constitution, nature performed wonders in his favour, and in 11 weeks his cure was completely effected. On the 18th of September a shell from the lines fell into a house where the town-major captain Burke, with majors

Mercier

Gibraltar.

By the beginning of June 1781, the enemy had relaxed considerably in their firing, seldom exceeding 600 shot in a day; and continued gradually to diminish this number so remarkably, that towards the end of August they seldom fired in the day, and only discharged six or seven, and sometimes not above three, shot in the night. The batteries at land, however, were succeeded by the gun-boats; which renewed their attacks every day, keeping the garrison in continual alarm, and never failing to do more or less execution. To restrain them, therefore, a battery of guns capable of throwing their shot to a great distance was erected as near as possible to the enemy; and as it reached their very camp, it was determined to open it upon them as often as the gun-boats made their attacks; which being soon perceived, they thought it prudent to desist in some measure from that mode of hostility.

40
The works of the enemy brought to the utmost perfection.

41
They are entirely destroyed.

They continued still, however, to improve their works, and for this purpose employed the best engineers both of France and Spain; so that by the latter part of November 1781, they had them brought to such a state of perfection as filled both kingdoms with the most sanguine expectations of success. Governor Elliot, however, far from being dismayed at these formidable bulwarks, suffered them to proceed without molestation to the end of their scheme, that he might as in a moment destroy the labour of so many months, and thus render the disappointment the greater. In the night of the 27th of November, a chosen party of 2000 men was detached, in order to destroy the enemies works and batteries; and their success was equal to their most sanguine expectation. They marched out in great order and silence about two o'clock in the morning, under the command of brigadier-general Ross; after which they proceeded with the same circumspection, but with the utmost celerity, to the enemy's works, which they stormed and overthrew with astonishing rapidity. The Spaniards were instantly thrown into confusion, and fled

on every side; the guns and mortars on the batteries were all spiked up; and the artillery-men, artificers, and sailors, exerted themselves so vigorously, that in the space of an hour the magazines were blown up, the store-houses of arms, ammunition, and military implements of every kind, and all the works that had been constructed, were set on fire, and totally consumed; the whole damage done on this occasion being estimated at upwards of two millions sterling.

For several days after this disaster the Spaniards continued inactive, without even making any attempt to extinguish their batteries, which still continued in flames; but in the beginning of December, as if suddenly aroused from their reverie, upwards of 1000 men were set to work in order to prepare a great number of fascines, from whence it was concluded that they designed to repair their works. In this they proceeded with their usual perseverance and diligence; but as the former methods of attack had constantly failed, it was evident, that if the place could be reduced at all, it must be by some means hitherto unattempted; and for the reduction of this single fortress, the Spanish monarch, after the conquest of Minorca, determined to employ the whole strength of his empire. Among the various projects formed at this time, that of the chevalier D'Arcon, a French engineer of distinction, proved the most acceptable to the court of Spain; and though the expence attending it was immense, this seemed in the present circumstances to be but a matter of small consideration. His plan was to construct such floating batteries as might neither be liable to be sunk nor set on fire. With this view their bottoms were made of the thickest timber, and their sides of wood and cork long soaked in water, with a layer of wet-sand betwixt them. Their thickness was such, that they were impenetrable to cannon-shot; and to prevent the effects of red-hot balls, a number of pipes were contrived to carry water through every part of the vessel, and pumps sufficient to furnish

Gibraltar.

Mercier and Vignoles of the 39th regiment were sitting. It took off major Burke's thigh; afterwards fell through the floor into the cellar: there it burst, and forced the flooring with the unfortunate major up to the ceiling. When assistance came, they found him almost buried in the ruins of the room. He was instantly conveyed to the hospital, where he died soon after the wounded part had been amputated. Majors Mercier and Vignoles had time to escape before the shell burst; nevertheless they were slightly wounded by the splinters, as were a serjeant and his daughter, who happened to be in the cellar when the shell entered.

The following are related as instances of very extraordinary escapes from the destructive power of these engines, and which indeed it seems difficult to account for.—A corporal had the muzzle of his firelock closed, and the barrel twisted like a French horn, by a shell, without any injury to his person. A shell happened to fall into a tent where two soldiers were asleep, without awaking them by its fall. A serjeant in an adjacent tent heard it, and ran near 40 yards to a place of safety, when he recollected the situation of his comrades. Thinking the shell had fallen blind, he returned and awakened them; both immediately rose, but continued by the place, debating on the narrow escape they had had, when the shell exploded, and forced them with great violence against a garden wall, but, “miraculously” did no further mischief than destroying every thing in the tent. On the new year's day of 1782, an officer of artillery observed a shell falling towards the place where he stood, and got behind a traverse for protection. This he had scarcely done, when the shell fell into the traverse, and instantly entangled him in the rubbish: one of the guard, named *Martin*, observing his distress, generously risked his own life in defence of his officer, and ran to extricate him: but finding his own efforts ineffectual, called for assistance; when another of the guard joining him, they relieved the officer from his situation; and almost the same instant the shell burst, and levelled the traverse with the ground. *Martin* was afterwards promoted, and rewarded by the governor; who at the same time told him, that “he should equally have noticed him for attending to his comrade.” A shell happening to fall into the room where ensign Mackenzie of the 73d regiment was sitting, carried away part of his chair, and fell into the room below, where it burst, lifting him and the chair from the floor without further injury.

Gibraltar. nish a constant supply for the purpose. The people at the batteries were sheltered from the bombs by a rope-netting made sloping, that they might roll off, and spread with wet skins to prevent fire. Ten of these batteries were constructed out of the hulls of large vessels, some of 50 or 60 guns, cut down for that purpose, and carrying from 10 to 28 guns each, with about half as many in reserve in case of accidents. Each gun was served by 36 artillery-men; and these floating batteries were to be seconded by 80 large boats carrying guns and mortars of heavy metal; a great number of ships of force and frigates, with some hundreds of small craft, were to accompany them with troops, for the instant execution of what might be judged necessary. On this occasion upwards of 1000 pieces of artillery and 80,000 barrels of gun-powder were provided. A body of 12,000 of the best troops of France were now added to the Spanish army before the place; the body of engineers was the best that both kingdoms could produce; and numbers of volunteers, of the best families in both, attended the siege. Numbers of military gentlemen also came from every part of Europe to be witnesses of what passed at this celebrated siege, which was now compared to the most famous recorded in history. The conducting of it was committed to the duke de Crillon, who had distinguished himself by the conquest of Minorca. Two princes of the blood royal of France, the count of Artois brother to the king, and the duke of Bourbon his cousin, came to be witnesses of this extraordinary enterprise. These behaved with the greatest politeness both to the governor and garrison. The count of Artois transmitted a packet of letters for various individuals in the garrison, which had been intercepted and carried to Madrid, and which he requested that he might be the means of conveying to those for whom they were designed. Both he and the duke of Bourbon signified to General Elliot the high regard they had for his person and character; and the duke de Crillon himself took this opportunity of expressing the same sentiments, and to intreat him to accept of some refreshments. General Elliot returned a polite answer, but accepted of the present with reluctance, and requested him for the future not to confer any favours of that kind upon him.

43
Prodigious
armament
brought
before the
fortress.

Such a prodigious armament raised the confidence of the besiegers so high that they looked upon the conquest of the place as an absolute certainty. They began to be impatient at the delays which arose in bringing matters to the utmost point of perfection; and the commander in chief was thought by far too modest, when he said, that the garrison might hold out for a fortnight. "It appeared (says Captain Drinkwater) that they meant, previous to their final efforts, to strike if possible a terror through their opponents, by displaying an armament more powerful than had probably ever been brought before any fortress. Forty-seven sail of the line, including three inferior two deckers; ten battering ships, deemed perfect in design, and esteemed invincible, carrying 212 guns; innumerable frigates, xebèques, bomb-ketches

cutters, gun and mortar boats, and smaller craft for disembarking men, were assembled in the bay. On the land side were most stupendous and strong batteries and works, mounting 200 pieces of heavy ordnance, and protected by an army of near 40,000 men, commanded by a victorious and active general, and animated by the immediate presence of two princes of the blood royal of France, with other dignified personages, and many of their own nobility. In their certainty of success, however, the enemy seemed entirely to have overlooked the nature of that force which was opposed to them; for though the garrison scarcely consisted of more than 7000 effective men, including the marine brigade, they forgot that they were now veterans in this service, had long been habituated to the effects of artillery, and were by degrees prepared for the arduous conflict that awaited them. We were at the same time commanded by officers of approved courage, prudence, and activity; eminent for all the accomplishments of their profession, and in whom we had unbounded confidence. Our spirits too were not a little elevated by the success attending the firing of red-hot shot (c), which in this attack we hoped would enable us to bring our labours to a conclusion, and relieve us from the tedious cruelty of a vexatious blockade."

As a prelude to the dreadful storm which was about to be poured forth on this devoted garrison, the enemy, on the 9th of September 1782, opened a battery of 64 of their largest cannon, which was shortly accompanied with a terrible fire from other batteries, and a great number of mortars. On this and the following day an attack was made upon the batteries erected on Europa Point (so called from being the most southerly point of the continent of Europe), which at that time were entirely under the management of captain Curtis of the Brilliant frigate, who had distinguished himself during the siege, and now commanded a brigade of seamen by whom the batteries were served. By these the fire of the Spaniards was so warmly returned, that they not only could make no impression, but were forced to retire, after having received so much damage, that two of their principal ships were obliged to withdraw to the bay of Algeiras, opposite to Gibraltar, in order to refit. On the 12th the enemy made preparations for the ensuing day, which was allotted for their grand and decisive attack. Accordingly, on the morning of the 13th, the ten float-

Gibraltar:

44
Decisive at-
tack on the
13th of Sep-
tember,
1782.

(c) This was suggested by lieutenant-governor Boyd, and had been attended with remarkable success, September 8th, when the enemy's advanced works were almost destroyed by it.

Gibraltar. that of the Spaniards began to slacken, and the fire of the garrison to obtain a superiority. About two o'clock the principal battering ship commanded by Don Moreno was observed to emit smoke as if on fire, and some men were seen busy upon the roof searching from whence it proceeded. The fire from the garrison was now kept up without the least discontinuance or diminution, while that from the floating batteries was perceived sensibly to decrease; so that about seven in the evening they fired but few guns, and that only at intervals. At midnight the admiral's ship was plainly seen to burn, and an hour after was completely in flames. Eight more of these batteries took fire successively; and on the signals of distress made by them, the multitude of feluccas, launches, and boats, with which they were surrounded, all came to their assistance, and began to take the men out of the burning vessels. Captain Curtis, who lay ready with the gunboats to take advantage of any favourable circumstance, came upon them at two in the morning, and forming a line on the enemy's flank, advanced upon them with such order and expedition as to throw them into immediate confusion. At this sudden and unexpected attack they were so astonished and disconcerted, that they fled precipitately with all their boats, totally abandoning their floating batteries to be burnt, and all who were in them to perish in the flames. This would undoubtedly have been their fate, had not captain Curtis extricated them from the fire at the imminent danger of his own life and that of his men. In this work he was so eager, that while his boat was alongside of one of the largest batteries, it blew up, and the fragments of the wreck spreading all around to a vast distance, some heavy pieces of timber fell into his boat and pierced through its bottom, killing one man and wounding several others. He escaped with difficulty out of this boat, which was sunk, as well as another, by the same accident. The floating batteries were every one consumed; and the violence with which they exploded was such, that doors and windows at a great distance from shore were burst open. About 400 people were saved from them; many of whom were picked up floating on rafts and pieces of timber. Indeed the blowing up of the batteries as the flames reached their powder rooms, and the discharge of the guns in succession as the metal became heated by the fire, rendered any attempt to save them very dangerous.

45
Terrible
destruction
of the Spaniards.

46
Inactivity
of the combined fleet.

This terrible catastrophe took place in sight of the combined fleets of France and Spain. It had been proposed that they should co-operate upon this important occasion, by attacking the garrison at Europa Point, and such places as appeared most exposed to an attempt by sea. This, it was afterwards said, must have occasioned a material diversion of the garrison's force, and, by dividing it, have weakened considerably the vigorous means of defence used in those parts which were actually attacked. The reason assigned for this inactivity was the want of wind.

47
The blockade continued.

Though this terrible repulse effectually convinced the Spaniards that Gibraltar could not be taken by force, some hope still remained, that, without any further exertions on their part, the garrison would be obliged to surrender from want of ammunition and provisions. With this view they continued to blockade it closely, and to cut off all communication, flattering

themselves that Britain would not be able to collect a naval force sufficient to drive their fleet from the bay before the fortress was reduced to extremity; and this, they imagined, must be the case in a few days. Such diligence, however, had been used on the part of the British, that a fleet was already assembled at Portsmouth, consisting of 35 sail of the line, in excellent condition, and filled with the best officers and sailors in Europe. The command was given to Lord Howe, who was accompanied in the expedition by admirals Barrington, Milbank, Hood, Sir Richard Hughes, and commodore Hotham, all of them men eminent in their profession. At the same time also it fortunately happened, that a large British fleet of merchantmen had just arrived in safety from the Baltic; and that a Dutch squadron, which had been cruising on their own coasts, not being able to penetrate southwards in order to join the French, had retired into port, and given up the intention of effecting any junction for that season.

At this time the British nation was in the utmost anxiety about the fate of Gibraltar. The progress of the ships was delayed by contrary winds, and it was not until they had gained the southern coast of Portugal that they received information of the defeat of the enemy's attempt on the 13th of September. On the 11th of October Lord Howe entered the Straits, and several of the storeships destined for Gibraltar came safe to anchor under the cannon of the fort without any molestation from the enemy. The combined fleet in the mean time had been much damaged by a storm; two ships of the line were driven ashore near Algeiras; two more were driven out of the bay into the Mediterranean; others lost their masts, and most of them suffered considerably. One in particular, a ship of 70 guns, was carried by the storm across the bay, and ran aground under the works of Gibraltar, where she was taken by the garrison, with her whole complement of men, consisting of 700. Notwithstanding the endeavours of the enemy to destroy her, she was safely got off, and properly repaired. The combined fleet, however, put to sea on the 13th, with a view to prevent the remaining storeships that had overshot the bay to the east, from making good their entrance into it; and at the same time to rejoin the two ships that had been separated from the main body by the storms. Having the advantage of the wind, they bore down upon the British fleet, which drew up in order of battle to receive them; but notwithstanding their superiority, they declined coming to an engagement. On the wind becoming more favourable next day, Lord Howe took the opportunity to bring in the storeships that were in company; and the day following the remainder were conveyed to Gibraltar, the troops for the reinforcement of the garrison were landed, with a large supply of powder and ample provision in every other respect. As they returned through the straits they were threatened with an engagement by the combined fleets; but though the latter had a superiority of 12 ships of the line, they kept at a wary distance. Some firing indeed took place, but it was attended with little effect on either side.

48
The garrison finally relieved.

This last relief proved entirely decisive; for though the blockade continued till news arrived of the preliminaries of peace being signed, in the beginning of February 1783, no other attack was made. The news of the

Gibraltar,
Gibson.

the pacification were received with the utmost joy by the Spaniards. Mutual civilities passed between the commanders in chief, and the Duke de Crillon paid many handsome compliments to the governor and garriſon for their noble defence; declaring that he had exerted himſelf to the utmoſt of his abilities, and though he had not proved ſucceſſful, yet he was happy in having his ſovereign's approbation of his conduct.

The poſſeſſion of Gibraltar is eſteemed of very great conſequence to Britain. It not only gives her the command of the Straits, and their navigation; but affords reſreſhment and accommodation to her fleets in time of war, and to her merchantmen at all times; which, to a maritime power, is of very great advantage. From its ſituation, it divides both the kingdoms of France and Spain; that is, it hinders a ready communication by ſea between the different parts of theſe kingdoms. This, of courſe, hinders the conjunction of the fleets and ſquadrons with each other, or at leaſt renders it ſo difficult as to be a perpetual check upon theſe ambitious powers. It aweiſes alſo the piratical ſtates of Barbary, and in like manner the emperor of Morocco; inſomuch, that the Britiſh commerce is more ſafe than that of any other European power, which gives it great advantages in point of freight. It is otherwiſe highly favourable to its trade in the Mediterranean and Levant. It procures Britain the reſpect of the Italian and other powers; who, though far diſtant from her, muſt conſider this as an inſtance of her power to hurt or aſſiſt them. It alſo ſaves her the expence of ſquadrons and convoys, upon any diſputes or diſturbances that may happen among theſe powers, and which would otherwiſe be neceſſary for the protection of her navigation.

GIBSON (RICHARD), an Engliſh painter, commonly called the *Dwarf*, was originally page to a lady at Mortlake; who, obſerving that his genius led him to painting, had the generoſity to get him inſtructed in the rudiments of that art. He devoted himſelf to Sir Peter Lely's manner, and copied his pictures to admiration, eſpecially his portraits; his paintings in water-colours were alſo eſteemed. He was in great favour with Charles I. who made him his page of the back-ſtairs; and he had the honour to inſtruct in drawing queen Mary and queen Anne when they were princeſſes. He married one Mrs Anne Shepherd, who was alſo a dwarf; on which occaſion king Charles I. honoured their marriage with his preſence, and gave away the bride. Mr Waller wrote a poem on this occaſion, intitled "The marriage of the Dwarfs; in which are theſe lines:

" Deſign or chance makes others wiſe,
" But nature did this match contrive,
" Eve might as well have Adam fled,
" As ſhe deny'd her little bed
" To him, for whom heav'n ſeem'd to frame
" And meaſure out this only dame."

Mr Fenton, in his notes on this poem, obſerves that he had ſeen this couple painted by Sir Peter Lely; and that they were of an equal ſtature, each being three feet ten inches high. However, they had nine children, five of whom arrived at maturity; theſe well proportioned, and of the uſual ſtandard of mankind. But what nature denied this couple in ſtature, ſhe gave them in length of days: for Mr Gibſon died in the

75th year of his age; and his wife, having ſurvived him almoſt 20 years, died in 1709, aged 89.

Gibson.

GIBSON (Dr Edmund), biſhop of London, was born in Weſtmoreland, in 1669. He applied himſelf early and vigorouſly to learning, and diſplayed his knowledge in ſeveral writings and tranſlations, which recommended him to the patronage of archbiſhop Tenniſon. He was appointed domeſtic chaplain to his Grace; and we ſoon after find him rector of Lambeth, and archdeacon of Surry. Becoming thus a member of the convocation, he engaged in a controverſy, which was carried on with great warmth by the members of both houſes, and defended his patron's rights, as preſident, in eleven pamphlets; he then formed and completed his more comprehensive ſcheme of the legal duties and rights of the Engliſh clergy, which was at length publiſhed under the title of *Codex Juris Eccleſiaſtici Anglicani*, in folio. Archbiſhop Tenniſon dying in 1715, and Dr Wake biſhop of Lincoln being made archbiſhop of Canterbury, Dr Gibſon ſucceeded the latter in the ſee of Lincoln, and in 1720 was promoted to the biſhopric of London. He now not only governed his diocēſe with the moſt exact regularity, but by his great care promoted the ſpiritual affairs of the church of England colonies in the Weſt Indies. He was extremely jealous of the leaſt of the privileges belonging to the church; and therefore, though he approved of the toleration of the Proteſtant Diſſenters, he continually guarded againſt all the attempts made to procure a repeal of the corporation and teſt acts; in particular, his oppoſition to thoſe licentious aſſemblies called *maſquerades*, gave great umbrage at court, and effectually excluded him from all further favours. He ſpent the latter part of his life in writing and printing paſtoral letters, viſitation-charges, occaſional ſermons, and tracts againſt the prevailing immoralities of the age. His paſtoral letters are juſtly eſteemed as the moſt maſterly productions againſt infidelity and enthuſiaſm. His moſt celebrated work, the *Codex*, has been already mentioned. His other publications are, 1. An edition of Drummond's *Polemo-Middinia*, and James V. of Scotland's *Cantilena Ruſtica*, with notes. 2. The *Chronicon Saxonicum*, with a Latin tranſlation, and notes. 3. *Reliquia Spelmanianæ*, the poſthumous works of Sir Henry Spelman, relating to the laws and antiquities of England. 4. An edition of *Quintilian de Arte Oratoria*, with notes. 5. An Engliſh tranſlation of Cambden's *Britannia*, with additions, two volumes folio: and, 6. A number of ſmall pieces, that have been collected together and printed in three volumes folio.— His intenſe application to ſtudy impaired his health; notwithſtanding which, he attained the age of 79. He expired in September 1748, after an epiſcopate of near 33 years. With regard to biſhop Gibſon's private life and character, he was in every reſpect a perfect ecomiſt. His abilities were ſo well adapted to diſcharge the duties of his ſacred function, that, during the incapacity of archbiſhop Wake, the tranſaction of eccleſiaſtical affairs was committed to the biſhop of London. He was a true friend to the eſtabliſhed church and government, and as great an enemy to perfecution. He was uſually conſulted by the moſt learned and exalted perſonages in church and ſtate, and the great-

wick.

greatest deference was paid to his judgment. He possessed the social virtues in an eminent degree; his beneficence was very extensive; and had such generosity, that he freely gave two thousand five hundred pounds, left him by Dr Crow, who was once his chaplain, to Crow's own relations, who were very poor.

GIDEON, the son of Joash, of the tribe of Manasseh. He dwelt in the city of Ophrah: and had a very extraordinary call to deliver the Israelites from the oppression of the Midianites, to which they had become subject after the death of Barak and Deborah. Having effected their deliverance by supernatural aid, he was chosen judge of Israel in the year of the world 2759, and died in 2768. (See Judges, Chap. vi, vii, & viii.)

GIFT, *Donum*, in law, is a conveyance which passeth either lands or goods; and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken strictly, it is applicable only to lands and tenements given in tail; but *gift* and *grant* are too often confounded.

New-Year's Gifts, presents made on new-year's day, as a token of the giver's good-will, as well as by way of presage of a happy year.

This practice is very ancient, the origin of it among the Romans being referred to Tatius king of the Sabines, who reigned at Rome conjointly with Romulus, and who having considered as a good omen a present of some springs of vervain gathered in a wood consecrated to Strenia the goddess of strength, which he received on the first day of the new year, authorised this custom afterwards, and gave to these presents the name of Strenæ. However this may be, the Romans on that day celebrated a festival in honour of Janus, and paid their respects at the same time to Juno; but they did not pass it in idleness, lest they should become indolent during the rest of the year. They sent presents to one another of figs, dates, honey, &c. to show their friends that they wished them a happy and agreeable life. Clients, that is to say those who were under the protection of the great, carried presents of this kind to their patrons, adding to them a small piece of silver. Under Augustus, the senate, the knights, and the people, presented such gifts to him, and in his absence deposited them in the Capitol. Of the succeeding princes some adopted this custom, and others abolished it, but it always continued among the people. The early Christians condemned it, because it appeared to be a relique of Paganism, and a species of superstition; but when it began to have no other object than that of being a mark of veneration and esteem, the church ceased to disapprove of it.

GIGG, **GIGA**, or **JIG**, in music and dancing, a gay, brisk, sprightly composition, and yet in full measure, as well as the allemand, which is more serious. Menage takes the word to arise from the Italian *giga*, a musical instrument mentioned by Dante. Others suppose it to be derived from the Teutonic *gieg*, or *ghiighe*, "a fiddle." This is a favourite air in most nations of Europe: its characteristic is duple time, marked $\frac{6}{8}$, or $\frac{7}{8}$: it consists of two strains, without any determinate number of bars.

GIGGLEWICK, a town in the West Riding of Yorkshire, half a mile from Settle, stands on the river

Ribble; where, at the foot of a mountain is a spring, the most noted in England for ebbing and flowing sometimes thrice in an hour, and the water subsides three quarters of a yard at the reflux, though the sea is 30 miles off. At this town is an eminent free grammar school; and in the neighbourhood are dug up flags, slate, and stone, with a good lime-kiln.

GILAN, or **GILAN**, a considerable province of Asia in Persia, lying on the side of the Caspian sea, and to the S. W. of it. It is supposed to be the Hyrcania of the ancients. It is very agreeably situated, having the sea on one side and high mountains on the other; and there is no entering it but through narrow passes, which may be easily defended. The sides of the mountains are covered with many sorts of fruit-trees, and in the highest parts of them there are deer, bears, wolves, leopards, and tygers; which last the Persians have a method of taming, and hunt with them as we do with dogs. Gilan is one of the most fruitful provinces of all Persia; and produces abundance of silk, oil, wine, rice, and tobacco, besides excellent fruits. The inhabitants are brave, and of a better complexion than the other Indians, and the women are accounted extremely handsome. Resht is the capital town.

GIHON, (anc. geog.) one of the rivers of Paradise; according to Wells, the eastern branch of the Euphrates, into which it divides after its conjunction with the Tigris.

GILBERT, or **GILBERD**, (William), a Physician, was born at Colchester in the year 1540, the eldest son of the recorder of that borough. Having spent some time in both universities, he went abroad; and at his return settled in London where he practised with considerable reputation. He became a member of the college of physicians, and physician in ordinary to Queen Elizabeth, who, we are told, gave him a pension to encourage him in his studies. From his epitaph it appears that he was also physician to King James I. He died in the year 1603, aged 63; and was buried in Trinity-church in Colchester, where a handsome monument was erected to his memory. His books, globes, instruments, and fossils, he bequeathed to the college of physicians, and his picture to the school-gallery at Oxford. He wrote, 1. *De magnetibus, magneticisque corporibus, et de magno magneti tellure, physiologia nova*; London 1600, folio. 2. *De mundo nostro sublunari, philosophia nova*; Amsterdam 1651, 4to. He was also the inventor of two mathematical instruments for finding the latitude at sea without the help of sun, moon, or stars. A description of these instruments was afterwards published by Thomas Blondeville in his *Theoriques of the planets*.

GILBERT (Sir Humphrey), a brave officer and skilful navigator, was born about the year 1539, in Devonshire, of an ancient and honourable family. Though a second son, he inherited a considerable fortune from his father. He was educated at Eaton, and afterwards at Oxford; where probably he did not continue long, as he hath escaped the industrious Anthony Wood. It seems he was intended to finish his studies in the Temple; but being introduced at court by his aunt Mrs Catherine Ashley, then in the queen's service, he was diverted from the study of the law, and commenced soldier. Having distinguished himself

self in several military expeditions, particularly that to Newhaven in 1563, he was sent over to Ireland to assist in suppressing a rebellion; where, for his signal services, he was made commander in chief and governor of Munster, and knighted by the lord deputy, Sir Henry Sidney, on the first day of the year 1570. He returned soon after to England, where he married a rich heiress. Nevertheless, in 1572, he sailed with a squadron of nine ships to reinforce Colonel Morgan, who at that time meditated the recovery of Flushing. Probably on his return to England he resumed his cosmographical studies, to which he was naturally inclined: for, in the year 1576, he published his book on the north-west passage to the East Indies; and as Martin Forbisher sailed the same year, probably it was in consequence of this treatise. In 1578, he obtained from the queen a very ample patent, empowering him to discover and possess in North America any lands then unsettled. He sailed to Newfoundland, but soon returned to England without success: nevertheless, in 1583, he embarked a second time with five ships, the largest of which put back on account of a contagious distemper on board. Our general landed on Newfoundland on the third of August, and on the fifth took possession of the harbour of St. John's. By virtue of his patent, he granted leases to several people; but though none of them remained there at that time, they settled afterwards in consequence of these leases: so that Sir Humphrey deserves to be remembered as the real founder of the vast American empire. On the 20th of August he put to sea again, on board a small sloop; which on the 29th foundered in a hard gale of wind. Thus perished Sir Humphry Gilbert; a man of quick parts, a brave soldier, a good mathematician, a skilful navigator, and of a very enterprising genius. We learn also, that he was remarkable for his eloquence, being much admired for his patriotic speeches both in the English and Irish parliaments. He wrote "A discourse to prove a passage by the north-west to Cathaia and the East Indies, printed Lond. 1576." This treatise, which is a masterly performance, is preserved in Hakluyt's collection of voyages, vol. iii. p. 11. The style is superior to most, if not to all, the writers of that age; and shows the author to have been a man of considerable reading. He mentions, at the close of this work, another treatise on navigation, which he intended to publish: it is probably lost.

GILBERTINES, an order of religious, thus called from St Gilbert of Sempringham, in the county of Lincoln, who founded the same about the year 1148: the monks of which observed the rule of St Augustine; and were accounted canons: and the nuns that of St Benedict.

The founder of this order created a double monastery, or rather two different ones, contiguous to each other, the one for men, the other for women, but parted by a very high wall.

St Gilbert himself founded 13 monasteries of this order, viz. four for men alone, and nine for men and women together, which had in them 700 brethren and 1500 sisters. At the dissolution there were about 25 houses of this order in England and Wales.

GILBOA, (anc. geog.), mountains of Samaria, stretching out from west to east, on the confines of the

half tribe of Manasseh, and of the tribe of Issachar; and to the south part of the valley of Jezreel, beginning westward at the city of Jezreel, situated at the foot of these mountains, reaching almost quite to the Jordan, lying at the distance of six miles from Scythopolis. Famous for the death of Saul and his son Jonathan, and the defeat of the Israelites by the Philistines.

GILCHRIST (Dr Ebenezer), an eminent Scots physician, was born at Dumfries in 1707. He began the study of medicine at Edinburgh, which he afterwards prosecuted at London and Paris. He obtained the degree of doctor of medicine from the university of Rheims; and in the year 1732 he returned to the place of his nativity, where he afterwards constantly resided, and continued the practice of medicine till his death. It may with justice be said, that few physicians of the present century have exercised their profession in a manner more respectable or successful than Dr Gilchrist; and few have contributed more to the improvement of the healing art. Having engaged in business in an early period of life, his attention was wholly devoted to observation. Endowed by nature with a judgment acute and solid, with a genius active and inventive, he soon distinguished himself by departing, in various important particulars, from established but unsuccessful modes of practice. Several of the improvements which he introduced have procured him great and deserved reputation, both at home and abroad. His practice, in ordinary cases, was allowed to be judicious, and placed him high in the confidence and esteem of the inhabitants of that part of the country where he lived. But his usefulness was not confined to his own neighbourhood. On many occasions he was consulted by letter from the most distant parts of the country. In different collections are to be found several of his performances, which prove that he had something new and useful to offer upon every subject to which he applied himself. But those writings which do him the greatest honour, are two long dissertations on Nervous Fevers, in the Medical Essays and Observations published by a Society in Edinburgh; and a treatise on the use of Sea-voyages in medicine, which first made its appearance in the year 1757, and was afterwards reprinted in 1771. By means of the former, the attention of physicians was first turned to a species of fever which is now found to prevail universally in Scotland; and the liberal use of wine, which he was the first among the moderns to recommend, has since been adopted in these fevers by the most judicious physicians of the present age, and has probably contributed not a little to the success of their practice. His treatise on Sea-voyages points out in a manner so clear, and so much on the sure footing of experience, their utility in various distempers, particularly in consumptions, that there is now a prospect of our being able to employ a remedy in this untractable disease much more efficacious than any hitherto in use. Dr Gilchrist died in 1774.

GILD, or GUILD. See GUILD.

GILDAS (surnamed *the Wise*), was born in Wales in the year 511. Where he was educated is uncertain; but it appears from his own writings that he was a monk. Some writers say that he went over to Ireland; others, that he visited France and Italy. They agree however in asserting, that after his return to Eng-

Gilchrist
||
Gildas.

Gilding. England he became a celebrated and most assiduous preacher of the gospel. Du Pin says he founded a monastery at Venetia in Britain. Gildas is the only British author of the sixth century whose works are printed; they are therefore valuable on account of their antiquity, and as containing the only information we have concerning the times of which he wrote. His History of Britain is, however, a very flimsy performance, and his style obscure and inelegant.

1
Gilding when first introduced at Rome.

GILDING, the art of spreading or covering a thing over with gold, either in leaf or liquid. The art of gilding was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it. Pliny assures us, that the first gilding seen at Rome was after the destruction of Carthage, under the censorship of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. But he adds, that luxury advanced on them so hastily, that in a little time you might see all, even private and poor persons, gild the very walls, vaults, &c. of the houses.

We need not doubt but they had the same method with us, of beating gold, and reducing it into leaves; though it should seem they did not carry it to the same height, if it be true which Pliny relates, that they only made 750 leaves of four fingers square out of a whole ounce. Indeed he adds, that they could make more; that the thickest were called *bractea Prænestina*, by reason of a statue of the goddess Fortune at Præneste gilt with such leaves; and that the thinner sort were called *bractea questoria*.

2
Ancient Gilding inferior to the modern.

The modern gilders do also make use of gold-leaves of divers thicknesses; but there are some so fine, that a thousand do not weigh above four or five drachms. The thickest are used for gilding on iron and other metals; and the thinnest on wood. But we have another advantage over the ancients in the manner of using or applying the gold; the secret of painting in oil, discovered of late ages, furnishes us with means of gilding works that shall endure all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies that would not endure the fire but with whites of eggs or size, neither of which will endure the water; so that they could only gild such places as were sheltered from the moisture of the weather.

The Greeks called the composition on which they applied their gilding on wood *leucophæum* or *leucophorum*; which is described as a sort of glutinous compound earth, serving in all probability to make the gold stick and bear polishing. But the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturalists are not agreed upon.

The lustre and beauty of gold have occasioned several inquiries and discoveries concerning the different methods of applying it to different substances. Hence the art of gilding is very extensive, and contains many particular operations and various management.

3
False gilding with laquer or Dutch-leaf.

A colour of gold is given by painting and by varnishes, without employing gold; but this is a false kind of gilding. Thus a very fine golden colour is given to brass and to silver, by applying upon these metals a gold-coloured varnish, which, being transparent, shows

all the brilliancy of the metals beneath. Many ornaments of brass are varnished in this manner, which is called *gold laquering*, to distinguish them from those which are really gilt. Silver-leaves thus varnished are put upon leather, which is then called *gilt leather*. See **LAQUER**.

Gilding.

Amongst the false gilding may also be reckoned those which are made with thin leaves of copper or brass, called *Dutch leaf*. In this manner are made all the kinds of what is called *gilt paper*.

In the true gilding, gold is applied to the surface of bodies. The gold intended for this purpose ought in general to be beat into thin leaves, or otherwise divided into very fine parts.

As metals cannot adhere well merely by contact to any but to other metallic substances, when gold is to be applied to the surface of some unmetallic body, that surface must be previously covered with some glaucy and tenacious substance, by which the gold shall be made to adhere. These substances are in general called *sizes*. Some of these are made of vegetable and animal glues, and others of oily, glaucy, and drying matters. Upon them the leaves of gold are applied, and pressed down with a little cotton or a hare's-foot; and when the whole is dry, the work is to be finished and polished with a hard instrument, called a *dog's tooth*, to give lustre.

4
Gilding with size.

When the work is required to be capable of resisting rain or moisture, it ought to be previously covered with a composition of drying oil and yellow ochre ground together; otherwise a water-size may be used, which is prepared by boiling cuttings of parchment or white leather in water, and by mixing with this some chalk or whiting; several layers of this size must be laid upon the wood, and over these a layer of the same size mixed with yellow ochre. Lastly, another mixture, called *gold size*, is to be applied above these; upon which the gold-leaves are to be fixed. This gold size, the use of which is to make the gold-leaf capable of being burnished, is composed of tobacco-pipe clay, ground with some ruddle or black lead, and tempered with a little tallow or oil of olives. The edges of glasses may be gilt by applying first a very thin coat of varnish, upon which the gold-leaf is to be fixed; and when the varnish is hardened, may be burnished. This varnish is prepared by boiling powdered amber with linseed oil in a brass vessel to which a valve is fitted, and by diluting the above solution with four or five times its quantity of oil of turpentine; and that it may dry sooner, it may be ground with some white lead.

5
With oil.

The method of applying gold upon metals is entirely different. The surface of the metal to be gilt is first to be cleaned; and then leaves are to be applied to it, which, by means of rubbing with a polished blood-stone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver-leaf is fixed and burnished upon brass in the making of what is called *French plate*, and sometimes also gold-leaf is burnished upon copper and upon iron.

6
Of gilding metals.

Gold is applied to metals in several other manners. One of these is by previously forming the gold into a paste or amalgam with mercury. In order to obtain a small amalgam of gold and mercury, the gold is first to be reduced into thin plates or grains, which are heated red-hot, and thrown into mercury previously

Gilding. heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally as six or eight to one.

With this amalgam the surface of the metal to be gilded is to be covered; then a sufficient heat is to be applied to evaporate the mercury: and the gold is lastly to be burnished with a blood-stone.

7
Uses of the
nitrous acid
in gilding;

This method of gilding by amalgamation is chiefly used for gilding copper, or an alloy of copper, with a small portion of zinc, which more readily receives the amalgam; and is also preferable for its colour, which more resembles that of gold than the colour of copper. When the metal to be gilt is wrought or chased, it ought to be previously covered with quicksilver before the amalgam is applied, that this may be easier spread: but when the surface of the metal is plain, the amalgam may be applied directly to it. The quicksilver or amalgam is made to adhere to the metal by means of a little aquafortis, which is rubbed on the metallic surface at the same time, by which this surface is cleansed from any rust or tarnish which might prevent the union or adhesion of the metals. But the use of the nitrous acid in this operation is not, as is generally supposed, confined merely to cleanse the surface of the metal to be gilt from any rust or tarnish it may have acquired; but it also greatly facilitates the application of the amalgam to the surface of that metal, probably in the following manner: It first dissolves part of the mercury of the amalgam: and when this solution is applied to the copper, this latter metal having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface, in the same manner as a polished piece of iron precipitates upon its surface copper from a solution of blue vitriol. When the metal to be gilt is thus covered over with a thin precipitated coat of mercury, it readily receives the amalgam. In this solution and precipitation of mercury, the principal use of the nitrous acid in the process of gilding appears to consist. The amalgam being equally spread over the surface of the metal to be gilt by means of a brush, the mercury is then to be evaporated by a heat just sufficient for that purpose; for if it be too great, part of the gold may also be expelled, and part of it will run together, and leave some of the surface of the metal bare: while the mercury is evaporating, the piece is to be from time to time taken from the fire, that it may be examined, that the amalgam may be spread more equally by means of a brush, that any defective parts of it may be again covered, and that the heat may not be too suddenly applied to it: when the mercury is evaporated, which is known by the surface being entirely become of a dull yellow colour, the metal must then undergo other operations, by which the fine gold colour is given to it. First, the gilded piece of metal is rubbed with a scratch brush (which is a brush composed of brass wire) till its surface is made smooth; then it is covered over with a composition called *gilding-wax*, and is again exposed to the fire till the wax be burnt off. This wax is composed of bees-wax, sometimes mixed with some of the following substances; red ochre, verdigrise, copper-scales, alum, vitriols, borax: but according to Dr Lewis, the saline substances alone are sufficient, without any wax. By this operation the colour of the gold-

ing is heightened; and this effect seems to be produced by a perfect dissipation of some mercury remaining after the former operation. This dissipation is well effected by this equable application of heat. The gilt surface is then covered over with a saline composition, consisting of nitre, alum, or other vitriolic salt, ground together, and mixed up into a paste with water or urine. The piece of metal thus covered is exposed to a certain degree of heat, and then quenched in water. By this method its colour is further improved, and brought nearer to that of gold. This effect seems to be produced by the acid of nitre (which is disengaged by the vitriolic acid of the alum or other vitriolic salt during the exposure to heat) acting upon any particles of copper which may happen to lie on the gilded surface. Lastly, some artists think that they give an additional lustre to their gilt work by dipping it into a liquor prepared by boiling some yellow materials, as sulphur, orpiment, or turmeric. The only advantage of this operation is, that a part of the yellow matter, as the sulphur or turmeric, remains in some of the hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and solid appearance.

Iron cannot be gilt by amalgamation, unless, as it is said, it be previously coated with copper by dipping it into a solution of blue vitriol. Iron may also receive a golden coat from a saturated solution of gold in aqua-regia, mixed with spirit of wine, the iron having a greater affinity with the acid, from which it therefore precipitates the gold. Whether any of these two methods be applicable to use, is uncertain: but the method commonly employed of fixing gold upon iron is that above-mentioned, of burnishing gold-leaf upon this metal when heated so as to become blue; and the operation will be more perfect if the surface has been previously scratched or graved.

Another method is mentioned by authors of gilding upon metals, and also upon earthen ware, and upon glass; which is, to fuse gold with regulus of antimony, to pulverise the mass which is sufficiently brittle to admit that operation, to spread this powder upon the piece to be gilt, and expose it to such a fire that the regulus may be evaporated, while the gold remains fixed. The inconveniences of this method, according to Dr Lewis, are, that the powder does not adhere to the piece, and cannot be equally spread; that part of the gold is dissipated along with the regulus; that glass is fusible with the heat necessary for the evaporation of regulus of antimony; and that copper is liable to be corroded by the regulus, and to have its surface rendered uneven.

On the subject of gilding by amalgamation Dr Lewis has the following remarks. "There are two principal inconveniences in this business: One, that the workmen are exposed to the fumes of the mercury, and generally, sooner or latter, have their health greatly impaired by them: the other, the loss of the mercury; for tho' part of it is said to be detained in cavities made in the chimney for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might in a good measure be avoided, by means of a furnace of a due construction. If the communication of a furnace with its chimney, instead

of Arts.

stead

Gilding. Instead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open; the current of air, which otherwise would have entered beneath, enters now at the top, and, passing down thro' the grate to the chimney, carries with it completely both the vapour of the fuel and the fumes of such matters as are placed upon it: the back part of the furnace should be raised a little higher above the fire than the fore part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands who will be thus effectually secured from the fumes, and from being incommoded by the heat, and at the same time have full liberty of introducing, inspecting, and removing the work. If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable: the upper end of the chimney may reach above a foot and a half higher than the level of the fire: over this is to be placed a larger tube, leaving an interval of an inch or more all round between it and the chimney, and reaching to the height of 10 or 12 feet, the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which, falling down to the bottom, is there caught in a hollow rim, formed by turning inwards a portion of the lower part, and conveyed, by a pipe at one side, into a proper receiver.

⁹ M du Fay's method of raising gold figures. "Mr Hellot communicates, in the Memoirs of the French Academy for the year 1745, a method of making raised figures of gold on works of gold or silver, found among the papers of M. du Fay, and of which M. du Fay himself had seen several trials. Fine gold in powder, such as results from the parting of gold and silver by aquafortis, is directed to be laid in a heap on a levigating stone, a cavity made in the middle of the heap, and half its weight of pure mercury put into the cavity; some of the fetid spirit obtained from garlic root by distillation in a retort, is then to be added, and the whole immediately mingled and ground with a muller till the mixture is reduced into an uniform grey powder. The powder is to be ground with lemon juice to the consistence of paint, and applied on the piece previously well cleaned and rubbed over with the same acid juice: the figures drawn with it may be raised to any degree by repeating the application. The piece is exposed to a gentle fire till the mercury is evaporated so as to leave the gold yellow, which is then to be pressed down, and rubbed with the finger and a little sand, which makes it appear solid and brilliant: after this it may be cut and embellished. The author observes, that being of a spongy texture, it is more advisable to cut it with a chissel than to raise it with a graver; that it has an imperfection of being always pale; and that it would be a desirable thing to find means of giving it colour, as by this method ornaments might be made of exquisite beauty and with great facility. As the paleness appears to proceed from a part of the mercury retained by the gold, I apprehend it might be remedied by the prudent application of a little warm aquafortis, which, dissolving the mercury from the exterior part, would give at least a superficial high colour: if the piece is silver, it must be defended from the aquafortis by covering it with wax. Instruments or ornaments of gold, stained by mercury,

where the gold is connected with substances incapable of bearing fire, may be restored to their colour by the same means.

"The foregoing process is given entirely on the authority of the French writer. I have had no experience of it myself, but have seen very elegant figures of gold raised upon silver, on the same principle, by a different procedure. Some cinnibar was ground, not with the distilled spirit, but with the expressed juice of garlic, a fluid remarkably tenaceous. This mixture was spread all over the polished silver; and when the first layer was dry, a second, and after this a third, was applied. Over these were spread as many layers of another mixture, composed chiefly of asphaltum and linseed oil boiled down to a due consistence. The whole being dried with a gentle heat on a kind of wire-grate, the figures were traced and cut down to the silver so as to make its surface rough: the incisions were filled with an amalgam of gold, raised to different heights in different parts according to the nature of the design; after which a gentle fire, at the same time that it evaporated the mercury, destroyed the tenacity of the gummy juice, so that the coating, which served to confine the amalgam, and as a guide in the application of it, was now easily got off. The gold was then pressed down and embellished as in the former method; and had this advantage, that the surface of the silver under it having been made rough, it adhered more firmly, so as not to be in danger of coming off, as M. du Fay says the gold applied in his way sometimes did. The artist, however, found the process so troublesome, that though he purchased the receipt for a considerable sum, he has laid the practice aside."

Finally, some metals, particularly silver, may be gilt in the following manner:

Let gold be dissolved in aqua-regia. In this solution pieces of linen are to be dipped, and burnt to black ashes. These ashes being rubbed on the surface of the silver by means of a wet linen rag, apply the particles of gold which they contain, and which by this method adhere very well. The remaining part of the ashes is to be washed off; and the surface of the silver, which in this state does not seem to be gilt, is to be burnished with a blood-stone, till it acquire a fine colour of gold. This method of gilding is very easy, and consumes a very small quantity of gold. Most gilt ornaments upon fans, snuff-boxes, and other toys of much show and little value, are nothing but silver gilt in this manner.

Gold may also be applied to glass, porcelain, and other vitrified matters. As the surface of these matters is very smooth, and consequently is capable of a very perfect contact with gold leaves, these leaves adhere to them with some force, although they are not of a metallic nature. This gilding is so much more perfect, as the gold is more exactly applied to the surface of the glass. The pieces are then to be exposed to a certain degree of heat, and burnished slightly to give them lustre.

A more substantial gilding is fixed upon glass, enamel, and porcelain, by applying to these substances powder of gold mixed with a solution of gum arabic, or with some essential oil, and a small quantity of borax; after which a sufficient heat is to be applied to soften the glass and the gold, which is then to be burnished. With this mixture any figures may be drawn.

The powders for this purpose may be made, 1. By grinding gold-leaf with honey, which is afterwards to be washed away with water. 2. By distilling to dryness a solution of gold in aqua-regia. 3. By evaporating the mercury from an amalgam of gold, taking care to stir well the mass near the end of the process. 4. By precipitating gold from its solution in aqua-regia by applying it to a solution of green vitriol in water, or some copper, and perhaps some other metallic substance.

GILEAD, the son of Machir, and grandson of Manasseh, had his inheritance allotted him in the mountains of Gilead, from whence he took his name. The mountains of Gilead were part of that ridge which runs from mount Lebanon southward, on the east of the Holy Land; gave their name to the whole country which lies on the east of the sea of Galilee, and included the mountainous region called in the New Testament *Trachonites*. Jeremiah (xxii. 6.) seems to say, that Gilead begins from mount Libanus. 'Thou art Gilead unto me, and the head of Lebanon.' Jacob, at his return from Mesopotamia, came in six days to the mountains of Gilead (Gen. xxxi. 21, &c.) where this patriarch, with Laban his father-in-law, raised a heap of stones, in memory of their agreement and covenant, and called it *Gilead*, i. e. "an heap of witnesses," and which Laban called *Jegar-sahadutha*. These mountains are covered with a sort of trees abounding with gum, called the *balm of Gilead*, which the scripture commends much. (Jer. viii. 21. xlv. 11. li. 8.) The merchants who bought Joseph came from Gilead, and were carrying balm into Egypt. (Gen. xxxvii. 25.)

The Gileadites being invaded by the Ammonites, &c. chose Jephthah for their general, who vanquished all their enemies.

Balm of GILEAD. See AMYRIS.

GILGAL (anc. geog.), a place between Jericho and Jordan, noted for the first encampment of the Israelites on this side Jordan, about a mile from Jericho. It sometimes also denotes Galilee, (Joshua xii. 23.)

GILL (John), D. D. a Protestant dissenting minister of the Baptist denomination, and the son of Edward and Elizabeth Gill, was born at Kettering in Northamptonshire, November 23, 1697. At a very early period of life, his father, who was a deacon of the Baptist church at Kettering, discovered in him an uncommon capacity for learning, and his ability for literary pursuits was afterwards evidenced by such rapid progress in whatever became the object of tuition, that it was found necessary to remove him from the school in which his striking talents were first manifested, and to place him in one more favourable to his improvement. He was therefore sent to a grammar school in the neighbourhood; where he very soon surpassed those boys who were much his seniors in age and as pupils. At this school he continued till he arrived at his 11th year; where, besides going through the common school-books, he read most of the Latin classics, and made very considerable proficiency in the Greek language.

Mr Gill's celebrity as a scholar, and his strong attachment to books, were soon observed by the neighbouring clergy, who frequently met and conversed with him at a bookseller's shop, to which he at every opportunity resorted for the purpose of reading; and

indeed such was his application to books, that it became a proverbial saying among the common people, "Such a thing is as certain, as that John Gill is in the bookseller's shop."

He left the grammar-school, however, early in life. This was occasioned by the imperious conduct of his master, who insisted that the children of dissenting parents should, with other scholars that belonged to the establishment, attend him to church on week days during the performance of divine service. The dissenters considered this requisition as a stretch of power to which his engagements with them gave no claim; and as it was virtually making conformity a test by which his pupils were to expect the benefits of tuition, they resented his conduct; and the children of those parents that were in affluent circumstances were removed to seminaries where the same advantages might be obtained without being subject to the impositions of clerical bigotry. But as the parents of Mr Gill had it not in their power to confer on him the same privilege, the same steps could not be taken to facilitate his advancement in learning. To pave the way, however, for the completion of his studies, efforts were made by several ministers, of different denominations, to get him upon one or other of the funds in London. For this purpose, specimens of his progress in the different branches of literature were transmitted to the metropolis: in answer to which it was objected, "that he was too young, and that should he continue, as it might be expected he would, to make such rapid advances in his studies, he would go through the common circle before he would be capable of taking care of himself, or of being employed in any public service." But these formidable objections were of no weight with our young scholar: his love of learning was unconquerable. Insuperable difficulties, it is true, obstructed the way in which literary eminence is usually acquired; but these difficulties could neither repress his ardent desire of knowledge, nor damp the zeal and application that had marked his former studies. For though his time was daily devoted to the business of his father; yet he had so far improved the hours of leisure, as to be able, before he arrived at his 19th year, to read all the Greek and Latin authors that fell in his way. He studied logic, rhetoric, moral and natural philosophy; and learnt the Hebrew language, so as to read it with ease, without any other assistance than Buxtorf's grammar and lexicon.

Neither the pursuit of learning, however, nor the other necessary avocations incumbent on Mr Gill, could eradicate those religious impressions received in early life. On November 1. 1716, he made a public profession of his faith before the Baptist church at Kettering, and was baptised the same day by Mr Thomas Willis. Of this church Mr Gill had not been long a member, before he was called to the work of the ministry: soon after which he removed to Higham-Ferrers, with a view to pursue his studies under the direction of Mr Davis; but his stay at this place was soon interrupted by an invitation from London in 1719, to preach to the Baptist church in Horslydown, over which he was the same year, being the 22d of his age, ordained pastor; which office he sustained upwards of 51 years.

Mr Gill had not been long in London before rab-

Gill.

binical

Gill. binical learning, of which he had before considerable knowledge, became an object of pursuit. To facilitate his progress through the intricacies of this labyrinth, he contracted an acquaintance with one of the most learned Jewish rabbies. He read the Targums, the Talmuds, the Rabbot; their ancient commentaries, the book Zohar, and whatever else of this kind he was able to procure. Of the Oriental languages he made himself a complete master: in short, there was no branch of knowledge that could either enlarge or enrich biblical learning, which, however difficult, was not attempted and attained: and it may be truly asserted, that in this line he had but few equals, and that the annals of literature do not exhibit a character by whom he was excelled.

In 1748 Mr Gill published a commentary on the New Testament in three vols folio. The immense reading and learning discoverable in this arduous work, attracted the attention of the Marischal College and University of Aberdeen; and procured for him, without either his solicitation or his knowledge, a diploma, creating him Doctor of divinity. This intelligence was communicated to the Doctor in the most handsome terms by the professors Osborn and Pollock; who declared, "that on account of his knowledge of the scriptures, of the Oriental languages, and of Jewish antiquities, of his learned defence of the scriptures against Deists and Infidels, and the reputation gained by his other works; the university had, without his privacy, unanimously agreed to confer on him the degree of Doctor in divinity.

Dr Gill's sentiments, as a divine, were throughout Calvinistic: "And perhaps no man (says the Reverend Mr Toplady, a minister in the Church of England) since the days of Austin, has written so largely in defence of the system of grace: and certainly no man has treated that momentous subject in all its branches, more closely, judiciously, and successfully. What was said of Edward the black prince, that he never fought a battle which he did not win; what has been remarked of the great Duke of Marlborough, that he never undertook a siege which he did not carry; may be justly accommodated to our great philosopher and divine; who, so far as the distinguishing doctrines of the gospel are concerned, never besieged an error which he did not force from its strongholds, nor ever encountered an adversary whom he did not baffle and subdue. His learning and labours, if exceedable, were exceeded only by the invariable sanctity of his life and conversation. From his childhood to his entrance to his ministry, and from his entrance on the ministry to the moment of his dissolution, not one of his most inveterate opposers was ever able to charge him with the least shadow of immorality. Himself, no less than his writings, demonstrated that the doctrine of grace does not lead to licentiousness. Those who had the honour and happiness of being admitted into the number of his friends, can go still farther in their testimony. They know that his moral demeanor was more than blameless: it was from first to last consistently exemplary. And indeed an undeviating consistency, both in his views of evangelical truths, and in his obedience as a servant of God, was one of those qualities by which his cast of character was eminently marked. He was in every respect

a burning and shining light: Burning with love to God, to truth, and to souls; shining as an example to believers, in word, in faith, in purity, a pattern of good works, and a model of all holy conversation and godliness; and while true religion and sound learning have a single friend remaining in the British empire, the works and name of Gill will be precious and revered."

He died at Camberwell, October 14. 1771, aged 73 years 10 months and 10 days. In 1718 the Doctor married Mrs Elizabeth Negus; by whom he had many children, two of whom only survived him. Mrs Gill died in 1764.

His works are, A Commentary on the Old and New Testament, in 9 vols folio. A Body of Divinity in 3 vols quarto. The Cause of God and Truth, 4 vols octavo. A Treatise concerning the Prophecies of the Old Testament respecting the Messiah. A Dissertation on the antiquity of the Hebrew Language, Letters, Vowel-Points, and Accents. Sermons on the Canticles, folio; besides a great number of sermons and controversial pieces on different subjects.

GILL, a measure of capacity, containing a quarter of an English pint.

GILLS, or BRANCHIÆ of fishes. See *COMPARATIVE Anatomy*, 1160.

GILLINGHAM, a parish in the county of Dorsetshire, on the river Stour, near the forest of its own name; where, *anno* 1016, king Edmund Ironside vanquished the Danes. It is one of the largest parishes in the county, being 41 miles in circuit, containing 64,000 acres. It lies on the borders of Wilts and Somerset 4 miles N. W. of Shaftsbury. It has a manufacture of linen, but the chief produce is grazing and the dairies. Near it are the traces of an ancient residence of Norman or Saxon kings, 340 feet long and 240 broad, surrounded by a rampart of earth. Henry I. resided here, and king John repaired it at the expence of the county. Edward I. spent his Christmas here in 1270; but the whole of the materials are removed, and the foundation of the house only can be traced, which was in the form of the letter L, in length 180 feet by 80 broad, and the foot of the letter 48 by 40. The area of the house containing 168,000 square feet. It stood half a mile from the church, on the road to Shafton, encompassed by a moat, now dry, in some places 9 feet deep and 20 broad. The rampart appears to have been 30 feet thick. Here is a free school, a large old building, and a workhouse, as well as two stone bridges. In 1694 it received damage of near 4000l. by a fire. Near it is Gillingham forest, four miles long and one mile broad. The church is a large ancient fabric.

GILLINGHAM, a parish of Kent, three miles below Chatham, and on the same side of the Medway. Part of Catham-dock is in the parish; and here is a castle well furnished with guns that commands the river, there being no less than 170 embrasures for cannon; which would stop the progress of any enemy that should happen to make way by Sheerness-fort, before they could reach Chatham. Here are also copperas works. At this place 600 Norman gentlemen, who came over in the retinue of the two princes Alfred and Edward, were all barbarously murdered by earl Godwin. It was in remote times the property of the archbishop of Canterbury

Gilolo,
Gilpin.

Canterbury, who had here an elegant palace, the old hall of which is now converted into a barn : it is built principally of flint, but the windows are filled up with brick. Near it are the remains of the chapel, &c. and a great part of the whole of its original outer walls may be traced.

GILOLO, a large island of the Pacific Ocean, lying between 1° S. Lat. and 2° N. Lat. and between 125° and 128° E. Long. It belongs to the Dutch ; but does not produce any of the fine spices, though it lies in the neighbourhood of the spice-islands. The natives are fierce and cruel savages.

GILPIN (Bernard), rector of Houghton, distinguished by his extraordinary piety and hospitality, was descended from an ancient and honourable family in Westmoreland, and born in 1517. As he was bred in the Catholic religion, so he for some time defended it against the reformers, and at Oxford held a disputation with Hooper afterward bishop of Worcester and martyr for the Protestant faith ; but was staggered in another disputation with Peter Martyr, and began seriously to examine the contested points by the best authorities. Thus, being presented to the vicarage of Norton in the diocese of Durham, he soon resigned it, and went abroad to consult eminent professors on both sides ; and after three years absence returned a little before the death of queen Mary, satisfied in the general doctrines of the reformation. He was kindly received by his uncle Dr Tonstall, bishop of Durham ; who soon after gave him the archdeaconry of Durham, to which the rectory of Essington was annexed. When repairing to his parish, though the persecution was then at its height, he boldly preached against the vices, errors and corruptions of the times, especially in the clergy, on which a charge consisting of 13 articles was drawn up against him, and presented in form to the bishop. But Dr Tonstall found a method of dismissing the cause in such a manner as to protect his nephew, without endangering himself, and soon after presented him to the rich living of Houghton le Spring. He was a second time accused to the bishop, and again protected ; when his enemies, enraged at this second defeat laid their complaint before Dr Bonner, bishop of London ; who immediately gave orders to apprehend him. Upon which Mr Gilpin bravely prepared for martyrdom ; and ordering his house-steward to provide him a long garment that he might make a decent appearance at the stake, set out for London. Luckily, however, he broke his leg on the journey ; which protracted his arrival until the news of the queen's death freed him from all further apprehensions. Being immediately set at liberty, he returned to Houghton, where he was received by his parishioners with the sincerest joy.

Upon the deprivation of the Popish bishops, he was offered the see of Carlisle, which he declined ; and confining his attention to his rectory, discharged all the duties of his function in the most exemplary manner. To the greatest humanity and courtesy, he added an unwearied application to the instruction of those under his care. He was not satisfied with the advice he gave in public, but used to instruct in private ; and brought his parishioners to come to him with their doubts and difficulties. He had a most engaging manner towards those whom he thought well-disposed ; nay, his very

reproof was so conducted, that it seldom gave offence ; the becoming gentleness with which it was urged, made it always appear the effect of friendship. Thus, with unceasing assiduity, did he employ himself in admonishing the vicious, and encouraging the well-intentioned ; by which means in a few years, he made a greater change in his neighbourhood than could well have been imagined. A remarkable instance, what reformation a single man may effect, when he hath it earnestly at heart !

But his hopes were not so much in the present generation as in the succeeding. It was an easier task, he found, to prevent vice, than to correct it ; to form the young to virtue, than to amend the bad habits of the old. He employed much of his time, therefore, in endeavouring to improve the minds of the younger part of his parish ; suffering none to grow up in an ignorance of their duty ; but pressing it as the wisest part to mix religion with their labour, and amidst the cares of this life to have a constant care upon the next. He attended to every thing which might be of service to his parishioners. He was very assiduous in preventing all law-suits among them. His hall is said to have been often thronged with people, who came to him about their differences. He was not indeed much acquainted with law ; but he could decide equitably, and that satisfied : nor could his sovereign's commission have given him more weight than his own character gave him.

His hospitable manner of living was the admiration of the whole country. He spent in his family every fortnight 40 bushels of corn, 20 bushels of malt, and a whole ox ; besides a proportionable quantity of other kinds of provision. Strangers and travellers found a cheerful reception. All were welcome that came ; and even their beasts had so much care taken of them, that it was humorously said, " If a horse was turned loose in any part of the country, it would immediately make its way to the rector of Houghton's."

Every Sunday, from Michaelmas till Easter, was a sort of public day with him. During this season he expected to see all his parishioners and their families. For their reception, he had three tables well covered : the first was for gentlemen, the second for husbandmen and farmers, and the third for day-labourers. This piece of hospitality he never omitted, even when losses, or a scarcity of provision, made its continuance rather difficult to him. He thought it is duty, and that was a deciding motive. Even when he was absent from home, no alteration was made in his family-expences ; the poor were fed as usual, and his neighbours entertained.

But notwithstanding all this painful industry, and the large scope it had in so extended a parish, Mr Gilpin thought the sphere of his benevolence yet too confined. It grieved him extremely to see every where, in the parishes around him, so great a degree of Ignorance and superstition, occasioned by the shameful neglect of the pastoral care in the clergy of those parts. These bad consequences induced him to supply, as far as he could, what was wanting in others. For this purpose, every year he used regularly to visit the most neglected parishes in Northumberland, Yorkshire, Cheshire, Westmoreland, and Cumberland ; and that his own parish in the mean time might not suffer, he

Gilpin:

Gilpin. he was at the expence of a constant assistant. In each place he staid two or three days; and his method was, to call the people about him, and lay before them, in as plain a way as possible, the danger of leading wicked or even careless lives; explaining to them the nature of true religion; instructing them in the duties they owed to God, their neighbour, and themselves: and showing them how greatly a moral and religious conduct would contribute to their present as well as future happiness.

As Mr Gilpin had all the warmth of an enthusiast, though under the direction of a very calm and sober judgment, he never wanted an audience, even in the wildest parts; where he roused many to a sense of religion, who had contracted the most inveterate habits of inattention to every thing of a serious nature. And wherever he came, he used to visit all the gaols and places of confinement; few in the kingdom having at that time any appointed minister. And by his labours, and affectionate manner of behaving, he is said to have reformed many very abandoned persons in those places. He would employ his interest likewise for such criminals whose cases he thought attended with any hard circumstances, and often procured pardons for them.

There is a tract of country upon the border of Northumberland, called *Reads-dale* and *Tine-dale*, of all barbarous places in the north, at that time the most barbarous. Before the Union, this place was called the *debateable land*, as subject by turns to England and Scotland, and the common theatre where the two nations were continually acting their bloody scenes. It was inhabited by a kind of desperate banditti, rendered fierce and active by constant alarms: they lived by theft, used to plunder on both sides of the barrier; and what they plundered on one, they exposed to sale on the other; by that means escaping justice. And in this dreadful country, where no man would even travel that could help it, Mr Gilpin never failed to spend some part of every year.

He generally chose the christian holidays for his journey, because he found the people at that season most disengaged, and most easily assembled. He had set places for preaching which were as regularly attended as the assize-towns of a circuit. If he came where there was a church, he made use of it: if not, of barns, or any other large building; where great crowds of people were sure to attend him, some for his instructions, and others for his charity.—This was a very difficult and laborious employment. The country was so poor, that what provision he could get, extreme hunger only could make palatable. The inclemency of the weather, and the badness of the roads through a mountainous country, and at that season covered with snow, exposed him likewise often to great hardships. Sometimes he was overtaken by the night, the country being in many places desolate for several miles together, and obliged to lodge out in the cold. At such times, we are told, he would make his servant ride about with his horses; whilst himself on foot used as much exercise as his age and the fatigues of the preceding day would permit. All this he cheerfully underwent; esteeming such services well compensated by the advantages which he hoped might accrue from them to his uninstructed fellow-creatures.

The disinterested pains he took among these barbarous people, and the good offices he was always ready to do them, drew from them the warmest and sincerest expressions of gratitude. Indeed he was little less than adored among them, and might have brought the whole country almost to what he pleased. One instance that is related, shows how greatly he was revered. By the carelessness of his servants, his horses were one day stolen. The news was quickly propagated, and every one expressed the highest indignation at the fact. The thief was rejoicing over his prize, when by the report of the country, he found whose horses he had taken. Terrified at what he had done, he instantly came trembling back, confessed the fact, returned the horses, and declared he believed the devil would have seized him directly, had he carried them off knowing them to have been Mr Gilpin's.

We have already taken notice of Mr Gilpin's uncommonly generous and hospitable manner of living. The value of his rectory was about 400l. a-year: an income, indeed, at that time very considerable, but yet in appearance very unproportionate to the generous things he did: indeed, he could not have done them, unless his frugality had been equal to his generosity. His friends, therefore, could not but wonder to find him, amidst his many great and continual expences, entertain the design of building and endowing a grammar-school: a design, however, which his exact œconomy soon enabled him to accomplish, though the expence of it amounted to upwards of 500l. His school was no sooner opened, than it began to flourish; and there was so great a resort of young people to it, that in a little time the town was not able to accommodate them. He put himself, therefore, to the inconvenience of fitting up a part of his own house for that purpose, where he seldom had fewer than 20 or 30 children. Some of these were the sons of persons of distinction, whom he boarded at easy rates: but the greater part were poor children, whom he not only educated, but clothed and maintained; he was at the expence likewise of boarding in the town many other poor children. He used to bring several every year from the different parts where he preached, particularly *Raidf-dale* and *Tine-dale*; which places he was at great pains in civilizing, and contributing not a little towards rooting out that barbarism which every year prevailed less among them.

As to the school, he not only placed able masters in it, whom he procured from Oxford, but himself likewise constantly inspected it. And, that encouragement might quicken the application of his boys, he always took particular notice of the most forward: he would call them *his own scholars*, and would send for them often into his study, and there instruct them himself. One method used by him to fill his school was a little singular. Whenever he met a poor boy upon the road, he would make trial of his capacity by a few questions, and if he found it such as pleased him, he would provide for his education. And besides those whom he sent from his own school to the universities, and there wholly maintained, he would likewise give to others, who were in circumstances to do something for themselves, what further assistance they needed. By which means he induced many parents to allow their children a liberal education, who otherwise would not have done it.

Gilpin.

Gilpin.

it. And Mr Gilpin did not think it enough to afford the means only of an academical education to these young people, but endeavoured to make it as beneficial to them as he could. He still considered himself as their proper guardian; and seemed to think himself bound to the public for their being made useful members of it, as far as it lay in his power to make them so. With this view he held a punctual correspondence with their tutors; and made the youths themselves frequently write to him, and give him an account of their studies. So solicitous indeed was he about them, knowing the many temptations to which their age and situation exposed them, that once every other year he generally made a journey to the universities to inspect their behaviour. And this uncommon care was not unrewarded; for many of his scholars became ornaments to the church, and exemplary instances of piety.

To the account that hath been already given of Mr Gilpin's hospitality and benevolence, the following particulars may be added. Every Thursday throughout the year, a very large quantity of meat was dressed wholly for the poor; and every day they had what quantity of broth they wanted. Twenty-four of the poorest were his constant pensioners. Four times in the year a dinner was provided for them; when they received from his steward a certain quantity of corn, and a sum of money: and at Christmas they had always an ox divided among them.

Whenever he heard of any in distress, whether of his own parish or any other, he was sure to relieve them. In his walks abroad, he would frequently bring home with him poor people, and send them away clothed as well as fed. He took great pains to inform himself of the circumstances of his neighbours, that the modesty of the sufferer might not prevent his relief. But the money best laid out was, in his opinion, that which encouraged industry. It was one of his greatest pleasures to make up the losses of his laborious neighbours, and prevent their sinking under them. If a poor man had lost a beast, he would send him another in his room: or if any farmer had had a bad year, he would make him an abatement in his tythes.—Thus as far as he was able, he took the misfortunes of his parish upon himself; and, like a true shepherd, exposed himself for his flock. But of all kinds of industrious poor, he was most forward to assist those who had large families; such never failed to meet with his bounty, when they wanted to settle their children in the world.

In the distant parishes where he preached, as well as in his own neighbourhood, his generosity and benevolence were continually showing themselves; particularly in the desolate parts of Northumberland. "When he began his journey," says an old manuscript life of him, "he would have 10 pounds in his purse; and at his coming home, he would be 20 nobles in debt, which he would always pay within a fortnight after."—In the gaols he visited, he was not only careful to give the prisoners proper instructions, but used to purchase for them likewise what necessaries they wanted.

Even upon the public road, he never let slip an opportunity of doing good. He has often been known to take off his cloak and give it to an half-naked traveller: and when he has had scarce money enough in

his pocket to provide himself a dinner, yet would he give away part of that little, or the whole, if he found any who seemed to stand in need of it.—Of this benevolent temper, the following instance is preserved. One day returning home, he saw in a field several people crowding together; and judging something more than ordinary had happened, he rode up, and found that one of the horses in a team had suddenly dropped down, which they were endeavouring to raise; but in vain, for the horse was dead. The owner of it seemed much dejected with his misfortune; and declaring how grievous a loss it would be to him, Mr Gilpin bade him not be disheartened: "I'll let you have (says he), honest man, that horse of mine," and pointed to his servant's—"Ah master (replied the countryman), my pocket will not reach such a beast as that." "Come, come (said Mr Gilpin), take him, take him; and when I demand my money, then thou shalt pay me."

This worthy and excellent divine, who merited and obtained the glorious titles of *the Father of the Poor*, and *the Apostle of the North*, died in 1583, in the 66th year of his age.

GILTHEAD, in ichthyology. See SPARUS.

GIN. See GENEVA.

GIN, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end where eight or nine men heave, and round which a rope is reeved that goes over the wheel at the top: one end of this rope is seized to an iron-monkey, that hooks to a beetle of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight; and when hove up to a cross-piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into the ground: then the monkey's own weight overhauls the windlass, in order for its being hooked again to the beetle.

GINGER, the root of a species of amomum. See AMOMUM.

GINGIDIUM, in botany: A genus of the digynia order, belonging to the pentandria class of plants. The calyx is an involucre, with about six linear leaves; the corolla consists of five oval-lanceolated petals; the stamina are five filaments; the antheræ roundish; the pericarpium an ovato-truncated fruit, with eight striæ; there are two striated seeds, in some places plane, and in others convex.

GINGIRO, or ZINDERO, a small territory of Africa to the south of Abyssinia; being separated from it by the river Zebce, by which it is also almost entirely surrounded. This river is extremely large, having more water than the Nile, and being much more rapid; so that, during the rainy season, it would be altogether impassable, were it not for the large rocks which are in its channel. The extreme difficulty which occurs in passing this river, however, is the means of preserving the kingdom of Gingiro, which would otherwise be conquered in a single season by the Galla.

The most remarkable particular with regard to this kingdom is, that the sovereign is a professed votary of the devil. "This superstition (says Mr Bruce) reaches down all the western side of the continent on the Atlantic ocean, in the countries of Congo, Angola, and Benin. In spite of the firmest foundation in true philo-

Gilthead
||
Gingiro.

Gingiro || philosophy, a traveller, who decides from the information and investigation of facts, will find it very difficult to treat these appearances as absolute fictions, or as owing to the superiority of cunning of one man in over-reaching another. For my own part, I confess, I am equally at a loss to assign reasons for disbelieving the fiction on which their pretensions to some preternatural information are founded, as to account for them by the operation of ordinary courses."

In this kingdom every thing is conducted, or pretended to be conducted, by magic; and all those slaves, which in other African countries are sold to Europeans, are here sacrificed to the devil, human blood being a necessary part in all their accursed solemnities. "How far (says Mr Bruce) this reaches to the southward, I do not know; but I look upon this to be the geographical bounds of the reign of the devil on the north side of the equator in the peninsula of Africa."

With regard to this country, very little farther is known than some of the customs of the people transiently picked up by the Jesuit missionaries in Abyssinia. From them we learn, that the kingdom is hereditary in one family, though it does not regularly descend to the eldest son, the king being chosen by the nobles; in which they resemble their neighbours the Abyssinians. When the king dies, his body is wrapped in a fine cloth, and a cow is killed. The body so wrapped up is next inclosed in the cow's skin; and all the princes of the royal family fly and hide themselves in the bushes, while those who are entrusted with the election enter the thickets, beating about every where as if for game. At last a bird of prey, called in their language *liber*, appears, and hovers over the person destined to be king; crying and making a great noise without quitting his station. By this means the person destined to be elected is found out, surrounded as is reported, by lions, tigers, panthers, and other wild beasts; all which are supposed to be brought by the power of magic or of the devil.—After the king is found, he flies upon those who came in quest of him with great fury, killing and wounding as many as he can reach, until at last he is dragged to the throne whether he will or not. One particular family have the privilege of conducting him to the throne; and if they should not happen to find him at first, they have a right to take him out of the hands of those who did so; and thus another battle ensues before the vacant throne can be filled. Lastly, before he enters his palace, two men must be killed; one at the foot of a tree by which the house is supported; and the other at the threshold of the door, which is besmeared with the blood of the victim. It is the particular privilege of one family to afford these victims; and so far are they from seeking to avoid this fate, that they glory in the occasion, and willingly offer themselves to meet it. This last particular, Mr Bruce says he had in Abyssinia from people coming from Gingiro.

GINGIVÆ, the gums. See GUMS.

GINGLYMUS, in anatomy, one of the species of articulation. It is that jointure of the bones where each bone mutually receives the other; so that each bone both receives and is received. See ANATOMY, n° 2.

VOL. VII.

GINKGO, the MADEN-HAIR-TREE. See MAURITIA.

GINORA, in botany: A genus of the monogynia order, belonging to the dodecandria class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is cleft into six parts; the petals six: the capsule unilocular, quadrivalved, coloured, and polyspermous.

GINSENG. See PANAX.

GIOIA (Flavio), of Amalfi, in the kingdom of Naples, the celebrated mathematician; who, from his knowledge of the magnetic powers, invented the mariner's compass, by which the navigation of the Europeans was extended to the most distant regions of the globe: before this invention, navigation was confined to coasting. The king of Naples being a younger branch of the royal family of France, he marked the north point with a fleur de lis, in compliment to that country. It is said the Chinese knew the compass long before; be this as it may, the Europeans are indebted to Gioia for this invaluable discovery. He flourished A. D. 1300.

GIORDANO (Luca.) See JORDANO.

GIORGIONE, so called from his comely aspect, was an illustrious Venetian painter, born in 1478. He received his first instructions from Giovanni Bellino; but studying afterwards the works of Leonardo da Vinci, he soon surpassed them both, being the first among the Lombards who found out the admirable effects of strong lights and shadows. Titian became his rival in this art; and was so careful in copying the life, that he exceeded Giorgione in discovering the delicacies of nature, by tempering the boldness of his colouring. The most valuable piece of Giorgione in oil is that of Christ carrying his cross, now in the church of San Rovo in Venice; where it is held in great veneration. He died of the plague young, in 1511.

GIOSEPPIO, an eminent painter, so called by way of contraction from *Gioseppe d' Arpino* the town of Naples where he was born in 1560. Being carried to Rome very young, and employed by painters then at work in the Vatican to grind their colours, he soon made himself master of the elements of design, and by degrees grew very famous. His wit and humour gained him the favour of popes and cardinals, who found him business in plenty. Gregory XIII. showed him great respect; and Louis XIII. of France made him a knight of the order of St Michael. By the force of a happy genius he acquired a light and agreeable manner of designing; though it is remarked by De Piles, that he degenerated into a style which neither partook of true nature nor of the antique. His battles in the Capitol are the most esteemed of all his pieces. He died at Rome in 1640.

GIOTTO, an ingenious painter, sculptor, and architect of Florence, born in 1276. He was the disciple of Cimabue; but far superior to his master in the air of his heads, the attitudes of his figures, and in the tone of his colouring; but could not express liveliness in the eyes, tenderness in the flesh, or strength in the muscles of his naked figures. He was principally admired for his works in mosaic; the best of which is over the grand entrance of St Peter's church at Rome.

Giotto.

Giraffe
|
Girdle.

The observation of Alberti on that piece is, that in the ship of Giotto, the expression of fright and amazement of the disciples at seeing St Peter walk upon the water is so excellent, that each of them exhibits some characteristic sign of his terror. His death happened in 1336, and the city of Florence honoured his memory with a statue of marble over his tomb.

GIRAFFE, in zoology. See CERVUS.

GIRALD (Barry), or *Giraldus Cambrensis*. See BARRY.

GIRALDI (Lilio Gregorio), an ingenious critic, and one of the most learned men that modern Italy has produced, was born at Ferrara in 1479. He was at Rome when it was plundered by the emperor Charles V.; and having thus lost all he had, and being tormented by the gout, he struggled through life with ill fortune and ill health. He wrote, nevertheless, 17 performances, which were collected and published at Basil in 2 vols folio in 1580, and at Leyden in 1696. Authors of the first rank have bestowed the highest eulogies on Giraldus; particularly Casaubon and Thuanus.

GIRALDI (John Baptist Cintio), an Italian poet of the same family with the foregoing Lilio, was born in 1504. He was secretary to the duke of Ferrara, and afterwards became professor of rhetoric at Pavia. He died in 1573. His works, which consist chiefly of tragedies, were collected and published at Venice by his son Celfo Giraldi, in 1583; and some scruple not to rank him among the best tragic writers Italy has produced.

GIRARDON (Francis), a celebrated French architect and sculptor, born at Troyes in 1627. Louis XIV. being informed of his great talents, sent him to Rome with a pension of 1000 crowns. At his return into France, he laboured for the royal palaces, and the gardens of Versailles and Trianon; where there are many of his works executed in bronze and in marble, from the designs of Charles le Brun. The mausoleum of cardinal de Richelieu, in the Sorbonne, and the equestrian statue of Louis XIV. at the Place de Vendome, where the statue and horse are cast in one piece, pass for his most excellent performances. Girardon was professor, rector, and chancellor, of the Academy of Painting and Sculpture; and had the post of inspector-general of all the works done in sculpture. He died in 1715.

GIRDERS, in architecture, the largest pieces of timber in a floor. Their ends are usually fastened into the summers, on breast-summers; and the joists are framed in at one end to the girders.

By the statute for rebuilding London, no girder is to lie less than ten inches into the wall, and their ends to be always laid in loam, &c.

GIRDLE (*Gingulus* or *Zona*), a belt or band of leather or other matter, tied about the reins to keep that part more firm and tight.

It was anciently the custom for bankrupts and other insolvent debtors to put off and surrender their girdle in open court. The reason of this was, that our ancestors used to carry all their necessary utensils, as purse, keys, &c. tied to the girdle; whence the girdle became a symbol of the estate. History relates, that the widow of Philip I. duke of Burgundy, renounced

her right of succession by putting off her girdle upon the duke's tomb.

The Romans always wore a girdle to tuck up the tunica when they had occasion to do any thing: this custom was so general, that such as went without girdles, and let their gowns hang loose, were reputed idle, dissolute, persons.

Maiden or *Virgins* GIRDLE. It was the custom among the Greeks and Romans for the husband to untie his bride's girdle. Homer, lib. xi. of his *Odysssey*, calls the girdle *παρθενικὴ ζώνη*, *maid's girdle*. Festus relates, that it was made of sheep's wool, and that the husband untied it in bed: he adds, that it was tied in the Herculean knot; and that the husband unloosed it, as a happy presage of his having as many children as Hercules, who at his death left seventy behind him.

The poets attribute to Venus a particular kind of girdle called *cestus*, to which they annexed a faculty of inspiring the passion of love.

GIRGASHITES, or GERGESENES, an ancient people of the land of Canaan, whose habitation was beyond the sea of Tiberias, where we find some footsteps of their name in the city of *Gergefa*, upon the lake of Tiberias. The Jewish doctors inform us, that when Joshua first came into the land of Canaan, the Girgashites took a resolution rather to forsake their country, than submit to the Hebrews, and accordingly retired into Africa. Nevertheless, it is certain that a good number of them staid behind, since Joshua (xxiv. 11.) informs us that he subdued the Girgashites, and they whom he overcame were on this side Jordan.

GIRGENTI, a town of Sicily, which occupies part of the site of the ancient *Agrigentum*. It has only one street fit for carriages. It is inhabited by 15,000 persons; but has no remarkable buildings or works of art that deserve mention: the only antiquities to be seen were a Latin inscription of the time of the Antonines, as is pretended, relative to some association between Agrigentum and Lilybæum; and a piece of ancient masonry in the foundations of a church pretended to be the remains of a temple of Jupiter. At some distance, on the old ground in the vale, stands the cathedral, a clumsy building patched up by barbarous architects with various discordant parts. This church is enriched with no works of modern painters or sculptors that claim any title to praise, but the baptismal font is made out of an ancient sarcophagus faced with very beautiful basso relievos. This see is the richest in Sicily, but has the character of being less enlightened and polished than the rest of the island. Among the curiosities belonging to the cathedral is an Etruscan vase of rare size and preservation. There are also some golden pateras of extreme rarity. The monastery of San Nicolo stands on a little eminence in the centre of the old city, admirably situated. The range of hills towards the south east sinks gradually, so as to admit a noble reach of sea and of plain, terminated on each side by thick groves of fruit-trees. Above appear the remains of ancient grandeur, wonderfully contrasted with the humble straw cottages built at their feet. In the orchard of this convent is a square building with pilasters, which is supposed to have been part of the palace of the Roman prætor.

Girga
shites,
Girgenti.

Gir-

Gironne
Giula.

Girgenti has the convenience of a port: for which, however, it is less indebted to its natural situation than to the recent assistance of art. The harbour is formed by means of a pier carried out in three sides of an octagon, with a battery at the head; the lighthouse is to be erected on the cliffs on shore, as there is no possibility of raising it high enough on the mole without danger of sinking. The work is admirable as to strength and neatness, but the intention of creating a safe and complete haven has not been fully answered; the Scirocco commands it entirely, and drives in great quantities of sand, which it is feared will in time choak up the port; even now ships of burden find it difficult to get in, but the Caricatore is considerable, and the magazines in the rocks along the shore are very spacious.

GIRONNE, or GIRONNY, in heraldry, a coat of arms divided into girones, or triangular figures, meeting in the centre of the shield, and alternately colour and metal.

GISCO, son of Himilco the Carthaginian general, was banished from Carthage by the influence of his enemies. Being afterwards recalled, he was made general in Sicily against the Corinthians, about 309 years before the Christian era, and by his success and intrepidity he obliged the enemies of his country to sue for peace. See CARTHAGE.

GISBOROUGH, a town of England, in the West Riding of Yorkshire, on the road from Whitby to Durham, 224 miles from London, and 4 miles from the mouth of the Tees, where is a bay and harbour for ships. It had formerly an abbey, which was once the common burial-place of the nobility of these parts, and its church by the ruins seems to have been equal to the best cathedrals in England. The soil, besides its fertility in pasture and a constant verdure adorned with plenty of field-flowers almost all the year, has earths of sundry colours, some iron, and mines of alum, which were first discovered in the reign of king James I. and have been since very much improved. Sir Paul Pindar, who first farmed them, paid rents to the king 12,500 l. to the Earl Musgrave 1640 l. and to Sir William Penniman 600 l. and had moreover 800 men by sea and land in constant pay; yet he was a considerable gainer, because there was then scarce any other to be had, and the price was 26 l. a ton: but now there are several other alum-works in this county, which have taken a great part of the trade from hence; so that the works here have for some years lain neglected.

GITTITH, a Hebrew word occurring frequently in the Psalms, and generally translated *wine presses*. The conjectures of interpreters are various concerning this word. Some think it signifies a sort of musical instrument; others, that the psalms with this title were sung after the vintage; lastly, others, that the hymns of this kind were invented in the city of Gath. Calmet is rather of opinion, that it was given to the class of young women or songstresses of Gath to be sung by them; Psal. viii. i. lxxxii. i. lxxxiv. i. Dr Hammond thinks that the psalms with this title were all set to the same tune, and made on Goliath the Gittite.

GIULA, a strong town of Upper Hungary, on the frontiers of Transilvania. It was taken by the Turks in 1566, and retaken by the Imperialists in

1695. It is seated on the river Keresblan, in E. Long. 21. 1. N. Lat. 46. 25.

GIUSTANDEL, a large and strong town of Turkey in Europe, and in Macedonia, with a Greek archbishop's see. It is seated near the lake Ochrida, in E. Long. 20. 50. N. Lat. 41. 10.

GLACIERS, a name given to some very extensive fields of ice among the ALPS.—Mr Coxe observes of these mountains in general, that they are composed of many parallel chains, the highest of which occupy the centre, and the others gradually diminish in proportion as we recede from thence. The central chain appears covered with pointed rocks: all parts of which, that are not absolutely perpendicular, lie hid under perpetual snow and ice even in summer. On each side of this ridge are fertile and cultivated valleys, interspersed with numerous villages, and watered by numerous streams. The elevated peaks of the central chain are covered with snow: but their declivities, excepting those that are extremely steep, have all a covering of ice as well as snow; the intermediate parts being filled with vast fields of ice, terminating in the cultivated valley above mentioned. The same phenomena, though on a smaller scale, occur in those chains that are at a distance from the principal one: In those which are most remote, no ice, and scarcely any snow, is observed, unless upon some of the most elevated summits; and the mountains diminishing in height and ruggedness, appear covered with verdure, until at last they terminate in small hills and plains.

Thus the glaciers may be divided into two sorts; one occupying the deep valleys situated in the bosom of the Alps, distinguished by the name of Ice-valleys; the others are those which clothe the declivities and sides of the mountains. These two kinds of glaciers are distinguished by Mr Coxe into the upper and lower glaciers.

The lower glaciers are by far the most considerable; some of them extending several leagues in length. They do not communicate with each other, as has been generally supposed, few of them being parallel to the central chain; but, stretching mostly in a transverse direction, are bordered at the higher extremity by inaccessible rocks, and at the lower extending into the cultivated valleys. The thickness of the ice varies in different parts. In the glacier des Bois, which extends more than 15 miles in length, and upwards of three in breadth, M. Saussure found it generally from 80 to 100 feet; but he was credibly informed that in some places it was not less than 600 feet, and even more. These vast masses of ice usually rest on an inclined plain; where, being pushed forward by their own weight, and but weakly supported by the rugged rocks beneath them, they are intersected by large crevices, and have an appearance of walls, pyramids, &c. according to the position of the eye in viewing them. In those parts, however, where they lie upon even ground, or such as has only a gentle inclination, the surface of the ice is nearly uniform, the crevices being few and narrow, and the glacier being crossed by travellers on foot without any difficulty. The surface of the ice is rough and granulated, so that people may walk upon it excepting such places as have a steep descent. It is opaque, full of small bubbles about the size of a pea, very porous, and greatly resembles a mixture of snow and water congeal-

Giustandel
Glaciers.

Glaciers.

ed. A vast quantity of stones and earth falls down from the mountains upon the glaciers, and are by them thrown off on each side according to the descent of the ice, as will be afterwards explained. The place on which these rest is more hard and elevated than the rest of the ice, and is very difficult to walk upon; the earth is likewise laid upon them in such regular heaps, that it appears to have been done by art. This collection of earth and stones is termed by the natives the *Moraine*.

Mr Coxe, who visited the glacier des Bois, informs us, that the appearance of it at a distance was so tremendous, that it seemed impracticable to cross it. Numerous and broad chasms intersected it in every direction; but entering upon it, the company found that courage and activity were only required to accomplish the task. They had large nails in their shoes and spiked sticks; which on this occasion were found to be particularly serviceable. Having passed the Moraine, and descended upon the glacier itself, they found the ice softened by a warm wind which rendered it less slippery than usual. Having walked across it for about a quarter of an hour, they came again to the Moraine, along which they continued their journey for half an hour, and then entered upon the great body of the glacier. "Here (says Mr Coxe) it was curious to observe the numerous little rills produced by the collection of drops occasioned by the thawing of the ice on the upper part of the glacier: these little rills hollow out small channels, and, torrent-like, precipitate themselves into the chasms with a violent noise, increasing the body of waters formed by the melting of the interior surface, and finding an outlet under the immense arch of ice in the valley of Chamouni, from which the Arveron rushes." As our traveller proceeded on his journey, he was surprised by the noise of a large fragment of rock which had detached itself from one of the highest needles, and bounded from one precipice to another with great rapidity; but before it reached the plain it was almost reduced to dust. "Having proceeded about an hour (says she), we were astonished with a view more magnificent than imagination can conceive: hitherto the glaciers had scarcely answered my expectations, but now they far surpassed them. Nature had clad herself in all her terrors. Before us was a valley of ice 20 miles in extent, bounded by a circular glacier of pure unbroken snow, named Takul, which leads directly to the foot of Mont Blanc, and is surrounded by large conical rocks, terminating in sharp points like the towers of an ancient fortification; to the right rose a range of magnificent peaks, their intervals filled with glaciers; and far above the rest, the magnificent summit of Mont Blanc, his highest point obscured with clouds. He appeared of such immense magnitude, that, at his presence, the circumjacent mountains, however gigantic, seemed to shrink before him, and *hide their diminished heads*. In half an hour we arrived at the Moraine, which forms a boundary of the valley, crossed it, and proceeded upon a body of ice about three quarters of a mile broad. Here the ice was more even and free from chasms than in the great valley. We then passed a second moraine, and beyond that another mass of ice to a third moraine: descending from thence we came upon the last ridge of ice, broader considerably than the two former, and full of large chasms: it is separated from

the rock only by a very narrow moraine. These moraines contain great quantities of crystal."

Glaciers.

They continued to ascend the valley of ice, the scene constantly increasing in magnificence and horror; and having walked about five miles on the ice, they arrived at last at the foot of the eminence named *Couvercle*, where they were obliged to quit the ice. The doing this was extremely dangerous, and at one place very tremendous. It was a bulging smooth rock, with a precipice of considerable depth terminated by a vast crevice in the ice, which seemed to stop all further progress: a small hollow in the middle, however, afforded room for one foot: and having fixed this, they sprung over to the other side, being helped and directed by the guides who went over first. Having gained the top of the *Couvercle*, they had a view of three of the glaciers, viz. that of *Talefre* to the left, *l'Echaut* in front, and *Takul* on the right; all uniting in that great one called the *Glacier de Bois*. The *Couvercle* itself is a most extraordinary rock, having the appearance of a large irregular building with many sides; the substance of which is granite. Having reached the top, they were surprized with a thunder-storm, from whence they took shelter under an impending rock. The view was exceedingly magnificent; the glaciers appearing like a rugged expanse of frozen sea bounded by gigantic rocks, and terminated by Mount Blanc. A single rock appeared of a triangular figure, covered with Alpine plants; and which, by reason of its contrast with the rugged and snowy mountains in the neighbourhood, has obtained the name of the *Garden*.—During this, as well as other excursions among the Alps, Mr Coxe had occasion to observe that the colour of the sky was of a much deeper blue than in the lower regions.

The upper glaciers may be subdivided into those which cover the summits, and those which extend along the sides of the Alps. Those on the very summit, however, though they have the appearance of ice, are not so in reality, but consist entirely of snow hardened by the extreme cold. M. Saussure found that which covered the top of Mount Blanc to be penetrable, though with difficulty, by a stick; but below this hard crust was a soft snow without coherence. The sides are covered with a mixture of ice and snow; by reason of the superior power of the summer sun to dissolve the snow, which afterwards congeals into hard ice.

Several conjectures have been made concerning the formation of these extraordinary bodies of ice. Mr Coxe agrees with M. Gruner in opinion, that they are produced by the continual dissolution of the snow in summer, and its congelation by the succeeding frosts. Hence, on the summits of the mountains where the sun has very little power, the glacier is soft, and contains no ice: as we descend the mountains the consistence becomes firmer, because there is a considerable mixture of snow-water, the congelation of which augments the hardness; and in the valleys, the glacier is hardest of all, because the portion of water is there much superior to that of the snow. Hence it seems plain that the glaciers derive their origin from the melting of the snow on the upper parts of the mountains, and the congelation of the water as it advances: and to this cause M. Saussure adds the quantity of snow which often rolls down into the valleys and congeals along with the water just mentioned.

Another

Glaciers.

Another question concerning the glaciers naturally occurs, namely, Whether they are to be considered as in a state of increase or diminution? Mr Coxe is of opinion, that they occasionally increase and decrease; in proof of which he adduces the following observation. "The borders of the glacier of Montanvert are mostly skirted with trees: towards its base a vast arch of ice rises to near 100 feet in height; under which the river Arveron rushes with considerable force, and in a large body of water. As we approached the ice, we passed through a wood of firs; those trees which stand at a little distance from the arch are about 80 feet high, and are undoubtedly of a very great age. Between these and the glacier the trees are of a later growth; as is evident from their texture and inferior size. Others still smaller, have been overturned and enveloped in the ice: there seems to be a kind of regular gradation in the age of these several trees, from the largest which are standing, to the smallest that lie prostrate."—Hence our author concludes, that the glacier once extended as far as the row of small firs; but that, upon its gradual dissolution, a number of trees shot up on the spot it had occupied; since which time the ice has again advanced, and overturned the last grown trees before they had attained to any considerable height.—This he thinks also confirmed by the following fact.—"Large stones of granite are usually found at a small distance from the extremities of the glacier. These stones have certainly fallen from the mountains upon the ice; have been carried on in its progress; and have tumbled into the plain upon the dissolution or sinking of the ice which supported them. These stones, which the natives call *Moraine*, form a kind of border towards the foot of the valley of ice, and have been pushed forward by the glacier in its advances: they extend even to the place occupied by the larger pines."

In opposition to those who maintain that there is a constant accumulation of ice and snow in the Alpine regions, our author makes the following remarks. 1. Between the years 1776 and 1785 the glacier of Grindevald had diminished to such a degree, that the spot which its extremity occupied in the former year, was at least 400 paces from that occupied by it in the latter. 2. In the year 1785 the Murailles de Glace, which in 1776 he had described as forming the border of the glacier of Bosson, no longer existed; and young trees had shot up in the parts which were then covered by the glacier of Montanvert. Still, however, it may be urged, that these changes only take place in the valleys where the power of the sun is considerable; and that from thence we cannot form any adequate idea of what passes in the more elevated regions, where in all probability more snow falls than can be dissolved. In support of this opinion, it is alleged, that the cold produced by the mass of ice already formed ought to augment it still more; and that, within the memory of the present generation, many places have been covered with ice which were not so before. To these arguments, however, Mr Coxe replies, that the causes, which diminish the ice in the upper regions, are no less powerful than the cold which tends to augment it. These are, 1. Rain or sleet; which falling upon the lower glaciers, thaw the ice, increase the rills on its surface, excavate channels, and in many ways tend to diminish its quantity. 2. Evaporation, which takes

place even from the surface of the ice itself, acts still more powerfully; and its action is not confined to any particular season. 3. The falling of the snow and ice; both that which comes gradually from the clouds, and which descends from the mountains in great masses, called by the natives *avalanches*. When these last fall down into milder regions, though sometimes they may resist the influence of the sun and form ice-valleys, yet they generally dissolve. They are most common in the upper glaciers, though sometimes they descend upon the lower, while the gradual descent of snow from the clouds, which chiefly takes place in the lower, contributes very much to lessen the mass. 4. All the lower glaciers or valleys of ice rest on an inclined plane, are hollow, and undermined by torrents which are constantly flowing from the upper glaciers, as well as from their own lowermost surface. Their foundation being thus constantly diminishing, the lower glaciers are carried imperceptibly forward into the cultivated fields, where an end is necessarily put to their progress by the heat of the sun. Hence we may see the reason of that strange phenomenon taken notice of by Mr Coxe, that with one hand he could touch ripe corn, and with the other solid ice. This descent of the glacier is demonstrated from the trees overturned by it, and the moraine always observed at the bottom of the lower glaciers. 5. The heat of the sun is an evident cause of the diminution of the glaciers. To this Mr Coxe adds another cause less generally known, viz. the warm winds which blow by night as well as by day, both in the upper and lower glaciers. "These warm winds (says he) are during summer so common in those parts, that I never crossed a glacier without feeling in some particular positions a warmth similar to the air of a hot-bath." 6. Another cause is the mean temperature of the earth itself; which, where it is not exposed to the piercing cold of the atmosphere, is found to have a temperature always above the freezing point. As the vast thickness of the superincumbent ice, therefore, is in the present case abundantly sufficient to prevent the access of the atmosphere, it is plain that the lower surface of it must, by being in contact with the earth, continually decay. With regard to the other argument drawn from the known increase of the ice in some places, Mr Coxe does not deny it; both insists, that there is no continual increase of the whole, but that if it increases in some places, it diminishes in others; and his opinion in this respect was confirmed by those who frequent the mountains.

GLACIS, in building, an easy insensible slope or declivity.

The descent of the glacis is less steep than that of the talus. In gardening, a descent sometimes begins in talus, and ends in glacis.

The glacis of the corniche, is an easy imperceptible slope in the cymatium, to promote the descent and draining off the rain-water.

GLACIS, in fortification, that mass of earth which serves as a parapet to the covered way, sloping easily towards the champaign or field.

GLADE, in gardening and agriculture, an opening and light passage made through a wood, by lopping off the branches of trees along that way.

GLADIATORS, in antiquity, persons who fought, generally

Glaciers

Gladiators.

Gladiators. generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity; though sometimes freemen made profession thereof, like prize-fighters, for a livelihood.

The Romans borrowed this cruel diversion from the Asiatics; some suppose that there was policy in the practice, the frequent combats of gladiators tending to accustom the people to despise dangers and death.

The origin of such combats seems to be as follows. From the earliest times with which we have any acquaintance in profane history, it had been the custom to sacrifice captives, or prisoners of war, to the manes of the great men who had died in the engagement: thus Achilles, in the Iliad, lib. xxiii. sacrifices twelve young Trojans to the manes of Patroclus; and in Virgil, lib. xi. ver. 81. Æneas sends captives to Evander, to be sacrificed at the funeral of his son Pallas.

In course of time they came also to sacrifice slaves at the funerals of all persons of condition: this was even esteemed a necessary part of the ceremony; but as it would have appeared barbarous to have massacred them like beasts, they were appointed to fight with each other, and endeavour to save their own lives by killing their adversary. This seemed somewhat less inhuman, because there was a possibility of avoiding death, by an exertion of skill and courage.

This occasioned the profession of gladiator to become an art: hence arose masters of the art, and men learned to fight and exercise it. These masters, whom the Latins called *lanistæ*, bought them slaves to be trained up to this cruel trade, whom they afterwards sold to such as had occasion to present the people with so horrible a show.

These exhibitions were at first performed near the sepulchre of the deceased, or about the funeral pile; but were afterwards removed to the circus and amphitheatres, and became ordinary amusements.

The first show of gladiators, called *munus gladiatorum*, was exhibited at Rome, according to Valerius Maximus, by M. and D. Brutus, upon the death of their father, in the year of the city 490. On this occasion there were probably only three pair of gladiators. In 573, the three sons of M. Æmilius Lepidus the augur, who had been threetimes consul, entertained the people with the cruel pleasure of seeing 22 gladiators fight in the forum. In 547, the first Africanus diverted his army at New Carthage with a show of gladiators, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In process of time, the Romans became so fond of these bloody entertainments, that not only the heir of any great and rich citizen lately deceased, but all the principal magistrates, presented the people with shows of this nature, to procure their affection. The ædiles, pretors, consuls, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with these fights: and the priests were sometimes the exhibitors of the barbarous shows; for we meet with the *ludi pontificales* in Suetonius, August. cap. 44. and with the *ludi sacerdotales*, in Pliny, Epist. lib. vii. As for the emperors, it was so much their interest to ingratiate themselves with the populace, that they obliged them with combats of gladiators almost upon all occasions: and as these increased, the number of combatants in-

creased likewise. Accordingly, Julius Cæsar, in his Gladiators. ædileship, diverted the people with 320 couple. Titus exhibited a show of gladiators, wild beasts, and representations of sea-fights, which lasted 200 days; and Trajan continued a solemnity of this nature for 123 days; during which time he brought out 1000 pair of gladiators. Before this time, under the republic, the number of gladiators was so great, that when the conspiracy of Catiline broke out, the senate ordered them to be dispersed into the garrison and secured, lest they should have joined the disaffected party. See *GLADIATOR'S War*.

These sports were become so common, and their consequences in a variety of respects so dangerous, that Cicero preferred a law that no person should exhibit a show of gladiators within two years before he appeared candidate for any office. Julius Cæsar ordered, that only a certain number of men of this profession should be in Rome at a time; Augustus decreed, that only two shows of gladiators should be presented in a year, and never above sixty couple of combatants in a show; and Tiberius provided by an order of senate, that no person should have the privilege of gratifying the people with such a solemnity unless he was worth 400,000 sesterces. They were also considerably regulated by Nerva.

The emperor Claudius restrained them to certain occasions: but he soon afterwards annulled what he decreed, and private persons began to exhibit them at pleasure as usual; and some carried the brutal satisfaction so far as to have them at their ordinary feasts. And not slaves only, but other persons, would hire themselves to this infamous office.

The master of the gladiators made them all first swear that they would fight to death; and if they failed, they were put to death either by fire or swords, clubs, whips, or the like.

It was a crime for the wretches to complain when they were wounded, or to ask for death or seek to avoid it when overcome; but it was usual for the emperor or the people to grant them life when they gave no sign of fear, but waited the fatal stroke with courage and intrepidity: Augustus even decreed that it should always be granted them.

From slaves and freedmen the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict that none of the senatorian order should become gladiators; and soon after he laid the same restraint on the knights: nevertheless Nero is related to have brought upwards of 400 senators and 600 Roman knights upon the arena; though Lipsius takes both these numbers to be falsified, and not without reason reduces them to 40 senators and 60 knights: yet Domitian, that other monster of cruelty, refined upon Nero, exhibiting combats of women in the night-time.

Constantine the Great is said to have first prohibited the combats of gladiators in the East. At least he forbade those who were condemned to death for their crimes to be employed; there being an order still extant to the *præfectus prætorii* rather to send them to work in the mines in lieu thereof: it is dated at Berytus in Phœnicia the 1st of October 325.

The emperor Honorius forbade them at Rome on occasion of the death of Telemachus, who coming out
of

Gladiator. of the East into Rome at the time of one of these spectacles, went down into the arena, and used all his endeavours to prevent the gladiators from continuing the sport; upon which the spectators of that carnage, fired with anger, stoned him to death. It must be observed, however, that the practice was not entirely abolished in the West before Theodoric king of the Ostrogoths. Honorius, on the occasion first mentioned, had prohibited them; but the prohibition does not seem to have been executed. Theodoric, in the year 500, abolished them finally.

Some time before the day of combat, the person who presented the people with the shows gave them notice thereof by programmas or bills, containing the names of the gladiators, and the marks whereby they were to be distinguished: for each had his several badge; which was most commonly a peacock's feather, as appears from the scholiast of Juvenal on the 158th verse of the third satire, and Turnebus Advers. lib. ii. cap. 8. They also gave notice how long the shows would last, and how many couples of gladiators there were; and it even appears from the 52d verse of the seventh satire of the second book of Horace, that they sometimes made representations of these things in painting, as is practised among us by those who have any thing to show at fairs.

The day being come, they began the entertainment by bringing two kinds of weapons; the first were staves or wooden files, called *rudes*; and the second were effective weapons, as swords, poniards, &c. The first were called *arma lusoria*, or *exercitoria*; the second *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, they advanced to the second at the sound of the trumpets, with which they fought naked. Then they were said *vertere arma*. The terms of striking were *petere* & *repetere*; of avoiding a blow, *exire*; and when one of the combatants received a remarkable wound, his adversary or the people cried out, *Habet* or *Hoc habet*. The first part of the engagement was called *ventilare, præludere*; and the second, *dimicare ad certum*, or *versis armis pugnare*: and some authors think, with much probability, that it is to these two kinds of combat that St Paul alludes in the passage 1. Cor. ix. 26, 27. "I fight, not as one that beateth the air; but I keep my body, and bring it into subjection."

If the vanquished surrendered his arms, it was not in the victor's power to grant him life: it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant the boon. The reward of the conqueror was a branch of palm-tree, and a sum of money, probably collected among the spectators: sometimes they gave him his congé, or dismissed him by putting one of the wooden files or *rudis* in his hand; and sometimes they even gave him his freedom, putting the pileus on his head. The sign or indication, whereby the spectators showed that they granted the favour, was *premere pollicem*, which M. Dacier takes to be a clenching of the fingers

of both hands between one another, and so holding the two thumbs upright close together; and, when they would have the combat finished and the vanquished slain, *verterunt pollicem*, they bent back the thumb; which we learn from Juvenal, Sat. iii. ver. 36. The gladiators challenged or defied each other, by showing the little finger; and, by extending this, or some other, during the combat, they owned themselves vanquished, and begged mercy from the people: *Victi ostensam digiti veniam a populo postulabant*, says the old scholiast on Persius.

There were various kinds of gladiators, distinguished by their weapons, manner, and time of fighting, &c. as, The *andabate*, mentioned under *ANDABATÆ*. The *catervarii*, who always fought in troops and companies, number against number; or, according to others, who fought promiscuously, without any certain order. The *dimachæ*, who fought armed with two poniards or swords, or with sword and dagger. The *essedarii*, who fought in cars. The *fiscals*, or *Cæsariani*, who belonged to the emperor's company; and who, being more robust and dexterous than the rest, were frequently called for; and therefore named also *postulatii*. Several other kinds are mentioned in the ancient authors.

GLADIATORS War (*bellum Gladiatorum* or *Spartacum*), called also the *servile war*, was a war which the Romans sustained about the year of their city 680. Spartacus, Crinus, and Ocnomaus, having escaped, with other gladiators to the number of seventy-four, out of the place where they had been kept at Capua, gathered together a body of slaves, put themselves at their head, rendered themselves masters of all Campania, and gained several victories over the Roman prætors. At length they were defeated in the year 682, at the extremity of Italy; having, in vain, attempted to pass over into Sicily.

This war proved very formidable to the Romans. Crassus was not able to finish it: the great Pompey was forced to be sent as general.

The *Dying GLADIATOR*, a most valuable monument of ancient sculpture, which is now preserved in the palace of Chighi. This man, when he had received the mortal stroke, is particularly careful *ut procumbat honeste*, that he might fall honourably. He is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm: and in his expiring moments it is plainly seen, that he does not abandon himself to grief and dejection; but is solicitous to maintain that firmness of aspect which the gladiators valued themselves on preserving in this season of distress, and that attitude which they had learnt of the masters of defence. He fears not death, nor seems to betray any tokens of fear by his countenance, nor to shed one tear: *quis mediocris gladiator ingemuit, quis vultum mutavit unquam, quis non modo stetit, verum etiam decubuit turpiter*, says Cicero, in that part of his Tusculan where he is describing the astonishing firmness of those persons. We see, in this instance, notwithstanding his remaining strength, that he has but a moment to live; and we view him with attention, that we may see him expire and fall: thus the ancients knew how to animate marble, and to give it almost every expression of life.

GLADIOLUS, CORN-FLAG: A genus of the
monogynia

Glair,
Glamor-
ganshire.

monogynia order, belonging to the triandria class of plants; and in the natural method ranking under the sixth order, *Ensatæ*. The corolla is sexpartite, and ringent; the stamina ascending and bending upwards. There are 10 species, of which the most remarkable is the communis, or common gladiolus. This hath a round, compressed, tuberous root; long sword-shaped leaves; an erect flower-stalk, two or three feet high; the top garnished with several pretty large flowers of a red or white colour, having each six petals. They appear in May and June, and are succeeded by plenty of seed in August. The plants are very hardy, and will thrive in any soil or situation. They are propagated by offsets from the roots.

GLAIR of eggs, is the same as the white of eggs, and is used as a varnish for preserving paintings. For this purpose it is beat to an unctuous consistence, and commonly mixed with a little brandy or spirit of wine, to make it work more freely, and with a lump of sugar to give it body and prevent its cracking: and then spread over the picture or painting with a brush.

GLAMORGANSHIRE, a county of South Wales, said to have derived its name from a contraction of the Welsh words *Gwald Morgan*, or "the county of Morgan," and supposed to have been thus called from a prince of this part of the country, said to have been killed 800 years before the birth of our Saviour: but some other writers derive the name from the word *Mor*, which in the British tongue signifies the *sea*; this being a maritime county. It is bounded on the south, and part of the west, by Bristol channel; on the north-west, by Caermarthenshire; on the north, by Brecknockshire; and on the east, by Monmouthshire. It extends 48 miles in length, from east to west, 27 in breadth from north to south, and is 116 in circumference. It is divided into 10 hundreds, in which are one city, 7 market-towns, 118 parishes, about 10,000 houses, and 58,000 inhabitants. It is in the diocese of Llandaff. This county, in the time of the Romans, was part of the district inhabited by the Silures and had several Roman stations. Thus Boverton, a few miles to the south of Cowbridge, is supposed to be the Bovium of Antoninus; Neath to be his Nidum; and Loghor, to the west of Swansea, to be his Lancaurum. The principal rivers of this county are the Rhymny, the Taff, the Ogmore, the Avon, the Cleddagh, and the Tawe. The air, in the south part, towards the sea, is temperate and healthful; but the northern part, which is mountainous, is cold and piercing, full of thick woods, extremely barren, and thin of inhabitants. The mountains, however, serve to feed herds of cattle, and send forth streams which add greatly to the fertility of the other parts of the county: they have likewise coal and lead ore. The south part is so remarkably fertile, pleasant, and populous, that it is generally styled the garden of Wales; but it has no manufacture. This county was formerly full of castles, most of which are now fallen to decay. It has many small harbours on the coast for exporting coals and provisions. Of the former it sends large quantities both to England and Ireland; but of the latter, to England almost solely, especially butter. It sends two members to parliament, one for the shire, and one for the borough of Cardiff the capital.

GLAMOUR, or GLAMER, an old term of popular superstition in Scotland, denoting a kind of magical mist believed to be raised by forcerers, and which deluded their spectators with visions of things which had no real existence, altered the appearance of those which really did exist, &c.—The eastern nations have a similar superstition, as we may learn from the Arabian Nights Entertainments and other works of Oriental fiction.

GLAND, in anatomy. See ANATOMY, n^o 128.

GLANDERS. See FARRIERY, § XVI.

GLANDORE, a town of Ireland, situated in the county of Cork and province of Munster, near the harbour of that name.

GLANDORE-Harbour, situated two leagues west of the Galley-head in the county of Cork, province of Munster, N. Lat. 51. 22. West. Lon. 8. 56. Between this harbour and Ross the coast continues high and bold, with only two small coves; that to the east called *Millcove*, and that to the west *Cowcove*. This harbour lies three miles west of Ross; and though small, is an exceeding good one; near it is a castle of the same name, and on the upper-end is a deep and dangerous glyn, called the *Leap*. Glandore gives title of earl to the family of Crosbie.

GLANDORP (Matthias), a learned physician, born in 1595, at Cologne, in which town his father was a surgeon. After receiving a doctor's degree at Padua, and visiting the principal towns of Italy, he settled at Bremen in 1618, where he practised physic and surgery with so much success, that he was made physician to the republic and to the archbishop. He published at Bremen, *Speculum chirurgorum, Methodus medendæ paronychiæ, Tractatus de polyponarium affectu gravissimo*, and *Gazophylacium polypusium fontivissimo*; which four pieces were collected and published, with his life prefixed, at London, in 4to, 1729. Glandorp died young; and it must suggest a high opinion of his abilities, that, notwithstanding the great improvements in all branches of science, his works should be deemed worthy a republication 100 years after his death.

GLANDULÆ *Renales*. See ANATOMY, n^o 100.

GLANS, in anatomy, the tip or button of the penis, or that part covered with the prepuce, called also *balanus*. See ANATOMY, p. 739, col. 1.

GLANS is also used to denote the tip or extremity of the clitoris, from its resemblance, both in form and use, to that of the penis. See ANATOMY, p. 739, col. 2.

GLANVIL (Joseph), a learned and ingenious, but fanciful and credulous writer in the 17th century, was born at Plymouth in 1636, and bred at Oxford. He became a great admirer of Mr Baxter, and a zealous person for a commonwealth. After the restoration, he published *The vanity of dogmatizing*; was chosen a fellow of the Royal Society; and, taking orders in 1662, was presented to the vicarage of Frome-Selwood in Somersetshire. This same year he published his *Lux Orientalis*; in 1665, his *Sceptis Scientifica*; and in the year following, *Some philosophical considerations touching the being of witches and witchcraft*, and other pieces on the same subject. In 1660, he published *Plus ultra*; or, *The progress and advancement of knowledge since the days of Aristotle*. He likewise published

Glamour
||
Glanvil.

Glaris *A seasonable recommendation and defence of reason; and Philosophia Pia, or A discourse of the religious temper and tendencies of the experimental philosophy.* In 1678 he was made a prebendary of Worcester, and died in 1680.

GLARIS, one of the cantons of Swisserland, is bounded on the east, partly by the Grisons, and partly by the territory of Sargans; on the north, by the bailiwick of Gaster, and by the lake Wahlestatt; on the east, by the canton of Schwits; and on the south, by part of the canton of Uri, and part of the league of the Grisons. It is a mountainous country, being entirely within the Alps.

GLARIS, a town of Swisserland, capital of the canton of the same name, is seated in a plain, at the foot of high craggy mountains. The streets are large, and the houses kept in good repair. It has some public buildings; among which are two churches, one in the middle of the town, and the other without upon an eminence. On this eminence there is a cavern, with grotesque figures formed by the water that drops therein. The general assemblies of the country are held here on the first Sundays in May, where all the males above the age of sixteen are obliged to appear. Both the Calvinists and the Roman Catholics are tolerated in this town, and they have divine service by turns in the same church. It is seated on the river Lint, E. Long. 9. 13. N. Lat. 47. 6.

GLASGOW, a large city of Lanerksire or Clydesdale in Scotland, situated in W. Long. 4. 30. N. Lat. 55. 50.

Concerning the foundation of this city we have no authentic records. The word in the Gaelic language signifies a *gray smith*; from whence it has been inferred, that some spot in the most ancient part of the city was originally the residence of some blacksmith who had become eminent in his profession, so that the place went by his name.

Bishopric of Glasgow, when founded. In the year 560, a bishopric is said to have been founded here by Saint Mungo, or Kentigern, supposed to be the son of Thamates, daughter of Loth king of the Picts; but in what state the town at that time was, is altogether uncertain. Most probably the priests and disciples who attended St Kentigern would contribute considerably towards its advancement: the aged and infirm, who were unfit for the purposes of war, or such as were religiously inclined, would come and settle round the habitation of the holy man, in order to have the benefit of his prayers; and as a number of miracles were said to have been wrought at his tomb, the same causes would still contribute to the increase of the town.

History has not informed us of the name of the prince who founded and endowed the bishopric of Glasgow in favour of St Kentigern. But from an abstract of the life of Kentigern (contained in Mr Innes's Critical Essay on the ancient inhabitants of Scotland), which was written in the 12th century, we learn, that the saint being ill used by Marken or Marcus, one of the kings of the Britons, retired into Wales. On the invitation of Roderic, however, one of Marken's successors, he returned to Glasgow, and enjoyed the see till 601, when he died. He was buried in the church of Glasgow, where his monument is still to be seen;

VOL. VII.

and we find him marked among the saints in the Roman kalendar, January 13. 578.

The immediate successors of Kenigern were Baldrede and Conwal. The first established a religious house at Inchinnan; the second went into Lothian to preach to the Saxons; and both of them are ranked as saints in the Roman kalendar, Baldrede on the 6th of March 608, and Conwal on the 18th of May 612. From this time, however, till the year 1115, we have no distinct accounts concerning the city or bishopric of Glasgow. We find then, that David I. king of Scotland made an attempt to retrieve the people from a state of gross barbarity into which they were fallen, and restored to the church those lands of which she had been robbed. The only account we have of the transactions with regard to Glasgow, during that period, is in the inquisition made by David concerning the church-lands of Glasgow, and is as follows.—“This church, by the divine appointment, admitted St Kentigern into the bishopric, who furnished large draughts of knowledge to those thirsting after heavenly things, &c. But a fraudulent destroyer, employing his common wiles, brought in, after a long series of time, unaccountable scandals into the Cumbrian church. For after St Kentigern and many of his successors were removed to heaven, various disturbances every where arising, not only destroyed the church and her possessions, but, wasting the whole country, drove the inhabitants into exile. These good men being destroyed, various tribes of different nations flocking in from several quarters, possessed the aforesaid deserted country; but being of different origins, and varying from each other in their languages and customs, and not easily agreeing among themselves, they followed the manners of the Gentiles, rather than those of the true faith. The inhabitants of which unhappy and abandoned country, though living like brutes, the Lord, who chooses that none should perish, vouchsafed to visit in mercy,” &c.

From the year 1116 to the reformation, the records of the bishopric are tolerably complete. The most remarkable particulars furnished by them are the following.

In 1136, John Achaius, chosen bishop of Glasgow by David I. built and adorned part of the cathedral, which he solemnly consecrated on the 9th of July. The king was present at the ceremony; and bestowed on the church the lands of Perdeyk, now Patrick. This prelate also divided the diocese into the two archdeanries of Glasgow and Teviotdale; and established the offices of dean, subdean, chancellor, treasurer, sacrist, chanter, and successor; and settled a prebendary upon each of them, out of the donatives he received from the king.

In 1174, Joceline, abbot of Melrose, was elected bishop, and consecrated by Eskilus, bishop of Lunden in Denmark, the pope's legate for that kingdom, on the 1st of June 1175. He rebuilt the cathedral, or rather made an addition to the church already built by John Achaius. He also procured a charter from William king of Scotland, erecting Glasgow into a royal borough, and likewise a charter for a fair to be held there annually for eight days.

In 1335, John Lindsay, bishop of Glasgow, was killed

Glasgow.

² Barbarity of the people in the time of David I.

³ Glasgow erected into a royal borough.

Glasgow. killed in an engagement at sea with the English as he was returning home from Flanders. His successor, William Rae, built the stone bridge over the Clyde. In the time of Matthew Glendoning, who was elected bishop in 1387, the great spire of the church, which had been built only of wood, was consumed by lightning. The bishop intended to have built another of stone, but was prevented by death, in 1408, from accomplishing his purpose. His successor, William Lauder laid the foundation of the vestry of the cathedral, and built the great tower of stone as far as the first battlement. The great tower of the episcopal palace was founded about the year 1437, on which bishop Cameron expended a great deal of money.

4
Glasgow erected into a regality, and the university founded.

In 1477, William Turnbull, a son of the family of Bedrule in Roxburgh-shire, was chosen bishop. He obtained from king James II. in 1450, a charter erecting the town and the patrimony of the bishops into a regality. He also procured a bull from pope Nicholas V. for erecting a university within the city, which he endowed, and on which he also bestowed many privileges. He died in 1454, leaving behind him a most excellent character. The establishment of the college contributed more than any thing that had been formerly done towards the enlargement of the town. Before this time the town seems to have been inconsiderable. Mr Gibson* is of opinion, that the number of its inhabitants did not exceed 1500. But though the establishment of the university greatly increased the number of inhabitants, it in fact destroyed the freedom of the town. Bishop Turnbull seems to have made a point of it with king James II. that the city of Glasgow, with the bishop's forest, should be erected into a regality in his favour; which was accordingly done at the time abovementioned; and this at once took away all power from the citizens, and transferred it to the bishop. As the powers of the bishop, however, were reckoned by Turnbull insufficient to convey to the members of the university all that freedom which he wished to bestow upon them, he therefore obtained from the king a great many privileges for them; and afterwards he himself, with the consent of his chapter, granted them many more.

* Hist. of Glasgow, p. 74.

5
Which destroys the freedom of the city.

6
Population of Glasgow increased by the university.

The good effects of the establishment of the college were very soon obvious in Glasgow. The number of inhabitants increased exceedingly; the high street, from the convent of the Black friars, to where the cross is now placed, was very soon filled up; the ancient road which led to the commons being too far distant for the conveniency of the new inhabitants, the Gallows-gate began to be built. Soon after the collegiate church of the blessed Mary (now the Tron-church) being founded by the citizens, occasioned the Trongate street to be carried to the westward as far as the church. The rest of the city increased gradually towards the bridge, by the building of the Salt-market-street. The borough-roads, and the cattle that grazed on the commons, were now found insufficient to maintain the increased number of inhabitants; for which reason a greater degree of attention than formerly was paid to the fishing in the river. Many poor people subsisted themselves by this occupation; they were incorporated into society; and in order that they might be at hand to prosecute their business, they built a considerable

part of the street now called the *Bridge-gate*, but at that time *Fisher's-gate*.

Notwithstanding all this, however, the city of Glasgow did not for a long time attain the rank among the other towns of Scotland which it holds at present. In 1556, it held only the 11th place among them, as appears by queen Mary's taxation. The introduction of the reformed religion proved for some time prejudicial to the opulence of the city. The money which had formerly been expended among the citizens by the bishop and his clergy, was now diverted into other channels: the advantages resulting from the university were also for a time lost; for as the reformers generally despised human learning, the college was in a manner deserted.

In the time of the civil wars, Glasgow suffered severely. To the mischiefs attending intestine discord, were added a pestilence and famine; and to complete their misfortunes, a violent fire broke out in June 1652, which destroyed the greatest part of the Saltmarket, Trongate, and High-street. The fronts of the houses at that time were mostly of wood, so that they became an easy prey to the flames. The fire continued with great violence for the space of 18 hours; by which a great many of the inhabitants were ruined, the habitations of almost 1000 families being totally destroyed. On this account collections were made through different parts of the country; and to prevent such accidents for the future, the fronts were built with free-stone, which abounds in the neighbourhood.

7
Great part of the town destroyed by a fire.

By the charter given to bishop Turnbull in 1450, the citizens had been deprived of the power of electing their own magistrates, which was thenceforth exercised by the bishop; which, however, was not done without some resistance on the part of the inhabitants. After the reformation was introduced into Scotland, we find this power exercised by the citizens, the bishop, the earl of Lenox, and others. The idea that the town was a bishop's borough, and not a royal free borough, gave occasion to this unsettled manner of appointing the magistracy; and though, in 1633, they were declared to be a royal free borough by the parliament, yet their freedom of election was afterwards disturbed by the privy-council, by Cromwell, and the duke of York. But on the 4th of June 1690, the town was declared free by a charter of William and Mary; and in confirmation of this charter it was inserted in the act of parliament, dated June 4th the same year, that they should have power to elect their own magistrates as fully and freely, in all respects, as the city of Edinburgh, or any other royal borough within the kingdom; which freedom of election still continues.

8
Glasgow declared free by William and Mary.

By the assessment of the boroughs in 1695, we find the city of Glasgow reckoned the second in Scotland in point of wealth, which place it still continues to hold. To account for this great increase of wealth, we must observe, that for a long time, even before the restoration of Charles II. the inhabitants of Glasgow had been in possession of the sale both of raw and refined sugars for the greatest part of Scotland; they had a privilege of distilling spirits from their molasses, free of all duty and excise; the herring fishery was also carried on to what was at that time thought a very considerable extent; they were the only people in Scotland who made soap;

9
Great increase of its wealth.

Glasgow. soap; and they sent annually some hides, linen, &c. to Bristol, from whence they brought back in exchange, a little tobacco, sugar, and goods of the manufacture of England, with which they supplied a considerable part of the kingdom. From the year 1707, however, in which the union between Scotland and England took place, we may date the prosperity of Glasgow. By the union, the American trade was laid open to the inhabitants: and so sensible were they of their advantageous situation, that they began almost instantly to prosecute that commerce; an assiduous application to which, ever since, hath greatly contributed to raise the city to the pitch of affluence and splendor which it at present enjoys. The city was now greatly enlarged; and as the community were sensible of the inconvenience that attended the want of a sufficiency of water in the river for carrying on their commerce, they resolved to have a port of their own nigher to the mouth of the river. At first, they thought of making their harbour at Dumbarton: but as this is a royal borough, the magistrates opposed it; because they thought that the influx of sailors and others, occasioned by the harbour, would be so great, that a scarcity of provisions would be occasioned. The magistrates and town-council of Glasgow, therefore, purchased some lands on the south-side of the river Clyde for this purpose; and so expeditious were they in making their harbour, and rearing their town, that in 1710 a bailie was appointed for the government of Port-Glasgow. It is now a very considerable parish, and lies 12 miles nigher the mouth of Clyde than Glasgow.

10

gow.

11
Disturb-
ance about
the excise
bill.

In 1725, Mr Campbell, the member of parliament for Glasgow, having given his vote for having the malt-tax extended over Scotland, a riot ensued among the lower class of people. In this disturbance, Mr Campbell's furniture was destroyed, and some excisemen were maltreated for attempting to take an account of the malt. General Wade, who commanded the forces in Scotland, had sent two companies of soldiers, under the command of Captain Bushel, to prevent any disturbance of this kind. Captain Bushel drew up his men in the street, where the multitude pelted them with stones. He first endeavoured to disperse the mob by firing with powder only: but this expedient failing, he ordered his men to load their pieces with ball; and, without the sanction of the civil authority, commanded them to fire four different ways at once. By this discharge about 20 persons were killed and wounded; which enraged the multitude to such a degree, that having procured some arms, they pursued Bushel and his men to the castle of Dumbarton, about 14 miles distant. General Wade being informed of this transaction, assembled a body of forces, and being accompanied by Duncan Forbes, lord advocate took possession of the town: the magistrates were apprehended and carried prisoners to Edinburgh; but on an examination before the lords, their innocence clearly appeared, upon which they were immediately dismissed. Bushel was tried for murder, convicted, and condemned; but instead of suffering the penalties of law, he was indulged with a pardon, and promoted in the service. Mr Campbell petitioned the House of Commons for an indemnification of his losses: a bill was passed in his favour; and this, together with some other expences

incurred in the affair, cost the town 9000 l. Sterling. Glasgow.

During the time of the rebellion in 1745, the citizens of Glasgow gave proof of their attachment to revolution principles, by raising two battalions, of 600 men each, for the service of government. This piece of loyalty, however, had like to have cost them dear. The rebels, in their journey south, took a resolution to plunder and burn the city: which would probably have been done, had not Mr Cameron of Lochiel threatened, in that case, to withdraw his clan. A heavy contribution, however, was laid on. The city was compelled to pay 5000 l. in money, and 500 l. in goods; and on the return of the rebels from England, they were obliged to furnish them with 12,000 linnen shirts, 6000 cloth coats, 600 pairs of shoes, 600 pairs of hose, and 6000 bonnets. These goods, with the money formerly paid them, the expence of raising and subsisting the two city-battalions, and the charge of maintaining the rebel army in free quarters for ten days, cost the community about 14,000 l. sterling; 10,000 l. of which they recovered in 1749, by an application to parliament.

About the year 1750, a very considerable change took place in the manner of living among the inhabitants of Glasgow. Till this time, an attentive industry, and a frugality bordering upon parsimony, had been their general characteristic: the severity of the ancient manners prevailed in its full vigour: But now, when an extensive commerce and increased manufactures had produced wealth, the ideas of the people were enlarged, and schemes of trade and improvement were adopted which people would formerly have been denominated madmen if they had undertaken; a new style was introduced in living, dress, building, and furniture; wheel-carriages were set up, public places of entertainment were frequented, and an assembly-room, ball-room, and play-house, were built by subscription; and from this time we may date all the improvements that have taken place, not only in Glasgow, but all over the west of Scotland. The best method, however, of estimating the growing improvement of any town, is by the frequency of their applications for assistance to parliament; we shall therefore enumerate the acts of parliament which have been passed in favour of the city of Glasgow since the year 1750. In 1753, an act passed for repairing several roads leading into the city of Glasgow.—In 1756, an act for erecting and supporting a light-house in the island of Little Cumray, at the mouth of the Clyde, and for rendering the navigation of the frith and river more safe and commodious.—In 1759, an act for improving the navigation of the river Clyde to the city of Glasgow, and for building a new bridge across the river.—In 1767, the people of Glasgow having proposed to make a small cut or canal from the frith of Forth to that of Clyde, for the conveniency of their trade to the eastern side of the island, several gentlemen at Edinburgh, and throughout different parts of the kingdom, proposed that this canal should be executed upon a much larger scale than what had been originally projected. An act was accordingly obtained, and the canal executed in the manner described under

12
Change of
manners
and method
of living,

13
Acts of
Parliament
in favour of
the city,

Glasgow. the article CANAL.—In 1770, another act was obtained for improving the navigation of the river, building the bridge, &c. being an amendment of the former act for these purposes.—In 1771, an act for making and widening a passage from the Salt-market to St Andrew's church; for enlarging and completing the church-yard of that church, and likewise for building a convenient exchange or square in the city; also for amending and explaining the former act relative to the navigation of the Clyde.—An act for making and maintaining a navigable canal and waggon-way from the collieries in the parishes of Old and New Monkland, to the city of Glasgow. This last canal, which was undertaken with a view to reduce the price of coals, has not been attended with the desired effect, but the other improvements have been productive of very great advantages.

14
Description
of the city.

The most ancient part of the city stands on a rising ground. The foundation of the cathedral is 104 feet higher than the bed of the river; and the descent from the high ground reaches to about 100 yards below the college. The rest of the city is built chiefly upon a plain, bounded southward by the Clyde, and northward by a gentle ridge of hills lying in a parallel direction with that river. These grounds till lately consisted of gardens and fields; but are now covering with buildings, in consequence of the increasing wealth and population of the city. The streets are all clean and well paved; and several of them intersecting one another at right angles, produces a very agreeable effect. The four principal streets, crossing one another in that manner, divide the city nearly into four equal parts; and the different views of them from the cross, or centre of intersection, have an air of great magnificence. The houses consisting of four or five floors in height, are built of hewn stone, generally in an exceeding good taste, and many of them elegant. The most remarkable public buildings are,

15
Of the ca-
thedral.

1. *The Cathedral or High Church*, is a magnificent building, and its situation greatly to its advantage, as it stands higher than any part of the city. It has been intended to form a cross, though the traverse part has never been finished. The great tower is founded upon four large massy pillars, each of them about 30 feet in circumference. The tower itself is 25½ feet square within; and is surrounded by a ballustrade, within which rises an octangular spire terminated by a fane. The tower upon the west end is upon the same level, but appears not to have been finished, though it is covered over with lead. In this tower is a very large bell 11 feet four inches in diameter. The principal entry was from the west; the gate 11 feet broad at the base, and 17 feet in height. The west end of the choir is now appropriated for a place of divine worship; and is divided from the remaining part by a stone-partition, which is inclosed by another stone-wall parting it from the nave. It is impossible to form an adequate idea of the awful solemnity of the place occasioned by the loftiness of the roof and the range of pillars by which the whole is supported.

The nave of the church rises four steps higher than the choir; and on the west side stood the organ-loft, formerly ornamented with a variety of figures, but now defaced. The pillars here are done in a better taste than those in the choir, and their capitals are or-

namented with fruits. The arched roof of the altar is supported by five pillars, over which was a fine terrace walk, and above it a large window of curious workmanship, but now shut up. On the north side of the altar is the vestry, being a cube of 28 feet, the roof arched and vaulted at top, and supported by one pillar in the centre of the house. Arched pillars from every angle terminate in the grand pillar, which is 19 feet high. The lower part of the south cross is made use of as a burying-place for the clergy of the city; and is by much the finest piece of workmanship in the whole building. It is 55 feet long, 28 broad, and 15 high; arched and vaulted at top, and supported by a middle range of pillars, with their capitals highly ornamented; corresponding to which are columns adjoining to the walls, which as they rise, spring into semi-arches, and are every where met at acute angles by their opposites, and are ornamented with carvings at the closing and crossing of the lines. At the east end of the choir you descend by flights of steps upon each side into passages which, in former times, were the principal entrance to the burying vault which is immediately under the nave. It is now made use of as a parish church for the barony of Glasgow; and is full of pillars, some of them very massy, which support the arched roof; but it is a very uncomfortable place for devotion. The space under the altar and vestry, though now made use of as a burying-place by the heritors of the barony, was formerly, according to tradition, employed for keeping of the relics; and indeed, from the beautiful manner in which this place is finished, one would imagine that it had not been destined for common use. Here is shown the monument of St Mungo, or Kentigern, with his figure lying in an incumbent posture.

The whole length of the cathedral within the walls is 284 feet, its breadth 65; the height of the choir, from the floor to the canopy, 90 feet; the height of the nave, 85 feet; the height of the middle tower, 220 feet. This fabric was begun by John Achaius in 1123, and consecrated in 1136; and continued by succeeding bishops till such time as it was finished in the manner in which it stands at present. The wealth of the see of Glasgow, however, was not sufficient for so great an undertaking, so that they were obliged to have recourse to all the churches of Scotland for assistance in it.

This venerable edifice was in danger of falling a victim to the frenzy of fanaticism in 1579; and owed its preservation to the spirit and good sense of the tradesmen, who, upon hearing the beat of drum for collecting the workmen appointed to demolish it, flew to arms, and declared that the first man who pulled down a single stone should that moment be buried under it.

Near the cathedral are the ruins of the bishop's palace or castle, inclosed with a wall of hewn stone by archbishop James Beaton; the great tower built by archbishop Cameron.

2. *St Andrew's Church* was begun by the community in 1739, and finished in 1756. It is the finest piece of modern architecture in the city; and is built after the model of St Martin's in the Fields, London, whose architect was the famous Gibbs. The length of the

Glasgow,

16
St An-
drew's
church,
the

Glasgow. the church is 104 feet, and its breadth 66. It has a fine arched roof, well ornamented with figures in stucco, and sustained by stone-columns of the Corinthian order. Correspondent to the model, it has a place for the altar on the east, in which is a very ancient Venetian window; but the altar-place being seated, makes this end appear to no great advantage. The fronts of the galleries and the pulpit are done in mahogany in a very elegant manner. The spire by no means corresponds with the rest of the building; and, instead of being an ornament, disgraces this beautiful fabric. Its height is 170 feet.

Besides the cathedral (which contains three congregations) and St Andrew's church, there is a number of others, as the College-church, Ram's-horn, Tron-Wynd, &c. together with an English chapel, Highland church, several seceding meeting-houses, and others for sectaries of various denominations.

17
The college.

3. *The College.* The front of this building extends along the east side of the high street, and is upwards of 330 feet long. The gate at the entrance is decorated with rustics, and over it are the king's arms. The building consists of two principal courts or squares. The first is 88 feet long and 44 broad. The west side is elevated upon stone pillars, on which are placed pilasters supporting the Doric entablature, and ornamented with arches forming a piazza. Above these is the public hall; the ascent to which is by a double flight of steps inclosed by a handsome stone ballustrade, upon the right of which is placed a lion, and on the left an unicorn, cut in free stone. The spire stands on the east side, is 135 feet high; and has a very good clock. Under this is the gateway into the inner and largest court, which is 103 feet long and 79 broad. Over the entry, in a niche, is a statue of Mr Zacharias Boyd, who was a benefactor to the university. On the east side of the court is a narrow passage leading into a handsome terrace walk, gravelled, 122 feet long by 64 feet broad. This walk is inclosed to the east by an iron pallisade, in the centre of which is a gate leading into the garden. This last consists of seven acres of ground, laid out in walks for the recreation of the students; and there is also a botanic garden. On the south side of the walk stands the library; a very neat edifice, well constructed for the purpose intended, and containing a very valuable collection of books. Underneath are preserved in cases all the Roman inscriptions found on Graham's Dike, together with altars and other antiquities collected from different parts of Scotland.—Adjoining, there is an observatory, well furnished with astronomical instruments. The college also possesses, by bequest, the late Dr Hunter's famous anatomical preparations, library, and museum: And in the department of natural philosophy, it is furnished with an apparatus which is universally acknowledged to be the most extensive and useful in Britain, and which owes its perfection to the liberality and unremitting labour of Mr Anderson the present professor of that science.

18
Town house, &c.

4. *The Tolbooth, or Town House,* is a magnificent and extremely elegant building. The front is adorned with a range of Ionic pilasters; and is elevated on strong rusticated pillars with arches, forming a piazza for merchants and others to shelter themselves from the weather when met upon business. One of the apartments was the assem-

bly-hall; a neat room, 47 feet long, and 24 in breadth and height, finished in a good taste, though too small for the city. The town-hall is a very spacious and lofty apartment, 52 feet long by 27 broad, and 24 in height. It is finished in a very grand manner; the ceiling is divided into different compartments well ornamented. In it are full-length portraits of king James VI. and VII. Charles I. and II. William and Mary, queen Anne, king George I. II. and III. and Archibald duke of Argyle in his justiciary robes. The two last are by Ramsay. Opposite to the front of this building is the exchange-walk, which is well paved with free stone, and inclosed from the street by stone pillars. In the middle of this area is an equestrian statue of king William III. placed upon a lofty pedestal, and surrounded with an iron rail.—In 1781, the exchange under the piazzas was greatly enlarged, by taking down the lower part of the town-hall and assembly-room; and at the same time, by a tontine scheme entered into by the inhabitants, a most elegant coffee-room was added, with a suite of buildings adjoining for the purposes of a tavern and hotel, and offices for notaries and underwriters. The assembly-room, however, being found to be still too small, a subscription of above L. 5000 has been raised by a similar plan of a tontine for building a new one, which is proposed to be erected in the north corner of one of the new streets which join Ingram-street to Argyle-street.

Glasgow.

5. *The Guild-Hall or Merchant's House.* This building is situated upon the south side of Bridge-gate street; and is in length 82 feet, in breadth 31. The great hall, which is the whole length and breadth of the building, is so capacious, that it is better adapted for the reception of great and numerous assemblies than any other in the city. This house is adorned with a very elegant spire 200 feet high.

19
Guild-hall.

6. *The Town's Hospital* is a very neat building, consisting of two wings and a large front; the length 156 feet, the breadth of the centre 30 feet, and the depth of the wings 68 feet. Behind the building is an infirmary 127 feet long by 25 feet broad, the ascent to which is by a flight of steps. The lower part of this building is appointed for the reception of lunatics. The area between the buildings is large, which, with the agreeable open situation of the hospital on the river, must conduce to the health of the inhabitants.

20
Town's hospital.

7. *The Grammar School* is situated on the new taken in grounds to the north-west of the town, and was built in 1787. It is a very handsome building, containing a large hall, and six airy commodious teaching rooms. In this school there are four classes, the course being four years: each class is carried on the whole four years by the same master; so that, there being no rector, each master is head of the school one year in rotation. It is under the direction of a committee of the town-council; who assisted by the professors, clergy, and other persons of learning, frequently visit it during the session; and at an annual examination, prizes of books are distributed to the scholars according to their respective merits. The present number of scholars is above 300.—The building is not yet entirely finished; and the rooms which are not yet occupied by the Latin classes are intended for teaching writing, arithmetic, drawing, &c.

21
Grammar school.

8. *The New Bridge* is built in an elegant manner.

22
New It Bridge.

Glasgow.

It is 32 feet wide; with a commodious foot-way for passengers, five feet broad on each side, raised above the road made for carriages, and paved with free stone. This bridge is about 500 feet in length; and consists of seven arches, the faces of which are wrought in rustic, with a strong block cornice. The arches spring but a little way above low-water mark; which, though it renders the bridge stronger than if they sprung from taller piers, diminishes its beauty. Between every arch there is a smaller circular one: these break the force of the water when the river rises to a flood, and add to the strength of the whole. The parapet-wall or breast-work is cut out in the Chinese taste; and the two ends are finished off with a sweep. This bridge was begun in 1768, and finished in 1772.

23
Markets,
&c.

2. *The Markets in King's Street* are justly admired, as being the completest of their kind in Britain. They are placed on both sides of the street. That on the east side, appropriated entirely for butcher-meat, is 112 feet in length, and 67 in breadth. In the centre is a spacious gateway, decorated on each side with coupled Ionic columns, set upon their pedestals, and supporting an angular pediment. At the north end is a very neat hall belonging to the incorporation of butchers, the front ornamented with rustics and a pediment. The markets upon the west side of the street consist of three courts, set apart for fish, mutton, and cheese. The whole of the front is 173 feet, the breadth, 46 feet; in the centre of which, as on the opposite side, is a very spacious gateway of the Doric order, supporting a pediment. This is the entry to the mutton-market. Each of the other two has a well-proportioned arch faced with rusticks for their entrance. All these markets are well paved with free-stone: have walks all round them; and are covered over for shelter by roofs standing upon stone piers, under which the different commodities are exposed to sale. They have likewise pump-wells within, for cleansing away all the filth; which render the markets always sweet and agreeable. These markets were erected in 1754.

10. *The Herb-Market* is neat and commodious; and the principal entry is decorated with columns. It is situated in the Candleriggs, and is laid out in the same manner with the markets in King's-street.

24
Guard-
house.

11. *The Guard-House* is a very handsome building, with a piazza formed by arches, and columns of the Ionic order set upon their pedestals. It was originally situated on the Highstreet, at the corner of the Candleriggs street: but has lately been carried near half way up the Candleriggs, where it occupies the ground on which the weigh-house formerly stood, and is made larger and more commodious than it was before. An excellent new weigh-house has been erected at the head of the Candleriggs: And at the foot of the Candleriggs, or corner next the Highstreet, where the Guard-house was formerly situated, a superb new hotel has been built, containing 75 fire-rooms.

25
Public cha-
rities.

The most remarkable public charities in Glasgow are,
1. *Muirhead's or St Nicholas's Hospital*. This was originally appointed to subsist 12 old men and a chaplain: but its revenues have, from some unknown causes, been lost; so that no more of them now remains than the paltry sum of 139 l. 2s. 5d. Scots money, 128 l. of which is annually divided among four old men, at the rate of 2 l. 13 s. 4d. each.

Glasgow.

2. *Hutcheson's Hospital*, was founded and endowed in 1639 by George Hutcheson of Lamb-hill notary-public, and Mr Thomas Hutcheson his brother who was bred a preacher, for the maintenance of old men and orphans. The funds of this hospital were increased by James Blair merchant in Glasgow in 1710, and by subsequent donations. From the sale of some of their lands which lay convenient for building, and the rise of the rest, the income is now above L. 1400, which is distributed in pensions to old people from L. 3 to L. 20, and in educating about 50 children.

3. *The Merchants-House* likewise distributes in pensions and other charities about L. 800 yearly.

4. *The Town's Hospital*, above described, was opened for the reception of the poor on the 15th of November 1733. The funds whence this hospital is subsisted are, the general session, the town-council, the trades house and merchants house, the interest of money belonging to their funds, which are sums that have been mortgaged for the use of the house. These supplies, however, are found insufficient to defray the expences of the house; for which reason an assessment is annually made upon the inhabitants in the following manner. The magistrates nominate 12, 14, or sometimes more gentlemen of known integrity and character, who have a list laid before them of all the inhabitants in town. This list they divide into 16 or 18 columns. Each of these columns contains the names of such inhabitants as carry on trade to a certain extent, or are supposed to be well able to pay the sum affixed to the particular column in which their names are inserted. If it is necessary to raise 500 l. for instance, then each name, in every separate column, is valued at as much as the fortunes of the persons in each particular column are supposed to be. If 100 l. or more is to be raised, it is only continuing a proportionable increase through the whole of the columns. The highest sum that ever was thus raised, was 12 s. 6d. upon every thousand pounds that each person was supposed to be worth. The number of people maintained in this hospital are about 620.

5. *Wilson's Charity* for the education of boys, was founded by George Wilson, who in 1778 left 3000 l. for that purpose. This fund is now considerably increased, and gives education and clothing to 48 boys, each of whom continues four years, so that 12 are admitted annually.

Besides these, there are many public schools for the education of children; as well as many institutions of private societies for the purpose of relieving the indigent and instructing youth, such as *Graham's Society*, *Buchan's Society*, the *Highland Society*, &c. These last print annually 20 boys apprentices to trades, and during the first three years give them clothing and education.

The university of Glasgow owes its origin, as we have already observed, to bishop Turnbull. The institution consisted at first of a rector, a dean of faculty, a principal who taught theology, and three professors of philosophy; and, soon after this, the civil and canon laws were taught by some clergymen. From the time of its establishment in 1450 to the reformation in 1560, the college was chiefly frequented by those who were intended for the church; its members were all ecclesiastics, and its principal support was derived from the church. The reformation brought the university to
the

26
Members
of the uni-
versity.

Glasgow. the verge of destruction: masters, students, and servants, all forsook it. The magistrates were so sensible of the loss which the community had sustained by this desertion, that they endeavoured to restore it in 1572, by bestowing upon it considerable funds, and prescribing a set of regulations for its management. These however, proved insufficient; for which reason king James VI. erected it anew, by a charter called the *Nova Erectio*, in 1577, and bestowed upon it teinds of the parish of Govan. The persons who were to compose the new university were, a principal, three professors of philosophy, four students burfars, one œconomus, a principal's servant, a janitor, and cook.

Since the year 1577, the funds of the university have been considerably increased by the bounty of kings and the donations of private persons. The professors have therefore also been increased; so that at present the university of Glasgow consists of a chancellor, rector, dean of faculty, principal, and 14 professors (six of them in the gift of the crown), together with burfars, &c. The archbishop of Glasgow was formerly chancellor of the university *ex officio*; at present, the chancellor is chosen by the rector, dean of faculty, principal, and masters.

The chancellor, as being the head of the university, is the fountain of honour, and in his name are all academical degrees bestowed. The office of rector is to exercise that academical jurisdiction in disputes among the students themselves, or between the students and citizens, which is bestowed upon the greater part of the universities of Europe. He is chosen annually in the *comitia*; that is, in a meeting in which all the students, as well as the other members of the university, have a voice. Immediately after his admission, he has been in use to choose certain persons as his assessors and counsellors in his capacity of judge: and in former periods, it was customary to name the ministers of Glasgow, or any other gentlemen who had no connection with the university: but, for a great while past, the rector has constantly named the dean of faculty, the principal, and masters, for his assessor; and he has always been, and still is, in the daily practice of judging in the causes belonging to him, with the advice of his assessors. Besides these powers as judge, the rector summons and presides in the meetings of the university for the election of his successor; and he is likewise in use to call meetings of the professors for drawing up addresses to the king, electing a member to the general assembly, and other business of the same kind.

The dean of faculty has, for his province, the giving directions with regard to the course of studies; the judging, together with the rector, principal, and professors, of the qualifications of those who desire to be created masters of arts, doctors of divinity, &c.; and he presides in meetings which are called by him for these purposes. He is chosen annually by the rector, principal, and masters.

The principal and masters, independent of the rector and dean, compose a meeting in which the principal presides; and as they are the persons for whose behoof chiefly the revenue of the college was established, the administration of that revenue is therefore committed to them. The revenue arises from the teinds of the parish of Govan, granted by king James VI. in 1557; from the teinds of the parishes of Renfrew

and Kilbride, granted by the same monarch in 1617, Glasgow. and confirmed by Charles I. on the 28th of June 1630; from the teinds of the parishes of Calder, Old and New Monkland, conveyed to them by a charter from Charles II. in 1670; from a tack of the archbishopric; and from several donations conferred by private persons.

The college of Glasgow, for a very considerable time after its erection, followed the mode of public teaching which is common even to this day in Oxford and Cambridge, and in many other universities throughout Europe; that is, each professor gave a few lectures every year, *gratis*, upon the particular science which he professed: but, in place of this, the professors have, for a great while past, adopted the mode of private teaching; that is, they lecture and examine two hours every day during the session, viz. from the 10th of October to the 10th of June; a method which comes much cheaper to the student, as he has it in his power, if he is attentive, to acquire his education without being under the necessity of employing a tutor. They have also private classes, in which they teach one hour *per day*. The number of students who have attended this college for several years past, has been upwards of 500 each season.

The trade of Glasgow is said to have been first promoted by one Mr William Elphinstone in 1420. This trade was most probably the curing and exporting of salmon; but the first authentic documents concerning Glasgow as a trading city is in 1546. Complaints having been made by Henry VIII. king of England, that several English ships had been taken and robbed by vessels belonging to Scotland, an order of council was issued, discharging such captures for the future: and among other places made mention of in this order is the city of Glasgow. The trade which at that time they carried on could not be great. It probably consisted of a few small vessels to France loaded with pickled salmon; as this fishery was, even then, carried on to a considerable extent, by Glasgow, Renfrew, and Dumbarton. Between the year 1630 and 1660, a very great degree of attention seems to have been paid to inland commerce by the inhabitants of Glasgow. Principal Baillie informs us, that the increase of Glasgow arising from this commerce was exceedingly great. The exportation of salmon and of herrings were also continued and increased. In the war between Britain and Holland during the reign of Charles II. a privateer was fitted out in Clyde to cruise against the Dutch. She was called the *Lion of Glasgow*, Robert M'Allan commander; and carried five pieces of cannon, and 68 hands.

A spirit of commerce appears to have arisen among the inhabitants of Glasgow between the year 1660 and 1707. The citizens who distinguished themselves most during this period were Walter Gibson and John Anderson. Gibson cured and packed in one year 300 lasts of herrings, which he sent to St Martin's in France on board of a Dutch vessel, called the *St Agate*, of 450 tons burthen; his returns were brandy and salt. He was the first who imported iron from Stockholm into Clyde. Anderson is said to have been the first who imported white-wines.

Whatever their trade was at this time, it could not be considerable: the ports to which they were obliged

27
History of
the trade
Glasgow.

Glasgow obliged to trade lay all to the eastward: the circumnavigation of the island would therefore prove an almost unsurmountable bar to the commerce of Glasgow: and of consequence the people on the east coast would be possessed of almost all the commerce of Scotland. The union with England opened a field for commerce for which the situation of Glasgow, so convenient in respect to the Atlantic, was highly advantageous. Since that time the commerce of the east coast has declined, and that of the west increased to an amazing degree. No sooner was the treaty of union signed, than the inhabitants of Glasgow began to prosecute the trade to Virginia and Maryland; they chartered vessels from Whitehaven, sent out cargoes of goods, and brought back tobacco in return. The method in which they first proceeded in this trade, was certainly a very prudent one. A supercargo went out with every vessel. He bartered his goods for tobacco, until such time as he had either sold off his goods or procured as much tobacco as was sufficient to load his vessel. He then immediately set out on his return; and if any of his goods remained unsold, he brought them home with him. While they continued to trade in this way, they were of great advantage to the country, by the quantity of manufactures which they exported; their own wealth began to increase; they purchased ships of their own; and, in 1708, the first vessel of the property of Glasgow crossed the Atlantic. Their imports of tobacco were now considerable, and Glasgow began to be looked upon as a considerable port; the tobacco trade at the ports of Bristol, Liverpool, and Whitehaven, was observed to dwindle away; the people of Glasgow began to send tobacco to these places, and to undersell the English even in their own ports. Thus the jealousy of the latter was soon excited, and they took every method in their power to destroy the trade of Glasgow. The people of Bristol, presented remonstrances to the commissioners of the customs at London against the trade of Glasgow, in 1717. To these remonstrances the merchants of Glasgow sent such answers to the commissioners as convinced them that the complaints of the Bristol merchants were without foundation. But in 1721, a most formidable confederacy was entered into by almost all the tobacco merchants in South Britain against the trade of Glasgow. Those of London, Liverpool, and Whitehaven, presented severally to the Lords of the Treasury, petitions, arraigning the Glasgow merchants of frauds in the tobacco trade. To these petitions the Glasgow people gave in replies: and the Lords of the Treasury, after a full and impartial hearing, were pleased to dismiss the cause with the following sentence; "That the complaints of the merchants of London, Liverpool, and Whitehaven, were groundless; and that they proceeded from a spirit of envy, and not from a regard to the interest of trade, or of the king's revenue."

But the efforts of these gentlemen did not stop here. They brought their complaints into the House of Commons. Commissioners were sent from Glasgow in 1722, who gave in their reports to the house in 1723: The merchants sent up distinct and explicit answers to these reports but such was the interest of their adversaries, that these answers were disregarded. New officers were appointed at the ports of Greenock and

Port Glasgow, whose private instructions seem to have been, to ruin the trade if possible, by putting all imaginable hardships upon it. Hence it languished till the year 1735; but after that time it began to revive, though even after its revival it was carried on but slowly for a considerable space of time.

At last, however, the active and enterprising spirit of the merchants, seconding the natural advantages of their situation, prevailed over all opposition: and the American trade continued to flourish and increase until the year 1775, inasmuch that the importation of tobacco into Clyde that year from the provinces of Virginia, Maryland, and Carolina, amounted to 57,143 hogsheads. But since the breach with America, this trade has now fallen greatly off, and very large sums are said to remain due to the merchants from this quarter of the world.

With regard to the manufactures of Glasgow, Mr Gibson is of opinion; that the commerce to America first suggested the idea of introducing them, in any considerable degree at least. The first attempts in any way were about the year 1725, and their increase for some time was very slow, nor did they begin to be considerable till great encouragement was given by the legislature to the linen manufacture in Scotland. The first causes of the success of this manufacture were the act of parliament in 1748, whereby the wearing of French cambrics was prohibited under severe penalties; that of 1751, allowing weavers in flax and hemp to settle and exercise their trades any where in Scotland free from all corporation-dues: and the bounty of three halfpence per yard on all linens exported at and under 18d. per yard. Since that time a spirit of manufacture has been excited among the inhabitants of Glasgow; and great variety of goods, and in very great quantity, have been manufactured. Checks, linen, and linen and cotton, are manufactured to a great extent. Printed linens and cottons were begun to be manufactured in 1738; but they only made garments till 1754, when handkerchiefs were first printed.

Incles were first made here about the year 1732. The engine-loom used at that time were so inconvenient, and took up so much time in making the goods, that the Dutch, who were the only people possessed of the large incle-loom, were almost solely in possession of this manufacture. Mr Hervy, who began this branch in Glasgow, was so sensible of the disadvantages under which it laboured, that he went over to Holland; and in spite of the care and attention which the Dutch took to conceal their methods of manufacturing; he brought over with him from Haerlem two of their looms, and one of their workmen. This Dutchman remained some years in Glasgow: but on some disgust he went to Manchester, and instructed the people there in the method of carrying on the manufacture.

In 1757, carpets were begun to be made, and are now carried on to a considerable extent. Hunters cloths, English blankets, and other goods of the same kind, are also made.

Besides these, a great variety of articles are manufactured at Glasgow, of which our limits will not permit us to enter into detail, such as soap, refining of sugar, iron-mongery, brass, jewellery, glass both common and white, pottery, &c. Types for printing are made in this city by Dr Wilson and Sons, equal, if

z8
Manufactures of Glasgow.

Glasgow. if not superior, in beauty to any others in Britain. Printing of books was first began here by George Anderson about the year 1638. But there was no good printing in Glasgow till the year 1735, when Robert Urie printed several books in a very elegant manner. The highest perfection, however, to which printing hath yet been carried in this place, or perhaps in any other, was by the late Robert and Andrew Foulis, (who began in the year 1740); as the many correct and splendid editions of books printed by them in different languages sufficiently testify. Some of their classics, it is said, are held in such high esteem abroad, as to sell nearly at the price of ancient MSS. The same gentlemen also established an academy of painting; but the wealth of Scotland being unequal to the undertaking, it has been since given up.

Since the stagnation of the American trade, already noticed, the merchants of Glasgow have turned their attention more to manufactures, which have of late, especially that of cottons and muslins, increased in a very rapid degree, and bid fair for putting the city in a more flourishing condition than ever it was before. The manufacturing-houses, the influx of people for carrying on the manufactures, the means and encouragement which these afford to population, and the wealth thence derived by individuals as well as accruing to the community, have all tended lately to increase, and are daily increasing, the extent of the city and the elegance of the buildings. Besides various improvements in the old streets, several handsome new ones as well as new squares have been added. The site of these new buildings is the tract of rising ground already mentioned as the north boundary of the town previous to its late extension. The western part of it, which is perfectly level, is occupied by a spacious square, denominated *George's Square*; two sides of which are built and inhabited, and a third begun. The grass plot in the middle is inclosed with a handsome iron railing. The square is deficient in regularity; the houses on the west side being a story higher than those of the east; but in other respects it is very neat. To the east of this square are several new streets laid out and paved, and some of them almost completely built on. The principal, though as yet the most incomplete of those streets, is Ingram-Street, which runs from east to west. From this the others begin; some of them being carried northward up the hill, others going southward and joining the main street of the town. One of the finest of these cross streets is Hutchinson-Street.

²⁹ The river, &c. The south boundary of the city was mentioned to be the Clyde. Over this river there are two bridges. One of them, the Old Bridge, built about 400 years ago by archbishop Rae, but since repaired and partly rebuilt, consists of eight arches; and connects the suburbs of Gorbals, situated on the opposite side of the river, with the city. The other is the New Bridge, described above.—On the banks of the river, eastward, is the Green; a spot appropriated to the use of the inhabitants, with conveniences for washing and drying linens, and with agreeable and extensive walks for recreation.

On the same or south side of the town, westward, is the Broomie-law, where the quay is situated. Till within these few years, the river here and for several

miles distance, was so shallow and so obstructed by shoals as to admit only of small craft from Greenock, Port-Glasgow, and the Highlands; but of late it has been cleared and deepened so as to admit vessels of considerable burden; and it is intended to make the depth as nearly equal as possible to that of the canal, in order that the vessels from Ireland and the west coast may not be induced exclusively to ascend the west end of the canal and deliver their goods at Canal-bafon, but may come up Clyde and unload at the Broomie-law.

The government of the city of Glasgow is vested in a provost and three bailies, a dean of guild, deacon-conveener, and a treasurer, with a common council of 13 merchants and 12 mechanics. The provost and two of the bailies must, by the set of the borough, be elected from the merchant rank, and the other bailie from the trades rank, *i. e.* the mechanics. The provost is, from courtesy and custom, styled *lord provost*. He is properly lord of the police of the city, president of the community, and is *ex officio* a justice of the peace for both the borough and county.

The revenue of the town arises from a duty upon all grain and meal brought into the city (which tax is denominated *the ladles*); from the rents of lands and houses the property of the community; from an impost of two pennies Scots upon every Scots pint of ale or beer brewed, inbrought, or sold, within the city; from certain dues payable out of the markets; from the rents of the seats in churches; from the dues of cramage at the quay, at the weigh-house, &c. As to the tonnage on the river, the pontage of the bridge, and statute-work; these, making no part of the city revenue, are kept separate and distinct under the management of commissioners appointed by act of parliament.

About the time of the union, the number of inhabitants in Glasgow was reckoned about 14,000. In 1765, when a new division of the parishes took place, they were estimated at 28,000. In 1785, when an accurate survey was made, the number was about 36,000; besides the suburbs, containing the Calton, Gorbals, and Anderston, reckoned about 1000. Since that time many new buildings, as above noticed, have been erected, and the city has become considerably more populous, but no exact estimate has been made; though it is generally thought that the number of inhabitants cannot at present be computed at much less than 50,000

GLASS, a transparent, brittle, factitious body, produced from sand melted in a strong fire with fixed alkaline salts, lead, flags, &c. till the whole becomes perfectly clear and fine. The word is formed of the Latin *glastum*, a plant called by the Greeks *isafis*, by the Romans *vitrum*, by the ancient Britons *guadam*, and by the English *woad*. We find frequent mention of this plant in ancient writers, particularly Cæsar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with *glastum*, *guadam*, *vitrum*, &c. *i. e.* with the blue colour procured from this plant. And hence, the factitious matter we are speaking of came to be called *glass*; as having always somewhat of this bluishness in it.

At what time the art of glass-making was first invented, is altogether uncertain. Some imagine it to have

ing.

Glasf.

have been invented before the flood: but of this we have no direct proof, though there is no improbability in the supposition; for we know, that it is almost impossible to excite a very violent fire, such as is necessary in metallurgic operations, without vitrifying part of the bricks or stones wherewith the furnace is built. This indeed might furnish the first hints of glass-making; tho' it is also very probable, that such imperfect vitrifications would be observed a long time before people thought of making any use of them.

Neri traces the antiquity of glass as far back as the time of Job. That writer, speaking of the value of wisdom, chap. xxviii. verse 17. says, that gold and crystal cannot equal it. But this word, which Neri will have to signify factitious glass, is capable of a great many different interpretations, and properly signifies only whatever is beautiful or transparent. Dr Merret will have the art to be as ancient as that of pottery or the making of bricks, for the reasons already given, viz. that by all vehement heat, some imperfect vitrifications are produced. Of this kind undoubtedly was the fossil glass mentioned by Ferant. Imperator. to have been found under-ground where great fires had been. But it is evident, that such imperfect vitrifications might have passed unnoticed for ages; and consequently we have no reason to conclude from thence, that the art of glass-making is of such high antiquity.

The Egyptians boast, that this art was taught them by their great Hermes. Aristophanes, Aristotle, Alexander, Aphrodiseus, Lucretius, and St John the divine, put it out of all doubt that glass was used in their days. Pliny relates, that it was first discovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a storm at sea; who being obliged to continue there, and dress their victuals by making a fire on the ground, where there was great plenty of the herb kali; that plant, burning to ashes, its salts mixed and incorporated with the sand, or stones fit for vitrification, and thus produced glass; and that, this accident being known, the people of Sidon in that neighbourhood essayed the work, and brought glass into use; since which time the art has been continually improving. Be this as it will, however, the first glass-houses mentioned in history were erected in the city of Tyre, and here was the only staple of the manufacture for many ages. The sand which lay on the shore for about half a mile round the mouth of the river Belus was peculiarly adapted to the making of glass, as being neat and glittering; and the wide range of the Tyrian commerce gave an ample vent for the productions of the furnace.

Mr Nixon, in his observations on a plate of glass, found at Herculaneum, which was destroyed A. D. 80, on which occasion Pliny lost his life, offers several probable conjectures, as to the uses to which such plates might be applied. Such plates, he supposes, might serve for *specula*, or looking-glasses; for Pliny, in speaking of Sidon, adds, *siquidem etiam specula excogitaverat*: the reflexion of images from these ancient specula being effected by besmearing them behind, or tinging them through with some dark colour. Another use in which they might be employed, was for adorning the walls of their apartments, by way of wainscot, to which Pliny is supposed to refer by his *vitrea camera*, lib. xxxvi. cap. 25. § 64. Mr Nixon

farther conjectures, that these glass plates might be used for windows, as well as the lamina of lapis *specularis* and *phengites*, which were improvements in luxury mentioned by Seneca, and introduced in his time, Ep. xc. However, there is no positive authority relating to the usage of glass-windows earlier than the close of the third century: *Manifestius est* (says Lactantius*), *mentem esse, quæ per oculos ea quæ sunt opposita, transpiciat, quasi per fenestras lucente vitro aut speculari lapide obductas.*

The first time we hear of glass made among the Romans was in the reign of Tiberius, when Pliny relates that an artist had his house demolished for making glass malleable, or rather flexible; though Petronius Arbitrator, and some others, assure us, that the emperor ordered the artist to be beheaded for his invention.

It appears, however, that before the conquest of Britain by the Romans, glass-houses had been erected in the island, as well as in Gaul, Spain, and Italy. Hence, in many parts of the country are to be found annulets of glass, having a narrow perforation and thick rim, denominated by the remaining Britons *glei-neu naidreeah*, or *glass adders*, and which were probably in former times used as annulets by the druids†. It † See *Anguinum Ovum*. can scarcely be questioned that the Britons were sufficiently well versed in the manufacture of glass, to form out of it many more useful instruments than the glass-beads. History indeed assures us, that they did manufacture a considerable quantity of glass vessels. These, like their annulets, were most probably green, blue, yellow, or black, and many of them curiously streaked with other colours. The process in the manufacture would be nearly the same with that of the Gauls or Spaniards. The sand of their shores being reduced to a sufficient degree of fineness by art, was mixed with three-fourths of its weight of their nitre (much the same with our kelp), and both were melted together. The metal was then poured into other vessels, where it was left to harden into a mass, and afterwards replaced in the furnace, where it became transparent in the boiling, and was afterwards figured by blowing, or modelling in the lath, into such vessels as they wanted.

It is not probable that the arrival of the Romans would improve the glass manufacture among the Britons. The taste of the Romans at that time was just the reverse of that of the inhabitants of that island. The former preferred silver and gold to glass for the composition of their drinking vessels. They made indeed great improvements in their own at Rome, during the government of Nero. The vessels then formed of this metal rivalled the bowls of porcelain in their dearness, and equalled the cups of crystal in their transparency. But these were by far too costly for common use; and therefore, in all probability, were never attempted in Britain. The glass commonly made use of by the Romans was of a quality greatly inferior; and, from the fragments which have been discovered at the stations or towns of either, appear to have consisted of a thick, sometimes white, but mostly blue green, metal.

According to venerable Bede, artificers skilled in making glass for windows were brought over into England in the year 674, by abbot Benedict, who were employed in glazing the church and monastery of Weremouth. According to others, they were first brought over

Glasf.

* *De opif. Dei*, cap. 5.

Glasf.

over by Wilfrid, bishop of Worcester, about the same time. Till this time the art of making such *glafs* was unknown in Britain; though *glafs* windows did not begin to be common before the year 1180: till this period they were very scarce in private houses, and considered as a kind of luxury, and as marks of great magnificence. Italy had them first, next France, from whence they came into England.

Venice, for many years, excelled all Europe in the fineness of its *glasses*; and in the thirteenth century, the Venetians were the only people that had the secret of making crystal looking-*glasses*. The great *glafs*-works were at Muran, or Murano, a village near the city, which furnished all Europe with the finest and largest *glasses*.

The *glafs* manufacture was first begun in England in 1557: the finer sort was made in the place called Crutched Friars, in London; the fine flint *glafs*, little inferior to that of Venice, was first made in the Savoy-house, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with sea-coal or pit-coal instead of wood, and a monopoly was granted to Sir Robert Mansell, who was allowed to import the fine Venetian flint *glasses* for drinking, the art of making which was not brought to perfection before the reign of William III. But the first *glafs*-plates, for looking-*glasses* and coach windows, were made, 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1670, introduced the manufacture of fine *glafs* into England, by means of Venetian artists, with amazing success. So that within a century past, the French and English have not only come up to, but even surpassed the Venetians, and they are now no longer supplied from abroad.

The French made a considerable improvement in the art of *glafs*, by the invention of a method to cast very large plates, till then unknown, and scarce practised yet by any but themselves and the English. That court applied itself with a laudable industry to cultivate and improve the *glafs* manufacture. A company of *glafs*-men was established by letters patent; and it was provided by an arret, not only that the working in *glafs* should not derogate any thing from nobility, but even that none but nobles should be allowed to work therein.

An extensive manufactory of this elegant and valuable branch of commerce was first established in Lancashire about the year 1773, through the spirited exertions of a very respectable body of proprietors, who were incorporated by an act of parliament. From those various difficulties constantly attendant upon new undertakings, when they have to contend with powerful foreign establishments, it was for some time considerably embarrassed; but Government, of late, having taken off some restrictions that bore hard upon it, and made some judicious regulations relative to the mode of levying the excise duty, it now bids fair to rival, if not surpass, the most celebrated continental manufactures, both with respect to the quality, brilliancy, and size of its productions.

2
Theory of
vitrifica-
tion uncer-
tain.

With regard to the theory of vitrification, we are almost totally in the dark. In general, it seems to be that state in which solid bodies are, by the vehement action of fire, fitted for being dissipated or carried off in vapour. In all vitrifications there is a plentiful eva-

poration; and if any solid substance is carried off in vapour by the intense heat of a burning speculum, a vitrification is always observed previously to take place. The difference, then, between the state of fusion and vitrification of a solid body we may conceive to be, that in the former the element of fire acts upon the parts of the solid in such a manner as only to disjoin them, and render the substance fluid; but in vitrification the fire not only disjoins the particles, but combines with them in a latent state into a third substance; which, having now as much fire as it can contain, can receive no further change from that element except being carried off in vapour.

But though we are unable to effect this change upon solid bodies without a very violent heat, it is otherwise in the natural processes. By what we call *crystallization*, nature produces more perfect glasses than we can make with our furnaces. These are called *precious stones*; but in all trials they discover the essential properties of glass, and not of stones. The most distinguishing property of glass is its resisting the force of fire, so that this element cannot calcine or change it as it does other bodies, but can only melt it, and then carry it off in vapours. To this last all the precious stones are subject. The diamond (the hardest and most ponderous of them all) is dissipable in a less degree of heat than what would dissipate common glass. Nor can it be any objection to this idea, that some kinds of glass are capable of being converted into a kind of porcelain by a long-continued cementation with certain materials. This change happens only to those kinds of glass which are made of alkaline salt and sand; and Dr Lewis hath shown that this change is produced by the dissipation of the saline principle, which is the least fixed of the two. Glass, therefore, we may still consider as a substance upon which the fire has no other effect but either to melt or dissipate it in vapour.

The other properties of glass are very remarkable, some of which follow.

1. It is one of the most elastic bodies in nature. If Remark-
the force with which glass balls strike each other be ble pro-
reckoned 16, that wherewith they recede by virtue of 3
their elasticity will be nearly 15. perties of
glass,

2. When glass is suddenly cooled, it becomes ex-
ceedingly brittle; and this brittleness is sometimes
attended with very surprising phenomena. Hollow
bells made of annealed glass, with a small hole in them,
will fly to pieces by the heat of the hand only, if the
hole by which the internal and external air communi-
cate be stopped with a finger. Lately, however, some 4
vessels made of such annealed glass have been disco-
vered, which have the remarkable property of resisting
very hard strokes given from without, though they
shiver to pieces by the shocks received from the fall of
very light and minute bodies dropped into their cavi-
ties. These glasses may be made of any shape; all
that needs be observed in making them is, that their
bottom be thicker than their sides. The thicker the
bottom is, the easier do the glasses break. One whose
bottom is three fingers breadth in thickness, flies with
as much ease at least as the thinnest glass. Some of
these vessels have been tried with strokes of a mallet
sufficient to drive a nail into wood tolerably hard, and
have held good without breaking. They have also

Surprising
fragility of
annealed
glass.

Glasf.

Glasf.

resisted the shock of several heavy bodies let fall into their cavities, from the height of two or three feet; as musket-balls, pieces of iron, or other metal, pyrites, jasper, wood, bone, &c. But this is not surprising, as other glasses of the same shape and size will do the same: but the wonder is, that taking a shiver of flint of the size of a small pea, and letting it fall into the glass only from the height of three inches, in about two seconds the glass flies, and sometimes at the very moment of the shock; nay, a bit of flint no larger than a grain, dropped into several glasses successively, though it did not immediately break them, yet when set by, they all flew in less than three quarters of an hour. Some other bodies produce the same effect with flint; as sapphire, diamond, porcelain, hard tempered steel; also marbles such as boys play with, and likewise pearls.

These experiments were made before the Royal Society; and succeeded equally when the glasses were held in the hand, when they were rested on a pillow, put in water, or filled with water. It is also remarkable, that the glasses broke upon having their bottoms slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing. If the glasses are every where extremely thin, they do not break in these circumstances.

5
Attempts
to account
for it.

Some have pretended to account for these phenomena, by saying, that the bodies dropped into the vessels cause a concussion which is stronger than the cohesive force of the glass, and consequently that a rupture must ensue. But why does not a ball of iron, gold, silver, or copper, which are perhaps a thousand times heavier than the flint, produce the same effect? It is because they are not elastic. But surely iron is more elastic than the end of one's finger.—Mr Euler has endeavoured to account for these appearances from his principles of percussion. He thinks that this experiment entirely overthrows the opinion of those who measure the force of percussion by the *vis viva*, or absolute apparent strength of the stroke. According to his principles, the great hardness and angular figure of the flint, which makes the space of contact with the glass extremely small, ought to cause an impression on the glass vastly greater than lead, or any other metal; and this may account for the flint's breaking the vessel, though the bullet, even falling from a considerable height, does no damage.—Hollow cups made of green bottle-glass, some of them three inches thick at the bottom, were instantly broken by a shiver of flint, weighing about two grains, though they had resisted the shock of a musket-ball from the height of three feet.

That Mr Euler's theory cannot be conclusive more than the other, must appear evident from a very slight consideration. It is not by angular bodies alone that the glasses are broken. The marbles with which children play are round, and yet they have the same effect with the angular flint. Besides, if it was the mere force of percussion which broke the glasses, undoubtedly the fracture would always take place at the very instant of the stroke; but we have seen, that this did not happen sometimes till a very considerable space of time had elapsed. It is evident, therefore, that this effect is occasioned by the putting in motion some subtle fluid with which the substance of the glass is

Glasf.

filled; and that the motions of this fluid, when once excited in a particular part of the glass, soon propagate themselves through the whole or greatest of it, by which means the cohesive power becomes at last too weak to resist them. There can be little doubt that the fluid just now mentioned is that of electricity. It is known to exist in glass in very great quantity; and it also is known to be capable of breaking glasses, even when annealed with the greatest care, if put into too violent a motion. Probably the cooling of glass hastily may make it more electric than is consistent with its cohesive power, so that it is broken by the least increase of motion in the electric fluid by friction or otherwise. This is evidently the case when it is broken by rubbing with the finger; but why it should also break by the mere contact of flint and the other bodies abovementioned, has not yet been satisfactorily accounted for.

A most remarkable phenomenon also is produced in glass tubes placed in certain circumstances. When these are laid before a fire in an horizontal position, having their extremities properly supported, they acquire a rotatory motion round their axis, and also a progressive motion towards the fire, even when their supports are declining from the fire, so that the tubes will move a little way up hill towards the fire. When the progressive motion of the tubes towards the fire is stopped by any obstacle, their rotation still continues. When the tubes are placed in a nearly upright posture, leaning to the right hand, the motion will be from east to west; but if they lean to the left hand, their motion will be from west to east; and the nearer they are placed to the perfectly upright posture, the less will the motion be either way.

If the tube is placed horizontally on a glass plane, the fragment, for instance, of coach-window-glass, instead of moving towards the fire, it will move from it, and about its axis in a contrary direction to what it had done before; nay, it will recede from the fire, and move a little up-hill when the plane inclines towards the fire.—These experiments are recorded in the Philosophical Transactions.* They succeeded best with tubes about 20 or 22 inches long, which had in each end a pretty strong pin fixed in cork for an axis.

The reason given for these phenomena, is the swelling of the tubes towards the fire by the heat, which is known to expand all bodies. For, say the adopters of this hypothesis, granting the existence of such a swelling, gravity must pull the tube down when supported near its extremities; and a fresh part being exposed to the fire, it must also swell out and fall down, and so on.—But, without going farther in the explanation of this hypothesis, it may be here remarked, that the fundamental principle on which it proceeds is false: for though fire indeed makes bodies expand, it does not increase them in weight; and therefore the sides of the tube, though one of them is expanded by the fire, must still remain *in equilibrio*; and hence we must conclude, that the causes of these phenomena remain yet to be discovered.

4. Glass is less dilatible by heat than metalline substances, and solid glass sticks are less dilatible than tubes. This was first discovered by Col. Roy, in making experiments in order to reduce barometers to a greater degree of exactness than hath hitherto been found

6

found

Glasf.

found practicable; and since his experiments were made, one of the tubes 18 inches long, being compared with a solid glass-rod of the same length, the former was found by a pyrometer to expand four times as much as the other, in a heat approaching to that of boiling oil.—On account of the general quality which glass has of expanding less than metal, M. de Luc recommends it to be used in pendulums: and he says it has also this good quality, that its expansions are always equable, and proportioned to the degrees of heat; a quality which is not to be found in any other substance yet known.

Ibid.
vol. lxxviii.
p. 474.

5. Glass appears to be more fit for the condensation of vapours than metallic substances. An open glass filled with water, in the summer-time, will gather drops of water on the outside, just as far as the water in the inside reaches; and a person's breath blown on it, manifestly moistens it. Glass also becomes moist with dew, when metals do not. See DEW.

6. A drinking glass partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower as the glass is more or less full; and will make the liquor frisk and leap. See HARMONICA.

7. Glass is possessed of very great electrical virtues. See ELECTRICITY, *passim*.

8
Materials
for glassf.

Materials for making of GLASS. The materials whereof glass is made, we have already mentioned to be salt and sand or stones.

* See *Sal-feda,*

1. The salt here used is procured from a sort of ashes brought from the Levant, called *polverine*, or *rochetta*; which ashes are those of a sort of water-plant called *kali**, cut down in summer, dried in the sun, and burnt in heaps, either on the ground, or on iron grates; the ashes falling into a pit, grow into a hard mass, or stone, fit for use. It may also be procured from common kelp, or the ashes of the *fucus vesiculosus*. See KELP and FUCUS.

To extract the salt, these ashes, or *polverine*, are powdered and sifted, then put into boiling water, and there kept till one third of the water be consumed; the whole being stirred up from time to time, that the ashes may incorporate with the fluid, and all its salts be extracted: then the vessel is filled up with new water, and boiled over again, till one half be consumed; what remains is a sort of ley, strongly impregnated with salt. This ley, boiled over again in fresh coppers, thickens in about 24 hours, and shoots its salt; which is to be ladled out, as it shoots, into earthen pans, and thence into wooden vats to drain and dry. This done, it is grossly pounded, and thus put in a sort of oven, called *calcar*, to dry. It may be added, that there are other plants, besides *kali* and *fucus*, which yield a salt fit for glass: such are the common way-thistle, bramble, hops, wormwood, woods, tobacco, fern, and the whole leguminous tribe, as pease, beans, &c.

Pearl-ashes form a leading flux in the manufacture of glass, and mostly supply the place of the Levant-ashes, the barillas of Spain, and many other kinds, which were formerly brought here for making both glass and soap. See PEARL-Asbes.

There are other fluxes used for different kinds of glass, and for various purposes, as calcined lead, nire,

sea-salt, borax, arsenic, smiths clinkers, and wood-ashes, containing the earth and lixivate salts as produced by incineration. With regard to these several fluxes, we may observe, in general, that the more calx of lead, or other metallic earth, enters into the composition of any glass, so much the more fusible, soft, coloured, and dense this glass is, and reciprocally.

The colours given to glass by calxes of lead, are shades of yellow: on the other hand, glasses that contain only saline fluxes partake of the properties of salts; they are less heavy, less dense, harder, whiter, more brilliant, and more brittle than the former; and glasses containing both saline and metallic fluxes do also partake of the properties of both these substances. Glasses too saline are easily susceptible of alteration by the action of air and water; especially those in which alkalis prevail; and these are also liable to be injured by acids. Those that contain too much borax and arsenic, though at first they appear very beautiful, quickly tarnish and become opaque when exposed to air. By attending to these properties of different fluxes, phlogistic or saline, the artist may know how to adjust the proportions of these to sand, or powdered flints, for the various kinds of glass. See the article VITRIFICATION.

2. The sand or stone, called by the artists *tarso*, is the second ingredient in glass, and that which gives it the body and firmness. These stones, Agricola observes, must be such as will fuse: and of these such as are white and transparent are best; so that crystal challenges the precedency of all others.

At Venice they chiefly use a sort of pebble, found in the river Tesino, resembling white marble, and called *cuogolo*. Indeed Ant. Neri assures us, that all stones which will strike fire with steel, are fit to vitrify: but Dr Morret shows, that there are some exceptions from this rule. Flints are admirable; and when calcined, powdered, and searced, make a pure white crystalline metal; but the expences of preparing them makes the masters of glass-houses sparing of their use. Where proper stones cannot be so conveniently had, sand is used. The best for this purpose is that which is white, small, and shining; examined by the microscope, it appears to be small fragments of rock crystal. For green glass, that which is of a soft texture, and more gritty; it is to be well washed, which is all the preparation it needs. British glass-houses are furnished with white sand for their crystal glasses from Lynn in Norfolk and Maidstone in Kent, and with the coarser for green-glass from Woolwich.

Some mention a third ingredient in glass, viz. manganese, a kind of pseudo-loadstone, dug up in Germany, Italy, and even in Mendip hills in Somersetshire. But the proportion hereof to the rest is very inconsiderable; beside, that it is not used in all glass. Its office is to purge off the natural greenish colour, and give it some other tincture required.

For this purpose it should be chosen of a deep colour, and free from specks of a metalline appearance, or a lighter cast; manganese requires to be well calcined in a hot furnace, and then to undergo a thorough levigation. The effect of manganese in destroying the colours of glass, and hence called the soap of glass, is accounted for by M. Montamy, in his *Traité des Couleurs pour la Peinture en Email*, in the following manner: the

Glasf.

Glasf.

the manganese destroys the green, olive, and blue colours of glass, by adding to them a purple tinge, and by the mixture producing a blackish brown colour; and as blackness is caused merely by an absorption of the rays of light, the blackish tinge given to the glass by the mixture of colours, prevents the reflection of so many rays, and thus renders the glass less coloured than before. But the black produced by this substance suggests an obvious reason for using it very sparingly in those compositions of glass which are required to be very transparent. Nitre or saltpetre is also used with the same intention; for by destroying in a certain degree the phlogiston which gives a strong tinge of yellow to glass prepared with lead as a flux, it serves to free it from this coloured tinge; and in saline glasses, nitre is requisite in a smaller proportion to render them sufficiently transparent, as in the case of looking-glasses and other kinds of plates.

Kinds of GLASS. The manufactured glass now in use may be divided into three general kinds; white transparent glass, coloured glass, and common green or bottle glass. Of the first kind there is a great variety; as the flint glass, as it is called with us; and the German crystal glass, which are applied to the same uses; the glass for plates for mirrors or looking-glasses; the glass for windows and other lights; and the glass for phials and small vessels. And these again differ in the substances employed as fluxes in forming them, as well as in the coarseness or fineness of such as are used for their body. The flint and crystal, mirror and best window glass, not only require such purity in the fluxes, as may render it practicable to free the glass perfectly from all colour; but for the same reason likewise, either the white Lynn sand, calcined flints, or white pebbles, should be used. The others do not demand the same nicety in the choice of the materials; though the second kind of window glass, and the best kind of phial, will not be so clear as they ought, if either too brown sand, or impure salts, be suffered to enter into their composition.

Of coloured glass there is a great variety of sorts, differing in their colour or other properties according to the occasions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artists by whom they are manufactured, as will be afterwards explained.

Furnace for the making of GLASS. In this manufacture there are three sorts of furnaces; one called *cal-ear* is for the frit; the second is for working the glass; the third serves to anneal the glass, and is called the *leer*. See Plate CCXX.

The calcar resembles an oven ten feet long, seven feet broad, and two deep: the fuel, which in Britain is sea-coal, is put into a trench on one side of the furnace; and the flame reverberating from the roof upon the frit calcines it. The glass-furnace, or working-furnace, is round, of three yards diameter, and two high; or thus proportioned. It is divided into three parts, each of which is vaulted. The lower part is properly called the *crown*, and is made in that form. Its use is to keep a brisk fire, which is never put out. The mouth is called *bocca*. There are several holes in the arch of this crown, through which the flame passes into the second vault or partition; and reverbe-

Glasf.

rates into the pots filled with the ingredients above-mentioned. Round the insides are eight or more pots placed, and piling pots on them. The number of pots is always double that of the boccas or mouths, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in while he works out of the other. Through the working holes the metal is taken out of the pots; and the pots are put into the furnace; and these holes are stopped with moveable covers made of lute and brick, to screen the workmen's eyes from the scorching flames. On each side of the becca or mouth is a bocarella or little hole out of which coloured glass or finer metal is taken from the piling pot. Above this oven there is the third oven or *leer*, about five or six yards long, where the vessels or glass are annealed or cooled; this part consists of a tower, besides the leer; into which the flame ascends from the furnace. The tower has two mouths, through which the glasses are put in with a fork, and set on the floor or bottom: but they are drawn out on iron pans, called *fraches*, through the leer, to cool by degrees: so that they are quite cold by the time they reach the mouth of the leer, which enters the farosel or room where the glasses are to be stowed.

But the green glass-furnace is square: and at each angle it has an arch for annealing or cooling glasses. The metal is wrought on two opposite sides, and on the other two they have their colours, into which are made linnet holes for the fire to come from the furnace to bake the frit, and to discharge the smoke. Fires are made in the arches to anneal the work, so that the whole process is done in one furnace.

These furnaces must not be of brick, but of hard sandy stones. In France, they build the outside of brick; and the inner part, to bear the fire, is made of a sort of Fuller's earth, or tobacco-pipe clay, of which earth they also make their melting-pots. In Britain the pots are made of Sturbridge-clay.

Mr Blancourt observes, that the worst and roughest work in this art is the changing the pots when they are worn out or cracked. In this case, the great working hole must be uncovered; the faulty pot must be taken out with iron hooks and forks, and a new one must be speedily put in its place, through the flames, by the hands only. For this work, the man guards himself with a garment made of skins; in the shape of a pantaloon, that covers him all but his eyes, and is made as wet as possible: the eyes are defended with a proper sort of glass.

Instruments for making of GLASS. The instruments made use of in this work, may be reduced to these that follow. A blowing-pipe, made of iron, about two feet and a half long, with a wooden handle. An iron rod to take up the glass after it is blown, and to cut off the former. Scissors to cut the glass when it comes off from the first hollow iron. Shears to cut and shape great glasses, &c. An iron-ladle, with the end of the handle cased with wood, to take the metal out of the refining pot, to put it into the workmen's pots. A small iron-ladle, cased in the same manner, to skim the alkalic salt that swims at top. Shovels, one like a peel, to take up the great glasses; another, like a fire-shovel, to feed the furnace with coals. A hooked iron fork, to stir the matter in the pots. An
iron

Glasf.

iron rake for the same purpose, and to stir the frit. An iron fork, to change or pull the pots out of the furnace, &c.

Compositions for White and Crystal GLASS. 1. To make *crystal glass*, take of the whitest tarso, pounded small, and searced as fine as flour, 200 pounds; of the salt of polverine 130 pounds; mix them together, and put them into the furnace called the *calcar*, first heating it. For an hour keep a moderate fire, and keep stirring the materials with a proper rake; that they may incorporate and calcine together; then increase the fire for five hours; after which take out the matter; which being now sufficiently calcined, is called *frit*. From the calcar put the frit in a dry place, and cover it up from the dust for three or four months. Now to make the glass or crystal: take of this crystal frit, called also *bollito*; set it in pots in the furnace, adding to it a due quantity of magnesia or manganese: when the two are fused, cast the fluor into fair water, to clear it of the salt called *sandiver*; which would otherwise make the crystal obscure and cloudy. This lotion must be repeated again and again, as often as needful, till the crystal be fully purged; or this scum may be taken off by means of proper ladles. Then set it to boil four, five, or six days; which done, see whether it have manganese enough; and if it be yet greenish, add more manganese, at discretion, by little and little at a time, taking care not to overdose it, because the manganese inclines it to a blackish hue. Then let the metal clarify, till it becomes of a clear and shining colour; which done, it is fit to be blown or formed into vessels at pleasure.

2. *Flint glass*, as it is called by us, is of the same general kind with that which in other places is called crystal glass. It has this name from being originally made with calcined flints, before the use of the white sand was understood; and retains the name, though no flints are now used in the composition of it. This flint glass differs from the other, in having lead for its flux, and white sand for its body; whereas the fluxes used for the crystal glass are salts or arsenic, and the body consists of calcined flints or white river pebbles, tarso, or such stones. To the white sand and lead a proper proportion of nitre is added, to burn away the phlogiston of the lead, and also a small quantity of magnesia; and in some works they use a proportional quantity of arsenic to aid the fluxing ingredients. The most perfect kind of flint glass may be made by fusing with a very strong fire 120 pounds of the white sand, 50 pounds of red lead, 40 pounds of the best pearl-ashes, 20 pounds of nitre, and five ounces of magnesia. Another composition of flint glass, which is said to come nearer to the kind now made, is the following: 120 pounds of sand, 54 pounds of the best pearl-ashes, 36 pounds of red-lead, 12 pounds of nitre, and 6 ounces of magnesia. To either of these a pound or two of arsenic may be added, to increase the flux of the composition. A cheaper composition of flint glass may be made with 120 pounds of white sand, 35 pounds of the best pearl-ashes, 40 pounds of red-lead, 13 pounds of nitre, 6 pounds of arsenic, and 4 ounces of magnesia; or instead of the arsenic may be substituted 15 pounds of common salt; but this will be more brittle than the other. The cheapest composition for the worst kind of flint glass consists of 120 pounds of white sand;

30 pounds of red-lead, 20 pounds of the best pearl-ashes, 10 pounds of nitre, 15 pounds of common salt, and six pounds of arsenic. The best German crystal glass is made of 120 pounds of calcined flints or white sand, 70 pound of the best pearl-ashes, 10 pounds of saltpetre, half a pound of arsenic, and five ounces of magnesia. And a cheaper composition is formed of 120 pounds of calcined flints or white sand, 46 pounds of pearl-ashes, 7 pounds of nitre, 6 pounds of arsenic, and 5 ounces of magnesia.

A glass much harder than any prepared in the common way, may be made by means of borax in the following method: Take four ounces of borax, and an ounce of fine sand; reduce both to a subtile powder, and melt them together in a large close crucible set in a wind furnace, keeping up a strong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glass capable of cutting common glass like a diamond. This experiment, duly varied, says Dr Shaw, may lead to several useful improvements in the arts of glass, enamels, and factitious gems, and shows an expeditious method of making glass, without any fixed alkali, which has been generally thought an essential ingredient in glass, and it is not yet known whether calcined crystal or other substances being added to this salt instead of sand, it might not make a glass approaching to the nature of a diamond.

There are three principal kinds of glasses, distinguished by the form or manner of working them; viz. I. *Round glass*, as those of our vessels, phials, drinking-glasses, &c. II. *Table or window-glass*, of which there are divers kinds; viz. crown-glass, jealous-glass, &c. III. *Plate-glass*, or *mirror glass*.

I. *Working or Blowing Round GLASS.* The working furnace, we have observed, is round, and has six boccas or apertures: at one of these called the *great bocca*, the furnace is heated, and the pots of frit are at this set in the furnace; two other smaller holes, called *bo-carellas*, serve to lade or take out the melted metal, at the end of an iron, to work the glass. At the other holes they put in pots of fusible ingredients, to be prepared, and at last emptied into the lading-pot.

There are six pots in each furnace, all made of tobacco-pipe clay, proper to sustain not only the heat of the fire, but also the effect of the polverine, which penetrates every thing else. There are only two of these pots that work: the rest serve to prepare the matter for them. The fire of the furnace is made and kept up with dry hard wood, cast in without intermission at six apertures.

When the matter contained in the two pots is sufficiently vitrified, they proceed to blow or fashion it. For this purpose the workman dips his blowing pipe into the melting-pot; and by turning it about, the metal sticks to the iron more firmly than turpentine. This he repeats four times, at each time rolling the end of his instrument with the hot metal thereon, on a piece of plate-iron; over which is a vessel of water which helps to cool, and so to consolidate and to dispose that matter to bind more firmly with what is to be taken next out of the melting pot. But after he has dip't a fourth time, and the workman perceives there is metal enough on the pipe, he claps his mouth immediately to the other end of it, and blows gently through

Glasf.

Glas.

through the iron tube, till the metal lengthens like a bladder about a foot. Then he rolls it on a marble stone a little while to polish it; and blows a second time, by which he brings it to the shape of a globe of about 18 or 20 inches diameter. Every time he blows into the pipe, he removes it quickly to his cheek; otherwise he would be in danger, by often blowing, of drawing the flame into his mouth: and this globe may be flattened by returning it to the fire; and brought into any form by stamp-irons, which are always ready. When the glass is thus blown, it is cut off at the collet or neck; which is the narrow part that stuck to the iron. The method of performing this is as follows: the pipe is rested on an iron bar, close by the collet; then a drop of cold water being laid on the collet, it will crack about a quarter of an inch, which, with a slight blow or cut of the shears, will immediately separate the collet.

After this is done, the operator dips the iron rod into the melting-pot, by which he extracts as much metal as serves to attract the glass he has made, to which he now fixes this rod at the bottom of his work, opposite to the opening made by the breaking of the collet. In this position the glass is carried to the great bocca or mouth of the oven, to be heated and scalded; by which means it is again put into such a soft state, that, by the help of an iron instrument, it can be pierced, opened, and widened, without breaking. But the vessel is not finished till it is returned to the great bocca; where being again heated thoroughly, and turned quickly about with a circular motion, it will open to any size, by the means of the heat and motion.

If there remain any superfluities, they are cut off with the shears; for till the glass is cold, it remains in a soft flexible state. It is therefore taken from the bocca, and carried to an earthen bench, covered with brands, which are coals extinguished, keeping it turning; because that motion prevents any settling, and preserves an evenness in the face of the glass, where, as it cools, it comes to its consistency; being first cleared from the iron rod by a slight stroke by the hand of the workman.

If the vessel conceived in the workman's mind, and whose body is already made, requires a foot, or a handle, or any other member or decoration, he makes them separately; and now essays to join them with the help of hot metal, which he takes out of the pots with his iron-rod: but the glass is not brought to its true hardness till it has passed the leer or annealing oven, described before.

II. *Working or Blowing of Window or Table GLASS.* The method of working round glass, or vessels of any sort, is in every particular applicable to the working of window or table glass, till the blowing iron has been dipt the fourth time. But then instead of rounding it, the workman blows, and so manages the metal upon the iron plate, that it extends two or three feet in the form of a cylinder. The cylinder is put again to the fire, and blown a second time, and is thus repeated till it is extended to the dimensions required, the side to which the pipe is fixed diminishing gradually till it ends in a pyramidal form; so that, to bring both ends nearly to the same diameter, while the glass is thus flexible, he adds a little hot metal to the end

opposite the pipe, and draws it out with a pair of iron pincers, and immediately cuts off the same end with the help of a little cold water as before.

The cylinder being now open at one end, is carried back to the bocca; and there, by the help of cold water, it is cut about eight or ten inches from the iron pipe or rod; and the whole length at another place, by which also it is cut off from the iron rod. Then it is heated gradually on an earthen table, by which it opens in length; while the workman, with an iron tool, alternately lowers and raises the two halves of the cylinder; which at last will open like a sheet of paper, and fall into the same flat form in which it serves for use; in which it is preserved by heating it over again, cooling it on a table of copper, and hardening it 24 hours in the annealing furnace, to which it is carried upon forks. In this furnace an hundred tables of glass may lie at a time, without injury to each other, by separating them into tens, with an iron shiver between, which diminishes the weight by dividing it, and keeps the tables flat and even.

Of window or table glass there are various sorts, made in different places, for the use of building. Those most known among us are given us by the author of the Builder's Dictionary, as follows:

1. *Crown*, of which, says Neri, there are two kinds, distinguished by the places where they are wrought; viz. Ratcliff crown glass, which is the best and clearest, and was first made at the Bear-garden, on the Bank-side, Southwark, but since at Ratcliff: of this there are 24 tables to the case, the tables being of a circular form, about three feet six inches in diameter. The other kind, or Lambeth crown glass, is of a darker colour than the former, and more inclining to green.

The best window or crown glass, is made of white sand 90 pounds, of purified pearl ashes 30 pounds, of saltpetre 15 pounds, of borax one pound, and of arsenic half a pound. If the glass should prove yellow, magnesia must be added. A cheaper composition for window glass consists of 60 pounds of white sand, 15 pounds of unpurified pearl-ashes, 10 pounds of common salt, 5 pounds of nitre, 2 pounds of arsenic, and one ounce and a half of magnesia. The common or green window glass is composed of 60 pounds of white sand, 30 pounds of unpurified pearl ashes, 10 pounds of common salt, 2 pounds of arsenic, and two ounces of magnesia. But a cheaper composition for this purpose consists of 120 pounds of the cheapest white sand, 30 pounds of unpurified pearl-ashes, 60 pounds of wood ashes, well burnt and sifted, 20 pounds of common salt, and five pounds of arsenic.

2. *French glass*, called also *Normandy glass*, and formerly *Lorrain glass*, because made in those provinces. At present it is made wholly in the nine glass-works; five whereof are in the forest of Lyons, four in the county of Eu; the last at Beaumont near Rouen. It is of a thinner kind than our crown glass; and when laid on a piece of white paper, appears of a dirtyish green colour. There are but 25 tables of this to the case.

3. *German glass*, is of two kinds, the *white* and the *green*: the first is of a whitish colour, but is subject to those small curved streaks observed in the Newcastle glass, though free from the spots and blemishes thereof. The green, besides its colour, is liable to the same streaks

Glas.

Furnace for Artificial GEMS. Fig. 7.

GEMS. Fig. 6.

Fig. 4.

Fig. 5.

Glas.

freaks as the white; but both of them are straighter and less warped than the Newcastle glass.

4. *Dutch glass* is not much unlike the Newcastle glass either in colour or price. It is frequently much warped like that, and the tables are but small.

5. *Newcastle glass* is that most used in England. It is of an ash-colour, and much subject to specks, streaks, and other blemishes; and besides is frequently warped. Leybourn says, there are 45 tables to the case, each containing five superficial feet: some say there are but 35 tables, and six feet in each table.

6. *Phial glass* is a kind betwixt the flint glass and the common bottle or green glass. The best kind may be prepared with 120 pounds of white sand, 50 pound of unpurified pearl-ashes, 10 pounds of common salt, 5 pounds of arsenic, and 5 ounces of magnesia. The composition for green or common phial glass consists of 120 pounds of the cheapest white sand, 80 pounds of wood ashes well burnt and sifted, 20 pounds of pearl-ashes, 15 pounds of common salt, and 1 pound of arsenic.

The common bottle or green is formed of sand of any kind fluxed by the ashes of burnt wood, or of any parts of vegetables; to which may be added the *scoriae* or clinkers of forges. When the softest sand is used, 200 pounds of wood ashes will suffice for 100 pounds of sand, which are to be ground and mixed together. The composition with the clinkers consists of 170 pounds of wood-ashes, 100 pounds of sand, and 50 pounds of clinkers or *scoriae*, which are to be ground and mixed together. If the clinkers cannot be ground, they must be broke into small pieces, and mixed with the other matter without any grinding.

III. *Working of Plate or Mirror GLASS.* 1. The materials of which this glass is made are much the same as those of other works of glass, viz. an alkali as salt and sand.

The salt, however, should not be that extracted from pulverine or the ashes of the Syrian kali, but that from *BARILLA*, growing about Alicant in Spain. It is very rare that we can have the barilla pure; the Spaniards in burning the herb make a practice of mixing another herb along with it, which alters its quality; or of adding sand to it to increase the weight, which is easily discovered if the addition be only made after the boiling of the ashes, but next to impossible if made in the boiling. It is from this adulteration that those threads and other defects in plate glass arise. To prepare the salt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally sift it pretty fine.

Pearl-ashes, properly purified, will furnish the alkali salt requisite for this purpose; but it will be necessary to add borax or common salt, in order to facilitate the fusion, and prevent the glass from stiffening in that degree of heat in which it is to be wrought into plates. For purifying the pearl-ashes, dissolve them in four times their weight of boiling water, in a pot of cast iron, always kept clean from rust. Let the solution be removed into a clean tub, and remain there 24 hours or longer. Having decanted the clear part of the fluid from the dregs or sediment, put it again in the iron pot, and evaporate the water till the salts are left perfectly dry. Preserve them in stone-jars, well secured from air and moisture.

VOL. VII.

Glas.

Pearl-ashes may also be purified in the highest degree, so as to be proper for the manufacture of the most transparent glass, by pulverizing three pounds of the best pearl-ashes with six ounces of saltpetre in a glass of marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and exposing it in a furnace to a strong heat. When this is red-hot, throw in the rest gradually; and when the whole is red-hot, pour it out on a moistened stone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire till the salts be entirely melted; let it then stand to cool, and filter it through paper in a pewter cullender. When it is filtered, put the fluid again into the pot, and evaporate the salt to dryness, which will then be as white as snow; the nitre having burnt all the phlogistic matter that remained in the pearl-ashes after their former calcination.

As to the sand, it is to be sifted and washed till such time as the water come off very clear; and when it is well dried again, they mix it with the salt, passing the mixture through another sieve. This done, they lay them in the annealing furnace for about two hours; in which time the matter becomes very light and white: in this state they are called *frit* or *fritta*; and are to be laid up in a dry clean place, to give them time to incorporate: they lie here for at least a year.

When they would employ this frit, they lay it for some hours in the furnace, adding to it some the fragments or shards of old and ill made glasses; taking care first to calcine the shards by heating them red-hot in the furnace, and thus casting them into cold water. To the mixture must likewise be added manganese, to promote the fusion and purification.

The best composition for looking-glass plates consists of 60 pounds of white sand cleaned, 25 pounds of purified pearl-ashes, 15 pounds of saltpetre, and 7 pounds of borax. If a yellow tinge should affect the glass, a small proportion of magnesia, mixed with an equal quantity of arsenic, should be added. An ounce of the magnesia may be first tried; and if this proves insufficient, the quantity should be increased.

A cheaper composition for looking-glass plates consists of 60 pounds of the white sand, 20 pounds of pearl-ashes, 10 pounds of common salt, 7 pounds of nitre, 2 pounds of arsenic, and 1 pound of borax. The matter of which the glasses are made at the famous manufacture of St Gobin in France, is a composition of folder and of a very white sand, which are carefully cleaned of all heterogeneous bodies; afterwards washed for several times, and dried so as to be pulverized in a mill, consisting of many pestles, which are moved by horses. When this is done, the sand is sifted through silk sieves and dried.

The matter thus far prepared is equally fit for plate-glass, to be formed either for blowing or by casting.

The largest glasses at St Gobin are run; the middle-sized and small ones are blown.

2. *Blowing the Plates.* The workhouses, furnaces, &c. used in the making of this kind of plate-glass, are the same, except that they are smaller, and that the carquaisies are disposed in a large covered gallery, over against the furnace, as those in the following article, to which the reader is referred.

5 E

After

Glas.

After the materials are vitrified by the heat of the fire, and the glass is sufficiently refined, the workman dips in his blowing-iron, six feet long, and two inches in diameter, sharpened at the end which is put in the mouth, and widened at the other, that the matter may adhere to it. By this means he takes up a small ball of matter, which sticks to the end of the tube by constantly turning it. He then blows into the tube, that the air may swell the annexed ball; and carrying it over a bucket of water, which is placed on a support at the height of about four feet, he sprinkles the end of the tube to which the matter adheres, with water, still turning it, that by this cooling the matter may coalesce with the tube, and be fit for sustaining a greater weight. He dips the tube again into the same pot, and proceeds as before; and dipping it in the pot a third time, he takes it out, loaded with matter, in the shape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the same time blowing into the tube, and with the assistance of a labourer, giving it a balancing motion, he causes the matter to lengthen; which, by repeating this operation several times, assumes the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The assistant is then placed on a stool three feet and a half high; and on this stool there are two upright pieces of timber, with a cross beam of the same, for supporting the glass and tube, which are kept in an oblique position by the assistant, that the master workman may with a punchion set in a wooden handle, and with a mallet make a hole in the mass: this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the glass is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron tressel, placed on the support of the aperture of the furnace. Having exposed it to the heat for about a half a quarter of an hour, he takes it away, and with a pair of long and broad shears, extremely sharp at the end, widens the glass, by insinuating the shears into the hole made with the punchion, whilst the assistant, mounted on the stool, turns it round, till at last the opening is so large as to make a perfect cylinder at bottom. When this is done, the workman lays his glass upon the tressels at the mouth of the furnace to heat it: he then gives it to his assistant on the stool, and with large shears cuts the mass of matter up to half its height. There is at the mouth of the furnace an iron tool called *pontil*, which is now heating, that it may unite and coalesce with the glass just cut, and perform the office which the tube did before it was separated from the glass. This *pontil* is a piece of iron six feet long, and in the form of a cane or tube, having at the end of it a small iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the glass, about four inches thick. This red hot *pontil* is presented to the diameter of the glass, which coalesces immediately with the matter round the *pontil*, so as to support the glass for the following operation. When this is done, they separate the tube from the glass, by striking a few blows with a chissel upon the end of the tube which has been cooled; so that the glass breaks directly, and makes this separation, the tube being discharged of the glass

now adhering to the *pontil*. They next present to the furnace the *pontil* of the glass, laying it on the tressel to heat, and redden the end of that glass, that the workman may open it with his shears, as he has already opened one end of it, to complete the cylinder; the assistant holding it on his stool as before. For the last time, they put the *pontil* on the tressel, that the glass may become red-hot, and the workman cuts it quite open with his shears, right over-against the fore-mentioned cut; this he does as before, taking care that both cuts are in the same line. In the mean time, the man who looks after the *carquaiſſes* comes to receive the glass upon an iron shovel two feet and a half long without the handle, and two feet wide, with a small border of an inch and a half to the right and left, and towards the handle of the shovel. Upon this the glass is laid, flattening it a little with a small stick a foot and a half long, so that the cut of the glass is turned upwards. They separate the glass from the *pontil*, by striking a few gentle blows between the two with a chissel. The glass is then removed to the mouth of the hot *carquaiſſe*, where it becomes red-hot gradually; the workman, with an iron tool six feet long, and widened at the end in form of a club at cards four inches long, and two inches wide on each side, very flat, and not half an inch thick, gradually lifts up the cut part of the glass to unfold it out of its form of a flattened cylinder, and render it smooth, by turning it down upon the hearth of the *carquaiſſe*. The tool already described being insinuated within the cylinder, performs this operation by being pushed hard against all the parts of the glass. When the glass is thus made quite smooth, it is pushed to the bottom of the *carquaiſſe* or annealing furnace with a small iron raker, and ranged there with a little iron hook. When the *carquaiſſe* is full, it is stopped and cemented as in the case of run glasses, and the glass remains there for a fortnight to be annealed; after which time they are taken out to be polished. A workman can make but one glass in an hour, and he works and rests for six hours alternately.

Such was the method formerly made use of for blowing plate-glass, looking-glasses, &c.; but the workmen, by this method, could never exceed 50 inches in length, and a proportional breadth, because what were larger were always found to warp, which prevented them from reflecting the objects regularly, and wanted substance to bear the necessary grinding. These imperfections have been remedied by the following invention of the Sieur Abraham Thevart, in France, about the year 1688.

3. *Casting or Running of Large Mirror-Glass Plates.* The furnace is of a very large dimension, environed with several ovens, or annealing furnaces, called *carquaiſſes*, besides others for making of frit and calcining old pieces of glass. This furnace, before it is fit to run glass, costs 3500l. It seldom lasts above three years, and even in that time it must be refitted every six months. It takes six months to rebuild it, and three months to refit it. The melting pots are as big as large hogsheds, and contain about 2000 weight of metal. If one of them bursts in the furnace, the loss of the matter and time amounts to 250l. The materials in these pots are the same as described before. When the furnace is red-hot, these materials are put in at three different times,

Glas.

Plate
CCXX.

Glass. times, because that helps the fusion; and in 24 hours they are vitrified, refined, settled, and fit for casting. A is the bocca, or mouth of the furnace; B is the cistern that conveys the liquid glass it receives out of the melting pots in the furnace to the casting table. These cisterns are filled in the furnace, and remain therein six hours after they are filled; and then are hooked out by the means of a large iron chain, guided by a pulley placed upon a carriage with four wheels marked C, by two men. This carriage has no middle-piece; so that when it has brought the cistern to the casting-table D, they slip off the bottom of the cistern, and out rushes a torrent of flaming matter upon the table: this matter is confined to certain dimensions by the iron rulers EE, which are moveable, retain the fluid matter, and determine the width of the glass; while a man, with the roller F resting on the edge of the iron rulers, reduceth it as it cools to an equal thickness, which is done in the space of a minute. This table is supported on a wooden frame, with trussles for the convenience of moving to the annealing furnace; into which, strewn with sand, the new plate is shoved, where it will harden in about 10 days.

What is most surprising throughout the whole of this operation, is the quickness and address wherewith such massy cisterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured therein, the glass spread, &c. The whole is inconceivable to such as have not been eye-witnesses of that surprising manufacture.

As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they empty as before. This they continue to do so long as there are any full cisterns; laying as many plates in each carquaisse as it will hold, and stopping them up with doors of baked earth, and every chink with cement, as soon as they are full, to let them anneal and cool again, which requires about 14 days.

The first running being dispatched, they prepare another, by filling the cisterns anew from the matter in the pots; and after the second, a third; and even a fourth time, till the melting-pots are quite empty.

The cisterns at each running should remain at least six hours in the furnace to whiten; and when the first annealing furnace is full, the casting-table is to be carried to another. It need not here be observed, that the carquaises, or annealing furnaces, must first have been heated to the degree proper for them. It may be observed, that the oven-full, or the quantity of matter commonly prepared, supplies the running of 18 glasses, which is performed in 18 hours, being an hour for each glass. The workmen work six hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the cisterns, to scrape off what glass remains, which otherwise would grow green by continuance of fire, and spoil the glasses. They are not filled again in less than 36 hours, so that they put the matter into the furnace, and begin to run it every 54 hours.

The manner of heating the large furnaces is very singular: the two tisors, or persons employed for that purpose, in their shirts, run swiftly round the furnace without making the least stop: as they run along, they take two billets, or pieces of wood, which are cut for the purpose; these they throw into the first tiffart;

and continuing their course, do the same for the second. This they hold without interruption for six hours successively; after which they are relieved by others, &c. It is surprising that two such small pieces of wood, and which are consumed in an instant, should keep the furnace to the proper degree of heat; which is such, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in less than half a minute.

The glass, when taken out of the melting-furnace, needs nothing farther but to be ground, polished, and foliated.

4. *Grinding and Polishing of Plate-Glass.* Glass is made transparent by fire; but it receives its lustre by the skill and labour of the grinder and polisher; the former of whom takes it rough out of the hands of the maker.

In order to grind plate-glass, they lay it horizontally upon a flat stone table made of a very fine-grained free-stone; and for its greater security they plaster it down with lime or stucco; for otherwise the force of the workmen, or the motion of the wheel with which they grind it, would move it about.

This stone table is supported by a strong frame A, made of wood, with a ledge quite round its edges, rising about two inches higher than the glass. Upon this glass to be ground is laid another rough glass not above half so big, and so loose as to slide upon it; but cemented to a wooden plank, to guard it from the injury it must otherwise receive from the scraping of the wheel to which this plank is fastened, and from the weights laid upon it to promote the grinding or triture of the glasses. The whole is covered with a wheel B, made of hard light-wood, about six inches in diameter, by pulling of which backwards and forwards alternately, and sometimes turning round, the workmen, who always stand opposite to each other, produce a constant attrition between the two glasses, and bring them to what degree of smoothness they please, by first pouring in water and coarse sand; after that, a finer sort of sand, as the work advanceth, till at last they must pour in the powder of smalt. As the upper or incumbent glass polishes and grows smoother, it must be taken away, and another from time to time put in its place.

This engine is called a *mill* by the artists, and is used only in the largest-sized glasses; for in the grinding of the lesser glasses; they are content to work without a wheel, and to have only four wooden handles fastened to the four corners of the stone which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glass to an exact plainness, it is turned over to the polisher; who, with the fine powder of tripoli stone or emery, brings it to a perfect evenness and lustre. The instrument made use of in this branch is a board, *cc*, furnished with a felt, and a small roller, which the workman moves by means of a double handle at both ends. The artist, in working this roller, is assisted with a wooden hoop or spring, to the end of which it is fixed: for the spring, by constantly bringing the roller back to the same points, facilitates the action of the workman's arm.

Colouring of GLASS. That the colours given to glass may have their full beauty, it must be observed, that

Glas.

every pot when new, and first used, leaves a foulness in the glass from its own earthy parts; so that a coloured glass made in a new pot can never be bright or perfectly fine. For this reason, the larger of these, when new, may be glazed with white glass; but the second time of using the pots lose this foulness. The glazing may be done by reducing the glass to powder, and moistening the inside of the pot with water; while it is yet moist, put in some of the powdered glass, and shake it about, till the whole inner surface of the pot be covered by as much as will adhere to it, in consequence of the moisture. Throw out the redundant part of the powdered glass; and the pot being dry, set it in a furnace sufficiently hot to vitrify the glass adhering to it, and let it continue there sometime; after which, care must be taken to let it cool gradually. Those pots which have served for one colour must not be used for another; for the remainder of the old matter will spoil the colour of the new. The colours must be very carefully calcined to a proper degree; for if they are calcined either too much or too little, they never do well; the proper proportion, as to quantity, must also carefully be regarded, and the furnaces must be fed with dry hard wood. And all the processes succeed much the better if the colour be used dividedly, that is, a part of it in the frit, and the rest in the melted metal.

A hard glass, proper for receiving colours, may be prepared by pulverising 12 pounds of the best sand, cleansed by washing in a glass or flint mortar, and mixing seven pounds of pearl-ashes, or any fixed alkaline salt, purified with nitre, one pound of salt-petre, and half a pound of borax, and pounding them together. A glass less hard may be prepared of twelve pounds of white sand cleansed, seven pounds of pearl ashes purified with salt-petre, one pound of nitre, half a pound of borax, and four ounces of arsenic, prepared as before.

Amethyst coloured. See *Purple* below, and the article **AMETHYST**.

Balas-colour. Put into a pot crystal frit, thrice washed in water; tinge this with manganese, prepared into a clear purple; to this add *alumen cativum*, sifted fine, in small quantities, and at several times: this will make the glass grow yellowish, and a little reddish, but not blackish, and always dissipates the manganese. The last time you add manganese give no more of the *alumen cativum*, unless the colour be too full. Thus will the glass be exactly of the colour of the balas-ruby. See *Ruby-GLASS*.

The common black colour. The glass-makers take old broken glass of different colours, grind it to powder, and add to it, by different parcels, a sufficient quantity of a mixture of two parts zaffer and one part manganese: when well purified, they work it into vessels, &c.

Glass beads are coloured with manganese only.

Black velvet colour. To give this deep and fine colour to glass, take of crystalline and pulverine frit, of each 20 pounds; of calx of lead and tin four pounds; set all together in a pot in the furnace, well heated; when the glass is formed and pure, take steel well calcined and powdered, scales of iron that fly off from the smith's anvil, of each an equal quantity; powder and mix them well; then put six ounces of this powder to

Glas.

the above described metal while in fusion; mix the whole thoroughly together, and let them all boil strongly together; then let it stand in fusion 12 hours to purify, and after this work it. It will be a most elegant velvet black.

There is another way of doing this, which also produces a very fair black. It is this; take a hundred weight of rochetta frit, add to this two pounds of tartar and six pounds of manganese, both in fine powder; mix them well, and put to them the metal while in fusion, at different times, in several parcels; let it stand in fusion after this for four days, and then work it.

A glass perfectly black may also be formed, to ten pounds of either of the compositions for hard glass above described, add one ounce of zaffer, six drams of manganese, an equal quantity of iron strongly calcined.

Blue colour. A full blue may be made by adding six drams of zaffer and two drams of manganese to ten pounds of either of the compositions for hard glass, described above. For a very cool or pure blue glass, half an ounce of calcined copper may be used instead of the manganese, and the proportion of zaffer diminished by one half. Glass resembling sapphire may be made with ten pounds of either of the compositions for hard glass, three drams and one scruple of zaffer, and one dram of the *calx cassii*, or precipitation of gold by tin; or instead of this latter ingredient, two drams and two scruples of manganese. Or a sapphire-coloured glass may be made by mixing with any quantity of the hard glass one eighth of its weight of smalt. For a beautiful blue glass produced from the calx of regulus of cobalt, see **CHEMISTRY**, n^o 1299.

Venetian brown, with gold spangles, commonly called the *philosopher's stone*, may be prepared in the following manner: take of the second composition for hard glass above described, and of the composition for paste, of each five pounds, and of highly calcined iron an ounce; mix them well, and fuse them till the iron be perfectly vitrified, and has tinged the glass of a deep transparent yellow brown colour. Powder this glass, and add to it two pounds of powdered glass of antimony; grind them together, and thus mix them well. Take part of this mixture, and rub into it 80 to 100 leaves of the counterfeit leaf gold called *Dutch gold*; and when the parts of the gold seem sufficiently divided, mix the powder containing it with the other part of the glass. Fuse the whole with a moderate heat till the powder run into a vitreous mass, fit to be wrought into any of the figures or vessels into which it is usually formed; but avoid a perfect liquefaction, because that in a short time destroys the equal diffusion of the spangles, and vitrifies, at least in part, the matter of which they are composed; converting the whole into a kind of transparent olive-coloured glass. This kind of glass is used for a great variety of toys and ornaments with us, who at present procure it from the Venetians.

Chalcedony. A mixture of several ingredients with the common matter of glass, will make it represent the semi-opaque gems, the jaspers, agates, chalcedonies, &c. The way of making these seems to be the same with the method of making marbled paper, by several colours dissolved in several liquors, which are such as will

Glas. will not readily mix with one another when put into water, before they are cast upon the paper which is to be coloured. There are several ways of making these variously coloured glasses, but the best is the following.

Dissolve four ounces of fine leaf silver in a glass vessel in strong aquafortis; stop up the vessel, and set it aside.—In another vessel, dissolve five ounces of quicksilver in a pound of aquafortis, and set this aside.—In another glass vessel, dissolve in a pound of aquafortis three ounces of fine silver, first calcined in this manner: amalgamate the silver with mercury, mix the amalgam with twice its weight of common salt well purified, put the mixture in an open fire in a crucible, that the mercury may fly off, and the silver be left in form of powder. Mix this powder with an equal quantity of common salt well purified, and calcine this for six hours in a strong fire; when cold, wash off the salt by repeated boilings in common water, and then put the silver into the aquafortis. Set this solution also aside.—In another vessel, dissolve in a pound of aquafortis three ounces of sal ammoniac; pour off the solution, and dissolve in it a quarter of an ounce of gold. Set this also aside.—In another vessel, dissolve three ounces of sal ammoniac in a pound of aquafortis; then put into the solution cinnabar, crocus martis, ultramarine, and feretto of Spain, of each half an ounce. Set this also aside.—In another vessel, dissolve in a pound of aquafortis three ounces of sal ammoniac; then put into it crocus martis made with vinegar, calcined tin, zaffer, and cinnabar, of each half an ounce; let each of these be powdered very fine, and put gently into the aquafortis. Set this also aside.—In another vessel, dissolve three ounces of sal ammoniac in a pound of aquafortis, and add to it brass calcined with brimstone, brass thrice calcined, manganese, and scales of iron which fall from the smith's anvil, of each half an ounce; let each be well powdered, and put gently into the vessel. Then set this also aside.—In another vessel, dissolve two ounces of sal ammoniac in a pound of aquafortis, and put to it verdigris an ounce, red lead, crude antimony, and the caput mortuum of vitriol, of each half an ounce; put these well powdered leisurely into the vessel, and set this also aside.—In another vessel dissolve two ounces of sal ammoniac in a pound of aquafortis, and add orpiment, white arsenic, painters lake, of each half an ounce.

Keep the above nine vessels in a moderate heat for 15 days, shaking them well at times. After this pour all the matters from these vessels into one large vessel well luted at its bottom; let this stand six days, shaking it at times; and then set it in a very gentle heat, and evaporate all the liquor, and there will remain a powder of a purplish green.

When this is to be wrought, put into a pot very clear metal, made of broken crystalline and white glass that has been used; for with the virgin-frit, or such as has never been wrought, the chalcedony can never be made, as the colours do not stick to it, but are consumed by the frit. To every pot of 20 pounds of this metal put two or three ounces of this powder at three several times: incorporate the powder well with the glass; and let it remain an hour between each time of putting in the powders. After all are in, let it stand 24 hours; then let the glass be well mixed, and

take an assay of it, which will be found of a yellowish blue; return this many times into the furnace; when it begins to grow cold, it will show many waves of different colours very beautifully. Then take tartar eight ounces, foot of the chimney two ounces, crocus martis made with brimstone, half an ounce, let these be well powdered and mixed, and put them by degrees into the glass at six times, waiting a little while between each putting in. When the whole is put in, let the glass boil and settle for 24 hours; then make a little glass body of it; which put in the furnace many times, and see if the glass be enough, and whether it have on the outside veins of blue, green, red, yellow, and other colours, and have, beside these veins, waves like those of the chalcedonies, jaspers, and oriental agates, and if the body kept within looks as red as fire.

When it is found to answer thus, it is perfect, and may be worked into toys and vessels, which will always be beautifully variegated: these must be well annealed, which adds much to the beauty of their veins. Masses of this may be polished at the lapidary's wheel as natural stones, and appear very beautiful. If in the working the matter grow transparent, the work, must be stopped, and more tartar, foot and crocus martis must be put to it, which will give it again the necessary body and opacity, without which it does not show the colours well.

Chrysolite colour may be made of ten pounds of either of the compositions for hard glass described above, and six drams of calcined iron.

Red cornelian colour may be formed by adding one pound of glass of antimony, two ounces of the calcined vitriol called *scarlet ochre*, and one dram of manganese or magnesia, to two pounds of either of the compositions for hard glass. The glass of antimony and magnesia are first fused with the other glass, and then powdered and ground with the scarlet ochre: the whole mixture is afterwards fused with a gentle heat till all the ingredients are incorporated. A glass resembling the white cornelian may be made of two pounds of either of the compositions for hard glass, and two drams of yellow ochre well washed, and one ounce of calcined bones: grind them together, and fuse them with a gentle heat.

Emerald colour. See *Green* below.

Garnet colour. To give this colour to glass, the workmen take the following method. They take equal quantities of crystal and rochetta frit, and to every hundred weight of this mixture they add a pound of manganese and an ounce of prepared zaffer: these are to be powdered separately, then mixed and added by degrees to the frit while in the furnace. Great care is to be taken to mix the manganese and zaffer very perfectly; and when the matter has stood 24 hours in fusion, it may be worked.

Glass of this kind may be made by adding one pound of glass of antimony, one dram of manganese, and the same quantity of the precipitate of gold by tin, to two pounds of either of the compositions for hard glass; or the precipitate of gold may be omitted, if the quantities of the glass of antimony and manganese be doubled.

Gold colour. This colour may be produced by taking ten pounds of either of the compositions for hard glass,

Glas.

glass, omitting the salt petre; and for every pound adding an ounce of calcined borax, or, if this quantity doth not render the glass sufficiently fusible, two ounces; ten ounces of red tartar of the deepest colour; two ounces of magnesia; and two drams of charcoal of fallow, or any other soft kind. Precipitates of silver baked on glass will stain it yellow, and likewise give a yellow colour on being mixed and melted with 40 or 50 times their weight of vitreous compositions: the precipitate from aquafortis by fixed alkali seems to answer best. Yellow glasses may also be obtained with certain preparations of iron, particularly with Prussian blue. But Dr Lewis observes, that the colour does not constantly succeed, nor approach to the high colour of gold, with silver or with iron. The nearest imitations of gold which he has been able to produce have been effected with antimony and lead. Equal parts of the glass of antimony, of flint calcined and powdered, and of minium, formed a glass of a high yellow; and with two parts of glass of antimony, two of minium, and three of powdered flint, the colour approached still more to that of gold. The last composition exhibited a multitude of small sparkles interspersed throughout its whole substance, which gave it a beautiful appearance in the mass, but were really imperfections, owing to air-bubbles.

Neri directs, for a gold-yellow colour, one part of red tartar and the same quantity of manganese, to be mixed with a hundred parts of frit. But Kunckel observes, that these proportions are faulty; that one part, or one and a quarter, of manganese, is sufficient for a hundred of frit; but that six parts of tartar are hardly enough, unless the tartar is of a dark red colour, almost blackish; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds, that the glass swells up very much in melting, and that it must be left unstirred, and worked as it stands in fusion. Mr Samuel More, in repeating and varying this process in order to render the colour more perfect, found that the manganese is entirely unessential to the gold colour, and that the tartar is no otherwise in use than in virtue of the coaly matter to which it is in part reduced by the fire, the phlogiston or inflammable part of the coal appearing in several experiments to be the direct tinging substance. Mr Pot also observes, that common coals give a yellow colour to glass; that different coaly matters differ in their tinging power; that caput mortuum of foot and lamp black answer better than common charcoal; and that the sparkling coal, which remains in the retort after the rectification of the thick empyreumatic animal oils, is one of the most active of these preparations. This preparation, he says, powdered, and then burnt again a little in a close vessel, is excellent for tinging glass, and gives yellow, brown, reddish, or blackish colours, according to its quantity; but the frit must not be very hard of fusion, for in this case the strong fire will destroy the colouring substance before the glass melts: and he has found the following compositions to be nearly the best; viz. sand two parts, alkali three parts; or sand two, alkali three, calcined borax one; or sand two, alkali two, calcined borax one: and though saltpetre is hardly used at all, or very sparingly, for yellow glasses, as it too much volatilizes the colouring substance; yet here for the most

Glas.

part a certain proportion of it, easily determined by trial is very necessary; for without it the concentrated colouring matter is apt to make the glass too dark, and even of an opaque pitchy blackness. It does not certainly appear that there is any material diversity in the effects of different coals, the difference being probably owing to the different quantities of the inflammable matter which they contain; so that a little more shall be required of one kind than of another for producing the same degree of colour in the glass. Nor does the softness or fusibility of the frit appear to be in any respect necessary.

Gold-coloured spangles may be diffused through the substance of glass, by mixing the yellow talcs with powdered glass, and bringing the mixture into fusion.

Green. This colour may be imparted to glass by adding three ounces of copper precipitated from aquafortis, and two drams of precipitated iron to nine pounds of either of the compositions for hard glass. The finest method of giving this beautiful colour to glass is this: Take five pounds of crystalline metal that has been passed several times through water, and the same quantity of the common white metal of pulverine, four pounds of common pulverine frit, and three pounds of red-lead; mix the red-lead well with the frit, and then put all into a pot in a furnace. In a few hours the whole mass will be well purified: then cast the whole into water, and separate and take out the lead; then return the metal into the pot, and let it stand a day longer in fusion; then put in the powder of the residuum of the vitriol of copper, and a very little crocus martis, there will be produced a most lively and elegant green, scarce inferior to that of the oriental emerald. There are many ways of giving a green to glass, but all are greatly inferior to this.— To make a *sea-green*, the finest crystalline glass only must be used, and no manganese must be added at first to the metal. The crystal frit must be melted thus alone; and the salt, which swims like oil on its top, must be taken off with an iron ladle very carefully. Then to a pot of twenty pound of this metal add six ounces of calcined brass, and a fourth part of the quantity of powdered zaffer: this powder must be well mixed, and put into the glass at three times; it will make the metal swell at first, and all must be thoroughly mixed in the pot. After it has stood in fusion three hours, take out a little for a proof: if it be too pale, add more of the powder. Twenty-four hours after the mixing the powder the whole will be ready to work; but it must be well stirred together from the bottom, lest the colour should be deepest there, and the metal at the top less coloured, or even quite colourless. Some use for this purpose half crystal frit and half rochetta frit, but the colour is much the finest when all crystal frit is used.

Lapis lazuli colour. See *Lapis LAZULI*.

Opal colour. See *OPAL*.

Purple of a deep and bright colour may be produced by adding to ten pounds of either of the compositions for hard glass, above described, six drams of zaffer and one dram of gold precipitated by tin; or to the same quantity of either composition one ounce of manganese and half an ounce of zaffer. The colour of amethyst may be imitated in this way.

Red. A blood-red glass may be made in the following

Glass. lowing manner: Put six pounds of glass of lead, and ten pounds of common glass, into a pot glazed with white glass. When the whole is boiled and refined, add by small quantities, and at small distances of time, copper calcined to a redness as much as on repeated proofs is found sufficient: then add tartar in powder by small quantities at a time, till the glass is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect.

Ruby. The way to give the true fine red of the ruby, with a fair transparence, to glass, is as follows: Calcine in earthen vessels gold dissolved in aqua-regia; the menstruum being evaporated by distillation, more aqua regia added, and the abstraction repeated five or six times, till it becomes a red powder. This operation will require many days in a hot furnace. When the powder is of a proper colour, take it out: and when it is to be used, melt the finest crystal glass, and purify it by often casting it into water; and then add, by small quantities, enough of this red powder to give it the true colour of a ruby, with an elegant and perfect transparence.

The process of tinging glass and enamels by preparations of gold was first attempted about the beginning of the last century. Libavius, in one of his tracts intitled *Alchimia*, printed in 1606, conjectures that the colour of the ruby proceeds from gold, and that gold dissolved and brought to redness might be made to communicate a like colour to factitious gems and glass. On this principle Neri, in his *Art of Glass*, dated in 1611, gives the process above recited. Glauber in 1648 published a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfect glass. For this purpose he ground powdered flint or sand with four times its weight of fixed alkaline salt: this mixture melts in a moderately strong fire, and when cold looks like glass, but exposed to the air runs into a liquid state. On adding this liquor to solution of gold in aqua-regia, the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple. By mixing this powder with three or four times its weight of the alkaline solution of flint, drying the mixture, and melting it in a strong fire for an hour, a mass is obtained of a transparent ruby colour, and of a vitreous appearance; which nevertheless is soluble in water, or by the moisture of the air, on account of the redundancy of the salt. The honourable Mr Boyle, in a work published in 1680, mentions an experiment in which a like colour was introduced into glass without fusion; for having kept a mixture of gold and mercury in digestion for some months, the fire was at last immoderately increased, so that the glass burst with a violent explosion; and the lower part of the glass was found tinged throughout of a transparent red colour, hardly to be equalled by that of rubies.

About the same time Cassius is said to have discovered the precipitation of gold by tin, and that glass might be tinged of a ruby colour by melting it with this precipitate; though he does not appear, says Dr Lewis, from his treatise *De Auro*, to have been the discoverer of either. He describes the preparation of the precipitate and its use; but gives no account of the manner of employing it, only that he says one

dram of gold duly prepared will tinge ten pounds of glass.

This process was soon after brought to perfection by Kunckel; who says, that one part of the precipitate is sufficient to give a ruby colour to 1280 parts of glass, and a sensible redness to upwards of 1900 parts; but that the success is by no means constant. Kunckel also mentions a purple-gold powder, resembling that of Neri; which he obtained by inspissating solution of gold to dryness; abstracting from it fresh aqua-regia three or four times, till the matter appears like oil; then precipitating with strong alkaline ley, and washing the precipitate with water. By dissolving this powder in spirit of salt and precipitating again, it becomes, he says, extremely fair; and in this state he directs it to be mixed with a due proportion of Venice glass.

Orchal, in a treatise intitled *Sol sine Vestige*, gives the following process for producing a very fine ruby. He directs the purple precipitate made by tin to be ground with six times its quantity of Venice glass into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous composition to be tinged. His frit consists of equal parts of borax, nitre, and fixed alkaline salt, and four times as much calcined flint as of each of the salts; but he gives no directions as to the proportion of the gold precipitate or mode of fusion. Hellot describes a preparation, which, mixed with Venice glass, was found to give a beautiful purple enamel. This preparation consists of equal parts of solution of gold and of solution of zinc in aqua-regia mixed together, with the addition of a volatile salt prepared from sal ammoniac by quicklime, in sufficient quantity to precipitate the two metals. The precipitate is then gradually heated till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on glass or enamels, and introduced into the mass by fusion, the way of equally diffusing such a colour through a quantity of fluid glass is still, says Dr Lewis, a secret. The following process for making the ruby glass was communicated to Dr Lewis by an artist, who ascribed it to Kunckel. The gold is directed to be dissolved in a mixture of one part of spirit of salt and three of aquafortis, and the tin in a mixture of one part of the former of these acids with two of the latter. The solution of gold being properly diluted with water, the solution of tin is added, and the mixture left to stand till the purple matter has settled to the bottom. The colourless liquor is then poured off, and the purple sediment, while moist and not very thick, is thoroughly mixed with powdered flint or sand. This mixture is well ground with powdered nitre, tartar, borax, and arsenic, and the compound melted with a suitable fire. The proportions of the ingredients are 2560 parts of sand, 384 of nitre, 240 of tartar, 240 of borax, 28 of arsenic, 5 of tin, and 5 of gold.

Topaz colour. Glass resembling this stone may be made by pulverizing ten pounds of either of the compositions for hard glass with an equal quantity of the gold-coloured glass, and fusing them together.

White opaque and semi-transparent glass may be made of ten pounds of either of the compositions for hard glass and one pound of well calcined horn, ivory, or bone;

Glass.

Glasf.

or an opaque whiteness may be given to glass by adding one pound of very white arsenic to ten pounds of flint glass. Let them be well powdered and mixed by grinding them together, and then fused with a moderate heat till they are thoroughly incorporated. A glass of this kind is made in large quantities at a manufacture near London; and used not only for different kinds of vessels, but as a white ground for enamel in dial-plates and snuff-boxes, which do not require finishing with much fire, because it becomes very white and fusible with a moderate heat.

Yellow. See *Gold colour* above.

Painting in GLASS. The ancient manner of painting in glass was very simple; it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called *Mosaic work*. See *MOSAIC*.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright red colour; and upon this they drew the principal lineaments of the face, &c. with black.

At length, the taste for this sort of painting improving considerably, and the art being found applicable to the adorning of churches, basilics, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree; having first laid on the colours. A French painter at Marseilles is said to have given the first notion of this improvement, upon going to Rome under the pontificate of Julius II.; but Albert Durer and Lucas of Leyden were the first that carried it to any height.

This art, however, has frequently met with much interruption, and sometimes been almost totally lost; of which Mr Walpole gives us the following account, in his *Anecdotes of Painting in England*.

“The first interruption given to it was by the reformation, which banished the art out of churches; yet it was in some measure kept up in the escutcheons of the nobility and gentry in the windows of their seats. Towards the end of queen Elizabeth’s reign it was omitted even there; yet the practice did not entirely cease. The chapel of our Lady at Warwick was ornamented anew by Robert Dudley earl of Leicester, and his countess, and the cipher of the glass painter’s name yet remains, with the date 1574: and in some of the Chapels at Oxford the art again appears, dating itself in 1622, by the hand of no contemptible master.

“I could supply even this gap of 48 years by many dates on Flemish glass: but nobody ever supposed that the secret was lost so early as the reign of James I. and that it has not perished since will be evident from the following series, reaching to the present hour.

“The portraits in the windows of the library at All Souls, Oxford. In the chapel at Queen’s College there are twelve windows dated 1518. P. C. a cipher on the painted glass in the chapel at Warwick, 1574. The windows at Wadham-college: the drawing pretty good, and the colours fine, by Bernard Van Linge, 1622. In the chapel at Lincoln’s Inn, a window, with the name Bernard, 1623. This was

2

Glasf.

probably the preceding Van Linge. In the church of St Leonard, Shoreditch, two windows by Baptista Sutton, 1634. The windows in the chapel at University-college, Hen. Giles *pinxit*, 1687. At Christ-church Isaac Oliver, aged 84, 1700. Window in Merton-chapel, William Price, 1700. Windows at Queen’s New-College, and Maunlin, by William Price, the son, now living, whose colours are fine, whose drawing is good, and whose taste in ornaments and mosaic is far superior to any of his predecessors; is equal to the antique, to the good Italian masters, and only surpassed by his own singular modesty.

“It may not be unwelcome to the curious reader to see some anecdotes of the revival of taste for painted glass in England. Price, as we have said, was the only painter in that style for many years in England. Afterwards one Rowell, a plumber at Reading, did some things, particularly for the late Henry earl of Pembroke; but Rowell’s colours soon vanished. At last he found out a very durable and beautiful red; but he died in a year or two, and the secret with him. A man at Birmingham began the same art in 1756 or 1757, and fitted up a window for Lord Lyttleton, in the church of Hagely; but soon broke. A little after him, one Peckitt at York began the same business, and has made good proficiency. A few lovers of that art collected some dispersed panes from ancient buildings, particularly the late lord Cobham, who erected a Gothic temple at Stowe, and filled it with arms of the old nobility, &c. About the year 1753, one Ascotti, an Italian, who had married a Flemish woman, brought a parcel of painted glass from Flanders, and sold it for a few guineas to the honourable Mr Bateman, of Old Windsor. Upon that I sent Ascotti again to Flanders, who brought me 450 pieces, for which, including the expence of his journey, I paid him 36 guineas. His wife made more journeys for the same purpose; and sold her cargoes to one Palmer, a glazier in St Martin’s-lane, who immediately raised the price to one, two, or five guineas for a single piece, and fitted up entire windows with them, and with mosaics of plain glass of different colours. In 1761, Paterson, an auctioneer at Essex house in the Strand, exhibited the two first auctions of painted glass, imported in like manner from Flanders. All this manufacture consisted in rounds of scripture stories, stained in black and yellow, or in small figures of black and white; birds and flowers in colours, and Flemish coats of arms.”

The colours used in painting or staining of glass are very different from those used in painting either in water or oil colours.

For black, take scales of iron, one ounce; scales of copper, one ounce; jet, half an ounce: reduce them to powder, and mix them. For blue, take powder of blue, one pound; sal nitre, half a pound; mix them and grind them well together. For carnation, take red chalk, eight ounces; iron scales, and litharge of silver, of each two ounces; gum arabic, half an ounce; dissolve in water; grind all together for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle fourteen days. For green, take red-lead, one pound; scales of copper, one pound; and flint, five pounds: divide them into three parts; and add to them as much sal nitre;

put

Glas. put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, take silver, an ounce; antimony, half an ounce; melt them in a crucible; then pound the mass to powder, and grind it on a copper plate; add to it yellow ochre, or brick-dust calcined again, fifteen ounces; and grind them well together with water. For the purple, take minium one pound; brown stone, one pound; white flint, five pounds: divide them into three parts, and add to them as much sal nire as one of the parts; calcine, melt, and grind it as you did the green. For red, take jet, four ounces; litharge of silver, two ounces; red chalk, one ounce; powder them fine, and mix them. For white, take jet, two parts; white flint, ground on a glass very fine, one part; mix them. For yellow, take Spanish brown, ten parts; leaf-silver, one part; antimony, half a part; put all into a crucible, and calcine them well.

In the windows of ancient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains, by reason that this sort of painting is not now so much in esteem as formerly. Those beautiful works which were made in the glass-houses were of two kinds.

In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one-third of a line; though this was more or less according to the nature of the colour, the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, by reason that on the same glass, though already coloured, they could show other kinds of colours where there was occasion to embroider draperies, enrich them with foliages, to represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass till such time as they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By these means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glass was only bared of its coloured with emery, without tinging the place with any colour at all; and this was the manner by which they wrought their lights and heightenings on all kinds of colour.

The first thing to be done, in order to paint or stain glass, in the modern way, is to design, and even colour the whole subject on paper. Then they choose such pieces of glass as are clear, even, and smooth, and proper to receive the several parts; and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass; always taking care that the glasses may join in the contours of the figures and the folds of the draperies; that the carnations, and other finer parts, may not be impaired by

Glas. the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again: which done, applying every part of the design upon the glass intended for it, they copy or transfer the design upon this glass with the back colour diluted in gum-water, by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black; and repeat it several times, according as the shades are desired to be heightened; with this precaution, never to apply a new wash till the former is sufficiently dried.

This done, the lights and risings are given by rubbing off the colour in the respective places with a wooden point, or the handle of the pencil.

As to the other colours abovementioned, they are used with gum-water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the outlines of the design; or even, for the greater security, to apply them on the other side; especially yellow, which is very pernicious to the other colours, by blending therewith. And here too, as in pieces of black and white, particular regard must always be had not to lay colour on colour, or lay on a new lay, till such time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glass, and incorporates therewith by the fire; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace or oven to anneal or bake the colours.

The furnace here used is small, built of brick, from 18 to 30 inches square. At six inches from the bottom is an aperture to put in the fuel and maintain the fire. Over this aperture is a grate made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, six or seven inches deep, and five or six inches less every way than the perimeter of the furnace. On the one side hereof is a little aperture, through which to make trials, placed directly opposite to that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed in the following manner: First, the bottom of the pan is covered with three strata or layers of quicklime pulverised; these strata being separated by two others of old broken glass, the design whereof is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last or uppermost layer of lime.

The first row of glass they cover over with a layer of the same powder an inch deep; over this they lay another range of glasses, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the lime-powder.

The pan being thus prepared, they cover up the

Glass. furnace with tiles, on a square table of earthen ware closely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to serve as chimneys. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the coction advances, for the space of ten or twelve hours; in which time it is usually completed. At last the fire, which at first was charcoal, is to be of dry wood, so that the flame covers the whole pan, and even issues out at the chimneys.

During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace and pan, to see whether the yellow be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses.

GLASS-Balls, which are circular or otherwise shaped hollow vessels of glass, may be coloured within, so as to imitate the semipellucid gems. The method of doing it is this: make a strong solution of ichthyocolla, or isinglass, in common water, by boiling; pour a quantity of this while warm into the hollow of a white glass vessel; shake it thoroughly about, that all the sides may be wetted, and then pour off the rest of the moisture. Immediately after this, throw in red-lead, shake it and turn it about, throw it into many places with a tube, and the moisture will make it stick and run in waves and pretty figures. Then throw in some of the painter's blue smalt, and make it run in waves in the ball as the red-lead; then do the same with verdgris, next with orpiment, then with red lake, all well ground; always casting in the colours in different places, and turning the glass, that the moisture within may run them into the waves. Then take fine plaster of Paris, and put a quantity of it into the ball; shake it also nimbly about; this will every where stick firmly to the glass, and give it a strong inner coat, keeping all the colours on very fairly and strongly. These are set on frames of carved wood, and much esteemed as ornaments in many places.

GLASS of Lead, a glass made with the addition of a large quantity of lead, of great use in the art of making counterfeit gems. The method of making it is this: Put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a grey loose powder; then spread it in the kiln, and give it a greater heat, continually stirring it to keep it from running into lumps; continue this several hours, till the powder become of a fair yellow; then take it out, and sift it fine: this is called *calcined lead*. Take of this calcined lead 15 pounds, and crystalline or other frit 12 pounds; mix these as well as possible together; put them into a pot, and set them in the furnace for ten hours; then cast the whole, which will be now perfectly melted, into water; sepa-

rate the loose lead from it, and return the metal into the pot; and after standing in fusion 12 hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wetting the marble it is wrought upon.

It is well known that cerufs or white lead, minium, litharge, and all the other preparations and calces of lead, are easily fused by a moderate fire, and formed into a transparent glass of a deep yellow colour. But this glass is so penetrating and powerful a flux, that it is necessary to give it a greater consistence, in order to render it fit for use. With this view, two parts of calx of lead, e. g. minium, and one part of sand or powdered flints, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well closed with a luted lid, be placed in a melting furnace, and gradually heated for an hour or an hour and a half; and afterwards let the heat be increased so as to obtain a complete fusion, and continued in that state for the same time: let the crucible remain to cool in the furnace; and when it is broken, a very transparent yellow-coloured glass will be found in it. Some add nitre and common salt to the above mixture, because these salts promote the fusion and the more equal distribution of the sand. This glass of lead has a considerable specific gravity, and its lowest part is always the heaviest. It is an important flux in the essays of ores to facilitate their scorifications.

Glass of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are these: for green, take pulverine frit 20 pounds, lead calcined 16 pounds; sift both the powders very fine; then melt them into a glass, separating the unmixed lead, by plunging the mass in water; after this return it into the pot, and add brass thrice calcined six ounces, and one penny-weight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally settle an hour, then mix it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined brass the same quantity of the caput mortuum of the vitriolum veneris be used, the green is yet much finer.

For topaz-colour, take crystal frit 15 pounds, calcined lead 12 pounds; mix them well together, by sifting the powders through a fine sieve; then set them in a furnace not too hot, and separate the superfluous unmixed lead, by casting the whole into water; repeat this twice: then add half gold yellow glass, and let them incorporate and purify, and they will be of the true and exact colour of the oriental topazes.

For sea-green, take crystal frit 16 pounds, calcined lead 10 pounds: mix and sift them together, and set them in a pot in a furnace; in 12 hours the whole will be melted; then cast it into water, and separate it from the loose lead; put them into the furnace again for eight hours; then separate the loose lead by washing a second time, and return it to the pot for eight hours more.

Muscovy GLASS. See *MICA*.

Painting on Glass by means of Prints. See *BACK-painting*.

GLASS-Porcelain, the name given by many to a modern invention of imitating the china-ware with glass.

The

Glass. The method given by Mr Reaumur, who was the first that carried the attempt to any degree of perfection, is shortly this: The glass-vessels to be converted into porcelain are to be put into a large earthen vessel, such as the common fine earthen dishes are baked in, or into sufficiently large crucibles; the vessels are to be filled with a mixture of fine white sand, and of fine gypsum or plaster-stone burnt into what is called plaster of Paris, and all the interstices are to be filled up with the same powder, so that the glass vessels may nowhere touch either one another, or the sides of the vessel they are baked in. The vessel is to be then covered down and luted, and the fire does the rest of the work; for this is only to be put into a common potter's furnace, and when it has stood there the usual time of the baking the other vessels, it is to be taken out, and the whole contents will be found no longer glass, but converted into a white opaque substance, which is a very elegant porcelain, and has almost the properties of that of China.

The powder which has served once will do again as well as fresh, and that for a great many times: nay, it seems ever so often. The cause of this transformation, says Macquer, is probably that the vitriolic acid of the gypsum quits its basis of calcareous earth, and unites with the alkaline salt and saline earth, of the glass, with which it forms a kind of salt or selenites, different from the calcareous selenites, by the interposition of which matter the glass acquires the qualities of porcelain. See further on this subject the article CHEMISTRY, n° 591—594.

Glass-Pots, the vessels in the glass trade used for melting the glass. Those for the white glass works are made of a tobacco-pipe clay, brought from the Isle of Wight, which is first well washed, then calcined and afterwards ground to a fine powder in a mill; which being mixt with water, is then trod with the bare feet till it is of a proper consistence to mould with the hands into the proper shape of the vessels. When these are thus made, they are afterwards annealed over the furnace. Those for the green glass work are made of the nonsuch, and another kind of clay from Staffordshire: they make these so large as to hold three or four hundred weight of metal. And besides these, they have a small sort called piling-pots, which they set upon the larger, and which contain a finer and more nice metal fit for the nicest works.

The clay that is used for this purpose should be of the purest and most refractory kind, and well cleansed from all sandy, ferruginous, and pyritous matters; and to this it will be proper to add ground crucibles; white sand, calcined flints duly levigated, or a certain proportion of the same clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or exposed to a great heat, is not absolutely determined, but depends on the equality of the crude clay, which is more or less fat. M. D'Antic, in a memoir on this subject, proposes the following method of ascertaining it; the burnt and crude clay, being mixed in different proportions, should be formed into cakes, one inch thick, and four inches long and wide. Let these cakes be slowly dried; and exposed to a violent heat, till they become as hard and as much contracted as possible, and in this state be examined;

and the cake, he says, which has suffered a diminution of its bulk equal only to an eighteenth part, is made of the best proportions. He observes, in general, that most clays require that the proportion of the burnt should be to the fresh as four to five.

Tin-Glass, the same with Bismuth. See the article BISMUTH; also CHEMISTRY, n° 1250.

Vessels of Glass used in Chemical Experiments. See CHEMISTRY, n° 556.

GLASSES are distinguished, with regard to their form, use, &c. into various kinds, as, drinking glasses, optical-glasses, looking-glasses, burning glasses, &c.

Drinking-GLASSES, are simple vessels of common glass or crystal; usually made in form of an inverted cone.

Each glass consists of three parts, viz. the calyx or bowl, the bottom, and the foot; which are all wrought or blown separately.

Nothing can be more dexterous and expeditious than the manner wherein these parts are blown; two of them opened, and all three joined together. An idea is only to be had thereof by seeing them actually at work.

The glasses chiefly used in England are made of the ashes of fern, crystal glasses being less frequent in use. The exceeding brittleness of this commodity, notwithstanding the easy rate of each glass, renders the consumption thereof very considerable. For the method of gilding the edges of drinking glasses, see *GILDING on Enamel and Glass*.

Optical-GLASSES. See OPTICS.

The improvements hitherto made in telescopes by means of combining lenses made of different kinds of glass, though very great, are yet by no means adequate to the expectations that might reasonably be formed if opticians could fall on any method of obtaining pieces of glass sufficiently large for pursuing the advantages of Mr Dollond's discovery. Unfortunately, however, though the board of longitude have offered a considerable reward for bringing this art to the requisite perfection, no attempt of any consequence has hitherto been made. Mr Kier is of opinion, that the accomplishment of this by no means an easy task; as it requires not only a competent knowledge of the properties of glass fittest for the purpose (the faults not being evident to common inspection), but a considerable degree of chemical knowledge is also necessary in order to invent a composition by which these faults may be avoided; and lastly, a kind of dexterity in the execution of the work, which can only be acquired by practice. Our author, however, thinks, that if the subject were more generally understood, and the difficulties more fully pointed out, for which purpose he makes the following remarks, the end might be more easily accomplished.

1. The rays of light passing through a glass lens or prism, or through any other medium of unequal thickness, are refracted; but not in an equal manner, the blue, violet, &c. being more refracted than the red.

2. Hence it happens, that the rays of light, when refracted by a common lens, do not all unite in one focus, but in reality form as many different foci as there are colours; and hence arise the prismatic colours, or irises, which appear towards the borders of the image formed by the common convex lenses, and which render the vision extremely indistinct.

3. The indistinctness of vision produced by this cause,

Glass.

which is sensible in telescopes of a small aperture, increases in so great a proportion, viz. as the cubes of the diameters, that it seemed impossible to increase the power of dioptric telescopes greatly, without extending them to a very inconvenient length, unless this confusion of colours could be corrected.

4. It was known that different transparent bodies possessed different degrees of refractive power; and, until Mr Dollond discovered the contrary, it was supposed, that the refractions of the coloured rays were always in a determinate ratio to one another. On this supposition it seemed impossible to correct the faults of refracting telescopes: for it was supposed, that if the dispersion of light produced by a convex lens were counteracted by another lens or medium of a concave form, the refraction would be totally destroyed; and this indeed would be the case, if the two mediums were made of the same matter; and from some experiments made by Sir Isaac Newton, this was supposed to be actually the case in all substances whatever.

5. From considering that the eyes of animals are formed of mediums of different colours, it occurred first to Mr David Gregory, the celebrated professor of astronomy at Oxford, and then to Mr Euler, that, by a combination of mediums which had different refractive powers, it might be possible to remedy the imperfections of dioptric telescopes. It does not, however, appear, that either of these gentlemen understood the true principle on which these phenomena depend. Mr Euler executed his idea by forming a compound object lens from two glass lenses with water interposed; but his attempt was not attended with success. Mr Dollond, however, was led by some arguments adduced by Mr Klingesternia, to repeat one of Sir Isaac Newton's experiments, and which had induced even that great philosopher himself to suppose that the improvement afterwards executed by Mr Dollond was impossible. This experiment was made by Sir Isaac Newton, by placing a glass prism within a prismatic vessel filled with water, in such a manner that the rays of light which were refracted by the glass prism should pass through and be refracted in a contrary direction by the water prism. In this manner the refraction of the light was entirely destroyed. But when Mr Dollond repeated the experiment, he found, that contrary to his own expectations, when the angles of the two prisms were so proportioned that they counteracted each other's mean refraction, then colours appeared; and on the other hand, when they were so proportioned, that the dispersion of the coloured rays was counteracted, the mean refraction still subsisted; which evidently proved, that the mean refractive and dispersive powers of glass and water were not proportional to one another.

6. To apply this to the proposed improvement, Mr Dollond examined several kinds of glass. Crown-glass was found to possess the smallest dispersive power in proportion to its refraction; while flint-glass possessed the greatest dispersive power in proportion to its refraction, which was also very great. On comparing these two exactly together, he found, that a wedge of white flint glass whose angle was about 25 degrees, and another of crown-glass whose angle was 29 degrees, refracted very nearly alike. He found also, that, when the wedges were ground to such angles, the refraction produced by the flint-glass was to that produced

by the crown-glass nearly as two to three, the refracted light was then free from colour. On measuring the general refracting powers of these two glasses, he found that in flint-glass, the sine of incidence to the rays was to the sine of mean refraction as 1 to 1.583; and that, in crown-glass, the sine of incidence was to the sine of mean refraction as 1 to 1.53.

The methods of determining the different refractive powers of glass are given under the article OPTICS. Here we shall only observe, that two kinds of glass are necessary for the construction of achromatic telescopes; one of which shall possess as small, and the other as great, dispersive powers, relative to their mean refracting powers, as can be procured. The difference of glasses in this respect depends on the quality of the ingredients employed in their composition. Crown-glass, which is composed of sand melted by means of the ashes of sea-weeds; barilla, or kelp, both which fluxes are known to consist of vegetable earth, alkali, and neutral salt, is found to give the smallest dispersive power. Plate glass, which consists of sand melted by means of fixed vegetable alkali, with little or no vegetable earth, gives a greater dispersive power; but both these give much less than flint-glass, which consists of sand melted by means of minium and fixed alkali. It appears, therefore, that the dispersion of the rays is greatest when minium, or probably other metallic calces, are made use of; and that alkalies give a greater power of dispersion than vegetable or other earths. Mr Zieher of Petersburg, however, informs us, that he has made a kind of glass, much superior in this respect to flint-glass; but it does not as yet appear, whether it be more fit for optical purposes than that commonly made use of. There seems no difficulty in augmenting the dispersive power, as that is found to depend on the quantity of minium or other flux: but thus we unfortunately increase also the capital fault to which flint-glass and all compositions of that kind are subject; namely, the being subject to veins or small threads running through it. By these, even when so small as to be imperceptible to the naked eye, the rays which fall on them are diverted from their proper direction, and thereby render the images confused. This is owing to the greater density of the veins, as appears by their image being received on white paper, when the glass is held between the paper and the sun or a candle, at a proper distance. The rays of light being then made to converge by the superior density of the veins, their images will appear as bright lines bordered with obscure edges on the paper. Flint-glass is so much subject to this kind of imperfection, that it is with difficulty the opticians can pick out pieces of the size commonly used from a large quantity of the glass. It is farther to be regretted, that the minium which produces the greatest dispersive power, is likewise the very substance which renders flint-glass much more subject to these imperfections than any other. The reason is; that the sand and earthy matters mix uniformly in fusion; and, having not only a considerable degree of affinity towards each other, but also being not much different from each other, they are not apt to separate. On the other hand, when such a heavy substance as minium is added to these earthy substances, though it has a pretty strong tendency to unite with the earthy substances, it has none with the fixed alkali, which

Glass.

Glass. is another ingredient in this glass. Hence some parts of the glass will contain more metallic matter than the rest; particularly near the bottom of the pot, which is so full of large veins as to be applied only to the making of wares of little value. The veins in this case are formed by the descent of the minium to the bottom, which in its passage forms threads or veins by dragging other parts of the glass along with them.

The correction of this fault appears therefore to be very difficult. M. Macquer informs us, that he had in vain tried to remove it by a very long fusion and a fierce fire; which indeed others have found by experience not to correct, but augment the evil. Mr Keir is of opinion that some new composition must be discovered, which, along with a sufficient refractive power, should possess a greater uniformity of texture; but he is likewise of opinion, that scarce any alteration in this respect could be made without injuring the colour of the glass. For optical purposes, however, our author does not think that an alteration in the colour of the ingredients would be very detrimental. "I am convinced (says he), that glasses sensibly tinged with colour, might transmit as much or more light than the best flint-glass. For the colourless appearance of flint-glass is an optical deception. The minium gives it a considerable tinge of yellow, and the alkali inclines it to a bluish cast, besides the colour arising from a greater or less impurity of the materials; so that the glass would actually be very sensibly coloured, unless by the addition of manganese, which is known to give a purplish red. Thus the other tinges are counteracted, but not effaced or destroyed as has been frequently imagined. By the mixture of the three principal colours, red, yellow, and blue, more or less exactly counterpoised, a certain dark shade is introduced, in which, as not any one of the colours predominates, no coloured tinge appears, but the effect is merely a diminution of the transparency of the glass, which, however, is too small for ordinary observation." Mr Keir is even of opinion, that a certain tinge of yellow would in many cases be of service, because it would exclude some of the blue rays, which being most refrangible are most injurious to the distinctness of vision.

Very considerable difficulties, however, must arise in attempting improvements of this kind; as the experiments must all be tried on a very large scale. This is not only attended with a very heavy expence in itself on account of the quantity of materials employed, but from the heavy duty of excise which is rigorously exacted whether the glass be manufactured into saleable articles or not. It is observed in the manufacture of every kind of glass, that the glass in the middle of the area or tranverse section of a pot is much purer and freer from veins and other imperfections than the part which is near the sides, and that the glass at the bottom is the worst of all. Consequently it is chiefly in large pots, such as are used in manufactures, that there is a probability of success. Very fine and beautiful glasses, called *paste* and *artificial gems*, may be made in smaller pots or crucibles; but this glass is suffered to cool and subside in the vessel, by which means the contiguous parts are more uniform in their texture than can be expected in a piece of glass taken out of the pot while hot in the common way, by making it adhere and twist round an iron rod or pipe. But although

the method of allowing the glass to cool in the pots is very advantageous for the purposes of the jeweller, it is by no means applicable to those of the optician. Glass cooled in that gradual manner, suffers some degree of crystallization or peculiar arrangement of its parts; the consequence of which is, that the rays of light undergo certain refractions independent on the form of the glass, which greatly affect the distinctness of vision in telescopes.

GLASTONBURY, a town of Somersetshire in England; seated in W. Long. 2. 46. N. Lat. 51. 15. —It is noted for a famous abbey, some magnificent ruins of which are still remaining; but they are every day diminishing for the sake of the stones. However, the curious structure called *the Abbot's kitchen* is still pretty entire, and is of a very unusual contrivance. The monks pretend that it was the residence of Joseph of Arimathea, and of St Patrick; but for this assertion they produce no good authority. The king of the West Saxons erected a church here, which he and the succeeding kings enriched to such a degree, that the abbot lived like a prince, had the title of *lord*, and sat among the barons in parliament; and no person, not even a bishop or prince, durst set foot on the isle of Avalon, in which the abbey stands, without his leave. The revenue of the abbey was above 4,000*l.* per ann. besides seven parks well stocked with deer. The last abbot (Richard Whiting), who had 100 monks, and 300 domestics, was hanged in his pontificals, with two of his monks, on the Tor, a high hill in the neighbourhood, for refusing to take the oath of supremacy to Henry VIII. and surrender his abbey when required. Edgar and many other Saxon kings were buried here; and, as some will have it, Arthur the British king. Every cottage here has a part of a pillar, a door, or a window of this fabric; of which there still remain the ruins of the choir, the middle tower, and chapels. The walls that remain of the abbey are overgrown with ivy, and the aspect of the whole is both melancholy and venerable. Here are two parish churches. This town, while under the protection of its abbots, was a parliamentary borough, but it lost that and its privilege of a corporation; the latter of which was, however, restored by queen Anne, who granted it a new charter for a mayor and burgesses. The only manufactory here is stockings, but the chief support of the place is the resort of the people to see the ruins of the abbey. The George Inn here was formerly called *the Abbot's Inn*; because it was a receptacle for the strollers that came in pilgrimage to the abbey. At a little distance from the old-church and facing the monk's church-yard are two remarkable pyramids, with inscriptions, that are in characters unintelligible, and an image in bishop's vestments.—The story of the Glastonbury thorn, and of its budding always upon Christmas-day, is well known; however that circumstance is false; though if the win-

Glaux.

ter is mild, it always buds about the latter end of December, but later if the weather is severe.

GLATZ, a handsome and strong town of Bohemia, and capital of a county of the same name. It is seated on the river Neisse; and has strong fortifications, with a castle built upon a mountain. The county was ceded to the king of Prussia by the queen of Hungary in 1742; and is about 45 miles in length, and 25 in breadth. It has mines of pit-coal, silver, and iron; good quarries, plenty of cattle, and fine springs of mineral water. The town is situated in E. Long. 15. 16. N. Lat. 50. 25.

GLAUBER (John Rhodolphus), a celebrated German chemist, who flourished about the year 1646. He wrote a great number of different treatises on chemistry, some of which have been translated into Latin and French. All his works have been collected into one volume, intitled, *Glauberus concentratus*, which has been translated into English, and was printed at London, in folio, in 1689.

GLAUBER'S Salts. See *CHEMISTRY-Index*.

GLAUCOMA, in medicine and surgery, the name of a disease in the eye, wherein the crystalline humour is turned of a bluish or greenish colour, and its transparency hereby diminished.—The word comes from *γλαυκος, cæsius*, “sea-green, sky-coloured, or greyish.”

Those in whom this disorder is forming, discover it hence, that all objects appear to them as through a cloud or mist; when entirely formed, the visual rays are all intercepted, and nothing is seen at all.

It is reckoned incurable, when inveterate, and in aged persons; and even under other circumstances, is very difficult of cure, externals proving of little service.

The internals best suited, are those used in the gutta serena. Jul. Cæsar Claudinus, Consul. 74. gives a remedy for the glaucoma.

The glaucoma is usually distinguished from the cataract or suffusion, in this, that in the cataract the whiteness appears in the pupil, very near the cornea; but it shows deeper in the glaucoma.

Some late French authors, however, maintain the cataract and glaucoma to be one and the same disease. According to them the cataract is not a film, or pellicle, formed before the pupil, as had always been imagined; but an inspissation or induration of the humour itself, whereby its transparency is prevented; which brings the cataract to the glaucoma. According to Mr. Sharp, the glaucoma of the ancient Greeks is the present cataract; but M. St Yves says it is a cataract accompanied with a gutta serena. See *SURGERY*.

GLAUCUS, a marine god, or deity of the sea. There are a great many fabulous accounts of this divinity: but the poetical history of him is, that before his deification, he was a fisherman of the town of Anthedon, who having one day taking a considerable number of fishes which he laid upon the bank, on a sudden perceived that these fishes, having touched a kind of herb that grew on the shore, received new strength, and leaped again into the sea; upon the sight of which extraordinary accident, he was tempted to taste of the herb himself, and presently leaped into the sea after them, where he was metamorphosed into a Triton, and became one of the sea-gods.

GLAUX, in botany: A genus of the monogynia

order belonging to the pentandria class of plants; and in the natural method ranking under the 17th order, *Calycanthemæ*. The calyx is monophyllous; there is no corolla; the capsule is unilocular, quinquevalved, and pentaspermous.

GLAZIER, an artificer who works in glass.—The principal part of a glazier's business consists in fitting panes of glass to the sashes and window-frames of houses, pictures, &c. and in cleaning the same.

GLAZING, the crusting over earthen ware by a vitreous substance, the basis of which is lead. See *GLASS of Lead*.

The workers of common earthen ware, however, are not at the trouble of thus previously making a pure glass of lead. Their usual composition for glazing their ware is formed of white sand 40 pounds, of red lead 20 pounds, of pearl-ashes 20 pounds, and of common salt 12 pounds. Powder the sand by grinding it, and then add it to the other ingredients and grind them together: after which calcine them for some time with a moderate heat, and when the mixture is cold, pound it to powder; and when wanted for use temper it with water. The proportion of these ingredients may be occasionally varied. The ware, after being turned on the wheel and dried in the open air, is covered over with the above composition by means of a brush; and when set in the furnace the violent heat soon reduces it to a perfect glass, covering the whole internal and external surface of the vessel.

We may observe, however, in general, that lead ought to be excluded from the composition of glazings, and other fluxes substituted in its stead. A transparent glazing may be prepared without lead by calcining 40 pounds of white sand, 25 pounds of pearl-ashes, and 15 pounds of common salt; and proceeding as before: and a more perfect transparent glazing may be made of sand 40 pounds, of wood-ashes perfectly burnt 50 pounds, of pearl-ashes 10 pounds, and of common salt 12 pounds. The following recipes are taken for the most part from Kunckel, who says that they are the true glazings used at Delft and other Dutch manufactories.

Black is made of eight parts of red-lead, iron filings three, copper-ashes three, and zaffer two measures. This when melted will make a brown-black; and if you want it blacker, add more zaffer to it.

Blue is thus prepared: Take lead-ashes or red lead one pound, clear-sand or powdered flints two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glass half a pound, zaffer half a pound; mix them well together and melt them for several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two.

Another blue glazing may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of zaffer, and a quarter of a pound of powdered flints, which are to be fused and managed as in the last recipe. Or, take two pounds of calcined lead and tin, and five pounds of common salt, five pounds of powdered flints, and of zaffer, tartar, and Venetian glass, each one pound. Calcine and fuse the mixture as before. Or, again, take of red-lead one part, of sand three parts, and of zaffer one part. For a violet blue gla-

Glazier,
Glazing.

Glaſs. glazing, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flints, and half a dram of manganese.

Brown is made of red-lead and flints of each 14 parts, and of manganese two parts fused; or of red-lead 12 parts, and manganese one part fused. A brown glazing, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white-glaſs of each one part, twice fused.

Fleſh-coloured is made of 12 parts of lead aſhes, and one of white-glaſs.

Gold-coloured. Take of litharge three parts, of ſand or calcined flint one part; pound and mix theſe very well together, then run them into a yellow glaſs with a ſtrong fire. Pound this glaſs and grind it into a ſubtile powder, which moiſten with a well ſaturated ſolution of ſilver; make it into a paſte, which put into a crucible, and cover it with a cover. Give at firſt a gentle degree of fire; then increaſe it, and continue it till you have a glaſs, which will be green. Pound this glaſs again, and grind it to a fine powder; moiſten this powder with ſome beer, ſo that by means of an hair pencil you may apply it upon the veſſels or any piece of earthen ware. The veſſels that are painted or covered over with this glazing muſt be firſt well heated, then put under a muffle; and as ſoon as the glaſs runs, you muſt ſmoak them, by holding them over burning vegetables, and take out the veſſels. Mr Heiſius of Petersburgh, who ſent this receipt to the Royal Society, uſes the words *afflare debes fumen*, which is rendered *ſmoak them*, in the Tranſactions. Phil. Tranſ. N. 465. § 6.

Kunckel gives ſeveral preparations for a gold coloured yellow glazing. This may be produced by fuſing a mixture of three parts of red-lead, two parts of antimony, and one part of ſaffron of Mars; by again melting the powdered maſs, and repeating the operation four times, or by fuſing four or five times a compoſition of red-lead and antimony of each an ounce, and of ſcales of iron half an ounce; or by calcining and fuſing together eight parts of red-lead, ſix parts of flints, one part of yellow ochre, one part of antimony, and one part of white glaſs. A transparent gold-coloured glazing may be obtained by twice fuſing red-lead and white-flints, of each 12 parts, and of filings of iron one part.

Green may be prepared of eight parts of litharge or red-lead, eight parts of Venice glaſs, four parts of braſs-duſt or filings of copper: or of ten parts of litharge, twelve of flint or pebble, and one of *us eſtum* or copper-aſhes.—A fine green glazing may be produced by fuſing one part of the Bohemian granate, one part of filings of copper, one part of red-lead, and one part of Venetian glaſs; or by fuſing one part of white glaſs, the ſame quantity of red-lead, and alſo of filings of copper; powdering the maſs, and adding one part of Bohemia granate to two parts of this powder. A fine green may be obtained by mixing and grinding together any part of the yellow glazings with equal quantities of the blue glazings, and all the ſhades and tints of green will be had by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

Sea-green is made of five pounds of lead-aſhes, one pound of tin-aſhes, three pounds of flint, three quar-

ters of a pound of ſalt, half a pound of tartar, and half a pound of copper-duſt.

Iron-colour is prepared of 15 parts of lead-aſhes or red-lead, 14 of white-ſand or flints, and five of calcined copper. This mixture is to be calcined and fuſed.

Liver-colour is prepared of 12 parts of litharge, eight of ſalt, ſix of pebble or flint, and one of manganese.

Purple-brown conſiſts of lead-aſhes 15 parts, clean ſand or powdered flints 18 parts, manganese one part, and white-glaſs 15 meaſures, to which ſome add one meaſure of zaffer.

Red is made of antimony three pounds, litharge or red-lead three, and ruſt of iron one; grind them to a fine powder. Or, take two pounds of antimony, three of red-lead, and one of calcined ſaffron of Mars, and proceed as before.

White. The white glazing for common ware is made of 40 pounds of clear ſand, 75 pounds of litharge or lead-aſhes, 26 of pot-aſhes, and 10 pounds of ſalt: theſe are three times melted into a cake, quenching it each time in clear cold water. Or it may be made of 50 pounds of clean ſand, 70 of lead-aſhes, 30 of wood-aſhes, and 12 of ſalt.

For a fine white: Take two pounds of lead and one of tin; calcine them to aſhes: of this take two parts, calcined flint, white ſand, or broken white glaſs, one part, and ſalt one part: mix them well together and melt them into a cake for uſe. The trouble of calcining the tin and lead may be prevented by procuring them in a proper ſtate.

A very fine white glazing may be obtained by calcining two parts of lead and one part of tin; and taking one part of this maſs, and of flints and common ſalt of each one part, and fuſing the mixture.

A white glazing may be alſo prepared by mixing 100 pounds of maſticor, 60 pounds of red-lead, 20 pounds of calcined tin or putty, and 10 pounds of common ſalt, and calcining and powdering the mixture ſeveral times.

Yellow is prepared of red-lead three pounds; calcined antimony and tin of each two pounds; or, according to ſome, of equal quantities of the three ingredients. Theſe muſt be melted into a cake, then ground fine: and this operation repeated ſeveral times; or it may be made of 15 parts of lead-ore, three parts of litharge of ſilver, and 15 parts of ſand.—A fine yellow glazing may be procured by mixing five parts of red-lead, two parts of powdered brick, one part of ſand, one part of the white glazings, and two parts of antimony, calcining the mixture and then fuſing it. Or, take four parts of white-glaſs, one part of antimony, three parts of red-lead, and one part of iron-ſcales, and fuſe the mixture; or fuſe 16 parts of flints, one part of iron-filings, and 24 parts of litharge. A light yellow glazing may be produced with ten parts of red-lead, three parts of antimony, and three of glaſs, and two parts of calcined tin. See *Gold colour*, above.—A *citron yellow* is made of ſix parts of red-lead, ſeven parts of fine red brick-duſt, and two parts of antimony. This mixture muſt be calcined day and night for the ſpace of four days, in the aſh-hole of a glaſs-ſtove furnace, and at laſt urged to fuſion.

For the glazing of Delft-ware, Porcelain, Stone-ware,

Glaſs.

Glead were, &c. see the articles *DELFT-Ware*, *PORCELAIN*, and *POTTERY*.

Glead
||
Gleditsia.

The Romans had a method of glazing their earthen vessels, which in many respects appears to have been superior to ours. The common brown glazing easily scales off, cracks, and in a short time becomes disagreeable to the eye. Besides, it is very easily destroyed by acids; nor can vessels glazed in this manner be even employed to hold water, without part of it oozing through their pores. Lead is also very destructive to the human body; and if acids are unwarily put into vessels glazed with lead, the liquors will receive a very dangerous impregnation from the metal. The Roman glazing, which is yet to be seen upon urns dug up in several places, appears to have been made of some kind of varnish; and Pliny gives us a hint that it was made of bitumen. He tells us that it never lost its beauty, and that at length it became customary to glaze statues in this manner. As this varnish sunk deep into the substance of the ware it was not subject to those cracks and flaws which disfigure our vessels; and as it was not liable to be corroded by acids, it could not be subject to any of the accidents which may ensue from the use of vessels glazed with lead.

GLEAD, or GLADE, a name used in the northern parts of Britain for the kite. See *FALCO*.

GLEAM is popularly used for a ray or beam of light. Among falconers a hawk is said to gleam when she casts or throws up filth from the gorge.

GLEANNING, the act of gathering or picking up the ears of corn left behind after the field has been reaped and the crop carried home. By the customs of some countries, particularly those of Melun and Estampes, all farmers and others are forbid, either by themselves or servants, to put any cattle into the fields, or prevent the gleaning in any manner whatever for the space of 24 hours after the carrying off the corn, under the penalty of confiscation.

GLEBE, among miners, signifies a piece of earth in which is contained some mineral ore.

GLEBE, in law, the land belonging to a parish-church besides the tithes.

GLECHOMA, *GROUND-IVY*: a genus of the gymnospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 42d order, *Verticillate*. Each part of the antheræ come together in the form of a cross; the calyx is quinquefid. There are three species: the most remarkable of which is the hederacea, or common ground-ivy, which is so well known that it requires no description. Many virtues were formerly attributed to this plant, which it is now found not to be possessed of. Some, however, it has. The leaves are thrown into the vat with ale to clarify it and give it a flavour. Ale thus prepared is often drunk as an antiscorbutic. The expressed juice mixed with a little wine, and applied morning and evening, destroys the white specks upon horses eyes. The plants that grow near it do not flourish. It is said to be hurtful to horses if they eat much of it. Sheep eat it, horses are not fond of it; cows, goats, and swine, refuse it.

GLEDITSIA, *TRIPLE-THORNED ACACIA*, or *Honey-locust*: A genus of the dioecia order, belonging to the polygamia class of plants; and in the natural

method ranking under the 33d order, *Lomentaceæ*. The hermaphrodite calyx is quadrifid; the corolla tetrapetalous; the stamina six, one pistil and legumen. The male calyx is pentaphyllous; the corolla tripetalous; with six stamina. The female calyx is pentaphyllous; the corolla pentapetalous; one pistil and legumen. There are two species.

1. The triacanthos, a native of Virginia and Pennsylvania, is of an upright growth, and its trunk is guarded by thorns of three or four inches in length in a remarkable manner. These thorns have also others coming out of their sides at nearly right angles: Their colour is red. The branches are smooth, and of a white colour. These are likewise armed with red thorns, they are proportionally smaller: they are of several directions, and at the ends of the branches often stand single. The young shoots of the preceding summer are perfectly smooth, of a reddish green, and retain their leaves often until the middle of November. Although there is a peculiar oddity in the nature and position of the spines, yet the leaves constitute the greatest beauty of these trees: they are doubly pinnated, and of a delightful shining green. The pinnated leaves, that form the duplication, do not always stand opposite by pairs on the middle rib; the pinnæ of which they are composed are small and numerous; no less than 10 or 11 pair belong to each of them; and as no less than four or five pair of small leaves are arranged along the middle rib, the whole compound leaf consists often of more than 200 pinnæ of this fine green colour: They sit close, and spread open in fine weather; though during bad weather they will droop, and their upper surfaces nearly join, as if in a sleeping state. The flowers are produced from the sides of the young branches in July: They are a greenish catkin, and make little show; though many are succeeded by pods, that have a wonderful effect; for these are exceedingly large, more than a foot, sometimes a foot and a half in length, and two inches in breadth, and of a nut-brown colour when ripe; so that the effect they occasion, when hanging on the sides of the branches, may easily be guessed.—There is a variety of this species, with fewer thorns, smaller leaves, and oval pods. It has nearly the resemblance of the other; though the thorns being not so frequent, and the pods being smaller, each containing only one seed, this sort loses that singular effect which the other produces by them.

These trees are easily propagated. Europeans receive the seeds from America in the spring, which keep well in the pods, and are for the most part good. They generally arrive in February, and, as soon as possible after, they should be sown in a well-sheltered warm border of light sandy earth. If no border is to be found that is naturally so, it may be improved by applying drift sand and making it fine. The seeds should be sown about half an inch deep; and they will for the most part come up the first spring. If the summer should prove dry, they must be constantly watered; and if shade could be afforded them in the heat of the day, they would make stronger plants by the autumn. A careful attention to this article is peculiarly requisite; for as the ends of the branches are often killed, if the young plant has not made some progress, it will be liable to be wholly destroyed by the

Gleet,
Glenda-
lagh.

the winter's frost without protection; and this renders the sowing the seeds in a warm border, under an hedge, in a well-sheltered place necessary; for these shrubs will endure the winters, even when feedings, and so will require no farther trouble; nay, though the tops should be nipped, they will shoot out again lower, and will soon overcome it. It will be proper to let them remain two years in the feed-bed before they are planted out in the nursery. The spring is the best time for the work. Their distances should be one foot by two; the rows should be dug between every winter; and, being weeded in summer, here they may remain, with no other particular care, until they are set out to remain. These trees are late in the spring before they exhibit their leaves, but keep shooting long in the autumn.

2. The other species is the inermis, the stem of which is unarmed or without thorns. It is a native of South America, and in this country requires to be kept in a stove.

GLEET, in medicine, the flux of a thin limpid humour from the urethra. See the index subjoined to MEDICINE.

GLENDALAGH, otherwise called *the Seven Churches*, anciently a celebrated town of Ireland, situated five miles north west of Rothdrum, in the county of Wicklow, and province of Leinster. The name signifies "the valley of the two lakes." In this valley, surrounded by high and almost inaccessible mountains, St Kevin or Cavin, called also *St Coemgene*, about the middle of the 6th century, founded a monastery, which in a short time from the sanctity of its founder was much resorted to, and at length became a bishopric and a religious city. St Kevin died 3d June 618, aged 120; and on that day annually numbers of persons flock to the Seven Churches to celebrate the festival of that venerated saint. During the middle ages the city of Glendalagh, called by Hovedon *Episcopatus Bistagnensis*; was held in great esteem, and received several valuable donations and privileges, its episcopal jurisdiction extending to the walls of Dublin.—About the middle of the 12th century, on some account or other, it was much neglected by the clergy; and became, instead of a holy city, a den of thieves, wherefore Cardinal Papiro, in 1214, united it to the see of Dublin, which union was confirmed by king John. The O'Tools, chiefs of Firthuathal, however, by the assistance of the Pope, continued long after this period to elect bishops and abbots to Glendalagh, though they had neither revenues or authority, beyond the district of Tuathal, which was the western part of the county of Wicklow; in consequence of which the city was suffered to decay, and had become nearly a desert, in 1497, when Dennis White, the last titular bishop, surrendered his right in the cathedral church of St Patrick, Dublin. From the ruins of this ancient city still remaining, it appears to have been a place of consequence, and to have contained seven churches and religious houses; small indeed, but built in a neat elegant style, in imitation of the Greek architecture: the cathedral, the walls of which are yet standing, was dedicated to St Peter and St Paul. South of the cathedral stands a small church roofed with stone, nearly entire; and in several parts

VOL. VII.

of the valley are a number of stone crosses, some of which are curiously carved, but without any inscriptions. In the north-west corner of the cemetery belonging to the cathedral stands a round tower, 95 feet high, and 15 in diameter; and in the cemetery of a small church, on the south side of the river, near the great lake, called the *Rhescart church*, are some tombs, with Irish inscriptions, belonging to the O'Tools. In a perpendicular projecting rock on the south side of the great lake, 30 yards above the surface of the water, is the celebrated bed of St Kevin, hewn out of the rock, exceedingly difficult of access and terrible in prospect. Amongst the ruins have been discovered a number of stones, curiously carved, and containing inscriptions in the Latin, Greek, and Irish languages. As this city was in a valley, surrounded on all sides except the east, by high, barren, and inaccessible mountains, the artificial roads leading thereto are by no means the least curious part of the remains; the principal is that leading into the county of Kildare through Glendafon. This road for near two miles is yet perfect, composed of stones placed on their edges, making a firm and durable pavement about 10 feet broad. At a small distance from St Kevin's bed, on the same side of the mountain, are to be seen the ruins of a small stone building called *Saint Kevin's cell*.

GLENOIDES, the name of two cavities, or small depressions, in the inferior part of the first vertebra of the neck.

GLICAS, or GLYCAS, (Michael), a Greek historian about the middle of the 15th century, lived in Sicily, and wrote annals of what passed from the creation of the world to the death of Alexis Comnenus, in 1118. Leunclavius added to it a fifth part, which carries it down to the taking of Constantinople. Glucas was also the author of several useful and curious letters.

GLIMMER, or GLIST. See MICA.

GLINUS, in botany: A genus of the pentagynia order, belonging to the decandria class of plants; and in the natural method ranking under the 22d class, *Caryophylliei*. The calyx is pentaphyllous; there is no corolla; the nectarium is composed of bifid bristles; the capsule is quinqueangular, quinquelocular, quinquevalved, and polyspermous.

GLIRES, the name of Linnæus's fourth order of mammalia. See ZOOLOGY.

GLISSON (Francis) a learned English physician in the 17th century, was educated at Cambridge, and was made regius professor of that university. In 1634 he was admitted a fellow of the college of physicians in London. During the civil wars, he practised physic at Colchester, and afterwards settled in London. He greatly improved physic by his anatomical dissections and observations, and made several new discoveries of singular use towards establishing a rational practice. He wrote, 1. *De rachitide, &c.* 2. *De lymphæductis nuper repertis*; with the *Anatomica prolegomena, & Anatomia hepatis.* 3. *De naturæ substantia energetica; seu de via vitæ naturæ, ejusque tribus primis facultatibus, &c.* quarto. 4. *Tractatus de ventriculo & intestinis, &c.* The world is obliged to him for the *capsula communis*, or *vagina portæ*.

GLISTER,

Glénoides
Gliffon.

Glister
||
Globe.

GLISTER, in surgery. See CLYSTER.

GLOBBA, in botany: A genus of the monogynia order, belonging to the monandria class of plants. The corolla is equal and trifold; the calyx trifold above; the capsule trilobular, with many seeds.

GLOBE, in geometry, a round or spherical body more usually called a *sphere*. See SPHERE.

GLOBE, is more particularly used for an artificial sphere of metal, plaster, paper, or other matter; on whose convex surface is drawn a map, or representation either of the earth or heavens, with the several circles conceived thereon. See GEOGRAPHY.

Globes are of two kinds *terrestrial* and *celestial*; each of very considerable use, the one in astronomy, and the other in geography, for performing many of the operations thereof in an easy obvious manner, so as to be conceived without any knowledge of the mathematical grounds for those arts.

The fundamental parts, common to both globes, are an axis, representing that of the world; and a spherical shell, or cover, which makes the body of the globe, on the external surface of which the representation is drawn. See AXIS, POLE, &c.

Globes, we have observed, are made of different materials, viz. silver, brass, paper, plaster, &c. Those commonly used are of plaster and paper; The construction whereof is as follows:

Construction of GLOBES.—A wooden axis is provided, somewhat less than the intended diameter of the globe; and into the extremes hereof two iron wires are driven for poles: this axis is to be the beam, or basis of the whole structure.

On the axis are applied two spherical or rather hemispherical caps, formed on a kind of wooden mould or block.—These caps consist of pasteboard, or paper, laid one lay after another, on the mould, to the thickness of a crown-piece; after which, having stood to dry and embody, making an incision along the middle, the two caps thus parted are slipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on those of the mould: and to fix them in their new place, the two edges are sewed together with pack-thread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are hasped in a metalline semicircle of the size intended; and a kind of plaster, made of whiting, water, and glue, heated, melted, and incorporated together, is daubed all over the paper-surface. In proportion as the plaster is applied, the ball is turned round in the semicircle, the edge whereof pares off whatever is superfluous and beyond the due dimension, leaving the rest adhering in places that are short of it. After such application of plaster, the ball stands to dry; which done, it is put again in the semicircle, and fresh matter applied: thus they continue alternately to apply the composition, and dry it, till such time as the ball every where accurately touches the semicircle; in which state it is perfectly smooth, regular, firm, &c.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several gores, or gussets; all which join accurately on the spherical surface, and cover the

whole ball. To direct the application of these gores, lines are drawn by a semicircle on the surface of the ball, dividing it into a number of equal parts, corresponding to those of the gores, and subdividing those again answerably to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe; and to varnish it, the better to resist dust, moisture, &c.—The globe itself thus finished, they hang it in a brass meridian, with an hour-circle, and a quadrant of altitude; and thus fit it into a wood horizon.

To describe the gores, or gussets, for the globes. In Chamber's Dictionary, the following method is directed.

“1. From the given diameter of the globe, find a right line AB, fig. 1. equal to the circumference of a great circle, and divide it into twelve equal parts. Plate CCXXI.

2. Through the several points of division, 1, 2, 3, 4, &c. with the interval of ten of them, describe arches mutually intersecting each other in D and E; these figures or pieces duly pasted or joined together will make the whole surface of the globe.

3. Divide each part of the right line AB into 30 equal parts, so that the whole line AB, representing the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, fig. 2. with the interval of $23\frac{1}{2}$ deg. describe arches *ab*; these will be twelfth-parts of the polar circles.

5. After the like manner, from the same poles D and E, with the interval of $66\frac{1}{2}$ deg. reckoned from the equator, describe arches *cd*; these will be twelfth-parts of the tropics.

6. Through the degree of the equator *e*, corresponding to the right ascension of any given star, and the poles D and E, draw an inch of a circle; and taking in the compasses the complement of the declination from the pole D, describe an arch intersecting it in *i*: this point *i* will be the place of that star.

7. All the stars of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamsteed.

8. Lastly, after the same manner are the declinations and right ascensions of each degree of the ecliptic *dg* to be determined.

9. The surface of the globe thus projected on a plane is to be engraven on copper, to save the trouble of doing this over again for each other.

10. A ball, in the mean time, is to be prepared of paper, plaster, &c. as before directed, and of the intended diameter of the globe; on this, by means of a semicircle and style, is the equator to be drawn; and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, the latter are to be cut from the printed paper, and pasted on the ball.

11. Nothing now remains but to hang the globe as before in a brass meridian and wooden horizon; to which may be added a quadrant of altitude made of brass, and divided in the same manner as the ecliptic and equator.

If the declinations and right ascensions of the stars be not given, but the longitudes and latitudes in lieu thereof, the surface of the globe is to be projected after the same manner as before; except that, in this case,

Globe.

Globe. case, D and E, fig. 2. are the poles of the ecliptic, and *fh* the ecliptic itself; and that the polar circles and tropics with the equator *gd*, and the parallels thereof, are to be determined from their declinations.

M. De La Lande, in his *Astronomie* 1771, *Tom.* 3. p. 736, relates the following methods. "To construct celestial and terrestrial globes, gores must be engraved, which are a kind of projection, or inclosure of the globe (fig. 3.) similar to what is now to be explained. The length PC of the axis of the curve is equal to a quarter of the circumference of the globe; the intervals of the parallels on the axis PC are all equal, the radii of the circles KDI which represent the parallels are equal to the cotangents of the latitudes, and the arches of each, as DI, are nearly equal to the number of the degrees of the breadth of the gore (which is usually 30°) multiplied by the sine of the latitude; thus, there will be found no intricacy in tracing them; but the difficulty proceeds from the variation found in the trial of the gores when pasting them on the globe, and of the quantity that must be taken from the paper, less on the sides than in the middle; (because the sides are longer) to apply it exactly to the space that it should cover.

"The method used among workmen to delineate the gores, and which is described by Mr Bion (*Usage des Globes, Tome 3.*) and by Mr Robert de Vaugondy in the 7th volume of the *Encyclopédie* is little geometrical, but yet is sufficient in practice. Draw on the paper a line AC, equal to the chord of 30°, to make the half breadth of the gore; and a perpendicular PC, equal to three times the chord of 30°, to make the half length: for these papers, the dimensions of which will be equal to the chords, become equal to the arcs themselves when they are pasted on the globe. Divide the height CP into 9 parts, if the parallels are to be drawn in every 10°: divide also the quadrant BE into 9 equal parts through each division point of the quadrant as G; and through the corresponding point D of the right line CP draw the perpendiculars HGF and DF, the meeting of which in F gives one of the points of the curve BEP, which will terminate the circumference of the gore. When a sufficient number of points are thus found, trace the outline PIB with a curved rule. By this construction are given the gore breadths, which are on the globe, in the ratio of the cosines of the latitudes; supposing these breadths taken perpendicular to CD, which is not very exact, but it is impossible to prescribe a rigid operation sufficient to make a plane which shall cover a curved surface, and that on a right line AB shall make lines PA, PC, PB, equal among themselves, as they ought to be on the globe. To describe the circle KDI which is at 30° from the equator: there must be taken above D a point which shall be distant from it the value of the tangent of 60°, taken out either from the table, or on a circle equal to the circumference of the globe to be traced; the point will serve as a centre for the parallel DI, which should pass through the point D, for it is supposed equal to that of a cone circumscribing the globe, and which would touch at the point D.

"The meridians may be traced to every 10 degrees, by dividing each parallel, as KI, into three parts at the points L and M, and drawing from the pole P, through

all these division points, curves, which represent the intermediate meridians between PA and PB, (as BR and ST, fig. 4.). The ecliptic AQ may be described by means of the known declination from different points of the equator that may be found in a table; for 10°, it is 3° 58'; for 20°, 7° 50' = BQ; for 30°, 11° 29', &c."

It is observed in general, that the paper on which charts are printed, such as the *colombier*, shortens itself $\frac{1}{7}$ part of a line in six inches upon an average, when it is dried after printing; this inconvenience must therefore be corrected in the engraving of the gores: if notwithstanding that, the gores are found too short, it must be remedied by taking from the surface of the ball a little of the white with which it is covered; thereby making the dimensions suitable to the gore as it was printed. But what is singular is, that in drawing the gore, moistened with the paste to apply on the globe, the axis GH lengthens, and the side AK shortens, in such a manner, that neither the length of the side ACK nor that of the axis GEH of the gore are exactly equal to the quarter of the circumference of the globe, when compared to the figure on the copper, or to the numbered sides shown in fig. 4. Mr Bonne having made several experiments on the dimensions that gores take after they had been parted ready to apply to the globe, and particularly with the paper named *jesus* that he made use of for a globe of one foot in diameter, found that it was necessary to give to the gores, on the copper, the dimensions shown in fig. 4. Supposing that the radius of the globe contained 720 parts, the half breadth of the gore is $AG = 181\frac{5}{6}$, the distance AC for the parallel of 10 degrees taken on the right line LM is 128.1, the small deviation from the parallel of 10 degrees in the middle of the gore ED is 4, the line ABN is right, the radius of the parallel of 10° or of the circle CEF is 4083, and so of the others as marked in the figure. The small circular cap which is placed under H, has its radius 253 instead of 247, which it would have if the sine of 20° had been the radius of it.

For the uses, &c. of the globes, see GEOGRAPHY and ASTRONOMY, with the plates there referred to.

GLOBE Animal. See ANIMALCULE, n° 29.

GLOBE-Fish. See OSTRACION.

GLOBULARIA, **GLOBULAR BLUE DAISY**: A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 48th order, *Aggregata*. The common calyx is imbricated; the proper one tubulated inferior; the upper lip of the florets bipartite, the under one tripartite; the receptacle paleaceous. There are several species; but only one is commonly to be met with in our gardens, viz. the vulgaris, or common blue daisy. It hath broad thick radical leaves three parted at the ends, upright stalks from about six to 10 or 12 inches high garnished with spear-shaped leaves, and the top crowned by a globular head of fine blue flowers composed of many florets in one cup. It flowers in June, and makes a good appearance; but thrives best in a moist shady situation. It is propagated by parting the roots in September.

GLOBULE, a diminutive of globe, frequently used by physicians in speaking of the red particles of the blood. See BLOOD.

Gloceſter.

GLOCESTER, the capital of Glouceſterſhire in England, 101 miles from London. It is an ancient city; and by Antoninus is called *Glevum*, or *Glovum*, which Camden thinks was formed from the Britiſh *Caer-Glowe*, ſignifying “a fair city.” It was one of the 28 cities built by the Britons before the arrival of the Romans. By the Romans it was made one of their colonies, and in the eighth century it was eſteemed one of the nobleſt cities in the kingdom. It has ſuffered conſiderably by fire at different periods. It ſtands upon a hill; and from the middle of the city, where the four principal ſtreets meet, there is a deſcent every way, which makes it not only clean and healthy, but adds to the beauty of the place. Forging of iron ſeems to have been its manufactory ſo early as the time of William the Conqueror. King Henry VIII. made it the ſee of a biſhop, with a dean and ſix prebends. Its caſtle, which was erected in the time of William the Conqueror, is very much decayed: part of it is leaſed out by the crown; and the reſt ſerves for a priſon, one of the beſt in England. In its cathedral, which is an ancient but magnificent fabric, and has a tower reckoned one of the moſt curious pieces of architecture in England, are the tombs of Robert duke of Normandy, ſon to William the Conqueror, and of Edward II. and there is a wiſpering-place like to that of St Paul’s at London. In the chapter-houſe lies Strongbow who conquered Ireland. There are 12 chapels in it, with the arms and monuments of many great perſons. King John made it a borough to be governed by two bailiffs. Henry III. who was crowned here, made it a corporation. By its preſent charter from Charles I. it is governed by a ſteward, who is generally a nobleman; a mayor; a recorder; 12 aldermen, out of whom the mayor is choſen; a town-clerk; 2 ſheriffs, choſen yearly out of 26 common councilmen; a ſword-bearer; and four ſerjeants at mace. Here are 12 incorporated trading companies, whoſe maſters attend the mayor on all public occaſions, &c. Beſides the cathedral, there are five pariſh churches in this city; which is likewiſe well provided with hoſpitals, particularly an infirmary upon the plan of thoſe at London, Wincheſter, Bath, &c. Here is a good ſtone-bridge over the river Severn, with a quay, wharf, and cuſtomhouſe; but moſt of its buſineſs is engroſſed by Briſtol. King Edward I. held a parliament here in 1272, where in ſome good laws were made, now called the *Statutes of Gloceſter*; and he erected a gate on the ſouth ſide of the abbey, ſtill called by his name, though almoſt demolished in the civil wars. King Richard II. alſo held a parliament here: and King Richard III. in conſideration of his having (before his acceſſion to the crown) borne the title of *Duke of Gloceſter*, added the two adjacent hundreds of Dudſton and King’s Barton to it, gave it his ſword and cap of maintenance, and made it a county of itſelf by the name of the *county of the city of Gloceſter*. But after the reſtoration the hundreds were taken away by act of parliament, and the walls pulled down; becauſe the city ſhut the gates againſt Charles I. when he beſieged it in 1643: by which, though the ſiege was raiſed by the earl of Eſſex, it had ſuffered 20,000l. damage, having 241 houſes deſtroyed, which reduced it ſo much that it has ſcarce recovered its former ſize and grandeur. Before that time it had 11 pariſh churches, but ſix of

them were then demolished. Here are abundance of Glouceſterſhire. croſſes, and ſtatues of the English kings, ſome of whom kept their Chriſtmas here; ſeveral market-houſes ſupported with pillars; and large remains of monaſteries, which were once ſo numerous, that it gave occaſion to the monkish proverb, *as ſure as God is in Gloceſter*. Here is a barley market; and a hall for the aſſizes, called the *Booth-hall*. Its chief manufacture is pins. In this branch it is aſtoniſhing the number of people who are employed, there being at leaſt 14 or 15 different proceſſes. Under the bridge is a water engine to ſupply the town, and it is ſerved with it alſo from Robin Hood’s well, to which is a fine walk from the city. Camden ſays, that the famous Roman way, called *Ermin-ſtreet*, which begins at St David’s in Pembrokeſhire, and reaches to Southampton, paſſes through this city. Sudmead in the neighbourhood is noted for horſe-races. The markets here are on Wedneſday and Sunday; and fairs April 5th, July 5th, September 28th, and November 28th, the latter chiefly for fat hogs. Here is a charity-ſchool for above 80 children, of whom above 70 are alſo cloathed; and a well endowed blue-coat ſchool. The city ſends two members to parliament. The duke of Glouceſter is next brother to George III.

GLOCESTERSHIRE, a county of England, is bounded on the Weſt by Monmouthſhire and Herefordſhire, on the north by Worceſterſhire, on the eaſt by Oxfordſhire and Warwickſhire, and on the ſouth by Wilthire and part of Somerſetſhire. It is ſixty miles in length, twenty ſix in breadth, and one hundred and ſixty in circumference; containing 1,100,000 acres, 26,760 houſes, 162,560 inhabitants, 290 pariſhes, 140 are impropriations, 1229 villages, 2 cities, and 28 market-towns. It ſends only 8 members to parliament, 6 for three towns, viz. Gloceſter, Tewkeſbury, and Cirenceſter; and 2 for the county. Its manufactures are woollen cloths of various kinds, mens hats, leather, pens, paper, bar-iron, edge-tools, nails, wire, tinned-plates, braſs, &c.: and of the principal articles of commerce of the county, it exports cheeſe 8000 tons; bacon, grain, cyder, 5000l. worth; perry, fiſh, 4000l. worth, &c. It lies in the dioceſe that takes its name from the capital, and in the Oxford circuit. The air of the county is very wholeſome, but the face of it is very different in different parts: for the eaſtern part is hilly, and is called *Cotteswold*; the weſtern woody, and called the *Forest of Dean*; and the reſt is a fruitful valley, through which runs the river Severn. This river is in ſome places between two and three miles broad, and its courſe through the country, including its windings, is not leſs than ſeventy miles. The tide of flood, called the *Boar*, riſes very high, and is very impetuous. It is remarkable, that the greateſt tides are one year at the full moon, and the other at the new; one year the night-tides, and the next the day. This river affords a noble conveyance for goods and merchandiſe of all ſorts to and from the county; but it is watered by ſeveral others, as the Wye, the Avon, the Iſis, the Leden, the Frome, the Stroud, and Windruſh, beſides leſſer ſtreams, all abounding with fiſh, the Severn in particular with falmon, conger-ells, and lampreys. The ſoil is in general very fertile, though pretty much diverſified, yielding plenty of corn, paſture, fruit, and wood. In the hilly

Glocester-
shire.
|
Glogaw.

part of the county, or Cotteswold, the air is sharper than in the lowlands; and the soil, though not so fit for grain, produces excellent pasture for sheep; so that of the four hundred thousand that are computed to be kept in the county, the greater part are fed here. Of these sheep the wool is exceeding fine; and hence it is that this shire is so eminent for its manufacture of cloth, of which fifty thousand pieces are said to have been made yearly, before the practice of clandestinely exporting English wool became so common. In the vale, or lower part of the county, through which the Severn passes, the air and soil are very different from those of the Cotteswold: for the former is much warmer, and the latter richer, yielding the most luxuriant pastures; in consequence of which, numerous herds of black cattle are kept, and great quantities of that excellent cheese, for which it is so much celebrated, made in it. The remaining part of the county, called the *Forest of Dean*, was formerly almost entirely over-run with wood, and extended 20 miles in length and 10 in breadth. It was then a nest of robbers, especially towards the Severn; but now it contains many towns and villages, consisting chiefly of miners, employed in the coal-pits, or in digging for or forging iron-ore, with both which the forest abounds. These miners have their particular laws, customs, courts, and judges; and the king, as in all royal forests, has a swain-mote for the preservation of the vert and venison. This forest was anciently, and is still, noted for its oaks, which thrive here surprisingly; but as there is a prodigious consumption of wood in the forges, it is continually dwindling away. A navigable canal is made from Stroud to Framilode, forming a junction between the Severn and Thames. Its chalybeate springs are; St Anthony's well, in Abbenhall parish; at Barrow and Maredon, in Bodington parish; at Ash-Church, near Tewkesbury; at Dumbleton, near Winchcomb; at Easington, near Dursley; and at Cheltenham. Its ancient fortifications attributed to the Romans, Saxons, or Danes, are at Abston and Wick, and at Dointon, Dixton, Addlesthorp, Knole, Over Upton, Hanham, Bodington, and Bourton on the Water.

GLOCHIDION, in botany: A genus of the syngenesia order, belonging to the monœsia class of plants. There is no calyx; the corolla consists of six egg-shaped concave petals; the stamina are three very small inconspicuous filaments; the antheræ cylindric and erect; the female flowers have no calyx; the corolla is parted into six; the pericarpium is a depressed roundish capsule with six cells; the seeds are roundish and solitary.

GLOGAW, a strong and considerable town of Germany, in Silesia, and capital of a duchy of the same name. It is not very large, but is well fortified on the side of Poland. It has a handsome castle, with a tower, in which several counsellors were condemned by Duke John, in 1498, to perish with hunger. Besides the Papists, there are a great number of Protestants and Jews. It was taken by assault, by the king of Prussia, in 1741, and the garrison made prisoners. After the peace in 1742, the king of Prussia settled the supreme court of Justice here, it being, next to Breslaw, the most populous place in Silesia. It is seated on the river Oder, in E. Long. 15. 13. N. Lat. 51. 40.

GLOGAW the LESS, a town of Silesia, in the duchy of Opelen, now in possession of the king of Prussia. It is two miles S. E. of great Glogaw, and 45 N. W. of Breslaw. E. Long. 16. 15. N. Lat. 51. 38.

GLORIA PATRI, among ecclesiastical writers. See **DOXOLOGY**.

GLORIOSA, **SUPERB LILY**: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 11th order, *Sarmentacea*. The corolla is hexapetalous, undulated, and reflected; the style oblique. There is but one species, a native of Malabar. It hath a thick, fleshy, tuberous root, sending forth from its centre declinated round stalks growing eight or ten feet long, and garnished with very long narrow leaves running out into a point, terminated by a long tendril. From the upper part of the stalks proceed large flame-coloured drooping flowers, consisting of six widely-spreading reflected petals. It flowers in June and July; and is of admirable beauty, whence its name of *Gloriosa*, or Superb Lily.—This plant being a native of a very warm climate, requires the protection of a hot house in this country. The flower-stalks shoot forth in March or April; which being long and trailing, must have tall sticks placed for their support. The plants are propagated by offsets, which are produced in tolerable plenty, and may be separated any time after the stalks decay, or in spring before new ones arise.

GLORY, renown or celebrity. The love of renown, or desire of fame and reputation, appears to be one of the principal springs of action in human society. Glory therefore is not to be contemned, as some of the ancient philosophers affected to teach: but it imports us to regulate our pursuit after it by the dictates of reason; and if the public approbation will not follow us in that course, we must leave her behind. We ought to have our judgements well instructed as to what actions are truly glorious; and to remember, that in every important enterprise, as Seneca observes, *Recte facti fecisse merces est; officii fructus ipsum officium est*: "The reward of a thing well done, is to have done it; the fruit of a good office is the office itself." Those who by other methods scatter their names into many mouths, show they rather hunt after a great reputation than a good one, and their reward is oftener infamy than fame.

Men generally, and almost instinctively, affix glory only to such actions as have been produced by an innate desire for public good; and we measure it by that degree of influence which any thing done has upon the common happiness.

If the actions of the hero conduct soonest to glory and with the greatest splendor, and if the victorious general is so great after a signal engagement; it is because the service he has done is for the moment, and for all; and because we think, without reflecting, that he has saved our habitations, our wealth, and our children, and every thing that attaches us to life. If the man of science, who in his study has discovered and calculated the motions of the heavenly bodies, who in his alembics has unveiled some of the secrets of nature, or who has exhibited to mankind a new art, rises to fame with less noise; it is because the utility which he procures is more widely diffused; and is often of less

Glogaw
||
Glory.

Glory. less service to the present than to succeeding generations.

The consequences, therefore, of these two advantages are as opposite as the causes are different; and while the benefits procured by the warrior appear to have no more influence, and while his glory becomes obscure, that of a celebrated writer or inventor still increases, and is more and more enlarged. His works every day bring back his name to that age which uses them, and thus still add to his celebrity and fame.

This posthumous fame indeed has been decried by some writers. In particular, the author of the *Religion of Nature delineated*, has treated it as highly irrational and absurd. "In reality (says he) the man is not known ever the more to posterity, because his name is transmitted to them: He doth not live, because his name does. When it is said, Julius Cæsar subdued Gaul, conquered Pompey, &c. it is the same thing as to say, the conqueror of Pompey was Julius Cæsar; i. e. Cæsar and the conqueror of Pompey is the same thing; Cæsar is as much known by one designation as by the other. The amount then is only this, that the conqueror of Pompey conquered Pompey; or somebody conquered Pompey; or rather, since Pompey is as little known now as Cæsar, somebody conquered somebody. Such a poor business is this boasted immortality! and such is the thing called glory among us! To discerning men this fame is mere air, and what they despise if not shun."

But surely it were to consider too seriously (as Horatio says to Hamlet) to consider thus. For (as the elegant author of Fitzosburne's Letters observes) altho' fame with posterity should be, in the strict analysis of it, no other than what is here described, a mere uninteresting proposition, amounting to nothing more than that somebody acted meritoriously; yet it would not necessarily follow, that true philosophy would banish the desire of it from the human breast: for this passion may be (as most certain it is) wisely implanted in our species, notwithstanding the corresponding object should in reality be very different from what it appears in imagination. Do not many of our most refined and even contemplative pleasures owe their existence to our mistakes? It is but extending some of our senses to a higher degree of acuteness than we now possess them, to make the fairest views of nature, or the noblest productions of art, appear horrid and deformed. To see things as they truly and in themselves are, would not always, perhaps, be of advantage to us in the intellectual world, any more than in the natural. But, after all, who shall certainly assure us, that the pleasure of virtuous fame dies with the possessor, and reaches not to a farther scene of existence? There is nothing, it should seem, either absurd or unphilosophical in supposing it possible at least, that the praises of the good and the judicious, the sweetest music to an honest ear in this world, may be echoed back to the mansions of the next; that the poet's description of fame may be literally true, and though she walks upon earth, she may yet lift her head into heaven.

To be convinced of the great advantage of cherishing this high regard to posterity, this noble desire of an after-life in the breath of others, one need only look back upon the history of the ancient Greeks and Romans. For what other principle was it which produced that exalted strain of virtue in those days,

that may well serve, in too many respects, as a model to these? Was it not the *consentiens laus bonorum*, the *incorrupta vox bene judicantium* (as Tully calls it), "The concurrent approbation of the good, the uncorrupted applause of the wise," that animated their most generous pursuits?

In short, can it be reasonable to extinguish a passion which nature has universally lighted up in the human breast, and which we constantly find to burn with most strength and brightness in the noblest and best-formed bosoms? Accordingly revelation is so far from endeavouring to eradicate the seed which nature has thus deeply planted, that she rather seems, on the contrary, to cherish and forward its growth. To be *exalted with honour*, and to be *had in everlasting remembrance*, are in the number of those encouragements which the Jewish dispensation offered to the virtuous; and the person from whom the sacred Author of the Christian system received his birth, is herself represented as rejoicing that *all generations should call her blessed*.

GLOSS, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language or any other. See the article COMMENTARY.—The word, according to some, comes from the Greek *γλωσσα*, "tongue;" the office of a *gloss* being to explain the text, as that of the tongue is to discover the mind.

GLOSS is likewise used for a literal translation, or an interpretation of an author in another language word for word.

GLOSS is also used in matters of commerce, &c. for the lustre of a silk, stuff, or the like.

GLOSSARY, a sort of dictionary, explaining the obscure and antiquated terms in some old author; such are Du Cange's Latin and Greek Glossaries, Spelman's Glossary, and Kennet's Glossary at the end of his Parochial Antiquities.

GLOSSOPETRA, or GLOTTOPETRA, in natural history, a kind of extraneous fossil, somewhat in form of a serpent's tongue; frequently found in the island of Malta and divers other parts. See Plate CC.

The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of "*γλωσσα*, tongue," and *πετρα*, "stone." Hence also their traditionary virtue in curing the bites of serpents. The general opinion of naturalists is, that they are the teeth of fishes, left at land by the waters of the deluge, and since petrified.

The several sizes of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, bluish, whitish, yellowish, or brown; and in shape they usually approach to a triangular figure. Some of them are simple; others are tricuspidate, having a small point on each side of the large one: many of them are quite straight; but they are frequently found crooked, and bent in all directions; many of them are serrated on their edges, and others have them plain; some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller less than a quarter of an inch.

They are most usually found in the strata of blue clay, though sometimes also in other substances,

Gloss
||
Glossopetra.

Glottis and are frequent in the clay-pits of Richmond and other places. They are very frequent also in Germany, but no where so plentiful as in the island of Malta.

Glover.

The Germans attribute many virtues to these fossil teeth; they call them cordials, sudorifics, and alexipharmics: and the people of Malta, where they are extremely plentiful, hang them about their childrens necks to promote dentition. They may possibly be of as much service this way as an anodyne necklace; and if suspended in such a manner that the child can get them to its mouth, may, by their hardness and smoothness, be of the same use as a piece of coral.

GLOTTIS, in anatomy, the narrow slit at the upper part of the *aspera arteria*, which is covered by the *epiglottis* when we hold our breath and when we swallow. The *glottis*, by its dilatation and contraction, modulates the voice. See *ANATOMY*, n^o 116.

GLOVE, a covering for the hand and wrist.

Gloves, with respect to commerce, are distinguished into leather-gloves, silk-gloves, thread-gloves, cotton-gloves, worsted-gloves, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c. Gloves in Britain now pay a duty to the king, which increases according to their value.

To throw the glove, was a practice or ceremony very usual among our forefathers; being the challenge whereby another was defied to single combat.—It is still retained at the coronation of the British kings; when the king's champion casts his glove in Westminster hall. See *CHAMPION*.

Favyn supposes the custom to have arisen from the eastern nations, who in all their sales and deliveries of lands, goods, &c. used to give the purchaser their glove by way of livery or investiture. To this effect he quotes Ruth iv. 7. where the Chaldee paraphrase calls *glove*, what the common version renders by *shoe*. He adds, that the Rabbins interpret by *glove*, that passage in the cviiith Psalm, *In Idumeam extendam calceamentum meum*, "Over Edom will I cast out my shoe."—Accordingly, in Britain, he who took up the *glove*, declared thereby his acceptance of the challenge; and as a part of the ceremony, continues Favyn, took the *glove* off his own right hand, and cast it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each side, to meet at the time and place which should be appointed by the king, parliament, or judges.—The same author asserts, that the custom which still obtains of blessing *gloves* in the coronation of the kings of France, is a remain of the eastern practice of giving possession with the *glove*, l. xvi. p. 1017, &c.

Anciently it was prohibited the judges to wear gloves on the bench. And at present in the stables of most princes, it is not safe going in without pulling off the gloves.

GLOVER (Richard), the author of *Leonidas* and several other esteemed works, was the son of Richard Glover a Hamburg merchant in London, and was born in St Martin's-lane in the year 1712. He very early showed a strong propensity to and genius for poetry; and while at school, he wrote, amongst other pieces, a poem to the memory of Sir Isaac Newton, prefixed to the view of that incomparable author's philosophy, published in 4to, in 1728, by his intimate

friend Dr Pemberton. But though possessed of talents which were calculated to excel in the literary world, he was content to devote his attention to commerce, and at a proper period commenced a Hamburg merchant. He still, however, cultivated literature, and associated with those who were eminent in science. One of his earliest friends was Matthew Green, the ingenious but obscure author of some admirable poems, which in 1737, after his death, were collected and published by Mr Glover. In 1737, Mr Glover married Miss Nunn, with whom he received a handsome fortune; and in the same month published *Leonidas*, a poem in 4to, which in this and the next year passed through three editions. This poem was inscribed to Lord Cobham; and on its first appearance was received by the world with great approbation, though it has since been unaccountably neglected. Lord Lyttleton, in a popular publication called *Common Sense*, and in a poem addressed to the author, praised it in the warmest terms; and Dr Pemberton published, *Observations on Poetry*, especially epic, occasioned by the late poem upon *Leonidas*, 1738, 12mo, merely with a view to point out its beauties. In 1739, Mr Glover published "London, or the Progress of Commerce," 4to; and a ballad intitled, *Hofier's Ghost*. Both these pieces seem to have been written with a view to incite the public to resent the misbehaviour of the Spaniards; and the latter had a very considerable effect. The political dissensions at this time raged with great violence, and more especially in the metropolis; and at different meetings of the livery on these occasions, Mr Glover was always called to the chair, and acquitted himself in a very able manner, his conduct being patriotic and his speeches masterly. His talents for public speaking, his knowledge of political affairs, and his information concerning trade and commerce, soon afterwards pointed him out to the merchants of London as a proper person to conduct their application to parliament on the subject of the neglect of their trade. He accepted the office; and in summing up the evidence gave very striking proofs of his oratorical powers. This speech was pronounced Jan. 27. 1742.

In the year 1745 died the Duchess of Marlborough, and by her will left to Mr Glover and Mr Mallet 500 l. each, to write the History of the Duke of Marlborough's Life. This bequest, however, never took place. It is supposed that Mr Glover very early renounced his share of it; and Mallet, though he continued to talk of performing the task almost as long as he lived, is now known never to have made the least progress in it. About this period Mr Glover withdrew a good deal from public notice, and lived a life of retirement. He had been unsuccessful in his business; and with a very laudable delicacy had preferred an obscure retreat to popular observation, until his affairs should put on a more prosperous appearance. He had been honoured with the attention of Frederic Prince of Wales, who once presented him with a complete set of the Classics, elegantly bound; and, on his absenting himself for some time on account of the embarrassment in his circumstances, sent him, it is said, 500 l. The prince died in March 1751; and in May following Mr Glover was once more drawn from his retreat by the importunity of his friends, and stood candidate for the place of chamberlain of London. It unfortunately hap-

Glover.

Glover. happened that he did not declare himself until most of the livery had engaged their votes; by which means he lost his election.

In 1753, Mr Glover produced at Drury-lane his tragedy of Boadicea; which was acted nine nights, in the month of December. It had the advantage of the performance of Mr Garrick, Mr Mossop, Mrs Cibber, and Mrs Prichard. From the prologue it seems to have been patronized by the author's friends in the city; and Dr Pemberton wrote a pamphlet to recommend it.—In 1761, Mr Glover published Medea, a tragedy written on the Greek model; but it was not acted until 1767, when it appeared for the first time on the stage at Drury-lane for Mrs Yates's benefit. At the accession of his present majesty, he appears to have surmounted the difficulties of his situation. In the parliament which was then called, he was chosen member for Weymouth, and continued to sit as such until the dissolution of it. He about this time, interested himself about India affairs, at one of Mr Sullivan's elections; and in a speech introduced the fable of the man, horse, and bear; and drew this conclusion, that, whenever merchants made use of armed forces to maintain their trade, it would end in their destruction.

In 1770, the poem of Leonidas requiring a new edition, it was republished in two volumes 12mo, corrected throughout, and extended from nine books to twelve. It had also several new characters added, besides placing the old ones in new situations. The improvements made in it were very considerable; but we believe the public curiosity, at this period, was not sufficiently alive to recompense the pains bestowed on this once popular performance. The calamities arising from the wounds given to public credit, in June 1772, by the failure of the bank of Douglas, Heron, and Co. in Scotland, occasioned Mr Glover's taking a very active part in the settling those complicated concerns, and in stopping the distress then so universally felt. In February 1774, he called the annuitants of that banking-house together, at the King's Arms tavern, and laid proposals before them for the security of their demands, with which they were fully satisfied. He also undertook to manage the interests of the merchants and Traders of London concerned in the trade to Germany and Holland, and of the dealers in foreign linens, in their application to parliament in May 1774. Both the speeches made on these occasions were published in a pamphlet in that year. In the succeeding year he engaged on behalf of the West-India merchants in their application to parliament, and examined the witnesses and summed up the evidence in the same masterly manner he had done on former occasions. For the assistance he afforded the merchants in this business, he was complimented by them with a service of plate, of the value of 300l. The speech which he delivered in the house was in the same year printed. This, we believe, was the last opportunity he had of displaying his oratorical talents in public. Having now arrived at a period of life which demanded a recess from business, Mr Glover retired to ease and independence, and wore out the remainder of his days with dignity and with honour. It is probable that he still continued his attention to his muse, as we are informed that, besides an epic poem of considerable length, he has left some tragedies and comedies behind

him in manuscript. After experiencing for some time the infirmities of age, he departed this life 25th November 1785; leaving behind him a most estimable character as a man, a citizen, and a writer.

GLOW-WORM, in zoology. See LAMPYRIS.

GLUCKSTADT, a strong and considerable town of Germany, in the circle of Upper Saxony, and duchy of Holstein, with a strong castle, and subject to Denmark. It is seated on the river Elbe, near its mouth; E. Long. 9. 15. N. Lat. 52. 53.

GLUE, among artificers, a tenacious viscid matter, which serves as a cement to bind or connect things together.

Glues are of different kinds, according to the various uses they are designed for, as the common glue, glove-glue, and parchment glue; whereof the two last are more properly called *size*.

The common or strong glue is chiefly used by carpenters, joiners, cabinet-makers, &c. It is made of skins of animals, as oxen, cows, calves, sheep, &c.; and the older the creature is, the better is the glue made of its hide. Indeed whole skins are but rarely used for this purpose, but only the shavings, parings, or scraps of them; or the feet-sinews, &c. That made of whole skins, however, is undoubtedly the best; as that made of sinews is the very worst.

The Method of Making GLUE. In making glue of parings, they first steep them two or three days in water: then, washing them well out, they boil them to the consistence of a thick jelly; which they pass, while hot, through ozier-baskets, to separate the impurities from it; and then let it stand some time, to purify it further: when all the filth and ordures are settled to the bottom of the vessel, they melt and boil it a second time. They next pour it into flat frames or moulds: whence it is taken out pretty hard and solid, and cut into square pieces or cakes. They afterwards dry it in the wind, in a sort of coarse net; and at last string it, to finish its drying.

The glue made of sinews, feet, &c. is managed after the same manner; only with this difference, that they bone and scour the feet, and do not lay them to steep.

Of this commodity there is a very great exportation from England; the English glue being universally allowed to be the best in Europe, partly from the excellency of the material, and partly from the skill of the manufacturers. Next to this is the Flanders-glue. In both countries it is made by the tanners from fragments of good skins dried with much care. In France it is a separate trade: and the glue-makers pick up their materials as they can, from the several dealers in skins, and boiling these with cow-heels make their glue; which as they purchase every thing, must render it dear, as well as of an inferior quality. The duty on exportation is tenpence, and on importation three shillings and tenpence, on every hundred weight.

The best glue is that which is made from the skin of the oldest beast; especially if a bull's hide is used. Experience likewise shows that glue is considerably improved in quality by keeping after it is made; and the surest way to try its goodness is to lay a piece to steep three or four days, and if it swell considerably, without melting, and when taken out resumes its former dryness, it is excellent.

A glue that will hold against fire or water, it is said,

Glue ||
Gluttony. said, may be made thus : Mix a handful of quicklime with four ounces of linseed oil ; boil them to a good thickness ; then spread it on tin-plates in the shade, and it will become exceeding hard, but may be easily dissolved over a fire, as glue, and will effect the business to admiration.

Neumann observes, that glue dissolved in a solution of lapis calaminaris in spirit of nitre, and afterwards inspissated, forms an extremely slippery tenacious mass, which might be of use for entangling flies, caterpillars, and other insects, if it was not too expensive.

Method of Preparing and Using GLUE. Set a quart of water on the fire, then put in about half a pound of good glue, and boil them gently together till the glue be entirely dissolved and of a due consistence. When glue is to be used, it must be made thoroughly hot ; after which, with a brush dipped in it, besmear the faces of the joints as quick as possible : then clapping them together, slide or rub them lengthwise one upon another, two or three times, to settle them close ; and so let them stand till they are dry and firm.—Mr Boyle gives a receipt for preparing a fine strong glue from isinglass in the following manner: steep the isinglass for 24 hours in common brandy. When the menstruum has opened and mollified the isinglass, they must be gently boiled together, and kept stirring till they appear well mixed, and till a drop thereof, suffered too cool, turns into a strong jelly. Then strain it, whilst hot, through a clean linen cloth into a vessel to be kept close stopped. A gentle heat suffices to dissolve this glue into a transparent and almost colourless fluid, but very strong, so that pieces of wood glued together with it will separate elsewhere rather than in the place where they are joined. See ISINGLASS.

GLUME (*gluma*), among botanists, a species of calyx, consisting of two or three membranous valves, which are often pellucid at the edges. This kind of calyx belongs to the grasses.

GLUT, among falconers, the slimy substance that lies in a hawk's paunch.

GLUTA, in botany ; a genus of the pentandria order, belonging to the gynandria class of plants. The calyx is campanulated and deciduous ; there are five petals glued below to the column of the germ ; and the filaments inserted on the top of the column, on which also the germen sits.

GLUTÆUS, a name common to three muscles whose office is to extend the thigh. See ANATOMY, *Table of the Muscles.*

GLUTTON, in zoology. See MUSTELA.

GLUTTONY, a voracity of appetite, or a propensity to gormandizing.

There is a morbid sort of gluttony, called *fames canina*, "dog-like appetite," which sometimes occurs, and renders the person seized with it an object of pity and of cure as in other diseases: (see BULIMY.)—But professed habitual gluttons may be reckoned amongst the monsters of nature, and deemed in a manner punishable for endeavouring to bring a dearth or famine into the places where they live. For which reason, people think king James I. was in the right, when a man being presented to him that could eat a whole sheep at one meal, he asked "What he could do more than another

man?" and being answered "He could not do so much," said, "Hang him then ; for it is unfit a man should live that eats as much as twenty men, and cannot do so much as one."

The emperor Clodius Albinus would devour more apples at once than a bushel would hold. He would eat 500 figs to his breakfast, 100 peaches, 10 melons, 20 pound weight of grapes, 100 gnat-snippers, and 400 oysters. "Eye upon him (saith Lipsius) ; God keep such a curse from the earth.

One of the Danish kings named *Hardiknute* was so great a glutton, that a historian calls him *Bacca de Porco*, "Swine's-mouth." His tables were covered four times a-day with the most costly viands that either the air, sea, or land, could furnish: and as he lived he died ; for, revelling and carousing at a wedding banquet at Lambeth, he fell down dead. His death was so welcome to his subjects, that they celebrated the day with sports and pastimes, calling it *Hock-tide*, which signifies scorn and contempt. With this king ended the reign of the Danes in England.

One Phagon, under the reign of the emperor Aurelianus, at one meal, eat a whole boar, 100 loaves of bread, a sheep, a pig, and drank above three gallons of wine.

We are told by Fuller*, that one Nicolas Wood, of Harrisen in Kent, eat a whole sheep of 16s. price at one meal, raw ; at another time, 30 dozens of pigeons. At Sir William Sidley's, in the same county, he ate as much victuals as would have sufficed 30 men. At Lord Wotton's mansion-house in Kent, he devoured at one dinner 84 rabbits ; which, by computation, at half a rabbit a man, would have served 168 men. He eat to his breakfast 18 yards of black pudding. He devoured a whole hog at one sitting down ; and after it, being accommodated with fruit, he eat three pecks of damosins.

A counsellor at law, whose name was Mallet, well known in the reign of Charles I. eat at one time an ordinary provided in Westminster for 30 men at twelve pence a piece. His practice not being sufficient to supply him with better sort of meat, he fed generally on offals, ox livers, hearts, &c. He lived to almost 60 years of age, and for the seven last years of his life eat as moderately as other men. A narrative of his Life was published.

GLYCINE, **KNOBBED-ROOTED LIQUORICE-VETCH**: A genus of the decandria order, belonging to the diadelphia class of plants ; and in the natural method ranking under the 32d order, *Papilionaceæ*. The calyx is bilabiate ; the carina of the corolla turning back the vexillum with its point. There is but one species commonly cultivated in our gardens, viz. the frutescens, or Carolina kidney-bean tree. This hath shrubby climbing stalks, twining round any support, 15 or 20 feet high, adorned with pinnated leaves of three pair of follicles terminated by an odd one, and from the axillas clusters of large bluish purple flowers, succeeded by long pods like those of the climbing kidney-bean. It flowers in June and July, but the seeds do not ripen in Britain. It is easily propagated, either by seeds exported from America, where it is native, or by layers.—The stalks and roots of the abrus, another species of glycine, which grows in Egypt and the Indies, are very sweet to the taste. Herman affirms, that the juice obtained

za.

tained from them by decoction is little inferior to liquorice; whence its name of *wild-liquorice* in those parts of America where it is native.

GLYCIRRHIZA, LIQUORICE: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, *Papilionacea*. The calyx is bilabiate; the upper lip tripartite, and the under one entire; the legumen ovate and compressed. There are two

Species 1. The *glabra*, or common liquorice, hath a long, thick, creeping root, striking several feet deep into the ground; upright, firm, herbaceous stalks annually, three or four feet high, garnished with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale blue flowers in July, succeeded by short smooth pods. The root of this is the useful part, which is replete with a sweet balsamic, pectoral juice, much used in all compositions for coughs and disorders of the stomach. 2. The *echinata*, or prickly-podded liquorice, is nearly like the common sort, only the seed-pods are prickly. Both these species are very hardy perennials; but the first is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the other. The roots are perennial; but the stalks rise in spring and decay in autumn.

Propagation and culture. Their propagation is effected by cuttings of the small roots issuing from the sides of the main ones near the surface of the earth, dividing them into lengths of six or eight inches, each having one or more good buds or eyes; and the proper season for procuring the sets for planting is any time in open weather from October till March, though from the middle of February till the middle of March is rather the most successful season for planting. An open situation is the most suitable for a plantation of these plants. Particular regard should also be had to the soil: it ought to be of a light loose temperature, and three or four feet deep if possible; for the roots of the liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for sale by weight.

Having fixed on the ground, let it be trenched three spades deep, if the depth of proper soil will admit; then having your sets ready, proceed to plant them by line and dibble, planting the sets a foot distance in each row; putting them perpendicular into the ground, with the tops about an inch under the surface; and let the rows be a foot and a half asunder; though the London gardeners seldom allow more than twelve inches between row and row. These gardeners also sow a crop of onions on the same ground the first year; which, as the onions root but slender, and spread but little at top, may be done without and detriment to the liquorice, or to the onions, as it does not rise above ten or twelve inches high the first summer: observing to keep the ground clean from weeds during that season by hoeing. If there is a crop of onions, use the small hoe, cutting out the onions to four or five inches distance, clearing away such as grow immediately close to the liquorice plants; and when the onions are gathered, give the ground a thorough hoeing with a large hoe, to loosen the surface and destroy all weeds effectually; and in autumn cut down the decayed stalks of the liquorice, and nothing more is

necessary to be done till spring; when, in February or March, give a slight digging between the rows; during spring and summer, keep down all weeds by broad-hoeing; and in autumn, when the stalks are in a decaying state, cut them down to the surface of the earth.

In three years after planting, the roots of the liquorice will be fit to take up: and the proper season for this is, any time from the beginning of November till February; for it should neither be taken up before the stalks are fully decayed, nor deferred till late in spring, otherwise the roots will be apt to shrivel and diminish in weight. In taking them up, the small side-roots are trimmed off, and the best divided into lengths for fresh sets, and the main roots are tied in bundles ready for sale. It is of advantage to sell them as soon as possible after they are taken up, before they lose much of their weight. They are sold to the druggists from about twenty to thirty or forty shillings *per* hundred weight; and an acre of ground has produced three thousand and upwards, which has been sold for more than sixty pounds: but the price is commonly in proportion to the goodness of the roots.

Uses. The common liquorice is cultivated in most countries of Europe for the sake of its root. That which is cultivated in Britain is preferable to that of most other countries; this last being generally mouldy, which this root is very apt to become, unless kept in a dry place. The powder of liquorice usually sold is often mingled with flour, and probably too often with substances not quite so wholesome: the best sort is of a brownish yellow colour (the fine pale yellow being generally sophisticated), and of a very rich sweet taste, much more agreeable than that of the fresh root. Liquorice is almost the only sweet that quenches thirst; whence it was called by the Greeks *adipson*. Galen takes notice, that it was employed in this intention in hydropic cases, to prevent the necessity of drinking. Mr Fuller, in his *Medicina Gymnastica*, recommends this root as a very useful pectoral; and says it excellently softens acrimonious humours, at the same time that it proves gently detergent; and this account is warranted by experience. An extract is directed to be made from it in the shops; but this preparation is chiefly brought from abroad, though the foreign extract is not equal to such as is made with proper care among ourselves.

GLYPH, in sculpture and architecture, denotes any canal or cavity used as an ornament.

GMELIN (Dr Samuel), professor at Tubingen, and afterwards member of the Imperial Academy of Sciences at St Petersburg, commenced his travels in June 1768; and having traversed the provinces of Moscow, Voronetz, New Russia, Azof, Casan, and Astracan, he visited, in 1770 and 1771, the different harbours of the Caspian, and examined with peculiar attention those parts of the Persian Provinces which border upon that sea, of which he has given a circumstantial account in the three volumes of his travels already published. Actuated by a zeal for extending his observations, he attempted to pass through the western provinces of Persia, which are in a perpetual state of warfare, and infested by numerous banditti. Upon this expedition he quitted, in April 1772, Einzillee, a small trading place in Chilan, upon the southern

Glycirrhi-
za

Gmelin:

Gmelina,
Gnaphali-
um.

shore of the Caspian; and, on account of many difficulties and dangers, did not, until Dec. 2. 1773, reach Sallian, a town situated upon the mouth of the river Koor. Thence he proceeded to Baku and Kuba, in the province of Shirvan, where he met with a friendly reception from Ali Feth Khan, the sovereign of that district. After he had been joined by 20 Uralian Cossacks, and when he was only four days journey from the Russian fortrefs Kislar, he and his companions were, on the 5th of February 1774, arrested by order of Usmei Khan, a petty Tartar prince, through whose territories he was obliged to pass. Usmei urged as a pretence for this arrest, that 30 years ago several families had escaped from his dominions, and had found an asylum in the Russian territories; adding, that Gmelin should not be released until the families were restored. The professor was removed from prison to prison; and at length, wearied out with continued persecutions, he expired, July 27th, at Achmet-Kent, a village of Mount Caucasus. His death was occasioned partly by vexation for the loss of several papers and collections, and partly by disorders contracted from the fatigues of his long journey. Some of his papers had been sent to Kislar during his imprisonment, and the others were not without great difficulty rescued from the hands of the barbarian who had detained him in captivity. The arrangement of these papers, which will form a fourth volume of his travels, was at first consigned to the care of Guldenstaedt, but upon his death has been transferred to the learned Pallas.

GMELINA, in botany: A genus of the angiospermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, *Personatae*. The calyx is nearly quadridentated; the corolla campanulated or bell shaped; there are two bipartite and two simple antheræ; the fruit is a plum with a bilocular kernel.

GNAPHALIUM, CUDWEED, GOLDY-LOCKS, ETERNAL FLOWER, &c.: A genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the natural method ranking under the 49th order, *Compositae*. The receptacle is naked; the pappus feathered; the calyx imbricated, with the marginal scales roundish, parched, and coloured. There are 41 species; the most remarkable of which are, 1. The margaritaceum, or pearly white eternal flower, hath creeping, very spreading roots, crowned with broad, spear-shaped, white, hoary leaves; herbaceous thick, woolly stalks, a foot and an half high, branching outward, garnished with long, acute-pointed, white, woolly leaves, and terminated by a corymbose cluster of yellowish flowers, which appear in June and July, and are very ornamental. 2. The plantaginifolium, hath large woolly radical leaves, decumbent running roots, and herbaceous simple stalks, rising six or eight inches high, terminated by a corymbus of white flowers in June, July, &c. 3. The stechas, hath a shrubby stalk, dividing into slender branches three feet long, terminated by corymbose clusters of yellow flowers, appearing in May and June. 4. The orientale, or oriental goldilocks, hath three varieties, with yellow, gold coloured, and white silvery flowers. They have shrubby stalks, rising two or three feet high. 5. The odoratissimum, or sweet-scented eternal flower,

hath shrubby winged stalks, branching irregularly a yard high, with corymbose clusters of bright yellow flowers, changing to a dark yellow. 6. The arboreum, or tree gnaphalium, hath a woody stem, branching four or five feet high, narrow sessile leaves, with revolute borders, smooth on their upper side, and roundish bunches of pale yellow flowers. The first three sorts are hardy, and will thrive in any soil or situation. The two first increase exceedingly by their roots; and the third is easily propagated by slips. The fourth, fifth, and sixth sorts are somewhat tender; and therefore should be kept in pots, to be sheltered in a green house or garden frame in winter. Others may be planted in the full ground, in a dry and warm situation, especially the oriental kind and varieties, and likewise the sweet-scented kind; for these two species will struggle tolerably through an ordinary winter, and make a pretty appearance during the summer-months. All these are propagated by slips or cuttings of their shoots.—The flowers of all these species are remarkable for retaining their beauty for years, if carefully gathered in a dry day, soon after they are blown.

GNAT, in zoology. See **CULEX**.

GNESNA, a large and strong town of Great Poland, of which it is capital, and in the palatinate of Calish, with an archbishop's see, whose prelate is primate of Poland, and viceroy during the vacancy of the throne. It was the first town built in the kingdom, and formerly more considerable than at present. E. Long. 18. 20. N. Lat. 52. 28.

GNETUM, in botany; a genus of the adelphia order, belonging to the monœcia class of plants. The amentum of the male is a single scale; there is no corolla, and but one filament with a pair of antheræ. The calyx of the female is of the same form; there is no corolla; the style with the stigma is trifid; the fruit a monospermous plum.

GNIDIA, in botany; a genus of the monogynia order, belonging to the octandria class of plants. The calyx is funnel-shaped and quadrid, with four petals inserted into it: there is one seed somewhat resembling a berry.

GNOMES, **GNOMI**, certain imaginary beings, who, according to the cabbalists, inhabit the inner parts of the earth. They are supposed small in stature, and the guardians of quarries, mines, &c. See **FAIRY**.

GNOMON, in dialling, the style, pin, or cock of a dial, which by its shadow shows the hour of the day. The gnomon of every dial represents the axis of the world: (See **DIAL** and **DIALLING**.)—The word is Greek, γνομων, which literally implies something that makes a thing known; by reason that the style or pin indicates or makes the hour known.

GNOMON, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun. Thus, in the right-angled triangle ABC are given, AB the length of the style, BC the length of its shadow, and the right angle ABC. Hence, making CB the radius, we have this analogy for finding the angle ACB, the sun's altitude, viz. BC : AB :: radius : tangent of the angle C.

By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See **QUADRANT**.

Gnat

Gnostics.

By the same instrument the height of any object GH may be found: for as DF, the distance of the observer's eye from the gnomon, is to DE, the height of the style; so is FH, the distance of the observer's eye from the object, to GH, its height.

See further on the uses and application of Gnomons, the article GEOGRAPHY, n^o 49—53.

GNOMON of a Globe; the index of the hour circle.

GNOMONICS, the art of dialling. See **DIALLING**.

GNOSTICS, ancient heretics, famous from the first rise of Christianity, principally in the east.

It appears from several passages of the sacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many persons were infected with the gnostic heresy in the first century; though the sect did not render itself conspicuous, either for number or reputation, before the time of Adrian, when some writers erroneously date its rise.

The name is formed of the Latin *gnosticus*, and that of the Greek γνῶσις “knowing,” of γινώσκω “I know;” and was adopted by those of this sect, as if they were the only persons who had the true knowledge of Christianity. Accordingly, they looked on all other Christians as simple, ignorant, and barbarous persons, who explained and interpreted the sacred writings in a too low, literal, and unedifying signification.

At first the Gnostics were only the philosophers and wits of those times, who formed for themselves a peculiar system of theology, agreeable to the philosophy of Pythagoras and Plato; to which they accommodated all their interpretations of scripture. But

GNOSTICS afterwards became a generical name, comprehending divers sects and parties of heretics, who rose in the first centuries, and who, though they differed among themselves as to circumstances, yet all agreed in some common principles. They were such as corrupted the doctrine of the gospel by a profane mixture of the tenets of the oriental philosophy, concerning the origin of evil and the creation of the world, with its divine truths. Such were the Valentinians, Simonians, Carpocratians, Nicolaitans, &c.

GNOSTICS was sometimes also more particularly attributed to the successors of the first Nicolaitans and Carpocratians, in the second century, upon their laying aside the names of the first authors. Such as would be thoroughly acquainted with all their doctrines, reveries, and visions, may consult St Irenæus, Tertullian, Clemens Alexandrinus, Origen, and St Epiphanius; particularly the first of these writers, who relates their sentiments at large, and confutes them at the same time: indeed, he dwells more expressly on the Valentinians than any other sort of Gnostics; but he shows the general principles whereon all their mistaken opinions were founded, and the method they followed in explaining scripture. He accuses them with introducing into religion certain vain and ridiculous genealogies, i. e. a kind of divine processions or emanations, which had no other foundation but in their own wild imagination.

In effect, the Gnostics confessed, that these æons or emanations were nowhere expressly delivered in the sacred writings; but insisted at the same time, that Jesus Christ had intimated them in parables to such as could understand him. They built their theology not only on the gospels and the epistles of St Paul, but also on

the law of Moses and the prophets. These last laws were peculiarly serviceable to them, on account of the allegories and allusions with which they abound, which are capable of different interpretations: Though their doctrine, concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Testament, which contradicted this idle fiction, and filled them with an abhorrence of Moses and the religion he taught; alleging, that he was actuated by the malignant author of this world, who consulted his own glory and authority, and not the real advantage of men. Their persuasion that evil resided in matter, as its centre and source, made them treat the body with contempt, discourage marriage, and reject the doctrine of the resurrection of the body and its reunion with the immortal spirit. Their notion, that malevolent genii presided in nature, and occasioned diseases and calamities, wars, and desolations, induced them to apply themselves to the study of magic, in order to weaken the powers or suspend the influence of their malignant agents.

The Gnostics considered Jesus Christ as the Son of God, and consequently inferior to the Father, who came into the world for the rescue and happiness of miserable mortals, oppressed by matter and evil beings: but they rejected our Lord's humanity, on the principle that every thing corporeal is essentially and intrinsically evil; and therefore the greatest part of them denied the reality of his sufferings. They set a great value on the beginning of the gospel of St John, where they fancied they saw a great deal of their æons or emanations under the *Word*, the *Life*, the *Light*, &c. They divided all nature into three kinds of beings, viz. *hylic*, or material; *psychic*, or animal; and *pneumatic*, or spiritual. On the like principle they also distinguished three sorts of men; *material*, *animal*, and *spiritual*. The first, who were material, and incapable of knowledge, inevitably perished, both soul and body; the third, such as the Gnostics themselves pretended to be, were all certainly saved; the psychic, or animal, who were the middle between the other two, were capable either of being saved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greatest part of this sect adopted very austere rules of life, recommended rigorous abstinence, and prescribed severe bodily mortifications, with a view of purifying and exalting the mind. However, some maintained, that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a loose rein to all the passions, and asserted the innocence of following blindly all their motions, and of living by their tumultuous dictates. They supported their opinions and practice by various authorities: some referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaster, Christ, and his apostles; others boasted, that they had deduced their sentiments from secret doctrines of Christ, concealed from the vulgar; others affirmed, that they arrived at superior degrees of wisdom by an innate vigour of mind; and others asserted, that they were instructed in these mysterious parts of theological science by Theudas, a disciple of St Paul, and by Matthias, one of the friends of our Lord. The tenets of the

Gnostics.

ancient

Gnostics ancient Gnostics were revived in Spain, in the fourth century, by a sect called the *Priscillianists*.

||
Goa.

The appellation *Gnostic* sometimes also occurs in a good sense, in the ancient ecclesiastical writers, and particularly Clemens Alexandrinus, who, in the person of his Gnostic, describes the characters and qualities of a perfect Christian. This point he labours in the seventh book of his *Stromata*, where he shows, that none but the Gnostic, or learned person, has any true religion. He affirms, that were it possible for the knowledge of God to be separated from eternal salvation, the Gnostic would make no scruple to choose the knowledge; and that if God would promise him impunity in doing of any thing he has once spoken against, or offer him heaven on those terms, he would never alter a whit of his measures. In this sense the father uses Gnostics, in opposition to the heretics of the same name; affirming, that the true Gnostic is grown old in the study of the holy scripture; and that he preserves the orthodox doctrine of the apostles and of the church; whereas the false Gnostic abandons all the apostolical traditions, as imagining himself wiser than the apostles. At length the name *Gnostic*, which originally was the most glorious, became infamous, by the idle opinions and dissolute lives of the persons who bore it.

GOA, a large and strong town of Asia, in the peninsula on this side the Ganges, and on the Malabar coast. It was taken by the Portuguese in 1508, and is the chief town of all their settlements on this side the Cape of Good Hope. It stands in an island of the same name, about 12 miles in length, and 6 in breadth; and the city is built on the north side of it, having the conveniency of a fine salt-water river, capable of receiving ships of the greatest burden, where they lie within a mile of the town. The banks of the river are beautified with a great number of handsome structures; such as churches, castles, and gentlemen's houses. The air within the town is unwholesome, for which reason it is not so well inhabited now as it was formerly. The viceroy's palace is a noble building; and stands at a small distance from the river, over one of the gates of the city, which leads to a spacious street, terminated by a beautiful church. This city contains a great number of handsome churches, convents, and cloisters, with a stately large hospital; all well endowed, and kept in good repair. The market-place takes up an acre of ground; and in the shops about it may be had the produce of Europe, China, Bengal, and other countries of less note. Every church has a set of bells, some of which are continually ringing. There are a great many Indian converts; but they generally retain some of their old customs, particularly they cannot be brought to eat beef. The clergy are very numerous, and illiterate; but the

churches are finely embellished, and have great numbers of images. In one of these churches, dedicated to Bon Jesus, is the chapel of St Francisco de Xaviere, whose tomb it contains: this chapel is a most superb and magnificent place; the tomb of the saint is entirely of fine black marble, brought from Lisbon; on the four sides of it the principal actions of the life of the Saint are most elegantly carved in basso relievo; these represent his converting the different nations to the Catholic faith: the figures are done to the life, and most admirably executed: it extends to the top in a pyramidical form, which terminates with a coronet of mother-of-pearl. On the sides of this chapel are excellent paintings, done by Italian masters; the subjects chiefly from scripture. This tomb, and the chapel appertaining to it, must have cost an immense sum of money; the Portuguese justly esteem it the greatest rarity in the place. The houses are large, and make a fine shew: but within they are but poorly furnished. The inhabitants are contented with greens, fruits, and roots; which, with a little bread, rice, and fish, is their principal diet, though they have hogs and fowls in plenty. The river's mouth is defended by several forts and batteries, well planted with large cannon on both sides; and there are several other forts in different places.

Goa
||
Goat:

Goa is the residence of a captain-general, who lives in great splendor. He is also commander in chief of all the Portuguese forces in the East Indies. They have here two regiments of European infantry, three legions of sepoy, three troops of native light horse, and a militia; in all about five thousand men. Goa is at present on the decline, and in little or no estimation with the country powers; indeed their bigotry and superstitious attachment to their faith is so general, that the inhabitants, formerly populous, are now reduced to a few thinly inhabited villages; the chief part of whom have been baptized: for they will not suffer any Mussulman or Gentoo to live within the precincts of the city; and these few are unable to carry on the husbandry or manufactures of the country. The court of Portugal is obliged to send out annually a very large sum of money, to defray the current expences of the government; which money is generally swallowed up by the convents and soldiery.

There was formerly an inquisition at this place, but it is now abolished; the building still remains, and by its black outside appears a fit emblem of the cruel and bloody transactions that passed within its walls! Provisions are to be had at this place in great plenty and perfection. E. Long. 74. O. N. Lat. 15. 31.
